Persian Gulf. One of the things that ' s happened because of this is that, since 1969, the country of Nigeria, or the part of Nigeria that pumps oil, which is the delta — which is two times the size of Maryland — has had thousands of oil spills a year. I mean, we ' ve essentially been exporting oil spills when we import oil from places without tight environmental regulations. That has been the equivalent of an Exxon Valdez spill every year since 1969. And we can wrap our heads around the spills, because that ' s what we see here, but in fact, these **guys** actually live in a war zone. There ' s a thousand battle-related deaths a year in this area twice the size of Maryland, and it ' s all related to the oil. And these **guys**, I mean, if they were in the U. S., they might be actually here in this room. They have degrees in political science, degrees in business — they ' re entrepreneurs. They don ' t actually want to be doing what they ' re doing. And it ' s sort of one of the other groups of people who pay a price for us. The other thing that we ' ve done, as we ' ve continued to increase **demand**, is that we kind of play a shell game with the costs. One of the places we put in a big oil project in Chad, with Exxon. So the U. S. taxpayer paid for it ; the World Bank, Exxon paid for it. We put it in. There was a tremendous banditry problem. I was there in 2003. We were driving along this dark, dark road, and the **guy** in the green stepped out, and I was just like,"Ahhh! This is it."And then the **guy** in the Exxon uniform stepped out, and we realized it was okay. They have their own private sort of army around them at the oil fields. But at the same time, Chad has become much more unstable, and we are not paying for that price at the pump. We pay for it in our taxes on April 15th. We do the same thing with the price of policing the Persian Gulf and keeping the shipping lanes open. This is 1988 — we actually bombed two Iranian oil platforms that year. That was the beginning of an escalating U. S. involvement there that we do not pay for at the pump. We pay for it on April 15th, and we can ' t even calculate the cost of this involvement. The other place that is sort of **supporting** our dependence on oil and our increased consumption is the Gulf of Mexico, which was not part of the moratoriums. Now what ' s happened in the Gulf of Mexico — as you can see, this is the Minerals Management diagram of wells for gas and oil. It ' s become this intense industrialized zone. It doesn ' t have the same resonance for us that the Arctic National Wildlife Refuge has, but it should, I mean, it ' s a bird sanctuary. Also, every time you buy gasoline in the United States, half of it is actually being refined along the coast, because the Gulf actually has about 50 percent of our refining capacity and a lot of our **marine** terminals as well. So the people of the Gulf have essentially been subsidizing the rest of us through a less-clean environment. And finally, American families also pay a price for oil. Now on the one hand, the price at the pump is not really very high when you consider the actual cost of the oil, but on the other hand, the fact that people have no other transit options means that they pay a large amount of their income into just getting back and forth to work, generally in a fairly crummy car. If you look at people who make $50, 000 a year, they have two kids, they might have three jobs or more, and then they have to really commute. They ' re actually spending more on their car and fuel than they are on taxes or on health care. And the same thing happens at the 50th percentile, around 80, 000. Gasoline costs are a tremendous drain on the American economy, but they ' re also a drain on individual families and it ' s kind of terrifying to think about what happens when prices get higher. So, what I ' m going to talk to you about now is : what do we have to do this time? What are the laws? What do we have to do to keep ourselves focused? One thing is — we need to stay away from the theater. We need to stay away from the moratoriums. We need to focus really back again on the molecules. The moratoriums are fine, but we do need to focus on the molecules on the oil. One of the things that we also need to do, is we need to try to not kind of fool ourselves into thinking that you can have a green world, before you reduce the amount of oil that we use. We need to focus on reducing the oil. What you see in this top drawing is a schematic of how petroleum gets used in the U. S. economy. It comes in on the side — the useful **stuff** is the dark gray, and the un-useful **stuff**, which is called the rejected energy — the waste, goes up to the top. Now you can see that the waste far outweighs the actually useful amount. And one of the things that we need to do is, not only fix the fuel efficiency of our vehicles and make them much more efficient, but we also need to fix the economy in general. We need to remove the perverse incentives to use more fuel. For example, we have an insurance system where the person who drives 20, 000 miles a year pays the same insurance as somebody who drives 3, 000. We actually encourage people to drive more. We have **policies** that reward sprawl — we have all kinds of **policies**. We need to have more mobility choices. We need to make the gas price better reflect the real cost of oil. And we need to shift subsidies from the oil industry, which is at least 10 billion dollars a year, into something that allows middle-class people to find better ways to commute. Whether that ' s getting a much more efficient car and also kind of building markets for new cars and new fuels down the road, this is where we need to be. We need to kind of rationalize this whole thing, and you can find more about this **policy**. It ' s called STRONG, which is"Secure Transportation Reducing Oil Needs Gradually,"and the idea is instead of being helpless, we need to be more strong. They ' re up at NewAmerica. net. What ' s important about these is that we try to move from feeling helpless at the pump, to actually being active and to really sort of thinking about who we are, having kind of that special moment, where we connect the dots actually at the pump. Now supposedly, oil taxes are the third rail of American politics — the no- fly zone. I actually — I agree that a dollar a gallon on oil is probably too much, but I think that if we started this year with three cents a gallon on gasoline, and upped it to six cents next year, nine cents the following year, all the way up to 30 cents by 2020, that we could actually significantly reduce our gasoline consumption, and at the same time we would give people time to prepare, time to respond, and we would be raising money and raising consciousness at the same time. Let me give you a little sense of how this would work. This is a gas receipt, hypothetically, for a year from now. The first thing that you have on the tax is — you have a tax for a stronger America — 33 cents. So you ' re not helpless at the pump. And the second thing that you have is a kind of warning sign, very similar to what you would find on a cigarette pack. And what it says is,"The National Academy of Sciences estimates that every gallon of gas you burn in your car creates 29 cents in health care costs."That ' s a lot. And so this — you can see that you ' re paying considerably less than the health care costs on the tax. And also, the hope is that you start to be connected to the whole greater system. And at the same time, you have a number that you can call to get more information on commuting, or a low-interest loan on a different kind of car, or whatever it is you ' re going to need to actually reduce your gasoline dependence. With this whole sort of suite of **policies**, we could actually reduce our gasoline consumption — or our oil consumption — by 20 percent by 2020. So, three million barrels a day. But in order to do this, one of the things we really need to do, is we need to remember we are people of the hydrocarbon. We need to keep or minds on the molecules and not get distracted by the theater, not get distracted by the cognitive dissonance of the green possibilities that are out there. We need to kind of get down and do the gritty work of reducing our dependence upon this fuel and these molecules. Thank you.

It was my first year as an atmospheric science professor at Texas Tech University. We had just moved to Lubbock, Texas, which had recently been named the second most **conservative** city in the entire United States. A colleague asked me to guest teach his undergraduate geology class. I said,"Sure."But when I showed up, the lecture hall was cavernous and dark. As I tracked the history of the carbon cycle through geologic time to present day, most of the students were slumped over, dozing or looking at their **phones**. I ended my talk with a hopeful request for any questions. And one hand shot up right away. I looked encouraging, he stood up, and in a loud voice, he said,"You ' re a democrat, aren ' t you?""No,"I said,"I ' m Canadian."That was my baptism by fire into what has now become a sad fact of life here in the United States and increasingly across Canada as well. The fact that the number one predictor of whether we agree that **climate** is changing, humans are responsible and the **impacts** are increasingly serious and even dangerous, has nothing to do with how much we know about science or even how smart we are but simply where we fall on the political spectrum. Does the thermometer give us a different answer depending on if we ' re liberal or **conservative**? Of course not. But if that thermometer tells us that the planet is warming, that humans are responsible and that to fix this thing, we have to wean ourselves off fossil fuels as soon as possible — well, some people would rather cut off their arm than give the government any further excuse to disrupt their comfortable lives and tell them what to do. But saying,"Yes, it ' s a real problem, but I don ' t want to fix it,"that makes us the bad **guy**, and nobody wants to be the bad **guy**. So instead, we use arguments like,"It ' s just a natural cycle.""It ' s the sun."Or my favorite,"Those **climate** scientists are just in it for the money."I get that at least once a week. But these are just sciencey-sounding smoke screens, that are designed to hide the real reason for our objections, which have nothing to do with the science and everything to do with our ideology and our identity. So when we turn on the TV these days, it seems like pundit X is saying,"It ' s cold outside. Where is global warming now?"And politician Y is saying,"For every scientist who says this thing is real, I can find one who says it isn ' t."So it ' s no surprise that sometimes we feel like **everybody** is saying these myths. But when we look at the data — and the Yale Program on **Climate** [Change] Communication has done public opinion polling across the country now for a number of years — the data shows that actually 70 percent of people in the United States agree that the **climate** is changing. And 70 percent also agree that it will harm plants and animals, and it will harm future generations. But then when we dig down a bit deeper, the rubber starts to hit the road. Only about 60 percent of people think it will affect people in the United States. Only 40 percent of people think it will affect us personally. And then when you ask people,"Do you ever talk about this?"two-thirds of people in the entire United States say,"Never."And even worse, when you say,"Do you hear the media talk about this?"Over three-quarters of people say no. So it ' s a vicious cycle. The planet warms. Heat waves get stronger. Heavy precipitation gets more frequent. Hurricanes get more intense. Scientists release yet another doom-filled report. Politicians push back even more strongly, repeating the same sciencey-sounding myths. What can we do to break this vicious cycle? The number one thing we can do is the exact thing that we ' re not doing : talk about it. But you might say,"I ' m not a scientist. How am I supposed to talk about radiative forcing or cloud parametrization in **climate** models?"We don ' t need to be talking about more science ; we ' ve been talking about the science for over 150 years.

Did you know that it ’ s been 150 years or more since the 1850s, when **climate** scientists first discovered that digging up and burning coal and gas and oil is producing heat- trapping gases that is wrapping an extra blanket around the planet? That ’ s how long we ’ ve known. It ’ s been 50 years since scientists first formally warned a US president of the dangers of a changing **climate**, and that president was Lyndon B. Johnson. And what ’ s more, the social science has taught us that if people have built their identity on rejecting a certain set of facts, then arguing over those facts is a personal attack. It causes them to dig in deeper, and it digs a trench, rather than building a bridge. So if we aren ’ t supposed to talk about more science, or if we don ’ t need to talk about more science, then what should we be talking about? The most important thing to do is, instead of starting up with your head, with all the data and facts in our head, to start from the heart, to start by talking about why it matters to us, to begin with genuinely shared values. Are we both parents? Do we live in the same community? Do we enjoy the same outdoor activities : hiking, biking, fishing, even hunting? Do we care about the economy or national security? For me, one of the most foundational ways I found to connect with people is through my faith. As a Christian, I believe that God created this incredible planet that we live on and gave us responsibility over every living thing on it. And I furthermore believe that we are to care for and love the least fortunate among us, those who are already suffering the **impacts** of poverty, hunger, disease and more. If you don ’ t know what the values are that someone has, have a conversation, get to know them, figure out what makes them tick. And then once we have, all we have to do is connect the dots between the values they already have and why they would care about a changing **climate**. I truly believe, after thousands of conversations that I ’ ve had over the past decade and more, that just about every single person in the world already has the values they need to care about a changing **climate**. They just haven ’ t connected the dots. And that ’ s what we can do through our conversation with them. The only reason why I care about a changing **climate** is because of who I already am. I ’ m a mother, so I care about the future of my child. I live in West Texas, where water is already scarce, and **climate** change is **impacting** the availability of that water. I ’ m a Christian, I care about a changing **climate** because it is, as the military calls it, a”threat multiplier.”It takes those issues, like poverty and hunger and disease and lack of access to clean water and even political **crises** that lead to **refugee crises** — it takes all of these issues and it exacerbates them, it makes them worse. I ’ m not a Rotarian. But when I gave my first talk at a Rotary Club, I walked in and they had this giant banner that had the Four-Way Test on it. Is it the truth? Absolutely. Is it fair? Heck, no, that ’ s why I care most about **climate** change, because it is absolutely unfair. Those who have contributed the least to the problem are bearing the brunt of the **impacts**. It went on to ask : Would it be beneficial to all, would it build goodwill? Well, to fix it certainly would. So I took my talk, and I reorganized it into the Four-Way Test, and then I gave it to this group of **conservative** businesspeople in West Texas. And I will never forget at the end, a local bank owner came up to me with the most bemused look on his face. And he said,”You know, I wasn ’ t sure about this whole global warming thing, but it passed the Four-Way Test.”These values, though — they have to be genuine. I was giving a talk at a Christian college a number of years ago, and after my talk, a fellow scientist came up and he said,”I need some help. I ’ ve been really trying hard to get my foot in the door with our local churches, but I can ’ t seem to get any traction. I want to talk to them about why **climate** change matters.”So I said,”Well, the best thing to do is to start with the denomination that you ’ re part of, because you share the most values with those people. What type of church do you attend?””Oh, I don ’ t attend any church, I ’ m an atheist,”he said. I said,”Well, in that case, starting with a faith community is probably not the best idea. Let ’ s talk about what you do enjoy doing, what you are **involved** in.”And we were able to identify a community group that he was part of, that he could start with. The bottom line is, we don ’ t have to be a liberal tree hugger to care about a changing **climate**. All we have to be is a human living on this planet. Because no matter where we live, **climate** change is already affecting us today. If we live along the coasts, in many places, we ’ re already seeing”sunny-day flooding.”If we live in western North America, we ’ re seeing much greater area being burned by wildfires. If we live in many coastal locations, from the Gulf of Mexico to the South Pacific, we are seeing stronger hurricanes, typhoons and cyclones, powered by a warming ocean. If we live in Texas or if we live in Syria, we ’ re seeing **climate** change supersize our droughts, making them more frequent and more severe. Wherever we live, we ’ re already being affected by a changing **climate**. So you might say,”OK, that ’ s good. We can talk **impacts**. We can scare the pants off people, because this thing is serious.”And it is, believe me. I ’ m a scientist, I know. But fear is not what is going to motivate us for the long-term, sustained change that we need to fix this thing. Fear is designed to help us run away from the bear. Or just run faster than the person beside us. What we need to fix this thing is rational hope. Yes, we absolutely do need to recognize what ’ s at stake. Of course we do. But we need a vision of a better future — a future with abundant energy, with a stable economy, with resources available to all, where our lives are not worse but better than they are today. There are solutions. And that ’ s why the second important thing that we have to talk about is solutions — practical, viable, accessible, attractive solutions. Like what? Well, there ’ s no silver bullet, as they say, but there ’ s plenty of silver buckshot. There ’ s simple solutions that save us money and reduce our carbon footprint at the same time. Yes, light bulbs. I love my plug-in car. I ’ d like some solar shingles. But imagine if every home came with a switch beside the front door, that when you left the house, you could turn off everything except your fridge. And maybe the DVR. Lifestyle choices : eating local, eating lower down the food chain and reducing food waste, which at the global scale, is one of the most important things that we can do to fix this problem. I ’ m a **climate** scientist, so the irony of traveling around to talk to people about a changing **climate** is not lost on me. The biggest part of my personal carbon footprint is my travel. And that ’ s why I carefully collect my invitations. I usually don ’ t go anywhere unless I have a critical mass of invitations in one place — anywhere from three to four to sometimes even as many as 10 or 15 talks in a given place — so I can minimize the **impact** of my carbon footprint as much as possible. And I ’ ve transitioned nearly three-quarters of the talks I give to video. Often, people will say,”Well, we ’ ve never done that before.”But I say,”Well, let ’ s give it a try, I think it could work.”Most of all, though, we need to talk about what ’ s already happening today around the world and what could happen in the future. Now, I live in Texas, and Texas has the highest carbon emissions of any state in the United States. You might say,”Well, what can you talk about in Texas?”The answer is : a lot. Did you know that in Texas there ’ s over 25, 000 jobs in the wind energy industry? We are almost up to 20 percent of our electricity from clean, renewable sources, most of that wind, though solar is growing quickly. The largest army base in the United States, Fort Hood, is, of course, in Texas. And they ’ ve been powered by wind and solar energy now, because it ’ s saving taxpayers over 150 million dollars. Yes. What about those who don ’ t have the resources that we have? In sub-Saharan Africa, there are hundreds of millions of people who don ’ t have access to any type of energy except kerosine, and it ’ s very expensive. Around the entire world, the fastest-growing type of new energy today is solar. And they have plenty of solar. So social **impact** investors, nonprofits, even corporations are going in and using innovative new microfinancing schemes, like, pay-as-you-go solar, so that people can buy the power they need in increments, sometimes even on their cell **phone**. One company, Azuri, has distributed tens of thousands of units across 11 countries, from Rwanda to Uganda. They estimate that they ' ve powered over 30 million hours of electricity and over 10 million hours of cell **phone** charging. What about the giant growing economies of China and India? Well, **climate impacts** might seem a little further down the road, but **air** quality **impacts** are right here today. And they know that clean energy is essential to powering their future. So China is **investing** hundreds of billions of dollars in clean energy. They ' re flooding coal mines, and they ' re putting floating solar panels on the surface. They also have a panda-shaped solar farm. Yes, they ' re still burning coal. But they ' ve shut down all the coal plants around Beijing. And in India, they ' re looking to replace a quarter of a billion incandescent light bulbs with LEDs, which will save them seven billion dollars in energy costs. They ' re investing in green jobs, and they ' re looking to decarbonize their entire vehicle fleet. India may be the first country to industrialize without relying primarily on fossil fuels. The world is changing. But it just isn ' t changing fast enough. Too often, we picture this problem as a giant boulder sitting at the bottom of a hill, with only a few hands on it, trying to roll it up the hill. But in reality, that boulder is already at the top of the hill. And it ' s got hundreds of millions of hands, maybe even billions on it, pushing it down. It just isn ' t going fast enough. So how do we speed up that giant boulder so we can fix **climate** change in time? You guessed it. The number one way is by talking about it. The bottom line is this : **climate** change is affecting you and me right here, right now, in the places where we live. But by working together, we can fix it. Sure, it ' s a daunting problem. Nobody knows that more than us **climate** scientists. But we can ' t give in to despair. We have to go out and actively look for the hope that we need, that will inspire us to act. And that hope begins with a conversation today. Thank you.

Bryn Freedman : You ' re a **guy** whose company funds these AI programs and **invests**. So why should we **trust** you to not have a bias and tell us something really useful for the rest of us about the future of work? Roy Bahat : Yes, I am. And when you wake up in the morning and you read the newspaper and it says,"The robots are coming, they may take all our jobs,"as a start-up investor focused on the future of work, our fund was the first one to say artificial **intelligence** should be a focus for us. So I woke up one morning and read that and said,"Oh, my gosh, they ' re talking about me. That ' s me who ' s doing that."And then I thought : wait a minute. If things continue, then maybe not only will the start-ups in which we **invest** struggle because there won ' t be people to have jobs to pay for the things that they make and buy them, but our economy and society might struggle, too. And look, I should be the **guy** who sits here and tells you,"Everything is going to be fine. It ' s all going to work out great. Hey, when they introduced the ATM machine, years later, there ' s more tellers in banks."It ' s true. And yet, when I looked at it, I thought,"This is going to accelerate. And if it does accelerate, there ' s a chance the center doesn ' t hold."But I figured somebody must know the answer to this ; there are so many ideas out there. And I read all the books, and I went to the **conferences**, and at one point, we counted more than 100 efforts to study the future of work. And it was a frustrating experience, because I ’ d hear the same back-and-forth over and over again :”The robots are coming!”And then somebody else would say,”Oh, don ’ t worry about that, they ’ ve always said that and it turns out OK.”Then somebody else would say,”Well, it ’ s really about the meaning of your job, anyway.”And then **everybody** would shrug and go off and have a drink. And it felt like there was this Kabuki theater of this discussion, where nobody was talking to each other. And many of the people that I knew and worked with in the technology world were not speaking to **policy** makers ; the **policy** makers were not speaking to them. And so we partnered with a nonpartisan think tank NGO called New America to study this issue. And we brought together a group of people, including an AI czar at a technology company and a video game designer and a heartland **conservative** and a Wall Street investor and a socialist magazine editor — literally, all in the same room ; it was occasionally awkward — to try to figure out what is it that will happen here. The question we asked was simple. It was : What is the effect of technology on work going to be? And we looked out 10 to 20 years, because we wanted to look out far enough that there could be real change, but soon enough that we weren ’ t talking about teleportation or anything like that. And we recognized — and I think every year we ’ re reminded of this in the world — that predicting what ’ s going to happen is hard. So instead of predicting, there are other things you can do. You can try to imagine alternate possible futures, which is what we did. We did a scenario-planning exercise, and we imagined cases where no job is **safe**. We imagined cases where every job is **safe**. And we imagined every distinct possibility we could. And the result, which really surprised us, was when you think through those futures and you think what should we do, the answers about what we should do actually turn out to be the same, no matter what happens. And the irony of looking out 10 to 20 years into the future is, you realize that the things we want to act on are actually already happening right now. The automation is right now, the future is right now. BF : So what does that mean, and what does that tell us? If the future is now, what is it that we should be doing, and what should we be thinking about? RB : We have to understand the problem first. And so the data are that as the economy becomes more productive and individual workers become more productive, their wages haven ’ t risen. If you look at the proportion of prime working-age men, in the United States at least, who work now versus in 1960, we have three times as many men not working. And then you hear the stories. I sat down with a group of Walmart workers and said,”What do you think about this cashier, this futuristic self-checkout thing?”They said,”That ’ s nice, but have you heard about the cash recycler? That ’ s a machine that ’ s being installed right now, and is eliminating two jobs at every Walmart right now.”And so we just thought,”Geez. We don ’ t understand the problem.”And so we looked at the voices that were the ones that were excluded, which is all of the people affected by this change. And we decided to listen to them, sort of”automation and its discontents.”And I ’ ve spent the last couple of years doing that. I ’ ve been to Flint, Michigan, and Youngstown, Ohio, talking about entrepreneurs, trying to make it work in a very different environment from New York or San Francisco or London or Tokyo. I ’ ve been to prisons twice to talk to inmates about their jobs after they leave. I ’ ve sat down with truck drivers to ask them about the self-driving truck, with people who, in addition to their full-time job, care for an aging relative. And when you talk to people, there were two themes that came out loud and clear. The first one was that people are less looking for more money or get out of the fear of the robot taking their job, and they just want something stable. They want something predictable. So if you survey people and ask them what they want out of work, for **everybody** who makes less than 150, 000 dollars a year, they ’ ll take a more stable and secure income, on average, over earning more money. And if you think about the fact that not only for all of the people across the earth who don ’ t earn a living, but for those who do, the vast majority earn a different amount from month to month and have an instability, all of a sudden you realize,”Wait a minute. We have a real problem on our hands.”And the second thing they say, which took us a longer time to understand, is they say they want dignity. And that concept of self-worth through work emerged again and again and again in our conversations. BF : So, I certainly appreciate this answer. But you can ’ t eat dignity, you can ’ t clothe your children with self-esteem. So, what is that, how do you reconcile — what does dignity mean, and what is the relationship between dignity and stability? RB : You can ’ t eat dignity. You need stability first. And the good news is, many of the conversations that are happening right now are about how we solve that. You know, I ’ m a proponent of studying guaranteed income, as one example, conversations about how health care gets provided and other benefits. Those conversations are happening, and we ’ re at a time where we must figure that out. It is the **crisis** of our era. And my point of view after talking to people is that we may do that, and it still might not be enough. Because what we need to do from the beginning is understand what is it about work that gives people dignity, so they can live the lives that they want to live. And so that concept of dignity is... it ’ s difficult to get your hands around, because when many people hear it — especially, to be honest, rich people — they hear”meaning.”They hear”My work is important to me.”And again, if you survey people and you ask them,”How important is it to you that your work be important to you?”only people who make 150, 000 dollars a year or more say that it is important to them that their work be important. BF : Meaning, meaningful? RB : Just defined as,”Is your work important to you?”Whatever somebody took that to mean. And yet, of course dignity is essential. We talked to truck drivers who said,”I saw my cousin drive, and I got on the open road and it was amazing. And I started making more money than people who went to college.”Then they ’ d get to the end of their thought and say something like,”People need their fruits and vegetables in the morning, and I ’ m the **guy** who gets it to them.”We talked to somebody who, in addition to his job, was caring for his aunt. He was making plenty of money. At one point we just asked,”What is it about caring for your aunt? Can ’ t you just pay somebody to do it?”He said,”My aunt doesn ’ t want somebody we pay for. My aunt wants me.”So there was this concept there of being needed. If you study the word”dignity,”it ’ s fascinating. It ’ s one of the oldest words in the English language, from antiquity. And it has two meanings : one is self- worth, and the other is that something is suitable, it ’ s fitting, meaning that you ’ re part of something greater than yourself, and it connects to some broader whole. In other words, that you ’ re needed. BF : So how do you answer this question, this concept that we don ’ t pay teachers, and we don ’ t pay eldercare workers, and we don ’ t pay people who really care for people and are needed, enough? RB : Well, the good news is, people are finally asking the question. So as AI investors, we often get **phone** calls from foundations or CEOs and boardrooms saying,”What do we do about this?”And they used to be asking,”What do we do about introducing automation?”And now they ’ re asking,”What do we do about self-worth?”And they know that the employees who work for them who have a spouse who cares for somebody, that dignity is essential to their **ability** to just do their job. I think there ’ s two kinds of answers : there ’ s the money side of just making your life work. That ’ s stability. You need to eat. And then you think about our culture more broadly, and you ask : Who do we make into heroes? And, you know, what I want is to see the magazine cover that is the person who is the heroic caregiver. Or the Netflix series that dramatizes the person who makes all of our other lives work so we can do the things we do. Let ’ s make heroes out of those people. That ’ s the Netflix show that I would binge. And we ’ ve had chroniclers of this before — Studs Terkel, the oral history of the working experience in the United States. And what we need is the experience of needing one another and being connected to each other. Maybe that ’ s the answer for how we all fit as a society. And the thought exercise, to me, is : if you were to go back 100 years and have people — my grandparents, great- grandparents, a tailor, worked in a mine — they look at what all of us do for a living and say,”That ’ s not work.”We sit there and type and talk, and there ’ s no danger of getting hurt. And my guess is that if you were to imagine 100 years from now, we ’ ll still be doing things for each other. We ’ ll still need one another. And we just will think of it as work. The entire thing I ’ m trying to say is that dignity should not just be about having a job. Because if you say you need a job to have dignity, which many people say, the second you say that, you say to all the parents and all the teachers and all the caregivers that all of a sudden, because they ’ re not being paid for what they ’ re doing, it somehow lacks this essential human quality. To me, that ’ s the great puzzle of our time : Can we figure out how to provide that stability throughout life, and then can we figure out how to create an inclusive, not just racially, **gender**, but multi-generationally inclusive — I mean, every different human experience included — in this way of understanding how we can be needed by one another. BF : Thank you. RB : Thank you. BF : Thank you very much for your participation.

So, let me thank you for the opportunity to talk about the biggest **international** story of your professional lifetime, which is also the most important **international** challenge the world will face for as far as the eye can see. The story, of course, is the rise of China. Never before have so many people risen so far so fast, on so many different dimensions. The challenge is the **impact** of China ’ s rise — the discombobulation this will cause the Unites States and the **international** order, of which the US has been the principal architect and guardian. The past 100 years have been what historians now call an”American Century.”Americans have become accustomed to their place at the top of every pecking order. So the very idea of another country that could be as big and strong as the US — or bigger — strikes many Americans as an assault on who they are. For perspective on what we ’ re now seeing in this rivalry, it ’ s useful to locate it on the larger map of history. The past 500 years have seen 16 cases in which a rising power threatened to displace a ruling power. Twelve of those ended in war. So just in November, we ’ ll all pause to mark the 100th anniversary of the final day of a war that became so encompassing, that it required historians to create an entirely new category : world war. So, on the 11th hour of the 11th day of the 11th month in 1918, the guns of World War I fell silent, but 20 million individuals lay dead. I know that this is a sophisticated audience, so you know about the rise of China. I ’ m going to focus, therefore, on the **impact** of China ’ s rise, on the US, on the **international** order and on the prospects for war and peace. But having taught at Harvard over many years, I ’ ve learned that from time to time, it ’ s useful to take a short pause, just to make sure we ’ re all on the same page. The way I do this is, I call a time-out, I give students a pop quiz — ungraded, of course. So, let ’ s try this. Time-out, pop quiz. Question : forty years ago, 1978, China sets out on its march to the market. At that point, what percentage of China ’ s one billion citizens were struggling to survive on less than two dollars a day? Take a guess — 25 percent? Fifty? Seventy-five? Ninety. What do you think? Ninety. Nine out of every 10 on less than two dollars a day. Twenty eighteen, 40 years later. What about the numbers? What ' s your bet? Take a look. Fewer than one in 100 today. And China ' s president has promised that within the next three years, those last tens of millions will have been raised up above that threshold. So it ' s a miracle, actually, in our lifetime. Hard to believe. But brute facts are even harder to ignore. A nation that didn ' t even appear on any of the **international** league tables 25 years ago has soared, to rival — and in some areas, surpass — the United States. Thus, the challenge that will shape our world : a seemingly unstoppable rising China accelerating towards an apparently immovable ruling US, on course for what could be the grandest collision in history. To help us get our minds around this challenge, I ' m going to introduce you to a great thinker, I ' m going to present a big idea, and I ' m going to pose a most consequential question. The great thinker is Thucydides. Now, I know his name is a mouthful, and some people have trouble pronouncing it. So, let ' s do it, one, two, three, together : Thucydides. One more time : Thucydides. So who was Thucydides? He was the father and founder of history. He wrote the first-ever history book. It ' s titled"The History of the Peloponnesian War,"about the war in Greece, 2500 years ago. So if nothing else today, you can tweet your friends,"I met a great thinker. And I can even pronounce his name : Thucydides."So, about this war that destroyed classical Greece, Thucydides wrote famously :"It was the rise of Athens and the fear that this instilled in Sparta that made the war inevitable."So the rise of one and the **reaction** of the other create a toxic cocktail of pride, arrogance, paranoia, that drug them both to war. Which brings me to the big idea : Thucydides ' s Trap."Thucydides ' s Trap"is a term I coined several years ago, to make vivid Thucydides ' s insight. Thucydides ' s Trap is the dangerous dynamic that occurs when a rising power threatens to displace a ruling power, like Athens — or Germany 100 years ago, or China today — and their **impact** on Sparta, or Great Britain 100 years ago, or the US today. As Henry Kissinger has said, once you get this idea, this concept of Thucydides ' s Trap in your head, it will provide a lens for helping you look through the news and noise of the day to understand what ' s actually going on. So, to the most consequential question about our world today : Are we going to follow in the footsteps of history? Or can we, through a combination of imagination and common sense and courage find a way to manage this rivalry without a war nobody wants, and **everybody** knows would be catastrophic? Give me five minutes to unpack this, and later this afternoon, when the next news story pops up for you about China doing this, or the US reacting like that, you will be able to have a better understanding of what ' s going on and even to explain it to your friends. So as we saw with this flipping the pyramid of poverty, China has actually soared. It ' s meteoric. Former Czech president, Vaclav Havel, I think, put it best. He said,"All this has happened so fast, we haven ' t yet had time to be astonished."To remind myself how astonished I should be, I occasionally look out the window in my office in Cambridge at this bridge, which goes across the Charles River, between the Kennedy School and Harvard Business School. In 2012, the State of Massachusetts said they were going to renovate this bridge, and it would take two years. In 2014, they said it wasn ' t finished. In 2015, they said it would take one more year. In 2016, they said it ' s not finished, we ' re not going to tell you when it ' s going to be finished. Finally, last year, it was finished — three times over budget. Now, compare this to a similar bridge that I drove across last month in Beijing. It ' s called the Sanyuan Bridge. In 2015, the Chinese decided they wanted to renovate that bridge. It actually has twice as many lanes of traffic. How long did it take for them to complete the project? Twenty fifteen, what do you bet? Take a guess — OK, three — Take a look. The answer is 43 hours. Graham Allison : Now, of course, that couldn ' t happen in New York. Behind this speed in execution is a purpose-driven **leader** and a government that works. The most ambitious and most competent **leader** on the **international** stage today is Chinese President Xi Jinping. And he ' s made no secret about what he wants. As he said when he became president six years ago, his goal is to make China great again — a banner he raised long before Donald Trump picked up a version of this. To that end, Xi Jinping has announced specific targets for specific dates : 2025, 2035, 2049. By 2025, China means to be the **dominant** power in the major market in 10 leading technologies, including driverless cars, robots, artificial **intelligence**, quantum computing. By 2035, China means to be the innovation **leader** across all the advanced technologies. And by 2049, which is the 100th anniversary of the founding of the People ' s Republic, China means to be unambiguously number one, including, [says] Xi Jinping, an army that he calls"Fight and Win."So these are audacious goals, but as you can see, China is already well on its way to these objectives. And we should remember how fast our world is changing. Thirty years ago, the World Wide Web had not yet even been invented. Who will feel the **impact** of this rise of China most directly? Obviously, the current number one. As China gets bigger and stronger and richer, technologically more advanced, it will inevitably bump up against American positions and prerogatives. Now, for red-blooded Americans — and especially for red-necked Americans like me ; I ' m from North Carolina — there ' s something wrong with this picture. The USA means number one, that ' s who we are. But again, to repeat : brute facts are hard to ignore. Four years ago, Senator John McCain asked me to testify about this to his Senate Armed Services Committee. And I made for them a chart that you can see, that said, compare the US and China to kids on opposite ends of a seesaw on a playground, each represented by the size of their economy. As late as 2004, China was just half our size. By 2014, its GDP was equal to ours. And on the current trajectory, by 2024, it will be half again larger. The consequences of this tectonic change will be felt everywhere. For example, in the current trade **conflict**, China is already the number one trading partner of all the major Asian countries. Which brings us back to our Greek historian. Harvard ' s"Thucydides ' s Trap Case File"has reviewed the last 500 years of history and found 16 cases in which a rising power threatened to displace a ruling power. Twelve of these ended in war. And the tragedy of this is that in very few of these did either of the protagonists want a war ; few of these wars were initiated by either the rising power or the ruling power. So how does this work? What happens is, a third party ' s provocation forces one or the other to react, and that sets in motion a spiral, which drags the two somewhere they don ' t want to go. If that seems crazy, it is. But it ' s life. Remember World War I. The provocation in that case was the assassination of a second-level figure, Archduke Franz Ferdinand, which then led the Austro- Hungarian emperor to issue an ultimatum to Serbia, they dragged in the various allies, within two months, all of Europe was at war. So imagine if Thucydides were watching planet Earth today. What would he say? Could he find a more appropriate leading man for the ruling power than Donald J Trump? Or a more apt lead for the rising power than Xi Jinping? And he would scratch his head and certainly say he couldn ' t think of more colorful provocateur than North Korea ' s Kim Jong-un. Each seems determined to play his assigned part and is right on script. So finally, we conclude again with the most consequential question, the question that will have the gravest consequences for the rest of our lives : Are Americans and Chinese going to let the forces of history drive us to a war that would be catastrophic for both? Or can we summon the imagination and courage to find a way to survive together, to share the **leadership** in the 21st century, or, as Xi

Jinping [said], to create a new form of great power relations? That ' s the issue I ' ve been pursuing passionately for the last two years. I ' ve had the opportunity to talk and, indeed, to listen to **leaders** of all the relevant governments — Beijing, Washington, Seoul, Tokyo — and to thought **leaders** across the spectrum of both the arts and business. I wish I had more to report. The good news is that **leaders** are increasingly aware of this Thucydidean dynamic and the dangers that it poses. The bad news is that nobody has a feasible plan for escaping history as usual. So it ' s clear to me that we need some ideas outside the box of conventional statecraft — indeed, from another page or another space — which is what brings me to **TED** today and which brings me to a request. This audience includes many of the most creative minds on the planet, who get up in the morning and think not only about how to manage the world we have, but how to create worlds that should be. So I ' m hopeful that as this sinks in and as you reflect on it, some of you are going to have some bold ideas, actually some wild ideas, that when we find, will make a difference in this space. And just to remind you if you do, this won ' t be the first time. Let me remind you of what happened right after World War II. A remarkable group of Americans and Europeans and others, not just from government, but from the world of culture and business, engaged in a **collective** surge of imagination. And what they imagined and what they created was a new **international** order, the order that ' s allowed you and me to live our lives, all of our lives, without great power war and with more prosperity than was ever seen before on the planet. So, a remarkable story. Interestingly, every pillar of this project that produced these results, when first proposed, was rejected by the foreign **policy** establishment as naive or unrealistic. My favorite is the Marshall Plan. After World War II, Americans felt exhausted. They had demobilized 10 million troops, they were focused on an urgent domestic agenda. But as people began to appreciate how devastated Europe was and how aggressive Soviet communism was, Americans eventually decided to tax themselves a percent and a half of GDP every year for four years and send that money to Europe to help reconstruct these countries, including Germany and Italy, whose troops had just been killing Americans. Amazing. This also created the United Nations. Amazing. The Universal Declaration of Human Rights. The World Bank. NATO. All of these elements of an order for peace and prosperity. So, in a word, what we need to do is do it again. And I think now we need a surge of imagination, creativity, informed by history, for, as the philosopher Santayana reminded us, in the end, only those who **refuse** to study history are condemned to repeat it. Thank you.

Because I usually take the role of trying to explain to people how wonderful the new technologies that are coming along are going to be, and I thought that, since I was among friends here, I would tell you what I really think and try to look back and try to understand what is really going on here with these amazing jumps in technology that seem so fast that we can barely keep on top of it. So I ' m going to start out by showing just one very boring technology slide. And then, so if you can just turn on the slide that ' s on. This is just a random slide that I picked out of my file. What I want to show you is not so much the details of the slide, but the general form of it. This happens to be a slide of some analysis that we were doing about the power of RISC microprocessors versus the power of local area networks. And the **interesting** thing about it is that this slide, like so many technology slides that we ' re used to, is a sort of a straight line on a semi-log curve. In other words, every step here represents an order of magnitude in performance scale. And this is a new thing that we talk about technology on semi-log curves. Something really weird is going on here. And that ' s basically what I ' m going to be talking about. So, if you could bring up the lights. If you could bring up the lights higher, because I ' m just going to use a piece of paper here. Now why do we draw technology curves in semi-log curves? Well the answer is, if I drew it on a normal curve where, let ' s say, this is years, this is time of some sort, and this is whatever measure of the technology that I ' m trying to graph, the graphs look sort of silly. They sort of go like this. And they don ' t tell us much. Now if I graph, for instance, some other technology, say transportation technology, on a semi-log curve, it would look very **stupid**, it would look like a flat line. But when something like this happens, things are qualitatively changing. So if transportation technology was moving along as fast as microprocessor technology, then the day after tomorrow, I would be able to get in a taxi cab and be in Tokyo in 30 seconds. It ' s not moving like that. And there ' s nothing precedented in the history of technology development of this kind of self- feeding growth where you go by orders of magnitude every few years. Now the question that I ' d like to ask is, if you look at these exponential curves, they don ' t go on forever. Things just can ' t possibly keep changing as fast as they are. One of two things is going to happen. Either it ' s going to turn into a sort of classical S-curve like this, until something totally different comes along, or maybe it ' s going to do this. That ' s about all it can do. Now I ' m an optimist, so I sort of think it ' s probably going to do something like that. If so, that means that what we ' re in the middle of right now is a **transition**. We ' re sort of on this line in a **transition** from the way the world used to be to some new way that the world is. And so what I ' m trying to ask, what I ' ve been asking myself, is what ' s this new way that the world is? What ' s that new state that the world is heading toward? Because the **transition** seems very, very confusing when we ' re right in the middle of it. Now when I was a kid growing up, the future was kind of the year 2000, and people used to talk about what would happen in the year 2000. Now here ' s a **conference** in which people talk about the future, and you notice that the future is still at about the year 2000. It ' s about as far as we go out. So in other words, the future has kind of been shrinking one year per year for my whole lifetime. Now I think that the reason is because we all feel that something ' s happening there. That **transition** is happening. We can all sense it. And we know that it just doesn ' t make too much sense to think out 30, 50 years because everything ' s going to be so different that a simple extrapolation of what we ' re doing just doesn ' t make any sense at all. So what I would like to talk about is what that could be, what that **transition** could be that we ' re going through. Now in order to do that I ' m going to have to talk about a bunch of **stuff** that really has nothing to do with technology and computers. Because I think the only way to understand this is to really step back and take a long time scale look at things. So the time scale that I would like to look at this on is the time scale of life on Earth. So I think this picture makes sense if you look at it a few billion years at a time. So if you go back about two and a half billion years, the Earth was this big, sterile hunk of rock with a lot of chemicals floating around on it. And if you look at the way that the chemicals got organized, we begin to get a pretty good idea of how they do it. And I think that there ' s theories that are beginning to understand about how it started with RNA, but I ' m going to tell a sort of simple story of it, which is that, at that time, there were little drops of oil floating around with all kinds of different recipes of chemicals in them. And some of those drops of oil had a particular combination of chemicals in them which caused them to incorporate chemicals from the outside and grow the drops of oil. And those that were like that started to split and divide. And those were the most primitive forms of cells in a sense, those little drops of oil. But now those drops of oil weren ’ t really alive, as we say it now, because every one of them was a little random recipe of chemicals. And every time it divided, they got sort of unequal division of the chemicals within them. And so every drop was a little bit different. In fact, the drops that were different in a way that caused them to be better at incorporating chemicals around them, grew more and incorporated more chemicals and divided more. So those tended to live longer, get expressed more. Now that ’ s sort of just a very simple chemical form of life, but when things got **interesting** was when these drops learned a trick about abstraction. Somehow by ways that we don ’ t quite understand, these little drops learned to write down information. They learned to record the information that was the recipe of the cell onto a particular kind of chemical called DNA. So in other words, they worked out, in this mindless sort of evolutionary way, a form of writing that let them write down what they were, so that that way of writing it down could get copied. The amazing thing is that that way of writing seems to have stayed steady since it evolved two and a half billion years ago. In fact the recipe for us, our genes, is exactly that same code and that same way of writing. In fact, every living creature is written in exactly the same set of letters and the same code. In fact, one of the things that I did just for amusement purposes is we can now write things in this code. And I ’ ve got here a little 100 micrograms of white powder, which I try not to let the security people see at airports. But this has in it — what I did is I took this code — the code has standard letters that we use for symbolizing it — and I wrote my business card onto a piece of DNA and amplified it 10 to the 22 times. So if anyone would like a hundred million copies of my business card, I have plenty for everyone in the room, and, in fact, everyone in the world, and it ’ s right here. If I had really been a egotist, I would have put it into a **virus** and released it in the room. So what was the next step? Writing down the DNA was an **interesting** step. And that caused these cells — that kept them happy for another billion years. But then there was another really **interesting** step where things became completely different, which is these cells started exchanging and communicating information, so that they began to get communities of cells. I don ’ t know if you know this, but bacteria can actually exchange DNA. Now that ’ s why, for instance, antibiotic resistance has evolved. Some bacteria figured out how to stay away from penicillin, and it went around sort of creating its little DNA information with other bacteria, and now we have a lot of bacteria that are resistant to penicillin, because bacteria communicate. Now what this communication allowed was communities to form that, in some sense, were in the same boat together ; they were synergistic. So they survived or they failed together, which means that if a community was very successful, all the individuals in that community were repeated more and they were favored by evolution. Now the **transition** point happened when these communities got so close that, in fact, they got together and decided to write down the whole recipe for the community together on one string of DNA. And so the next stage that ’ s **interesting** in life took about another billion years. And at that stage, we have multi-cellular communities, communities of lots of different types of cells, working together as a single organism. And in fact, we ’ re such a multi- cellular community. We have lots of cells that are not out for themselves anymore. Your skin cell is really useless without a heart cell, muscle cell, a brain cell and so on. So these communities began to evolve so that the **interesting** level on which evolution was taking place was no longer a cell, but a community which we call an organism. Now the next step that happened is within these communities. These communities of cells, again, began to abstract information. And they began building very special structures that did nothing but process information within the community. And those are the neural structures. So neurons are the information processing apparatus that those communities of cells built up. And in fact, they began to get specialists in the community and special structures that were responsible for recording, understanding, learning information. And that was the brains and the nervous system of those communities. And that gave them an evolutionary advantage. Because at that point, an individual — learning could happen within the time span of a single organism, instead of over this evolutionary time span. So an organism could, for instance, learn not to eat a certain kind of fruit because it tasted bad and it got sick last time it ate it. That could happen within the lifetime of a single organism, whereas before they ’ d built these special information processing structures, that would have had to be learned evolutionarily over hundreds of thousands of years by the individuals dying off that ate that kind of fruit. So that nervous system, the fact that they built these special information structures, tremendously sped up the whole process of evolution. Because evolution could now happen within an individual. It could happen in learning time scales. But then what happened was the individuals worked out, of course, tricks of communicating. And for example, the most sophisticated version that we ’ re aware of is human language. It ’ s really a pretty amazing invention if you think about it. Here I have a very complicated, messy, confused idea in my head. I ’ m sitting here making grunting sounds basically, and hopefully constructing a similar messy, confused idea in your head that bears some analogy to it. But we ’ re taking something very complicated, turning it into sound, sequences of sounds, and producing something very complicated in your brain. So this allows us now to begin to start functioning as a single organism. And so, in fact, what we ’ ve done is we, humanity, have started abstracting out. We ’ re going through the same levels that multi-cellular organisms have gone through — abstracting out our methods of recording, presenting, processing information. So for example, the invention of language was a tiny step in that direction. Telephony, computers, videotapes, CD-ROMs and so on are all our specialized mechanisms that we ’ ve now built within our society for handling that information. And it all connects us together into something that is much bigger and much faster and able to evolve than what we were before. So now, evolution can take place on a scale of microseconds. And you saw Ty ’ s little evolutionary example where he sort of did a little bit of evolution on the Convolution program right before your eyes. So now we ’ ve speeded up the time scales once again. So the first steps of the story that I told you about took a billion years a piece. And the next steps, like nervous systems and brains, took a few hundred million years. Then the next steps, like language and so on, took less than a million years. And these next steps, like electronics, seem to be taking only a few decades. The process is feeding on itself and becoming, I guess, autocatalytic is the word for it — when something reinforces its rate of change. The more it changes, the faster it changes. And I think that that ’ s what we ’ re seeing here in this explosion of curve. We ’ re seeing this process feeding back on itself. Now I design computers for a living, and I know that the mechanisms that I use to design computers would be impossible without recent advances in computers. So right now, what I do is I design objects at such complexity that it ’ s really impossible for me to design them in the traditional sense. I don ’ t know what every transistor in the connection machine does. There are billions of them. Instead, what I do and what the designers at Thinking Machines do is we think at some level of abstraction and then we hand it to the machine and the machine takes it beyond what we could ever do, much farther and faster than we could ever do. And in fact, sometimes it takes it by methods that we don ’ t quite even understand. One method that ' s particularly **interesting** that I ' ve been using a lot lately is evolution itself. So what we do is we put inside the machine a process of evolution that takes place on the microsecond time scale. So for example, in the most extreme cases, we can actually evolve a program by starting out with random sequences of instructions. Say,"Computer, would you please make a hundred million random sequences of instructions. Now would you please run all of those random sequences of instructions, run all of those programs, and pick out the ones that came closest to doing what I wanted."So in other words, I define what I wanted. Let ' s say I want to sort numbers, as a simple example I ' ve done it with. So find the programs that come closest to sorting numbers. So of course, random sequences of instructions are very unlikely to sort numbers, so none of them will really do it. But one of them, by luck, may put two numbers in the right order. And I say,"Computer, would you please now take the 10 percent of those random sequences that did the best job. Save those. Kill off the rest. And now let ' s reproduce the ones that sorted numbers the best. And let ' s reproduce them by a process of recombination analogous to sex."Take two programs and they produce children by exchanging their subroutines, and the children inherit the traits of the subroutines of the two programs. So I ' ve got now a new generation of programs that are produced by combinations of the programs that did a little bit better job. Say,"Please repeat that process."Score them again. Introduce some mutations perhaps. And try that again and do that for another generation. Well every one of those generations just takes a few milliseconds. So I can do the equivalent of millions of years of evolution on that within the computer in a few minutes, or in the complicated cases, in a few hours. At the end of that, I end up with programs that are absolutely perfect at sorting numbers. In fact, they are programs that are much more efficient than programs I could have ever written by hand. Now if I look at those programs, I can ' t tell you how they work. I ' ve tried looking at them and telling you how they work. They ' re obscure, weird programs. But they do the job. And in fact, I know, I ' m very confident that they do the job because they come from a line of hundreds of thousands of programs that did the job. In fact, their life depended on doing the job. I was riding in a 747 with Marvin Minsky once, and he pulls out this card and says,"Oh look. Look at this. It says, ' This plane has hundreds of thousands of tiny parts working together to make you a **safe** flight. ' Doesn ' t that make you feel confident?"In fact, we know that the engineering process doesn ' t work very well when it gets complicated. So we ' re beginning to depend on computers to do a process that ' s very different than engineering. And it lets us produce things of much more complexity than normal engineering lets us produce. And yet, we don ' t quite understand the options of it. So in a sense, it ' s getting ahead of us. We ' re now using those programs to make much faster computers so that we ' ll be able to run this process much faster. So it ' s feeding back on itself. The thing is becoming faster and that ' s why I think it seems so confusing. Because all of these technologies are feeding back on themselves. We ' re taking off. And what we are is we ' re at a point in time which is analogous to when single- celled organisms were turning into multi-celled organisms. So we ' re the amoebas and we can ' t quite figure out what the hell this thing is we ' re creating. We ' re right at that point of **transition**. But I think that there really is something coming along after us. I think it ' s very haughty of us to think that we ' re the end product of evolution. And I think all of us here are a part of producing whatever that next thing is. So lunch is coming along, and I think I will stop at that point, before I get selected out.

Chris Anderson : We had Edward Snowden here a couple days ago, and this is response time. And several of you have written to me with questions to ask our guest here from the NSA. So Richard Ledgett is the 15th deputy director of the National Security Agency, and he ’ s a **senior** civilian officer there, acts as its chief operating officer, guiding strategies, setting internal **policies**, and serving as the principal advisor to the director. And all being well, welcome, Rick Ledgett, to **TED**. Richard Ledgett : I ’ m really thankful for the opportunity to talk to folks here. I look forward to the conversation, so thanks for arranging for that. CA : Thank you, Rick. We appreciate you joining us. It ’ s certainly quite a strong statement that the NSA is willing to reach out and show a more open face here. You saw, I think, the talk and interview that Edward Snowden gave here a couple days ago. What did you make of it? RL : So I think it was **interesting**. We didn ’ t realize that he was going to show up there, so kudos to you **guys** for arranging a nice surprise like that. I think that, like a lot of the things that have come out since Mr. Snowden started disclosing classified information, there were some kernels of truth in there, but a lot of extrapolations and half-truths in there, and I ’ m **interested** in helping to address those. I think this is a really important conversation that we ’ re having in the United States and internationally, and I think it is important and of import, and so given that, we need to have that be a fact-based conversation, and we want to help make that happen. CA : So the question that a lot of people have here is, what do you make of Snowden ’ s motivations for doing what he did, and did he have an alternative way that he could have gone? RL : He absolutely did have alternative ways that he could have gone, and I actually think that characterizing him as a whistleblower actually hurts legitimate whistleblowing activities. So what if somebody who works in the NSA — and there are over 35, 000 people who do. They ’ re all great citizens. They ’ re just like your husbands, fathers, sisters, brothers, neighbors, nephews, friends and relatives, all of whom are **interested** in doing the right thing for their country and for our allies internationally, and so there are a variety of venues to address if folks have a concern. First off, there ’ s their supervisor, and up through the supervisory chain within their organization. If folks aren ’ t comfortable with that, there are a number of inspectors general. In the case of Mr. Snowden, he had the option of the NSA inspector general, the Navy inspector general, the Pacific Command inspector general, the Department of Defense inspector general, and the **intelligence** community inspector general, any of whom would have both kept his concerns in classified channels and been happy to address them. He had the option to go to congressional committees, and there are mechanisms to do that that are in place, and so he didn ’ t do any of those things. CA : Now, you had said that Ed Snowden had other avenues for raising his concerns. The comeback on that is a couple of things : one, that he certainly believes that as a contractor, the avenues that would have been available to him as an employee weren ’ t available, two, there ’ s a track record of other whistleblowers, like [Thomas Andrews Drake] being treated pretty harshly, by some views, and thirdly, what he was taking on was not one specific flaw that he ’ d discovered, but programs that had been approved by all three branches of government. I mean, in that circumstance, couldn ’ t you argue that what he did was reasonable? RL : No, I don ’ t agree with that. I think that the — sorry, I ’ m getting feedback through the microphone there — the actions that he took were inappropriate because of the fact that he put people ’ s lives at risk, basically, in the long run, and I know there ’ s been a lot of talk in public by Mr. Snowden and some of the journalists that say that the things that have been disclosed have not put national security and people at risk, and that is categorically not true. They actually do. I think there ’ s also an amazing arrogance to the idea that he knows better than the framers of the Constitution in how the government should be designed and work for separation of powers and the fact that the executive and the legislative branch have to work together and they have checks and balances on each other, and then the judicial branch, which oversees the entire process. I think that ’ s extremely arrogant on his part. CA : Can you give a specific example of how he put people ’ s lives at risk? RL : Yeah, sure. So the things that he ’ s disclosed, the capabilities, and the NSA is a capabilities-based organization, so when we have foreign **intelligence** targets, legitimate things of interest — like, terrorists is the iconic example, but it includes things like human traffickers, drug traffickers, people who are trying to build advanced weaponry, nuclear weapons, and build delivery systems for those, and nation-states who might be executing aggression against their immediate neighbors, which you may have some visibility into some of that that ’ s going on right now, the capabilities are applied in very discrete and measured and controlled ways. So the unconstrained disclosure of those capabilities means that as adversaries see them and recognize,”Hey, I might be vulnerable to this,”they move away from that, and we have seen targets in terrorism, in the nation-state area, in smugglers of various types, and other folks who have, because of the disclosures, moved away from our **ability** to have insight into what they ’ re doing. The net effect of that is that our people who are overseas in dangerous places, whether they ’ re diplomats or military, and our allies who are in similar situations, are at greater risk because we don ’ t see the threats that are coming their way. CA : So that ’ s a general response saying that because of his revelations, access that you had to certain types of information has been shut down, has been closed down. But the concern is that the nature of that access was not necessarily legitimate in the first place. I mean, describe to us this Bullrun program where it ’ s alleged that the NSA specifically weakened security in order to get the type of access that you ’ ve spoken of. RL : So there are, when our legitimate foreign **intelligence** targets of the type that I described before, use the global telecommunications system as their communications methodology, and they do, because it ’ s a great system, it ’ s the most complex system ever devised by man, and it is a wonder, and lots of folks in the room there are responsible for the creation and enhancement of that, and it ’ s just a wonderful thing. But it ’ s also used by people who are working against us and our allies. And so if I ’ m going to pursue them, I need to have the capability to go after them, and again, the controls are in how I apply that capability, not that I have the capability itself. Otherwise, if we could make it so that all the bad **guys** used one corner of the Internet, we could have a domain, badguy. com. That would be awesome, and we could just concentrate all our efforts there. That ’ s not how it works. They ’ re trying to hide from the government ’ s **ability** to isolate and interdict their actions, and so we have to swim in that same space. But I will tell you this. So NSA has two missions. One is the Signals **Intelligence** mission that we ’ ve unfortunately read so much about in the press. The other one is the Information Assurance mission, which is to protect the national security systems of the United States, and by that, that ’ s things like the communications that the president uses, the communications that control our nuclear weapons, the communications that our military uses around the world, and the communications that we use with our allies, and that some of our allies themselves use. And so we make recommendations on standards to use, and we use those same standards, and so we are **invested** in making sure that those communications are secure for their intended purposes. CA : But it sounds like what you ’ re saying is that when it comes to the Internet at large, any strategy is fair game if it improves America ’ s safety. And I think this is partly where there is such a divide of opinion, that there ' s a lot of people in this room and around the world who think very differently about the Internet. They think of it as a momentous invention of humanity, kind of on a par with the Gutenberg press, for example. It ' s the bringer of knowledge to all. It ' s the connector of all. And it ' s viewed in those sort of idealistic terms. And from that lens, what the NSA has done is equivalent to the authorities back in Germany inserting some device into every printing press that would reveal which books people bought and what they read. Can you understand that from that viewpoint, it feels outrageous? RL : I do understand that, and I actually share the view of the utility of the Internet, and I would argue it ' s bigger than the Internet. It is a global telecommunications system. The Internet is a big chunk of that, but there is a lot more. And I think that people have legitimate concerns about the balance between transparency and secrecy. That ' s sort of been couched as a balance between privacy and national security. I don ' t think that ' s the right framing. I think it really is transparency and secrecy. And so that ' s the national and **international** conversation that we ' re having, and we want to participate in that, and want people to participate in it in an informed way. So there are things, let me talk there a little bit more, there are things that we need to be transparent about : our authorities, our processes, our oversight, who we are. We, NSA, have not done a good job of that, and I think that ' s part of the reason that this has been so revelational and so sensational in the media. Nobody knew who we were. We were the No Such Agency, the Never Say Anything. There ' s takeoffs of our logo of an eagle with headphones on around it. And so that ' s the public characterization. And so we need to be more transparent about those things. What we don ' t need to be transparent about, because it ' s bad for the U. S., it ' s bad for all those other countries that we work with and that we help provide information that helps them secure themselves and their people, it ' s bad to expose operations and capabilities in a way that allows the people that we ' re all working against, the generally recognized bad **guys**, to counter those. CA : But isn ' t it also bad to deal a kind of body blow to the American companies that have essentially given the world most of the Internet services that matter? RL : It is. It ' s really the companies are in a tough position, as are we, because the companies, we compel them to provide information, just like every other nation in the world does. Every industrialized nation in the world has a lawful intercept program where they are requiring companies to provide them with information that they need for their security, and the companies that are **involved** have complied with those programs in the same way that they have to do when they ' re operating in Russia or the U. K. or China or India or France, any country that you choose to name. And so the fact that these revelations have been broadly characterized as"you can ' t **trust** company A because your privacy is suspect with them"is actually only accurate in the sense that it ' s accurate with every other company in the world that deals with any of those countries in the world. And so it ' s being picked up by people as a marketing advantage, and it ' s being marketed that way by several countries, including some of our allied countries, where they are saying,"Hey, you can ' t **trust** the U. S., but you can **trust** our telecom company, because we ' re **safe**."And they ' re actually using that to counter the very large technological edge that U. S. companies have in areas like the cloud and Internet-based technologies. CA : You ' re sitting there with the American flag, and the American Constitution guarantees freedom from unreasonable search and seizure. How do you characterize the American citizen ' s right to privacy? Is there such a right? RL : Yeah, of course there is. And we devote an inordinate amount of time and pressure, inordinate and appropriate, actually I should say, amount of time and effort in order to **ensure** that we protect that privacy. and beyond that, the privacy of citizens around the world, it ’ s not just Americans. Several things come into play here. First, we ’ re all in the same network. My communications, I ’ m a user of a particular Internet email service that is the number one email service of choice by terrorists around the world, number one. So I ’ m there right beside them in email space in the Internet. And so we need to be able to pick that apart and find the information that ’ s relevant. In doing so, we ’ re going to necessarily encounter Americans and innocent foreign citizens who are just going about their business, and so we have procedures in place that shreds that out, that says, when you find that, not if you find it, when you find it, because you ’ re certain to find it, here ’ s how you protect that. These are called minimization procedures. They ’ re approved by the attorney general and constitutionally based. And so we protect those. And then, for people, citizens of the world who are going about their lawful business on a day-to-day basis, the president on his January 17 speech, laid out some additional protections that we are providing to them. So I think absolutely, folks do have a right to privacy, and that we work very hard to make sure that that right to privacy is protected. CA : What about foreigners using American companies ’ Internet services? Do they have any privacy rights? RL : They do. They do, in the sense of, the only way that we are able to compel one of those companies to provide us information is when it falls into one of three categories : We can identify that this particular person, identified by a selector of some kind, is associated with counterterrorist or proliferation or other foreign **intelligence** target. CA : Much has been made of the fact that a lot of the information that you ’ ve obtained through these programs is essentially metadata. It ’ s not necessarily the actual words that someone has written in an email or given on a **phone** call. It ’ s who they wrote to and when, and so forth. But it ’ s been argued, and someone here in the audience has talked to a former NSA analyst who said metadata is actually much more invasive than the core data, because in the core data you present yourself as you want to be presented. With metadata, who knows what the conclusions are that are drawn? Is there anything to that? RL : I don ’ t really understand that argument. I think that metadata ’ s important for a couple of reasons. Metadata is the information that lets you find connections that people are trying to hide. So when a terrorist is corresponding with somebody else who ’ s not known to us but is engaged in doing or **supporting** terrorist activity, or someone who ’ s violating **international** sanctions by providing nuclear weapons-related material to a country like Iran or North Korea, is trying to hide that activity because it ’ s illicit activity. What metadata lets you do is connect that. The alternative to that is one that ’ s much less efficient and much more invasive of privacy, which is gigantic amounts of content collection. So metadata, in that sense, actually is privacy- enhancing. And we don ’ t, contrary to some of the **stuff** that ’ s been printed, we don ’ t sit there and grind out metadata profiles of average people. If you ’ re not connected to one of those valid **intelligence** targets, you are not of interest to us. CA : So in terms of the threats that face America overall, where would you place terrorism? RL : I think terrorism is still number one. I think that we have never been in a time where there are more places where things are going badly and forming the petri dish in which terrorists take advantage of the lack of governance. An old boss of mine, Tom Fargo, Admiral Fargo, used to describe it as arcs of instability. And so you have a lot of those arcs of instability in the world right now, in places like Syria, where there ’ s a civil war going on and you have massive numbers, thousands and thousands of foreign fighters who are coming into Syria to learn how to be terrorists and practice that activity, and lots of those people are Westerners who hold passports to European countries or in some cases the United States, and so they are basically learning how to do jihad and have expressed intent to go out and do that later on in their home countries. You ’ ve got places like Iraq, which is suffering from a high level of sectarian violence, again a breeding ground for terrorism. And you have the activity in the Horn of Africa and the Sahel area of Africa. Again, lots of weak governance which forms a breeding ground for terrorist activity. So I think it ’ s very serious. I think it ’ s number one. I think number two is cyber threat. I think cyber is a threat in three ways : One way, and probably the most common way that people have heard about it, is due to the theft of intellectual property, so basically, foreign countries going in, stealing companies ’ secrets, and then providing that information to state-owned enterprises or companies connected to the government to help them leapfrog technology or to gain business **intelligence** that ’ s then used to win contracts overseas. That is a hugely costly set of activities that ’ s going on right now. Several nation- states are doing it. Second is the denial-of-service attacks. You ’ re probably aware that there have been a spate of those directed against the U. S. financial **sector** since 2012. Again, that ’ s a nation-state who is executing those attacks, and they ’ re doing that as a semi-anonymous way of reprisal. And the last one is destructive attacks, and those are the ones that concern me the most. Those are on the rise. You have the attack against Saudi Aramco in 2012, August of 2012. It took down about 35, 000 of their computers with a Wiper-style **virus**. You had a follow-on a week later to a Qatari company. You had March of 2013, you had a South Korean attack that was attributed in the press to North Korea that took out thousands of computers. Those are on the rise, and we see people expressing interest in those capabilities and a desire to employ them. CA : Okay, so a couple of things here, because this is really the core of this, almost. I mean, first of all, a lot of people who look at risk and look at the numbers don ’ t understand this belief that terrorism is still the number one threat. Apart from September 11, I think the numbers are that in the last 30 or 40 years about 500 Americans have died from terrorism, mostly from homegrown terrorists. The chance in the last few years of being killed by terrorism is far less than the chance of being killed by lightning. I guess you would say that a single nuclear incident or bioterrorism act or something like that would change those numbers. Would that be the point of view? RL : Well, I ’ d say two things. One is, the reason that there hasn ’ t been a major attack in the United States since 9 / 11, that is not an accident. That ’ s a lot of hard work that we have done, that other folks in the **intelligence** community have done, that the military has done, and that our allies around the globe have done. You ’ ve heard the numbers about the tip of the iceberg in terms of numbers of terrorist attacks that NSA programs contributed to stopping was 54, 25 of those in Europe, and of those 25, 18 of them occurred in three countries, some of which are our allies, and some of which are beating the heck out of us over the NSA programs, by the way. So that ’ s not an accident that those things happen. That ’ s hard work. That ’ s us finding **intelligence** on terrorist activities and interdicting them through one way or another, through law enforcement, through cooperative activities with other countries and sometimes through military action. The other thing I would say is that your idea of nuclear or chem-bio-threat is not at all far-fetched and in fact there are a number of groups who have for several years expressed interest and desire in obtaining those capabilities and work towards that. CA : It ’ s also been said that, of those 54 alleged incidents, that as few as zero of them were actually anything to do with these controversial programs that Mr. Snowden revealed, that it was basically through other forms of **intelligence**, that you ’ re looking for a needle in a haystack, and the effects of these programs, these controversial programs, is just to add hay to the stack, not to really find the needle. The needle was found by other methods. Isn ’ t there something to that? RL : No, there ’ s actually two programs that are typically implicated in that discussion. One is the section 215 program, the U. S. telephony metadata program, and the other one is popularly called the PRISM program, and it ’ s actually section 702 of the FISA Amendment Act. But the 215 program is only relevant to threats that are directed against the United States, and there have been a dozen threats where that was implicated. Now what you ’ ll see people say publicly is there is no”but for”case, and so there is no case where, but for that, the threat would have happened. But that actually indicates a lack of understanding of how terrorist investigations actually work. You think about on television, you watch a murder mystery. What do you start with? You start with a body, and then they work their way from there to solve the crime. We ’ re actually starting well before that, hopefully before there are any bodies, and we ’ re trying to build the case for who the people are, what they ’ re trying to do, and that **involves** massive amounts of information. Think of it is as mosaic, and it ’ s hard to say that any one piece of a mosaic was necessary to building the mosaic, but to build the complete picture, you need to have all the pieces of information. On the other, the non-U. S. -related threats out of those 54, the other 42 of them, the PRISM program was hugely relevant to that, and in fact was material in contributing to stopping those attacks. CA : Snowden said two days ago that terrorism has always been what is called in the **intelligence** world”a cover for action,”that it ’ s something that, because it invokes such a powerful emotional response in people, it allows the initiation of these programs to achieve powers that an organization like yours couldn ’ t otherwise have. Is there any internal debate about that? RL : Yeah. I mean, we debate these things all the time, and there is discussion that goes on in the executive branch and within NSA itself and the **intelligence** community about what ’ s right, what ’ s proportionate, what ’ s the correct thing to do. And it ’ s important to note that the programs that we ’ re talking about were all authorized by two different presidents, two different political parties, by Congress twice, and by federal judges 16 different times, and so this is not NSA running off and doing its own thing. This is a legitimate activity of the United States foreign government that was agreed to by all the branches of the United States government, and President Madison would have been proud. CA : And yet, when congressmen discovered what was actually being done with that authorization, many of them were completely shocked. Or do you think that is not a legitimate **reaction**, that it ’ s only because it ’ s now come out publicly, that they really knew exactly what you were doing with the powers they had granted you? RL : Congress is a big body. There ’ s 535 of them, and they change out frequently, in the case of the House, every two years, and I think that the NSA provided all the relevant information to our oversight committees, and then the dissemination of that information by the oversight committees throughout Congress is something that they manage. I think I would say that Congress members had the opportunity to make themselves aware, and in fact a significant number of them, the ones who are assigned oversight responsibility, did have the **ability** to do that. And you ’ ve actually had the chairs of those committees say that in public. CA : Now, you mentioned the threat of cyberattacks, and I don ’ t think anyone in this room would disagree that that is a huge concern, but do you accept that there ’ s a tradeoff between offensive and defensive strategies, and that it ’ s possible that the very measures taken to,”weaken encryption,”and allow yourself to find the bad **guys**, might also open the door to forms of cyberattack? RL : So I think two things. One is, you said weaken encryption. I didn ’ t. And the other one is that the NSA has both of those missions, and we are heavily biased towards defense, and, actually, the vulnerabilities that we find in the overwhelming majority of cases, we disclose to the people who are responsible for manufacturing or developing those products. We have a great track record of that, and we ’ re actually working on a proposal right now to be transparent and to publish transparency reports in the same way that the Internet companies are being allowed to publish transparency reports for them. We want to be more transparent about that. So again, we eat our own dog food. We use the standards, we use the products that we recommend, and so it ’ s in our interest to keep our communications protected in the same way that other people ’ s need to be. CA : Edward Snowden, when, after his talk, was wandering the halls here in the bot, and I heard him say to a couple of people, they asked him about what he thought of the NSA overall, and he was very complimentary about the people who work with you, said that it ’ s a really impassioned group of employees who are seeking to do the right thing, and that the problems have come from just some badly conceived **policies**. He came over certainly very reasonably and calmly. He didn ’ t come over like a crazy man. Would you accept that at least, even if you disagree with how he did it, that he has opened a debate that matters? RL : So I think that the discussion is an important one to have. I do not like the way that he did it. I think there were a number of other ways that he could have done that that would have not endangered our people and the people of other nations through losing visibility into what our adversaries are doing. But I do think it ’ s an important conversation. CA : It ’ s been reported that there ’ s almost a difference of opinion with you and your colleagues over any scenario in which he might be offered an amnesty deal. I think your boss, General Keith Alexander, has said that that would be a terrible example for others ; you can ’ t **negotiate** with someone who ’ s broken the law in that way. But you ’ ve been quoted as saying that, if Snowden could prove that he was surrendering all undisclosed **documents**, that a deal maybe should be considered. Do you still think that? RL : Yeah, so actually, this is my favorite thing about that”60 Minutes”interview was all the misquotes that came from that. What I actually said, in response to a question about, would you entertain any discussions of mitigating action against Snowden, I said, yeah, it ’ s worth a conversation. This is something that the attorney general of the United States and the president also actually have both talked about this, and I defer to the attorney general, because this is his lane. But there is a strong tradition in American jurisprudence of having discussions with people who have been charged with crimes in order to, if it benefits the government, to get something out of that, that there ’ s always room for that kind of discussion. So I ’ m not presupposing any outcome, but there is always room for discussion. CA : To a lay person it seems like he has certain things to offer the U. S., the government, you, others, in terms of putting things right and helping figure out a smarter **policy**, a smarter way forward for the future. Do you see, has that kind of possibility been entertained at all? RL : So that ’ s out of my lane. That ’ s not an NSA thing. That would be a Department of Justice sort of discussion. I ’ ll defer to them. CA : Rick, when Ed Snowden ended his talk, I offered him the chance to share an idea worth spreading. What would be your idea worth spreading for this group? RL : So I think, learn the facts. This is a really important conversation, and it **impacts**, it ’ s not just NSA, it ’ s not just the government, it ’ s you, it ’ s the Internet companies. The issue of privacy and personal data is much bigger than just the government, and so learn the facts. Don ’ t rely on headlines, don ’ t rely on sound bites, don ’ t rely on one-sided conversations. So that ’ s the idea, I think, worth spreading. We have a sign, a badge tab, we wear badges at work with lanyards, and if I could make a plug, my badge lanyard at work says,”Dallas Cowboys.”Go Dallas. I ’ ve just alienated half the audience, I know. So the lanyard that our people who work in the organization that does our crypto- analytic work have a tab that says,”Look at the data.”So that ’ s the idea worth spreading. Look at the data. CA : Rick, it took a certain amount of courage, I think, actually, to come and speak openly to this group. It ’ s not something the NSA has done a lot of in the past, and plus the technology has been challenging. We truly appreciate you doing that and sharing in this very important conversation. Thank you so much. RL : Thanks, Chris.

Text Sample 569: POS Dim 4 – 2014 – Score 20.00 – 2014/t001880.txt
Chris Anderson : The rights of citizens, the future of the Internet. So I would like to welcome to the **TED** stage the man behind those revelations, Ed Snowden. Ed is in a remote location somewhere in Russia controlling this bot from his laptop, so he can see what the bot can see. Ed, welcome to the **TED** stage. What can you see, as a matter of fact? Edward Snowden : Ha, I can see everyone. This is amazing. CA : Ed, some questions for you. You ’ ve been called many things in the last few months. You ’ ve been called a whistleblower, a traitor, a hero. What words would you describe yourself with? ES : You know, **everybody** who is **involved** with this debate has been struggling over me and my personality and how to describe me. But when I think about it, this isn ’ t the question that we should be struggling with. Who I am really doesn ’ t matter at all. If I ’ m the worst person in the world, you can hate me and move on. What really matters here are the issues. What really matters here is the kind of government we want, the kind of Internet we want, the kind of relationship between people and societies. And that ’ s what I ’ m hoping the debate will move towards, and we ’ ve seen that increasing over time. If I had to describe myself, I wouldn ’ t use words like”hero.”I wouldn ’ t use”patriot,”and I wouldn ’ t use”traitor.”I ’ d say I ’ m an American and I ’ m a citizen, just like everyone else. CA : So just to give some context for those who don ’ t know the whole story — — this time a year ago, you were stationed in Hawaii working as a consultant to the NSA. As a sysadmin, you had access to their systems, and you began revealing certain classified **documents** to some handpicked journalists leading the way to June ’ s revelations. Now, what propelled you to do this? ES : You know, when I was sitting in Hawaii, and the years before, when I was working in the **intelligence** community, I saw a lot of things that had disturbed me. We do a lot of good things in the **intelligence** community, things that need to be done, and things that help everyone. But there are also things that go too far. There are things that shouldn ’ t be done, and decisions that were being made in secret without the public ’ s awareness, without the public ’ s consent, and without even our representatives in government having knowledge of these programs. When I really came to struggle with these issues, I thought to myself, how can I do this in the most responsible way, that maximizes the public benefit while minimizing the risks? And out of all the solutions that I could come up with, out of going to Congress, when there were no laws, there were no legal protections for a private employee, a contractor in **intelligence** like myself, there was a risk that I would be buried along with the information and the public would never find out. But the First Amendment of the United States Constitution guarantees us a free press for a reason, and that ’ s to enable an adversarial press, to challenge the government, but also to work together with the government, to have a dialogue and debate about how we can inform the public about matters of vital importance without putting our national security at risk. And by working with journalists, by giving all of my information back to the American people, rather than **trusting** myself to make the decisions about publication, we ’ ve had a robust debate with a deep investment by the govern-

ment that I think has resulted in a benefit for everyone. And the risks that have been threatened, the risks that have been played up by the government have never materialized. We ’ ve never seen any evidence of even a single instance of specific harm, and because of that, I ’ m comfortable with the decisions that I made. CA : So let me show the audience a couple of examples of what you revealed. If we could have a slide up, and Ed, I don ’ t know whether you can see, the slides are here. This is a slide of the PRISM program, and maybe you could tell the audience what that was that was revealed. ES : The best way to understand PRISM, because there ’ s been a little bit of controversy, is to first talk about what PRISM isn ’ t. Much of the debate in the U. S. has been about metadata. They ’ ve said it ’ s just metadata, it ’ s just metadata, and they ’ re talking about a specific legal authority called Section 215 of the Patriot Act. That allows sort of a warrantless wiretapping, mass surveillance of the entire country ’ s **phone** records, things like that — who you ’ re talking to, when you ’ re talking to them, where you traveled. These are all metadata events. PRISM is about content. It ’ s a program through which the government could compel corporate America, it could deputize corporate America to do its dirty work for the NSA. And even though some of these companies did resist, even though some of them — I believe Yahoo was one of them — challenged them in **court**, they all lost, because it was never tried by an open **court**. They were only tried by a secret **court**. And something that we ’ ve seen, something about the PRISM program that ’ s very concerning to me is, there ’ s been a talking point in the U. S. government where they ’ ve said 15 federal judges have reviewed these programs and found them to be lawful, but what they don ’ t tell you is those are secret judges in a secret **court** based on secret interpretations of law that ’ s considered 34, 000 warrant requests over 33 years, and in 33 years only rejected 11 government requests. These aren ’ t the people that we want deciding what the role of corporate America in a free and open Internet should be. CA : Now, this slide that we ’ re showing here shows the dates in which different technology companies, Internet companies, are alleged to have joined the program, and where data collection began from them. Now, they have denied collaborating with the NSA. How was that data collected by the NSA? ES : Right. So the NSA ’ s own slides refer to it as direct access. What that means to an actual NSA analyst, someone like me who was working as an **intelligence** analyst targeting, Chinese cyber-hackers, things like that, in Hawaii, is the provenance of that data is directly from their servers. It doesn ’ t mean that there ’ s a group of company representatives sitting in a smoky room with the NSA palling around and making back-room deals about how they ’ re going to give this **stuff** away. Now each company handles it different ways. Some are responsible. Some are somewhat less responsible. But the bottom line is, when we talk about how this information is given, it ’ s coming from the companies themselves. It ’ s not stolen from the lines. But there ’ s an important thing to remember here : even though companies pushed back, even though companies **demanded**, hey, let ’ s do this through a warrant process, let ’ s do this where we actually have some sort of legal review, some sort of basis for handing over these users ’ data, we saw stories in the Washington Post last year that weren ’ t as well reported as the PRISM story that said the NSA broke in to the data center communications between Google to itself and Yahoo to itself. So even these companies that are cooperating in at least a compelled but hopefully lawful manner with the NSA, the NSA isn ’ t satisfied with that, and because of that, we need our companies to work very hard to guarantee that they ’ re going to represent the interests of the user, and also advocate for the rights of the users. And I think over the last year, we ’ ve seen the companies that are named on the PRISM slides take great strides to do that, and I encourage them to continue. CA : What more should they do? ES : The biggest thing that an Internet company in America can do today, right now, without consulting with lawyers, to protect the rights of users worldwide, is to enable SSL web encryption on every page you **visit**. The reason this matters is today, if you go to look at a copy of"1984"on Amazon. com, the NSA can see a record of that, the Russian **intelligence** service can see a record of that, the Chinese service can see a record of that, the French service, the German service, the services of Andorra. They can all see it because it ' s unencrypted. The world ' s library is Amazon. com, but not only do they not **support** encryption by default, you cannot choose to use encryption when browsing through books. This is something that we need to change, not just for Amazon, I don ' t mean to single them out, but they ' re a great example. All companies need to move to an encrypted browsing habit by default for all users who haven ' t taken any action or picked any special methods on their own. That ' ll increase the privacy and the rights that people enjoy worldwide. CA : Ed, come with me to this part of the stage. I want to show you the next slide here. This is a program called Boundless Informant. What is that? ES : So, I ' ve got to give credit to the NSA for using appropriate names on this. This is one of my favorite NSA cryptonyms. Boundless Informant is a program that the NSA hid from Congress. The NSA was previously asked by Congress, was there any **ability** that they had to even give a rough ballpark estimate of the amount of American communications that were being intercepted. They said no. They said, we don ' t track those stats, and we can ' t track those stats. We can ' t tell you how many communications we ' re intercepting around the world, because to tell you that would be to invade your privacy. Now, I really appreciate that sentiment from them, but the reality, when you look at this slide is, not only do they have the capability, the capability already exists. It ' s already in place. The NSA has its own internal data format that tracks both ends of a communication, and if it says, this communication came from America, they can tell Congress how many of those communications they have today, right now. And what Boundless Informant tells us is more communications are being intercepted in America about Americans than there are in Russia about Russians. I ' m not sure that ' s what an **intelligence** agency should be aiming for. CA : Ed, there was a story broken in the Washington Post, again from your data. The headline says,"NSA broke privacy rules thousands of times per year."Tell us about that. ES : We also heard in Congressional testimony last year, it was an amazing thing for someone like me who came from the NSA and who ' s seen the actual internal **documents**, knows what ' s in them, to see officials testifying under oath that there had been no abuses, that there had been no violations of the NSA ' s rules, when we knew this story was coming. But what ' s especially **interesting** about this, about the fact that the NSA has violated their own rules, their own laws thousands of times in a single year, including one event by itself, one event out of those 2, 776, that affected more than 3, 000 people. In another event, they intercepted all the calls in Washington, D. C., by accident. What ' s amazing about this, this report, that didn ' t get that much attention, is the fact that not only were there 2, 776 abuses, the chairman of the Senate Intelligence Committee, Dianne Feinstein, had not seen this report until the Washington Post contacted her asking for comment on the report. And she then requested a copy from the NSA and received it, but had never seen this before that. What does that say about the state of oversight in American **intelligence** when the chairman of the Senate Intelligence Committee has no idea that the rules are being broken thousands of times every year? CA : Ed, one response to this whole debate is this : Why should we care about all this surveillance, honestly? I mean, look, if you ' ve done nothing wrong, you ' ve got nothing to worry about. What ' s wrong with that point of view? ES : Well, so the first thing is, you ' re giving up your rights. You ' re saying hey, you know, I don ' t think I ' m going to need them, so I ' m just going to **trust** that, you know, let ' s get rid of them, it doesn ' t really matter, these **guys** are going to do the right thing. Your rights matter because you never know when you ' re going to need them. Beyond that, it ' s a part of our cultural identity, not just in America, but in Western societies and in democratic societies around the world. People should be able to pick up the **phone** and to call their family, people should be able to send a text message to their loved ones, people should be able to buy a book online, they should be able to travel by train, they should be able to buy an airline ticket without wondering about how these events are going to look to an agent of the government, possibly not even your government years in the future, how they ' re going to be misinterpreted and what they ' re going to think your intentions were. We have a right to privacy. We require warrants to be based on probable cause or some kind of individualized suspicion because we recognize that trusting anybody, any government authority, with the entirety of human communications in secret and without oversight is simply too great a temptation to be ignored. CA : Some people are furious at what you ' ve done. I heard a quote recently from Dick Cheney who said that Julian Assange was a flea bite, Edward Snowden is the lion that bit the head off the dog. He thinks you ' ve committed one of the worst acts of betrayal in American history. What would you say to people who think that? ES : Dick Cheney ' s really something else. Thank you. I think it ' s amazing, because at the time Julian Assange was doing some of his greatest work, Dick Cheney was saying he was going to end governments worldwide, the skies were going to ignite and the seas were going to boil off, and now he ' s saying it ' s a flea bite. So we should be suspicious about the same sort of overblown **claims** of damage to national security from these kind of officials. But let ' s assume that these people really believe this. I would argue that they have kind of a narrow conception of national security. The prerogatives of people like Dick Cheney do not keep the nation **safe**. The public interest is not always the same as the national interest. Going to war with people who are not our enemy in places that are not a threat doesn ' t make us **safe**, and that applies whether it ' s in Iraq or on the Internet. The Internet is not the enemy. Our economy is not the enemy. American businesses, Chinese businesses, and any other company out there is a part of our society. It ' s a part of our interconnected world. There are ties of fraternity that bond us together, and if we destroy these bonds by undermining the standards, the security, the manner of behavior, that nations and citizens all around the world expect us to abide by. CA : But it ' s alleged that you ' ve stolen 1. 7 million **documents**. It seems only a few hundred of them have been shared with journalists so far. Are there more revelations to come? ES : There are absolutely more revelations to come. I don ' t think there ' s any question that some of the most important reporting to be done is yet to come. CA : Come here, because I want to ask you about this particular revelation. Come and take a look at this. I mean, this is a story which I think for a lot of the techies in this room is the single most shocking thing that they have heard in the last few months. It ' s about a program called"Bullrun."Can you explain what that is? ES : So Bullrun, and this is again where we ' ve got to thank the NSA for their candor, this is a program named after a Civil War battle. The British counterpart is called Edgehill, which is a U. K. civil war battle. And the reason that I believe they ' re named this way is because they target our own infrastructure. They ' re programs through which the NSA intentionally misleads corporate partners. They tell corporate partners that these are **safe** standards. They say hey, we need to work with you to secure your systems, but in reality, they ' re giving bad advice to these companies that makes them degrade the security of their services. They ' re building in backdoors that not only the NSA can exploit, but anyone else who has time and money to research and find it can then use to let themselves in to the world ' s communications. And this is really dangerous, because if we lose a single standard, if we lose the **trust** of something like SSL, which was specifically targeted by the Bullrun program, we will live a less **safe** world overall. We won ' t be able to access our banks and we won ' t be able to access commerce without worrying about people monitoring those communications or subverting them for their own ends. CA : And do those same decisions also potentially open America up to cyberattacks from other sources? ES : Absolutely. One of the problems, one of the dangerous legacies that we ' ve seen in the post-9 / 11 era, is that the NSA has traditionally worn two hats. They ' ve been in charge of offensive operations, that is hacking, but they ' ve also been in charge of defensive operations, and traditionally they ' ve always prioritized defense over offense based on the principle that American secrets are simply worth more. If we hack a Chinese business and steal their secrets, if we hack a government office in Berlin and steal their secrets, that has less value to the American people than making sure that the Chinese can ' t get access to our secrets. So by reducing the security of our communications, they ' re not only putting the world at risk, they ' re putting America at risk in a fundamental way, because intellectual property is the basis, the foundation of our economy, and if we put that at risk through weak security, we ' re going to be paying for it for years. CA : But they ' ve made a calculation that it was worth doing this as part of America ' s defense against terrorism. Surely that makes it a price worth paying. ES : Well, when you look at the results of these programs in stopping terrorism, you will see that that ' s unfounded, and you don ' t have to take my word for it, because we ' ve had the first open **court**, the first federal **court** that ' s reviewed this, outside the secrecy arrangement, called these programs Orwellian and likely unconstitutional. Congress, who has access to be briefed on these things, and now has the desire to be, has produced bills to reform it, and two independent White House panels who reviewed all of the classified evidence said these programs have never stopped a single terrorist attack that was imminent in the United States. So is it really terrorism that we ' re stopping? Do these programs have any value at all? I say no, and all three branches of the American government say no as well. CA : I mean, do you think there ' s a deeper motivation for them than the war against terrorism? ES : I ' m sorry, I couldn ' t hear you, say again? CA : Sorry. Do you think there ' s a deeper motivation for them other than the war against terrorism? ES : Yeah. The bottom line is that terrorism has always been what we in the **intelligence** world would call a cover for action. Terrorism is something that provokes an emotional response that allows people to rationalize authorizing powers and programs that they wouldn ' t give otherwise. The Bullrun and Edgehill-type programs, the NSA asked for these authorities back in the 1990s. They asked the FBI to go to Congress and make the case. The FBI went to Congress and did make the case. But Congress and the American people said no. They said, it ' s not worth the risk to our economy. They said it ' s worth too much damage to our society to justify the gains. But what we saw is, in the post-9 / 11 era, they used secrecy and they used the justification of terrorism to start these programs in secret without asking Congress, without asking the American people, and it ' s that kind of government behind closed doors that we need to guard ourselves against, because it makes us less **safe**, and it offers no value. CA : Okay, come with me here for a sec, because I ' ve got a more personal question for you. Speaking of terror, most people would find the situation you ' re in right now in Russia pretty terrifying. You obviously heard what happened, what the treatment that Bradley Manning got, Chelsea Manning as now is, and there was a story in Buzzfeed saying that there are people in the **intelligence** community who want you dead. How are you coping with this? How are you coping with the fear? ES : It ' s no mystery that there are governments out there that want to see me dead. I ' ve made clear again and again and again that I go to sleep every morning thinking about what I can do for the American people. I don ' t want to harm my government. I want to help my government, but the fact that they are willing to completely ignore due process, they ' re willing to declare guilt without ever seeing a trial, these are things that we need to work against as a society, and say hey, this is not appropriate. We shouldn ' t be threatening dissidents. We shouldn ' t be criminalizing journalism. And whatever part I can do to see that end, I ' m happy to do despite the risks. CA : So I ' d actually like to get some feedback from the audience here, because I know there ' s widely differing **reactions** to Edward Snowden. Suppose you had the following two choices, right? You could view what he did as fundamentally a reckless act that has endangered America or you could view it as fundamentally a heroic act that will work towards America and the world ' s long-term good? Those are the two choices I ' ll give you. I ' m curious to see who ' s willing to vote with the first of those, that this was a reckless act? There are some hands going up. Some hands going up. It ' s hard to put your hand up when the man is standing right here, but I see them. ES : I can see you. CA : And who goes with the second choice, the fundamentally heroic act? And I think it ' s true to say that there are a lot of people who didn ' t show a hand and I think are still thinking this through, because it seems to me that the debate around you doesn ' t split along traditional political lines. It ' s not left or right, it ' s not really about pro-government, libertarian, or not just that. Part of it is almost a generational issue. You ' re part of a generation that grew up with the Internet, and it seems as if you become offended at almost a visceral level when you see something done that you think will harm the Internet. Is there some truth to that? ES : It is. I think it ' s very true. This is not a left or right issue. Our basic freedoms, and when I say our, I don ' t just mean Americans, I mean people around the world, it ' s not a partisan issue. These are things that all people believe, and it ' s up to all of us to protect them, and to people who have seen and enjoyed a free and open Internet, it ' s up to us to preserve that liberty for the next generation to enjoy, and if we don ' t change things, if we don ' t stand up to make the changes we need to do to keep the Internet **safe**, not just for us but for everyone, we ' re going to lose that, and that would be a tremendous loss, not just for us, but for the world. CA : Well, I have heard similar language recently from the founder of the world wide web, who I actually think is with us, Sir Tim Berners-Lee. Tim, actually, would you like to come up and say, do we have a microphone for Tim? Tim, good to see you. Come up there. Which camp are you in, by the way, traitor, hero? I have a theory on this, but — Tim Berners-Lee : I ' ve given much longer answers to that question, but hero, if I have to make the choice between the two. CA : And Ed, I think you ' ve read the proposal that Sir Tim has talked about about a new Magna Carta to take back the Internet. Is that something that makes sense? ES : Absolutely. I mean, my generation, I grew up not just thinking about the Internet, but I grew up in the Internet, and although I never expected to have the chance to defend it in such a direct and practical manner and to embody it in this unusual, almost avatar manner, I think there ' s something poetic about the fact that one of the sons of the Internet has actually become close to the Internet as a result of their political expression. And I believe that a Magna Carta for the Internet is exactly what we need. We need to encode our values not just in writing but in the structure of the Internet, and it ' s something that

I hope, I invite everyone in the audience, not just here in Vancouver but around the world, to join and participate in. CA : Do you have a question for Ed? TBL : Well, two questions, a general question — CA : Ed, can you still hear us? ES : Yes, I can hear you. CA : Oh, he ' s back. TBL : The wiretap on your line got a little interfered with for a moment. ES : It ' s a little bit of an NSA problem. TBL : So, from the 25 years, stepping back and thinking, what would you think would be the best that we could achieve from all the discussions that we have about the web we want? ES : When we think about in terms of how far we can go, I think that ' s a question that ' s really only limited by what we ' re willing to put into it. I think the Internet that we ' ve enjoyed in the past has been exactly what we as not just a nation but as a people around the world need, and by cooperating, by engaging not just the technical parts of society, but as you said, the users, the people around the world who contribute through the Internet, through social media, who just check the weather, who rely on it every day as a part of their life, to champion that. We ' ll get not just the Internet we ' ve had, but a better Internet, a better now, something that we can use to build a future that ' ll be better not just than what we hoped for but anything that we could have imagined. CA : It ' s 30 years ago that **TED** was founded, 1984. A lot of the conversation since then has been along the lines that actually George Orwell got it wrong. It ' s not Big Brother watching us. We, through the power of the web, and transparency, are now watching Big Brother. Your revelations kind of drove a stake through the heart of that rather optimistic view, but you still believe there ' s a way of doing something about that. And you do too. ES : Right, so there is an argument to be made that the powers of Big Brother have increased enormously. There was a recent legal article at Yale that established something called the Bankston-Soltani Principle, which is that our expectation of privacy is violated when the capabilities of government surveillance have become cheaper by an order of magnitude, and each time that occurs, we need to revisit and rebalance our privacy rights. Now, that hasn ' t happened since the government ' s surveillance powers have increased by several orders of magnitude, and that ' s why we ' re in the problem that we ' re in today, but there is still hope, because the power of individuals have also been increased by technology. I am living proof that an individual can go head to head against the most powerful adversaries and the most powerful **intelligence** agencies around the world and win, and I think that ' s something that we need to take hope from, and we need to build on to make it accessible not just to technical experts but to ordinary citizens around the world. Journalism is not a crime, communication is not a crime, and we should not be monitored in our everyday activities. CA : I ' m not quite sure how you shake the hand of a bot, but I imagine it ' s, this is the hand right here. TBL : That ' ll come very soon. ES : Nice to meet you, and I hope my beam looks as nice as my view of you **guys** does. CA : Thank you, Tim. I mean, The New York Times recently called for an amnesty for you. Would you welcome the chance to come back to America? ES : Absolutely. There ' s really no question, the principles that have been the foundation of this project have been the public interest and the principles that underly the journalistic establishment in the United States and around the world, and I think if the press is now saying, we **support** this, this is something that needed to happen, that ' s a powerful argument, but it ' s not the final argument, and I think that ' s something that public should decide. But at the same time, the government has hinted that they want some kind of deal, that they want me to compromise the journalists with which I ' ve been working, to come back, and I want to make it very clear that I did not do this to be **safe**. I did this to do what was right, and I ' m not going to stop my work in the public interest just to benefit myself. CA : In the meantime, courtesy of the Internet and this technology, you ’ re here, back in North America, not quite the U. S., Canada, in this form. I ’ m curious, how does that feel? ES : Canada is different than what I expected. It ’ s a lot warmer. CA : At **TED**, the mission is”ideas worth spreading.”If you could encapsulate it in a single idea, what is your idea worth spreading right now at this moment? ES : I would say the last year has been a reminder that democracy may die behind closed doors, but we as individuals are born behind those same closed doors, and we don ’ t have to give up our privacy to have good government. We don ’ t have to give up our liberty to have security. And I think by working together we can have both open government and private lives, and I look forward to working with everyone around the world to see that happen. Thank you very much. CA : Ed, thank you.

Text Sample 570: POS Dim 4 – 2014 – Score 15.00 – 2014/t001795.txt
Nicholas Negroponte : Can we switch to the video disc, which is in play mode? I ’ m really **interested** in how you put people and computers together. We will be using the TV screens or their equivalents for electronic books of the future. Very **interested** in touch-sensitive displays, high-tech, high-touch, not having to pick up your fingers to use them. There is another way where computers touch people : wearing, physically wearing. Suddenly on September 11th, the world got bigger. NN : Thank you. Thank you. When I was asked to do this, I was also asked to look at all 14 **TED** Talks that I had given, chronologically. The first one was actually two hours. The second one was an hour, and then they became half hours, and all I noticed was my bald spot getting bigger. Imagine seeing your life, 30 years of it, go by, and it was, to say the least, for me, quite a shocking experience. So what I ’ m going to do in my time is try and share with you what happened during the 30 years, and then also make a prediction, and then tell you a little bit about what I ’ m doing next. And I put on a slide where **TED** 1 happened in my life. And it ’ s rather important because I had done 15 years of research before it, so I had a backlog, so it was easy. It ’ s not that I was Fidel Castro and I could talk for two hours, or Bucky Fuller. I had 15 years of **stuff**, and the Media Lab was about to start. So that was easy. But there are a couple of things about that period and about what happened that are really quite important. One is that it was a period when computers weren ’ t yet for people. And the other thing that sort of happened during that time is that we were considered sissy computer scientists. We weren ’ t considered the real thing. So what I ’ m going to show you is, in retrospect, a lot more **interesting** and a lot more accepted than it was at the time. So I ’ m going to characterize the years and I ’ m even going to go back to some very early work of mine, and this was the kind of **stuff** I was doing in the ’ 60s : very direct manipulation, very influenced as I studied architecture by the architect Moshe Safdie, and you can see that we even built robotic things that could build habitat-like structures. And this for me was not yet the Media Lab, but was the beginning of what I ’ ll call sensory computing, and I pick fingers partly because **everybody** thought it was ridiculous. Papers were published about how **stupid** it was to use fingers. Three reasons : One was they were low-resolution. The other is your hand would occlude what you wanted to see, and the third, which was the winner, was that your fingers would get the screen dirty, and hence, fingers would never be a device that you ’ d use. And this was a device we built in the ’ 70s, which has never even been picked up. It ’ s not just touch sensitive, it ’ s pressure sensitive. Voice : Put a yellow circle there. NN : Later work, and again this was before **TED** 1 — Voice : Move that **west**

of the diamond. Create a large green circle there. Man : Aw, shit. NN : — was to sort of do interface concurrently, so when you talked and you pointed and you had, if you will, multiple channels. Entebbe happened. 1976, Air France was hijacked, taken to Entebbe, and the Israelis not only did an extraordinary rescue, they did it partly because they had practiced on a physical model of the airport, because they had built the airport, so they built a model in the desert, and when they arrived at Entebbe, they knew where to go because they had actually been there. The U. S. government asked some of us, ’ 76, if we could replicate that computationally, and of course somebody like myself says yes. Immediately, you get a contract, Department of Defense, and we built this truck and this rig. We did sort of a simulation, because you had video discs, and again, this is ’ 76. And then many years later, you get this truck, and so you have Google Maps. Still people thought, no, that was not serious computer science, and it was a man named Jerry Wiesner, who happened to be the president of MIT, who did think it was computer science. And one of the keys for anybody who wants to start something in life : Make sure your president is part of it. So when I was doing the Media Lab, it was like having a gorilla in the front seat. If you were stopped for speeding and the officer looked in the window and saw who was in the passenger seat, then,”Oh, continue on, sir.”And so we were able, and this is a cute, actually, device, parenthetically. This was a lenticular photograph of Jerry Wiesner where the only thing that changed in the photograph were the lips. So when you oscillated that little piece of lenticular sheet with his photograph, it would be in lip sync with zero bandwidth. It was a zero- bandwidth teleconferencing system at the time. So this was the Media Lab ’ s — this is what we said we ’ d do, that the world of computers, publishing, and so on would come together. Again, not generally accepted, but very much part of **TED** in the early days. And this is really where we were headed. And that created the Media Lab. One of the things about age is that I can tell you with great **confidence**, I ’ ve been to the future. I ’ ve been there, actually, many times. And the reason I say that is, how many times in my life have I said,”Oh, in 10 years, this will happen,”and then 10 years comes. And then you say,”Oh, in five years, this will happen.”And then five years comes. So I say this a little bit with having felt that I ’ d been there a number of times, and one of the things that is most quoted that I ’ ve ever said is that computing is not about computers, and that didn ’ t quite get enough traction, and then it started to. It started to because people caught on that the medium wasn ’ t the message. And the reason I show this car in actually a rather ugly slide is just again to tell you the kind of story that characterized a little bit of my life. This is a student of mine who had done a Ph. D. called”Backseat Driver.”It was in the early days of GPS, the car knew where it was, and it would give audio instructions to the driver, when to turn right, when to turn left and so on. Turns out, there are a lot of things in those instructions that back in that period were pretty challenging, like what does it mean, take the next right? Well, if you ’ re coming up on a street, the next right ’ s probably the one after, and there are lots of issues, and the student did a wonderful thesis, and the MIT patent office said”Don ’ t patent it. It ’ ll never be accepted. The liabilities are too large. There will be insurance issues. Don ’ t patent it.”So we didn ’ t, but it shows you how people, again, at times, don ’ t really look at what ’ s happening. Some work, and I ’ ll just go through these very quickly, a lot of sensory **stuff**. You might recognize a young Yo-Yo Ma and tracking his body for playing the cello or the hypercello. These fellows literally walked around like that at the time. It ’ s now a little bit more discreet and more commonplace. And then there are at least three heroes I want to quickly mention. Marvin Minsky, who taught me a lot about common sense, and I will talk briefly about

Muriel Cooper, who was very important to Ricky Wurman and to **TED**, and in fact, when she got onstage, she said, the first thing she said was,"I introduced Ricky to Nicky."And nobody calls me Nicky and nobody calls Richard Ricky, so nobody knew who she was talking about. And then, of course, Seymour Papert, who is the person who said,"You can ' t think about thinking unless you think about thinking about something."And that ' s actually — you can unpack that later. It ' s a pretty profound statement. I ' m showing some slides that were from **TED** 2, a little silly as slides, perhaps. Then I felt television really was about displays. Again, now we ' re past **TED** 1, but just around the time of **TED** 2, and what I ' d like to mention here is, even though you could imagine **intelligence** in the device, I look today at some of the work being done about the Internet of Things, and I think it ' s kind of tragically pathetic, because what has happened is people take the oven panel and put it on your cell **phone**, or the door key onto your cell **phone**, just taking it and bringing it to you, and in fact that ' s actually what you don ' t want. You want to put a chicken in the oven, and the oven says,"Aha, it ' s a chicken,"and it cooks the chicken."Oh, it ' s cooking the chicken for Nicholas, and he likes it this way and that way."So the **intelligence**, instead of being in the device, we have started today to move it back onto the cell **phone** or closer to the user, not a particularly enlightened view of the Internet of Things. Television, again, television what I said today, that was back in 1990, and the television of tomorrow would look something like that. Again, people, but they laughed cynically, they didn ' t laugh with much appreciation. Telecommunications in the 1990s, George Gilder decided that he would call this diagram the Negroponte switch. I ' m probably much less famous than George, so when he called it the Negroponte switch, it stuck, but the idea of things that came in the ground would go in the **air** and **stuff** in the **air** would go into the ground has played itself out. That is the original slide from that year, and it has worked in lockstep obedience. We started Wired magazine. Some people, I remember we shared the reception desk periodically, and some parent called up irate that his son had given up Sports Illustrated to subscribe for Wired, and he said,"Are you some porno magazine or something?"and couldn ' t understand why his son would be **interested** in Wired, at any rate. I will go through this a little quicker. This is my favorite, 1995, back page of Newsweek magazine. Okay. Read it. ["Nicholas Negroponte, director of the MIT Media Lab, predicts that we ' ll soon buy books and newspapers straight over the Internet. Uh, sure."— Clifford Stoll, Newsweek, 1995] You must admit that gives you, at least it gives me pleasure when somebody says how dead wrong you are."Being Digital"came out. For me, it gave me an opportunity to be more in the trade press and get this out to the public, and it also allowed us to build the new Media Lab, which if you haven ' t been to, **visit**, because it ' s a beautiful piece of architecture aside from being a wonderful place to work. So these are the things we were saying in those **TEDs**. [Today, multimedia is a desktop or living room experience, because the apparatus is so clunky. This will change dramatically with small, bright, thin, high-resolution displays. — 1995] We came to them. I looked forward to it every year. It was the party that Ricky Wurman never had in the sense that he invited many of his old friends, including myself. And then something for me changed pretty profoundly. I became more **involved** with computers and learning and influenced by Seymour, but particularly looking at learning as something that is best approximated by computer programming. When you write a computer program, you ' ve got to not just list things out and sort of take an algorithm and translate it into a set of instructions, but when there ' s a bug, and all programs have bugs, you ' ve got to de-bug it. You ' ve got to go in, change it, and then re-execute, and you iterate, and that iteration is really a very, very good approximation of learning. So that led to my own work with Seymour in places like Cambodia and the starting of One Laptop per Child. Enough **TED** Talks on One Laptop per Child, so I ’ ll go through it very fast, but it did give us the chance to do something at a relatively large scale in the area of learning, development and computing. Very few people know that One Laptop per Child was a $1 billion project, and it was, at least over the seven years I ran it, but even more important, the World Bank contributed zero, US-AID zero. It was mostly the countries using their own treasuries, which is very **interesting**, at least to me it was very **interesting** in terms of what I plan to do next. So these are the various places it happened. I then tried an experiment, and the experiment happened in Ethiopia. And here ’ s the experiment. The experiment is, can learning happen where there are no schools. And we dropped off tablets with no instructions and let the children figure it out. And in a short period of time, they not only turned them on and were using 50 apps per child within five days, they were singing”ABC”songs within two weeks, but they hacked Android within six months. And so that seemed sufficiently **interesting**. This is perhaps the best picture I have. The kid on your right has sort of nominated himself as teacher. Look at the kid on the left, and so on. There are no adults **involved** in this at all. So I said, well can we do this at a larger scale? And what is it that ’ s missing? The kids are giving a press **conference** at this point, and sort of writing in the dirt. And the answer is, what is missing? And I ’ m going to skip over my prediction, actually, because I ’ m running out of time, and here ’ s the question, is what ’ s going to happen? I think the challenge is to connect the last billion people, and connecting the last billion is very different than connecting the next billion, and the reason it ’ s different is that the next billion are sort of low-hanging fruit, but the last billion are rural. Being rural and being poor are very different. Poverty tends to be created by our society, and the people in that community are not poor in the same way at all. They may be primitive, but the way to approach it and to connect them, the history of One Laptop per Child, and the experiment in Ethiopia, lead me to believe that we can in fact do this in a very short period of time. And so my plan, and unfortunately I haven ’ t been able to get my partners at this point to let me announce them, but is to do this with a stationary satellite. There are many reasons that stationary satellites aren ’ t the best things, but there are a lot of reasons why they are, and for two billion dollars, you can connect a lot more than 100 million people, but the reason I picked two, and I will leave this as my last slide, is two billion dollars is what we were spending in Afghanistan every week. So surely if we can connect Africa and the last billion people for numbers like that, we should be doing it. Thank you very much. Chris Anderson : Stay up there. Stay up there. NN : You ’ re going to give me extra time? CA : No. That was wickedly clever, wickedly clever. You gamed it beautifully. Nicholas, what is your prediction? NN : Thank you for asking. I ’ ll tell you what my prediction is, and my prediction, and this is a prediction, because it ’ ll be 30 years. I won ’ t be here. But one of the things about learning how to read, we have been doing a lot of consuming of information going through our eyes, and so that may be a very inefficient channel. So my prediction is that we are going to ingest information You ’ re going to swallow a pill and know English. You ’ re going to swallow a pill and know Shakespeare. And the way to do it is through the bloodstream. So once it ’ s in your bloodstream, it basically goes through it and gets into the brain, and when it knows that it ’ s in the brain in the different pieces, it deposits it in the right places. So it ’ s ingesting. CA : Have you been hanging out with Ray Kurzweil by any chance? NN : No, but I ’ ve been hanging around with Ed Boyden and hanging around with one of the speakers who is here, Hugh Herr, and there are a number of people. This isn

’ t quite as far-fetched, so 30 years from now. CA : We will check it out. We ’ re going to be back and we ’ re going to play this clip 30 years from now, and then all eat the red pill. Well thank you for that. Nicholas Negroponte. NN : Thank you.

I ’ m going to share with you a paradigm-shifting perspective on the issues of **gender** violence : sexual assault, domestic violence, relationship abuse, sexual harassment, sexual abuse of children. That whole range of issues that I ’ ll refer to in shorthand as”**gender** violence issues,”they ’ ve been seen as women ’ s issues that some good men help out with, but I have a problem with that frame and I don ’ t accept it. I don ’ t see these as women ’ s issues that some good men help out with. In fact, I ’ m going to argue that these are men ’ s issues, first and foremost. Now obviously — Obviously, they ’ re also women ’ s issues, so I appreciate that, but calling **gender** violence a women ’ s issue is part of the problem, for a number of reasons. The first is that it gives men an excuse not to pay attention, right? A lot of men hear the term”women ’ s issues”and we tend to tune it out, and we think,”I ’ m a **guy** ; that ’ s for the girls,”or”that ’ s for the women.”And a lot of men literally don ’ t get beyond the first sentence as a result. It ’ s almost like a chip in our brain is activated, and the neural pathways take our attention in a different direction when we hear the term”women ’ s issues.”This is also true, by the way, of the word”**gender**,”because a lot of people hear the word”**gender**”and they think it means”women.”So they think that **gender** issues is synonymous with women ’ s issues. There ’ s some confusion about the term **gender**. And let me illustrate that confusion by way of analogy. So let ’ s talk for a moment about race. In the US, when we hear the word”race,”a lot of people think that means African-American, Latino, Asian-American, Native American, South Asian, Pacific Islander, on and on. A lot of people, when they hear the word”sexual orientation”think it means gay, lesbian, bisexual. And a lot of people, when they hear the word”**gender**,”think it means women. In each case, the **dominant** group doesn ’ t get paid attention to. As if white people don ’ t have some sort of racial identity or belong to some racial category or construct, as if heterosexual people don ’ t have a sexual orientation, as if men don ’ t have a **gender**. This is one of the ways that **dominant** systems maintain and reproduce themselves, which is to say the **dominant** group is rarely challenged to even think about its dominance, because that ’ s one of the key characteristics of power and privilege, the **ability** to go unexamined, lacking introspection, in fact being rendered invisible, in large measure, in the discourse about issues that are primarily about us. And this is amazing how this works in domestic and sexual violence, how men have been largely erased from so much of the conversation about a subject that is centrally about men. And I ’ m going to illustrate what I ’ m talking about by using the old **tech**. I ’ m old school on some fundamental regards. I make films and I work with high **tech**, but I ’ m still old school as an educator, and I want to share with you this exercise that illustrates on the sentence-structure level how the way that we think, literally the way that we use language, conspires to keep our attention off of men. This is about domestic violence in particular, but you can plug in other analogues. This comes from the work of the feminist linguist Julia Penelope. It starts with a very basic English sentence :”John beat Mary.”That ’ s a good English sentence. John is the subject, beat is the verb, Mary is the object, good sentence. Now we ’ re going to move to the second sentence, which says the same thing in the passive voice.”Mary was beaten by John.”And now a whole lot has happened in one sentence. We ’ ve gone from”John beat Mary”to”Mary was beaten by John.”We ’ ve shifted our focus in one sentence from John to Mary, and you can see John is very close to the end of the sentence, well, close to dropping off the map of our psychic plain. The third sentence, John is dropped, and we have,”Mary was beaten,”and now it ’ s all about Mary. We ’ re not even thinking about John, it ’ s totally focused on Mary. Over the past generation, the term we ’ ve used synonymous with”beaten”is”battered,”so we have”Mary was battered.”And the final sentence in this sequence, flowing from the others, is,”Mary is a battered woman.”So now Mary ’ s very identity — Mary is a battered woman — is what was done to her by John in the first instance. But we ’ ve demonstrated that John has long ago left the conversation. Those of us who work in the domestic and sexual violence field know that victim-blaming is pervasive in this realm, which is to say, blaming the person to whom something was done rather than the person who did it. And we say : why do they go out with these men? Why are they attracted to them? Why do they keep going back? What was she wearing at that party? What a **stupid** thing to do. Why was she drinking with those **guys** in that hotel room? This is victim blaming, and there are many reasons for it, but one is that our cognitive structure is set up to blame victims. This is all unconscious. Our whole cognitive structure is set up to ask questions about women and women ’ s choices and what they ’ re doing, thinking, wearing. And I ’ m not going to shout down people who ask questions about women. It ’ s a legitimate thing to ask. But ’ s let ’ s be clear : Asking questions about Mary is not going to get us anywhere in terms of preventing violence. We have to ask a different set of questions. The questions are not about Mary, they ’ re about John. They include things like, why does John beat Mary? Why is domestic violence still a big problem in the US and all over the world? What ’ s going on? Why do so many men abuse physically, emotionally, verbally, and other ways, the women and girls, and the men and boys, that they **claim** to love? What ’ s going on with men? Why do so many adult men sexually abuse little girls and boys? Why is that a common problem in our society and all over the world today? Why do we hear over and over again about new scandals erupting in major institutions like the Catholic Church or the Penn State football program or the Boy Scouts of America, on and on and on? And then local communities all over the country and all over the world. We hear about it all the time. The sexual abuse of children. What ’ s going on with men? Why do so many men rape women in our society and around the world? Why do so many men rape other men? What is going on with men? And then what is the role of the various institutions in our society that are helping to produce abusive men at **pandemic** rates? Because this isn ’ t about individual perpetrators. That ’ s a naive way to understanding what is a much deeper and more systematic social problem. The perpetrators aren ’ t these monsters who crawl out of the swamp and come into town and do their nasty business and then retreat into the darkness. That ’ s a very naive notion, right? Perpetrators are much more normal than that, and everyday than that. So the question is, what are we doing here in our society and in the world? What are the roles of various institutions in helping to produce abusive men? What ’ s the role of religious belief systems, the sports culture, the pornography culture, the family structure, economics, and how that intersects, and race and ethnicity and how that intersects? How does all this work? And then, once we start making those kinds of connections and asking those important and big questions, then we can talk about how we can be transformative, in other words, how can we do something differently? How can we change the practices? How can we change the socialization of boys and the definitions of manhood that lead to these current outcomes? These are the kind of questions that we need to be asking and the kind of work that we need to be doing, but if we ’ re endlessly focused on what women are doing and thinking in relationships or elsewhere, we ’ re not going to get to that piece. I understand that a lot of women who have been trying to speak out about these issues, today and yesterday and for years and years, often get shouted down for their efforts. They get called nasty names like”male-basher”and”man-hater,”and the disgusting and offensive”feminazi”, right? And you know what all this is about? It ’ s called kill the messenger. It ’ s because the women who are standing up and speaking out for themselves and for other women as well as for men and boys, it ’ s a statement to them to sit down and shut up, keep the current system in place, because we don ’ t like it when people rock the boat. We don ’ t like it when people challenge our power. You ’ d better sit down and shut up, basically. And thank goodness that women haven ’ t done that. Thank goodness that we live in a world where there ’ s so much women ’ s **leadership** that can counteract that. But one of the powerful roles that men can play in this work is that we can say some things that sometimes women can ’ t say, or, better yet, we can be heard saying some things that women often can ’ t be heard saying. Now, I appreciate that that ’ s a problem, it ’ s sexism, but it ’ s the truth. So one of the things that I say to men, and my colleagues and I always say this, is we need more men who have the courage and the strength to start standing up and saying some of this **stuff**, and standing with women and not against them and pretending that somehow this is a battle between the sexes and other kinds of nonsense. We live in the world together. And by the way, one of the things that really bothers me about some of the rhetoric against feminists and others who have built the battered women ’ s and rape **crisis** movements around the world is that somehow, like I said, that they ’ re anti-male. What about all the boys who are profoundly affected in a negative way by what some adult man is doing against their mother, themselves, their sisters? What about all those boys? What about all the young men and boys who have been traumatized by adult men ’ s violence? You know what? The same system that produces men who abuse women, produces men who abuse other men. And if we want to talk about male victims, let ’ s talk about male victims. Most male victims of violence are the victims of other men ’ s violence. So that ’ s something that both women and men have in common. We are both victims of men ’ s violence. So we have it in our direct self-interest, not to mention the fact that most men that I know have women and girls that we care deeply about, in our families and our friendship circles and every other way. So there ’ s so many reasons why we need men to speak out. It seems obvious saying it out loud, doesn ’ t it? Now, the nature of the work that I do and my colleagues do in the sports culture and the US military, in schools, we pioneered this approach called the bystander approach to gender-violence prevention. And I just want to give you the highlights of the bystander approach, because it ’ s a big thematic shift, although there ’ s lots of particulars, but the heart of it is, instead of seeing men as perpetrators and women as victims, or women as perpetrators, men as victims, or any combination in there. I ’ m using the **gender** binary. I know there ’ s more than men and women, there ’ s more than male and female. And there are women who are perpetrators, and of course there are men who are victims. There ’ s a whole spectrum. But instead of seeing it in the binary fashion, we focus on all of us as what we call bystanders, and a bystander is defined as anybody who is not a perpetrator or a victim in a given situation, so in other words friends, teammates, colleagues, coworkers, family members, those of us who are not directly **involved** in a dyad of abuse, but we are embedded in social, family, work, school, and other peer culture relationships with people who might be in that situation. What do we do? How do we speak up? How do we challenge our friends? How do we **sup-**

port our friends? But how do we not remain silent in the face of abuse? Now, when it comes to men and male culture, the goal is to get men who are not abusive to challenge men who are. And when I say abusive, I don ' t mean just men who are beating women. We ' re not just saying a man whose friend is abusing his girlfriend needs to stop the **guy** at the moment of attack. That ' s a naive way of creating a social change. It ' s along a continuum, we ' re trying to get men to interrupt each other. So, for example, if you ' re a **guy** and you ' re in a group of **guys** playing poker, talking, hanging out, no women present, and another **guy** says something sexist or degrading or harassing about women, instead of laughing along or pretending you didn ' t hear it, we need men to say,"Hey, that ' s not funny. that could be my sister you ' re talking about, and could you joke about something else? Or could you talk about something else? I don ' t appreciate that kind of talk."Just like if you ' re a white person and another white person makes a racist comment, you ' d hope, I hope, that white people would interrupt that racist enactment by a fellow white person. Just like with heterosexism, if you ' re a heterosexual person and you yourself don ' t enact harassing or abusive behaviors towards people of varying sexual orientations, if you don ' t say something in the face of other heterosexual people doing that, then, in a sense, isn ' t your silence a form of consent and complicity? Well, the bystander approach is trying to give people tools to interrupt that process and to speak up and to create a peer culture **climate** where the abusive behavior will be seen as unacceptable, not just because it ' s illegal, but because it ' s wrong and unacceptable in the peer culture. And if we can get to the place where men who act out in sexist ways will lose status, young men and boys who act out in sexist and harassing ways towards girls and women, as well as towards other boys and men, will lose status as a result of it, guess what? We ' ll see a radical diminution of the abuse. Because the typical perpetrator is not sick and twisted. He ' s a normal **guy** in every other way, isn ' t he? Now, among the many great things that Martin Luther King said in his short life was,"In the end, what will hurt the most is not the words of our enemies but the silence of our friends."In the end, what will hurt the most is not the words of our enemies but the silence of our friends. There ' s been an awful lot of silence in male culture about this ongoing tragedy of men ' s violence against women and children, hasn ' t there? There ' s been an awful lot of silence. And all I ' m saying is that we need to break that silence, and we need more men to do that. Now, it ' s easier said than done, because I ' m saying it now, but I ' m telling you it ' s not easy in male culture for **guys** to challenge each other, which is one of the reasons why part of the paradigm shift that has to happen is not just understanding these issues as men ' s issues, but they ' re also **leadership** issues for men. Because ultimately, the responsibility for taking a stand on these issues should not fall on the shoulders of little boys or teenage boys in high school or college men. It should be on adult men with power. Adult men with power are the ones we need to be holding **accountable** for being **leaders** on these issues, because when somebody speaks up in a peer culture and challenges and interrupts, he or she is being a **leader**, really. But on a big scale, we need more adult men with power to start prioritizing these issues, and we haven ' t seen that yet, have we? Now, I was at a dinner a number of years ago, and I work extensively with the US military, all the services. And I was at this dinner and this woman said to me — I think she thought she was a little clever — she said,"So how long have you been doing sensitivity training with the Marines?"And I said,"With all due respect, I don ' t do sensitivity training with the Marines. I run a **leadership** program in the Marine Corps."Now, I know it ' s a bit pompous, my response, but it ' s an important distinction, because I don ' t believe that what we need is sensitivity training. We need **leadership**

training, because, for example, when a professional coach or a manager of a baseball team or a football team — and I work extensively in that realm as well — makes a sexist comment, makes a homophobic statement, makes a racist comment, there will be discussions on the sports blogs and in sports talk radio. And some people will say,”He needs sensitivity training.”Other people will say,”Well, get off it. That ’ s political correctness run amok, he made a **stupid** statement, move on.”My argument is, he doesn ’ t need sensitivity training. He needs **leadership** training, because he ’ s being a bad **leader**, because in a society with **gender diversity** and sexual **diversity** — and racial and ethnic **diversity**, you make those kind of comments, you ’ re failing at your **leadership**. If we can make this point that I ’ m making to powerful men and women in our society at all levels of institutional authority and power, it ’ s going to change the paradigm of people ’ s thinking. You know, for example, I work a lot in college and university athletics throughout North America. We know so much about how to prevent domestic and sexual violence, right? There ’ s no excuse for a college or university to not have domestic and sexual violence prevention training mandated for all student athletes, coaches, administrators, as part of their educational process. We know enough to know that we can easily do that. But you know what ’ s missing? The **leadership**. But it ’ s not the **leadership** of student athletes. It ’ s the **leadership** of the athletic director, the president of the university, the people in charge who make decisions about resources and who make decisions about priorities in the institutional settings. That ’ s a failure, in most cases, of men ’ s **leadership**. Look at Penn State. Penn State is the mother of all teachable moments for the bystander approach. You had so many situations in that realm where men in powerful positions failed to act to protect children, in this case, boys. It ’ s unbelievable, really. But when you get into it, you realize there are pressures on men. There are constraints within peer cultures on men, which is why we need to encourage men to break through those pressures. And one of the ways to do that is to say there ’ s an awful lot of men who care deeply about these issues. I know this, I work with men, and I ’ ve been working with tens of thousands, hundreds of thousands of men for many decades now. It ’ s scary, when you think about it, how many years. But there ’ s so many men who care deeply about these issues, but caring deeply is not enough. We need more men with the guts, with the courage, with the strength, with the moral integrity to break our complicit silence and challenge each other and stand with women and not against them. By the way, we owe it to women. There ’ s no question about it. But we also owe it to our sons. We also owe it to young men who are growing up all over the world in situations where they didn ’ t make the choice to be a man in a culture that tells them that manhood is a certain way. They didn ’ t make the choice. We that have a choice, have an opportunity and a responsibility to them as well. I hope that, going forward, men and women, working together, can begin the change and the transformation that will happen so that future generations won ’ t have the level of tragedy that we deal with on a daily basis. I know we can do it, we can do better. Thank you very much.

Text Sample 572: POS Dim 4 – 2012 – Score 15.00 – 2012/t002162.txt

So if you ’ ve been following the news, you ’ ve heard that there ’ s a pack of giant asteroids headed for the United States, all scheduled to strike within the next 50 years. Now I don ’ t mean actual asteroids made of rock and metal. That actually wouldn ’ t be such a problem, because if we were really all going to die, we would put aside our differences, we ’ d spend whatever it took, and we ’ d find a way to deflect them. I ’ m talking instead about threats that are headed our way, but they ’ re wrapped in a special energy field that polarizes us, and therefore paralyzes us. Last March, I went to the **TED conference**, and I saw Jim Hansen speak, the NASA scientist who first raised the alarm about global warming in the 1980s, and it seems that the predictions he made back then are coming true. This is where we ’ re headed in terms of global temperature rises, and if we keep on going the way we ’ re going, we get a four- or five-degree-Centigrade temperature rise by the end of this century. Hansen says we can expect about a five-meter rise in sea levels. This is what a five-meter rise in sea levels would look like. Low- lying cities all around the world will disappear within the lifetime of children born today. Hansen closed his talk by saying,”Imagine a giant asteroid on a collision course with Earth. That is the equivalent of what we face now. Yet we dither, taking no action to deflect the asteroid, even though the longer we wait, the more difficult and expensive it becomes.”Of course, the left wants to take action, but the right denies that there ’ s any problem. All right, so I go back from **TED**, and then the following week, I ’ m invited to a dinner party in Washington, D. C., where I know that I ’ ll be meeting a number of **conservative** intellectuals, including Yuval Levin, and to prepare for the meeting, I read this article by Levin in National Affairs called”Beyond the Welfare State.”Levin writes that all over the world, nations are coming to terms with the fact that the social democratic welfare state is turning out to be untenable and unaffordable, dependent upon dubious economics and the demographic model of a bygone era. All right, now this might not sound as scary as an asteroid, but look at these graphs that Levin showed. This graph shows the national debt as a percentage of America ’ s GDP, and as you see, if you go all the way back to the founding, we borrowed a lot of money to fight the Revolutionary War. Wars are expensive. But then we ’ d pay it off, pay it off, pay it off, and then, oh, what ’ s this? The Civil War. Even more expensive. Borrow a lot of money, pay it off, pay it off, pay it off, get down to near zero, and bang! — World War I. Once again, the same process repeats. Now then we get the Great Depression and World War II. We rise to an astronomical level, around 118 percent of GDP, really unsustainable, really dangerous. But we pay it off, pay it off, pay it off, and then, what ’ s this? Why has it been rising since the ’ 70s? It ’ s partly due to tax cuts that were unfunded, but it ’ s due primarily to the rise of entitlement spending, especially Medicare. We ’ re approaching the levels of indebtedness we had at World War II, and the baby boomers haven ’ t even retired yet, and when they do, this is what will happen. This is data from the Congressional Budget Office showing its most realistic forecast of what would happen if current situations and expectations and trends are extended. All right, now what you might notice is that these two graphs are actually identical, not in terms of the x- and y-axes, or in terms of the data they present, but in terms of their moral and political implications, they say the same thing. Let me translate for you.”We are doomed unless we start acting now. What ’ s wrong with you people on the other side in the other party? Can ’ t you see reality? If you won ’ t help, then get the hell out of the way.”We can deflect both of these asteroids. These problems are both technically solvable. Our problem and our tragedy is that in these hyper-partisan times, the mere fact that one side says,”Look, there ’ s an asteroid,”means that the other side ’ s going to say,”Huh? What? No, I ’ m not even going to look up. No.”To understand why this is happening to us, and what we can do about it, we need to learn more about moral psychology. So I ’ m a social psychologist, and I study morality, and one of the most important principles of morality is that morality binds and blinds. It binds us into teams that circle around sacred values but thereby makes us go blind to objective reality. Think of it like this.

Large-scale cooperation is extremely rare on this planet. There are only a few species that can do it. That ' s a beehive. That ' s a termite mound, a giant termite mound. And when you find this in other animals, it ' s always the same story. They ' re always all siblings who are children of a single queen, so they ' re all in the same boat. They rise or fall, they live or die, as one. There ' s only one species on the planet that can do this without kinship, and that, of course, is us. This is a reconstruction of ancient Babylon, and this is Tenochtitlan. Now how did we do this? How did we go from being hunter-gatherers 10, 000 years ago to building these gigantic cities in just a few thousand years? It ' s miraculous, and part of the explanation is this **ability** to circle around sacred values. As you see, temples and gods play a big role in all ancient civilizations. This is an image of Muslims circling the Kaaba in Mecca. It ' s a sacred rock, and when people circle something together, they unite, they can **trust** each other, they become one. It ' s as though you ' re moving an electrical wire through a magnetic field that generates current. When people circle together, they generate a current. We love to circle around things. We circle around flags, and then we can **trust** each other. We can fight as a team, as a unit. But even as morality binds people together into a unit, into a team, the circling blinds them. It causes them to distort reality. We begin separating everything into good versus evil. Now that process feels great. It feels really satisfying. But it is a gross distortion of reality. You can see the moral electromagnet operating in the U. S. Congress. This is a graph that shows the degree to which voting in Congress falls strictly along the left-right axis, so that if you know how liberal or **conservative** someone is, you know exactly how they voted on all the major issues. And what you can see is that, in the decades after the Civil War, Congress was extraordinarily polarized, as you would expect, about as high as can be. But then, after World War I, things dropped, and we get this historically low level of polarization. This was a golden age of bipartisanship, at least in terms of the parties ' **ability** to work together and solve grand national problems. But in the 1980s and ' 90s, the electromagnet turns back on. Polarization rises. It used to be that **conservatives** and moderates and liberals could all work together in Congress. They could rearrange themselves, form bipartisan committees, but as the moral electromagnet got cranked up, the force field increased, Democrats and Republicans were pulled apart. It became much harder for them to socialize, much harder for them to cooperate. Retiring members nowadays say that it ' s become like gang warfare. Did anybody notice that in two of the three debates, Obama wore a blue tie and Romney wore a red tie? Do you know why they do this? It ' s so that the Bloods and the Crips will know which side to vote for. The polarization is strongest among our political elites. Nobody doubts that this is happening in Washington. But for a while, there was some doubt as to whether it was happening among the people. Well, in the last 12 years it ' s become much more apparent that it is. So look at this data. This is from the American National Elections Survey. And what they do on that survey is they ask what ' s called a feeling thermometer rating. So, how warm or cold do you feel about, you know, Native Americans, or the military, the Republican Party, the Democratic Party, all sorts of groups in American life. The blue line shows how warmly Democrats feel about Democrats, and they like them. You know, ratings in the 70s on a 100-point scale. Republicans like Republicans. That ' s not a surprise. But when you look at cross-party ratings, you find, well, that it ' s lower, but actually, when I first saw this data, I was surprised. That ' s actually not so bad. If you go back to the Carter and even Reagan administrations, they were rating the other party 43, 45. It ' s not terrible. It drifts downwards very slightly, but now look what happens under George W. Bush and Obama. It plummets. Something is going on here. The moral electromagnet is turning back on, and nowadays, just very recently, Democrats really dislike Republicans. Republicans really dislike the Democrats. We ' re changing. It ' s as though the moral electromagnet is affecting us too. It ' s like put out in the two oceans and it ' s pulling the whole country apart, pulling left and right into their own territories like the Bloods and the Crips. Now, there are many reasons why this is happening to us, and many of them we cannot reverse. We will never again have a political class that was forged by the experience of fighting together in World War II against a common enemy. We will never again have just three television networks, all of which are relatively centrist. And we will never again have a large group of **conservative** southern Democrats and liberal northern **Republicans** making it easy, making there be a lot of overlap for bipartisan cooperation. So for a lot of reasons, those decades after the Second World War were an historically anomalous time. We will never get back to those low levels of polarization, I believe. But there ' s a lot that we can do. There are dozens and dozens of reforms we can do that will make things better, because a lot of our **dysfunction** can be traced directly to things that Congress did to itself in the 1990s that created a much more polarized and dysfunctional institution. These changes are detailed in many books. These are two that I strongly recommend, and they list a whole bunch of reforms. I ' m just going to group them into three broad classes here. So if you think about this as the problem of a dysfunctional, hyper-polarized institution, well, the first step is, do what you can so that fewer hyper- partisans get elected in the first place, and when you have closed party primaries, and only the most committed Republicans and Democrats are voting, you ' re nominating and selecting the most extreme hyper-partisans. So open primaries would make that problem much, much less severe. But the problem isn ' t primarily that we ' re electing bad people to Congress. From my experience, and from what I ' ve heard from Congressional insiders, most of the people going to Congress are good, hard-working, intelligent people who really want to solve problems, but once they get there, they find that they are forced to play a game that rewards hyper-partisanship and that punishes independent thinking. You step out of line, you get punished. So there are a lot of reforms we could do that will counteract this. For example, this"Citizens United"ruling is a disaster, because it means there ' s like a money gun aimed at your head, and if you step out of line, if you try to reach across the aisle, there ' s a ton of money waiting to be given to your opponent to make **everybody** think that you are a terrible person through negative advertising. But the third class of reforms is that we ' ve got to change the nature of social relationships in Congress. The politicians I ' ve met are generally very extroverted, friendly, very socially skillful people, and that ' s the nature of politics. You ' ve got to make relationships, make deals, you ' ve got to cajole, please, flatter, you ' ve got to use your personal skills, and that ' s the way politics has always worked. But beginning in the 1990s, first the House of Representatives changed its legislative calendar so that all business is basically done in the middle of the week. Nowadays, Congressmen fly in on Tuesday morning, they do battle for two days, then they fly home Thursday afternoon. They don ' t move their families to the District. They don ' t meet each other ' s spouses or children. There ' s no more relationship there. And trying to run Congress without human relationships is like trying to run a car without motor oil. Should we be surprised when the whole thing freezes up and descends into paralysis and polarization? A simple change to the legislative calendar, such as having business stretch out for three weeks and then they get a week off to go home, that would change the fundamental relationships in Congress. So there ' s a lot we can do, but who ' s going to push them to do it? There are a number of groups that are working on this. No Labels and Common Cause, I think, have very good ideas for changes we need to do to make our democracy more responsive and our Congress more effective. But I ’ d like to supplement their work with a little psychological trick, and the trick is this. Nothing pulls people together like a common threat or a common attack, especially an attack from a foreign enemy, unless of course that threat hits on our polarized psychology, in which case, as I said before, it can actually pull us apart. Sometimes a single threat can polarize us, as we saw. But what if the situation we face is not a single threat but is actually more like this, where there ’ s just so much **stuff** coming in, it ’ s just,”Start shooting, come on, **everybody**, we ’ ve got to just work together, just start shooting.”Because actually, we do face this situation. This is where we are as a country. So here ’ s another asteroid. We ’ ve all seen versions of this graph, right, which shows the changes in wealth since 1979, and as you can see, almost all the gains in wealth have gone to the top 20 percent, and especially the top one percent. Rising inequality like this is associated with so many problems for a democracy. Especially, it destroys our **ability** to **trust** each other, to feel that we ’ re all in the same boat, because it ’ s obvious we ’ re not. Some of us are sitting there **safe** and sound in gigantic private yachts. Other people are clinging to a piece of driftwood. We ’ re not all in the same boat, and that means nobody ’ s willing to sacrifice for the common good. The left has been screaming about this asteroid for 30 years now, and the right says,”Huh, what? Hmm? No problem. No problem.”Now, why is that happening to us? Why is the inequality rising? Well, one of the largest causes, after globalization, is actually this fourth asteroid, rising nonmarital births. This graph shows the steady rise of out-of-wedlock births since the 1960s. Most Hispanic and black children are now born to unmarried mothers. Whites are headed that way too. Within a decade or two, most American children will be born into homes with no father. This means that there ’ s much less money coming into the house. But it ’ s not just money. It ’ s also stability versus chaos. As I know from working with street children in Brazil, Mom ’ s boyfriend is often a really, really dangerous person for kids. Now the right has been screaming about this asteroid since the 1960s, and the left has been saying,”It ’ s not a problem. It ’ s not a problem.”The left has been very reluctant to say that marriage is actually good for women and for children. Now let me be clear. I ’ m not blaming the women here. I ’ m actually more critical of the men who won ’ t take responsibility for their own children and of an economic system that makes it difficult for many men to earn enough money to **support** those children. But even if you blame nobody, it still is a national problem, and one side has been more concerned about it than the other. The New York Times finally noticed this asteroid with a front-page story last July showing how the decline of marriage contributes to inequality. We are becoming a nation of just two classes. When Americans go to college and marry each other, they have very low divorce rates. They earn a lot of money, they **invest** that money in their kids, some of them become tiger mothers, the kids rise to their full potential, and the kids go on to become the top two lines in this graph. And then there ’ s **everybody** else : the children who don ’ t benefit from a stable marriage, who don ’ t have as much **invested** in them, who don ’ t grow up in a stable environment, and who go on to become the bottom three lines in that graph. So once again, we see that these two graphs are actually saying the same thing. As before, we ’ ve got a problem, we ’ ve got to start working on this, we ’ ve got to do something, and what ’ s wrong with you people that you don ’ t see my threat? But if **everybody** could just take off their partisan blinders, we ’ d see that these two problems actually are best addressed together. Because if you really care about income inequality, you might want to talk to some evangelical Christian groups that are working on ways to promote marriage. But then you

’ re going to run smack into the problem that women don ’ t generally want to marry someone who doesn ’ t have a job. So if you really care about strengthening families, you might want to talk to some liberal groups who are working on promoting educational equality, who are working on raising the minimum wage, who are working on finding ways to stop so many men from being sucked into the criminal justice system and taken out of the marriage market for their whole lives. So to conclude, there are at least four asteroids headed our way. How many of you can see all four? Please raise your hand right now if you ’ re willing to admit that all four of these are national problems. Please raise your hands. Okay, almost all of you. Well, congratulations, you **guys** are the inaugural members of the Asteroids Club, which is a club for all Americans who are willing to admit that the other side actually might have a point. In the Asteroids Club, we don ’ t start by looking for common ground. Common ground is often very hard to find. No, we start by looking for common threats because common threats make common ground. Now, am I being naive? Is it naive to think that people could ever lay down their swords, and left and right could actually work together? I don ’ t think so, because it happens, not all that often, but there are a variety of examples that point the way. This is something we can do. Because Americans on both sides care about the decline in civility, and they ’ ve formed dozens of organizations, at the national level, such as this one, down to many local organizations, such as To The Village Square in Tallahassee, Florida, which tries to bring state **leaders** together to help facilitate that sort of working together human relationship that ’ s necessary to solve Florida ’ s problems. Americans on both sides care about global poverty and AIDS, and on so many humanitarian issues, liberals and evangelicals are actually natural allies, and at times they really have worked together to solve these problems. And most surprisingly to me, they sometimes can even see eye to eye on criminal justice. For example, the incarceration rate, the prison population in this country has quadrupled since 1980. Now this is a social disaster, and liberals are very concerned about this. The Southern Poverty Law Center is often fighting the prison-industrial complex, fighting to prevent a system that ’ s just sucking in more and more poor young men. But are **conservatives** happy about this? Well, Grover Norquist isn ’ t, because this system costs an unbelievable amount of money. And so, because the prison-industrial complex is bankrupting our states and corroding our souls, groups of fiscal **conservatives** and Christian **conservatives** have come together to form a group called Right on Crime. And at times they have worked with the Southern Poverty Law Center to oppose the building of new prisons and to work for reforms that will make the justice system more efficient and more humane. So this is possible. We can do it. Let us therefore go to battle stations, not to fight each other, but to begin deflecting these incoming asteroids. And let our first mission be to press Congress to reform itself, before it ’ s too late for our nation. Thank you.

Text Sample 573: POS Dim 4 – 2012 – Score 15.00 – 2012/t002337.txt

America ’ s public energy conversation boils down to this question : Would you rather die of A) oil wars, or B) **climate** change, or C) nuclear holocaust, or D) all of the above? Oh, I missed one : or E) none of the above? That ’ s the one we ’ re not normally offered. What if we could make energy do our work without working our undoing? Could we have fuel without fear? Could we reinvent fire? You see, fire made us human ; fossil fuels made us modern. But now we need a new fire that makes us **safe**, secure, healthy and durable. Let ’ s see how. Four-fifths of the world ’ s energy still comes from burning each year four cubic miles of the rotted remains of primeval swamp goo. Those fossil fuels have built our civilization. They ' ve created our wealth. They ' ve enriched the lives of billions. But they also have rising costs to our security, economy, health and environment that are starting to erode, if not outweigh their benefits. So we need a new fire. And switching from the old fire to the new fire means changing two big stories about oil and electricity, each of which puts two- fifths of the fossil carbon in the **air**. But they ' re really quite distinct. Less than one percent of our electricity is made from oil — although almost half is made from coal. Their uses are quite concentrated. Three-fourths of our oil fuel is transportation. Three-fourths of our electricity powers buildings. And the rest of both runs factories. So very efficient vehicles, buildings and factories save oil and coal, and also natural gas that can displace both of them. But today ' s energy system is not just inefficient, it is also disconnected, aging, dirty and insecure. So it needs refurbishment. By 2050 though, it could become efficient, connected and distributed with elegantly frugal autos, factories and buildings all relying on a modern, secure and resilient electricity system. We can eliminate our addiction to oil and coal by 2050 and use one-third less natural gas while switching to efficient use and renewable supply. This could cost, by 2050, five trillion dollars less in net present value, that is expressed as a lump sum today, than business as usual — assuming that carbon emissions and all other hidden or external costs are worth zero — a conservatively low estimate. Yet this cheaper energy system could **support** 158 percent bigger U. S. economy all without needing oil or coal, or for that matter nuclear energy. Moreover, this **transition** needs no new inventions and no acts of Congress and no new federal taxes, mandate subsidies or laws and running Washington gridlock. Let me say that again. I ' m going to tell you how to get the United States completely off oil and coal, five trillion dollars cheaper with no act of Congress led by business for profit. In other words, we ' re going to use our most effective institutions — private enterprise co-evolving with civil society and sped by military innovation to go around our least effective institutions. And whether you care most about profits and jobs and competitive advantage or national security, or environmental stewardship and **climate** protection and public health, reinventing fire makes sense and makes money. General Eisenhower reputedly said that enlarging the boundaries of a tough problem makes it soluble by encompassing more options and more synergies. So in reinventing fire, we integrated all four **sectors** that use energy — transportation, buildings, industry and electricity — and we integrated four kinds of innovation, not just technology and **policy**, but also design and business strategy. Those combinations yield very much more than the sum of the parts, especially in creating deeply disruptive business opportunities. Oil costs our economy two billion dollars a day, plus another four billion dollars a day in hidden economic and military costs, raising its total cost to over a sixth of GDP. Our mobility fuel goes three-fifths to automobiles. So let ' s start by making autos oil free. Two-thirds of the energy it takes to move a typical car is caused by its weight. And every unit of energy you save at the wheels, by taking out weight or drag, saves seven units in the tank, because you don ' t have to waste six units getting the energy to the wheels. Unfortunately, over the past quarter century, epidemic obesity has made our two-ton steel cars gain weight twice as fast as we have. But today, ultralight, ultrastrong materials, like carbon fiber composites, can make dramatic weight savings snowball and can make cars simpler and cheaper to build. Lighter and more slippery autos need less force to move them, so their engines get smaller. Indeed, that sort of vehicle fitness then makes electric propulsion affordable because the batteries or fuel cells also get smaller and lighter and cheaper. So sticker prices will ultimately fall to about the same as today, while the driving cost, even from the start, is very much lower. So these innovations together can transform automakers from wringing tiny savings out of Victorian engine and seal-stamping technologies to the steeply falling costs of three linked innovations that strongly reenforce each other — namely ultralight materials, making them into structures and electric propulsion. The sales can grow and the prices fall even faster with temporary feebates, that is rebates for efficient new autos paid for by fees on inefficient ones. And just in the first two years the biggest of Europe ’ s five feebate programs has tripled the speed of improving automotive efficiency. The resulting shift to electric autos is going to be as game-changing as shifting from typewriters to the gains in computers. Of course, computers and electronics are now America ’ s biggest industry, while typewriter makers have vanished. So vehicle fitness opens a new automotive competitive strategy that can double the oil savings over the next 40 years, but then also make electrification affordable, and that displaces the rest of the oil. America could lead this next automotive revolution. Currently the **leader** is Germany. Last year, Volkswagen announced that by next year they ’ ll be producing this carbon fiber plugin hybrid getting 230 miles a gallon. Also last year, BMW announced this carbon fiber electric car, they said that its carbon fiber is paid for by needing fewer batteries. And they said,”We do not intend to be a typewriter maker.”Audi **claimed** it ’ s going to beat them both by a year. Seven years ago, an even faster and cheaper American manufacturing technology was used to make this little carbon fiber test part, which doubles as a carbon cap. In one minute — and you can tell from the sound how immensely stiff and strong it is. Don ’ t worry about dropping it, it ’ s tougher than titanium. Tom Friedman actually whacked it as hard as he could with a sledgehammer without even scuffing it. But such manufacturing techniques can scale to automotive speed and cost with aerospace performance. They can save four-fifths of the capital needed to make autos. They can save lives because this **stuff** can absorb up to 12 times as much crash energy per pound as steel. If we made all of our autos this way, it would save oil equivalent to finding one and a half Saudi Arabias, or half an OPEC, by drilling in the Detroit formation, a very prospective play. And all those mega-barrels under Detroit cost an average of 18 bucks a barrel. They are all- American, carbon-free and inexhaustible. The same physics and the same business logic also apply to big vehicles. In the five years ending with 2010, Walmart saved 60 percent of the fuel per ton-mile in its giant fleet of heavy trucks through better logistics and design. But just the technological savings in heavy trucks can get to two-thirds. And combined with triple to quintuple efficiency airplanes, now on the drawing board, can save close to a trillion dollars. Also today ’ s military revolution in energy efficiency is going to speed up all of these civilian advances in much the same way that military R&D has given us the Internet, the Global Positioning System and the jet engine and microchip industries. As we design and build vehicles better, we can also use them smarter by harnessing four powerful techniques for eliminating needless driving. Instead of just seeing the travel grow, we can use innovative pricing, charging for road infrastructure by the mile, not by the gallon. We can use some smart IT to enhance transit and enable car sharing and ride sharing. We can allow smart and lucrative growth models that help people already be near where they want to be, so they don ’ t need to go somewhere else. And we can use smart IT to make traffic free-flowing. Together, those things can give us the same or better access with 46 to 84 percent less driving, saving another 0. 4 trillion dollars, plus 0. 3 trillion dollars from using trucks more productively. So 40 years hence, when you add it all up, a far more mobile U. S. economy can use no oil. Saving or displacing barrels for 25 bucks rather than buying them for over a hundred, adds up to a $4 trillion net saving counting all the hidden costs at zero. So to get mobility without oil, to phase out the oil, we can get efficient and then switch fuels. Those 125 to 240 mile-per-gallon-equivalent autos can use any mixture of **hydrogen** fuel cells, electricity and advanced biofuels. The trucks and planes can realistically use **hydrogen** or advanced biofuels. The trucks could even use natural gas. But no vehicles will need oil. And the most biofuel we might need, just three million barrels a day, can be made two-thirds from waste without displacing any cropland and without harming soil or **climate**. Our team speeds up these kinds of oil savings by what we call"institutional acupuncture."We figure out where the business logic is congested and not flowing properly, we stick little needles in it to get it flowing, working with partners like Ford and Walmart and the Pentagon. And the long **transition** is already well under way. In fact, three years ago mainstream analysts were starting to see peak oil, not in supply, but in **demand**. And Deutsche Bank even said world oil use could peak around 2016. In other words, oil is getting uncompetitive even at low prices before it becomes unavailable even at high prices. But the electrified vehicles don ’ t need to burden the electricity grid. Rather, when smart autos exchange electricity and information through smart buildings with smart grids, they ’ re adding to the grid valuable flexibility and storage that help the grid integrate varying solar and wind power. So the electrified autos make the auto and electricity problems easier to solve together than separately. And they also converge the oil story with our second big story, saving electricity and then making it differently. And those twin revolutions in electricity will bring to that **sector** more numerous and profound and diverse disruptions than any other **sector**, because we ’ ve got 21st century technology and speed colliding head-on with 20th and 19th century institutions, rules and cultures. Changing how we make electricity gets easier if we need less of it. Most of it now is wasted and the technologies for saving it keep improving faster than we ’ re installing them. So the unbought efficiency resource keeps getting ever bigger and cheaper. But as efficiency in buildings and industry starts to grow faster than the economy, America ’ s electricity use could actually shrink, even with the little extra use required for those efficient electrified autos. And we can do this just by reasonably accelerating existing trends. Over the next 40 years, buildings, which use three-quarters of the electricity, can triple or quadruple their energy productivity, saving 1. 4 trillion dollars, net present value, with a 33 percent internal rate of return or in English, the savings are worth four times what they cost. And industry can accelerate too, doubling its energy productivity with a 21 percent internal rate of return. The key is a disruptive innovation that we call integrative design that often makes very big energy savings cost less than small or no savings. That is, it can give you expanding returns, not diminishing returns. That is how our 2010 retrofit is saving over two-fifths of the energy in the Empire State Building — remanufacturing those six and a half thousand windows on site into super windows that pass light, but reflect heat. plus better lights and office equipment and such cut the maximum cooling load by a third. And then renovating smaller chillers instead of adding bigger ones saved 17 million dollars of capital cost, which helped pay for the other improvements and reduce the payback to just three years. Integrative design can also increase energy savings in industry. Dow ’ s billion-dollar efficiency investment has already returned nine billion dollars. But industry as a whole has another half-trillion dollars of energy still to save. For example, three-fifths of the world ’ s electricity runs motors. Half of that runs pumps and fans. And those can all be made more efficient, and the motors that turn them can have their system efficiency roughly doubled by integrating 35 improvements, paying back in about a year. But first we ought to be capturing bigger, cheaper savings that are normally ignored and are not in the textbooks. For example, pumps, the biggest use of motors, move liquid through pipes. But a standard industrial pumping loop was redesigned to use at least 86 percent less energy, not by getting better pumps, but just by replacing long, thin, crooked pipes with fat, short, straight pipes. This is not about new technology, it ' s just rearranging our metal furniture. Of course, it also shrinks the pumping equipment and its capital costs. So what do such savings mean for the electricity that is three-fifths used in motors? Well, from the coal burned at the power plant through all these compounding losses, only a tenth of the fuel energy actually ends up coming out the pipe as flow. But now let ' s turn those compounding losses around backwards, and every unit of flow or friction that we save in the pipe saves 10 units of fuel cost, pollution and what Hunter Lovins calls"global weirding"back at the power plant. And of course, as you go back upstream, the components get smaller and therefore cheaper. Our team has lately found such snowballing energy savings in more than 30 billion dollars worth of industrial redesigns — everything from data centers and chip fabs to mines and refineries. Typically our retrofit designs save about 30 to 60 percent of the energy and pay back in a few years, while the new facility designs save 40 to 90-odd percent with generally lower capital cost. Now needing less electricity would ease and speed the shift to new sources of electricity, chiefly renewables. China leads their explosive growth and their plummeting cost. In fact, these solar power module costs have just fallen off the bottom of the chart. And Germany now has more solar workers than America has steel workers. Already in about 20 states private installers will come put those cheap solar cells on your roof with no money down and beat your utility bill. Such unregulated products could ultimately add up to a virtual utility that bypasses your electric company just as your cellphone bypassed your wireline **phone** company. And this sort of thing gives utility executives the heebee-jeebees and it gives venture capitalists sweet dreams. Renewables are no longer a fringe activity. For each of the past four years half of the world ' s new generating capacity has been renewable, mainly lately in developing countries. In 2010, renewables other than big hydro, particularly wind and solar cells, got 151 billion dollars of private investment, and they actually surpassed the total installed capacity of nuclear power in the world by adding 60 billion watts in that one year. That happens to be the same amount of solar cell capacity that the world can now make every year — a number that goes up 60 or 70 percent a year. In contrast, the net additions of nuclear capacity and coal capacity and the orders behind those keep fading because they cost too much and they have too much financial risk. In fact in this country, no new nuclear power plant has been able to raise any private construction capital, despite seven years of 100-plus percent subsidies. So how else could we replace the coal-fired power plants? Well efficiency and gas can displace them all at just below their operating cost and, combined with renewables, can displace them more than 23 times at less than their replacement cost. But we only need to replace them once. We ' re often told though that only coal and nuclear plants can keep the lights on, because they ' re 24 / 7, whereas wind and solar power are variable, and hence supposedly unreliable. Actually no generator is 24 / 7. They all break. And when a big plant goes down, you lose a thousand megawatts in milliseconds, often for weeks or months, often without warning. That is exactly why we ' ve designed the grid to back up failed plants with working plants. And in exactly the same way, the grid can handle wind and solar power ' s forecastable variations. Hourly simulations show that largely or wholly renewable grids can deliver highly reliable power when they ' re forecasted, integrated and diversified by both type and location. And that ' s true both for continental areas like the U. S. or Europe and for smaller areas embedded within a larger grid. That is how, for example, four German states in 2010 were 43 to 52 percent wind powered. Portugal was 45 percent renewable powered, Denmark 36. And it ’ s how all of Europe can shift to renewable electricity. In America, our aging, dirty and insecure power system has to be replaced anyway by 2050. And whatever we replace it with is going to cost about the same, about six trillion dollars at present value — whether we buy more of what we ’ ve got or new nuclear and so- called clean coal, or renewables that are more or less centralized. But those four futures at the same cost differ profoundly in their risks, around national security, fuel, water, finance, technology, **climate** and health. For example, our over-centralized grid is very vulnerable to cascading and potentially economy-shattering blackouts caused by bad space weather or other natural disasters or a terrorist attack. But that blackout risk disappears, and all of the other risks are best managed, with distributed renewables organized into local micro-grids that normally interconnect, but can stand alone at need. That is, they can disconnect fractally and then reconnect seamlessly. That approach is exactly what the Pentagon is adopting for its own power supply. They think they need that ; how about the rest of us that they ’ re defending? We want our **stuff** to work too. At about the same cost as business as usual, this would maximize national security, customer choice, entrepreneurial opportunity and innovation. Together, efficient use and diverse dispersed renewable supply are starting to transform the whole electricity **sector**. Traditionally utilities build a lot of giant coal and nuclear plants and a bunch of big gas plants and maybe a little bit of efficiency renewables. And those utilities were rewarded, as they still are in 34 states, for selling you more electricity. However, especially where regulators are now instead rewarding cutting your bills, the investments are shifting radically toward efficiency, **demand** response, cogeneration, renewables and ways to knit them all together reliably with less transmission and little or no bulk electricity storage. So our energy future is not fate, but choice, and that choice is very flexible. In 1976, for example, government and industry insisted that the amount of energy needed to make a dollar of GDP could never go down. And I heretically suggested it could go down several-fold. Well that ’ s what ’ s actually happened so far. It ’ s fallen by half. But with today ’ s much better technologies, more mature delivery channels and integrative design, we can do far more and even cheaper. So to solve the energy problem, we just needed to enlarge it. And the results may at first seem incredible, but as Marshall McLuhan said,”Only puny secrets need protection. Big discoveries are protected by public incredulity.”Now combine the electricity and oil revolutions, both driven by modern efficiency, and you get the really big story : reinventing fire, where business enabled and sped by smart **policies** in mindful markets can lead the United States completely off oil and coal by 2050, saving 5 trillion dollars, growing the economy 2. 6- fold, strengthening out national security, oh, and by the way, by getting rid of the oil and coal, reducing the fossil carbon emissions by 82 to 86 percent. Now if you like any of those outcomes, you can **support** reinventing fire without needing to like all of them and without needing to agree about which of them is most important. So focusing on outcomes, not motives, can turn gridlock and **conflict** into a unifying solution to America ’ s energy challenge. This also turns out to be the best way to cope with global challenges — **climate** change, nuclear proliferation, energy insecurity, energy poverty — all of which make us less **safe**. Now our team at RMI helps smart companies to get unstuck and speed this journey via six sectoral initiatives, with some more hatching. Of course there ’ s still a lot of old thinking out there too. Former oil man Maurice Strong said,”Not all the fossils are in the fuel.”But as Edgar Woolard, who used to chair Dupont, reminds us,”Companies hampered by old thinking won ’ t be a problem because,”he said,”they simply won ’ t be around long-term.”I ’ ve described not just a once-in-a-civilization business opportunity, but one of the most profound **transitions** in the history of our species. We humans are inventing a new fire, not dug from below, but flowing from above ; not scarce, but bountiful ; not local, but everywhere ; not transient, but permanent ; not costly, but free. And but for a little transitional tail of natural gas and a bit of biofuel grown in ways that sustain and endure, this new fire is flameless. Efficiently used, it really can do our work without working our undoing. Each of you owns a piece of that $5 trillion prize. And our new book”Reinventing Fire”describes how you can capture it. So with the conversation just begun at ReinventingFire. com, let me invite you each to engage with us and with each other, with everyone around you, to help make the world richer, fairer, cooler and **safer** by together reinventing fire. Thank you.

Text Sample 574: POS Dim 4 – 2011 – Score 19.00 – 2011/t002551.txt
I was basically concerned about what was going on in the world. I couldn ’ t understand the starvation, the destruction, the killing of innocent people. Making sense of those things is a very difficult thing to do. And when I was 12, I became an actor. I was bottom of the class. I haven ’ t got any qualifications. I was told I was dyslexic. In fact, I have got qualifications. I got a D in pottery, which was the one thing that I did get — which was useful, obviously. And so concern is where all of this comes from. And then, being an actor, I was doing these different kinds of things, and I felt the content of the work that I was **involved** in really wasn ’ t cutting it, that there surely had to be more. And at that point, I read a book by Frank Barnaby, this wonderful nuclear physicist, and he said that media had a responsibility, that all **sectors** of society had a responsibility to try and progress things and move things forward. And that fascinated me, because I ’ d been messing around with a camera most of my life. And then I thought, well maybe I could do something. Maybe I could become a filmmaker. Maybe I can use the form of film constructively to in some way make a difference. Maybe there ’ s a little change I can get **involved** in. So I started thinking about peace, and I was obviously, as I said to you, very much moved by these images, trying to make sense of that. Could I go and speak to older and wiser people who would tell me how they made sense of the things that are going on? Because it ’ s obviously incredibly frightening. But I realized that, having been messing around with structure as an actor, that a series of sound bites in itself wasn ’ t enough, that there needed to be a mountain to climb, there needed to be a journey that I had to take. And if I took that journey, no matter whether it failed or succeeded, it would be completely irrelevant. The point was that I would have something to hook the questions of — is humankind fundamentally evil? Is the destruction of the world inevitable? Should I have children? Is that a responsible thing to do? Etc., etc. So I was thinking about peace, and then I was thinking, well where ’ s the starting point for peace? And that was when I had the idea. There was no starting point for peace. There was no day of global unity. There was no day of intercultural cooperation. There was no day when humanity came together, separate in all of those things and just shared it together — that we ’ re in this together, and that if we united and we interculturally cooperated, then that might be the key to humanity ’ s survival. That might shift the level of consciousness around the fundamental issues that humanity faces — if we did it just for a day. So obviously we didn ’ t have any money. I was living at my mom ’ s place. And we started writing letters to **everybody**. You very quickly work out what is it that you ’ ve got to do to fathom that out. How do you create a day voted by every

single head of state in the world to create the first ever Ceasefire Nonviolence Day, the 21st of September? And I wanted it to be the 21st of September because it was my granddad ' s favorite number. He was a prisoner of war. He saw the bomb go off at Nagasaki. It poisoned his blood. He died when I was 11. So he was like my hero. And the reason why 21 was the number is 700 men left, 23 came back, two died on the boat and 21 hit the ground. And that ' s why we wanted it to be the 21st of September as the date of peace. So we began this journey, and we launched it in 1999. And we wrote to heads of state, their ambassadors, Nobel Peace laureates, NGOs, faiths, various organizations — literally wrote to **everybody**. And very quickly, some letters started coming back. And we started to build this case. And I remember the first letter. One of the first letters was from the Dalai Lama. And of course we didn ' t have the money ; we were playing guitars and getting the money for the stamps that we were sending out all of [this mail]. A letter came through from the Dalai Lama saying,"This is an amazing thing. Come and see me. I ' d love to talk to you about the first ever day of peace."And we didn ' t have money for the flight. And I rang Sir Bob Ayling, who was CEO of BA at the time, and said,"Mate, we ' ve got this invitation. Could you give me a flight? Because we ' re going to go see him."And of course, we went and saw him and it was amazing. And then Dr. Oscar Arias came forward. And actually, let me go back to that slide, because when we launched it in 1999 — this idea to create the first ever day of ceasefire and non-violence — we invited thousands of people. Well not thousands — hundreds of people, lots of people — all the press, because we were going to try and create the first ever World Peace Day, a peace day. And we invited **everybody**, and no press showed up. There were 114 people there — they were mostly my friends and family. And that was kind of like the launch of this thing. But it didn ' t matter because we were **documenting**, and that was the thing. For me, it was really about the process. It wasn ' t about the end result. And that ' s the beautiful thing about the camera. They used to say the pen is mightier than the sword. I think the camera is. And just staying in the moment with it was a beautiful thing and really empowering actually. So anyway, we began the journey. And here you see people like Mary Robinson, I went to see in Geneva. I ' m cutting my hair, it ' s getting short and long, because every time I saw Kofi Annan, I was so worried that he thought I was a hippie that I cut it, and that was kind of what was going on. Yeah, I ' m not worried about it now. So Mary Robinson, she said to me,"Listen, this is an idea whose time has come. This must be created."Kofi Annan said,"This will be beneficial to my troops on the ground."The OAU at the time, led by Salim Ahmed Salim, said,"I must get the African countries **involved**."Dr. Oscar Arias, Nobel Peace laureate, president now of Costa Rica, said,"I ' ll do everything that I can."So I went and saw Amr Moussa at the League of Arab States. I met Mandela at the Arusha peace talks, and so on and so on and so on — while I was building the case to prove whether this idea would make sense. And then we were listening to the people. We were **documenting** everywhere. 76 countries in the last 12 years, I ' ve **visited**. And I ' ve always spoken to women and children wherever I ' ve gone. I ' ve recorded 44, 000 young people. I ' ve recorded about 900 hours of their thoughts. I ' m really clear about how young people feel when you talk to them about this idea of having a starting point for their actions for a more peaceful world through their poetry, their art, their literature, their music, their sport, whatever it might be. And we were listening to **everybody**. And it was an incredibly thing, working with the U. N. and working with NGOs and building this case. I felt that I was presenting a case on behalf of the global community to try and create this day. And the stronger the case and the more detailed it was, the better chance we had of creating this day. And it was this

stuff, this, where I actually was in the beginning kind of thinking no matter what happened, it didn ’ t actually matter. It didn ’ t matter if it didn ’ t create a day of peace. The fact is that, if I tried and it didn ’ t work, then I could make a statement about how unwilling the global community is to unite — until, it was in Somalia, picking up that young girl. And this young child who ’ d taken about an inch and a half out of her leg with no antiseptic, and that young boy who was a child soldier, who told me he ’ d killed people — he was about 12 — these things made me realize that this was not a film that I could just stop. And that actually, at that moment something happened to me, which obviously made me go,”I ’ m going to **document**. If this is the only film that I ever make, I ’ m going to **document** until this becomes a reality.”Because we ’ ve got to stop, we ’ ve got to do something where we unite — separate from all the politics and religion that, as a young person, is confusing me. I don ’ t know how to get **involved** in that process. And then on the seventh of September, I was invited to New York. The Costa Rican government and the British government had put forward to the United Nations General Assembly, with 54 co-sponsors, the idea of the first ever Ceasefire Nonviolence Day, the 21st of September, as a fixed calendar date, and it was unanimously adopted by every head of state in the world. Yeah, but there were hundreds of individuals, obviously, who made that a reality. And thank you to all of them. That was an incredible moment. I was at the top of the General Assembly just looking down into it and seeing it happen. And as I mentioned, when it started, we were at the Globe, and there was no press. And now I was thinking,”Well, the press it really going to hear this story.”And suddenly, we started to institutionalize this day. Kofi Annan invited me on the morning of September the 11th to do a press **conference**. And it was 8:00 AM when I stood there. And I was waiting for him to come down, and I knew that he was on his way. And obviously he never came down. The statement was never made. The world was never told there was a day of global ceasefire and nonviolence. And it was obviously a tragic moment for the thousands of people who lost their lives, there and then subsequently all over the world. It never happened. And I remember thinking,”This is exactly why, actually, we have to work even harder. And we have to make this day work. It ’ s been created ; nobody knows. But we have to continue this journey, and we have to tell people, and we have to prove it can work.”And I left New York freaked, but actually empowered. And I felt inspired by the possibilities that if it did, then maybe we wouldn ’ t see things like that. I remember putting that film out and going to cynics. I was showing the film, and I remember being in Israel and getting it absolutely slaughtered by some **guys** having watched the film — that it ’ s just a day of peace, it doesn ’ t mean anything. It ’ s not going to work ; you ’ re not going to stop the fighting in Afghanistan ; the Taliban won ’ t listen, etc., etc. It ’ s just symbolism. And that was even worse than actually what had just happened in many ways, because it couldn ’ t not work. I ’ d spoken in Somalia, Burundi, Gaza, the West Bank, India, Sri Lanka, Congo, wherever it was, and they ’ d all tell me,”If you can create a window of opportunity, we can move aid, we can vaccinate children. Children can lead their projects. They can unite. They can come together. If people would stop, lives will be saved.”That ’ s what I ’ d heard. And I ’ d heard that from the people who really understood what **conflict** was about. And so I went back to the United Nations. I decided that I ’ d continue filming and make another movie. And I went back to the U. N. for another couple of years. We started moving around the corridors of the U. N. system, governments and NGOs, trying desperately to find somebody to come forward and have a go at it, see if we could make it possible. And after lots and lots of meetings obviously, I ’ m delighted that this man, Ahmad Fawzi, one of my heroes and mentors really, he managed to get UNICEF **involved**. And UNICEF, God bless them, they said,"Okay, we ' ll have a go."And then UNAMA became **involved** in Afghanistan. It was historical. Could it work in Afghanistan with UNAMA and WHO and civil society, etc., etc., etc.? And I was getting it all on film and I was recording it, and I was thinking,"This is it. This is the possibility of it maybe working. But even if it doesn ' t, at least the door is open and there ' s a chance."And so I went back to London, and I went and saw this chap, Jude Law. And I saw him because he was an actor, I was an actor, I had a connection to him, because we needed to get to the press, we needed this attraction, we needed the media to be **involved**. Because if we start pumping it up a bit maybe more people would listen and there ' d be more — when we got into certain areas, maybe there would be more people **interested**. And maybe we ' d be helped financially a little bit more, which had been desperately difficult. I won ' t go into that. So Jude said,"Okay, I ' ll do some statements for you."While I was filming these statements, he said to me,"Where are you going next?"I said,"I ' m going to go to Afghanistan."He said,"Really?"And I could sort of see a little look in his eye of interest. So I said to him,"Do you want to come with me? It ' d be really **interesting** if you came. It would help and bring attention. And that attention would help leverage the situation, as well as all of the other sides of it."I think there ' s a number of pillars to success. One is you ' ve got to have a great idea. The other is you ' ve got to have a constituency, you ' ve got to have finance, and you ' ve got to be able to raise awareness. And actually I could never raise awareness by myself, no matter what I ' d achieved. So these **guys** were absolutely crucial. So he said yes, and we found ourselves in Afghanistan. It was a really incredible thing that when we landed there, I was talking to various people, and they were saying to me,"You ' ve got to get **everybody involved** here. You can ' t just expect it to work. You have to get out and work."And we did, and we traveled around, and we spoke to elders, we spoke to doctors, we spoke to nurses, we held press **conferences**, we went out with soldiers, we sat down with ISAF, we sat down with NATO, we sat down with the U. K. government. I mean, we basically sat down with **everybody** — in and out of schools with ministers of education, holding these press **conferences**, which of course, now were loaded with press, **everybody** was there. There was an interest in what was going on. This amazing woman, Fatima Gailani, was absolutely instrumental in what went on as she was the spokesperson for the resistance against the Russians. And her Afghan network was just absolutely everywhere. And she was really crucial in getting the message in. And then we went home. We ' d sort of done it. We had to wait now and see what happened. And I got home, and I remember one of the team bringing in a letter to me from the Taliban. And that letter basically said,"We ' ll observe this day. We will observe this day. We see it as a window of opportunity. And we will not engage. We ' re not going to engage."And that meant that humanitarian workers wouldn ' t be kidnapped or killed. And then suddenly, I obviously knew at this point, there was a chance. And days later, 1. 6 million children were vaccinated against polio as a consequence of **everybody** stopping. And like the General Assembly, obviously the most wonderful, wonderful moment. And so then we wrapped the film up and we put it together because we had to go back. We put it into Dari and Pashto. We put it in the local dialects. We went back to Afghanistan, because the next year was coming, and we wanted to **support**. But more importantly, we wanted to go back, because these people in Afghanistan were the heroes. They were the people who believed in peace and the possibilities of it, etc., etc. — and they made it real. And we wanted to go back and show them the film and say,"Look, you **guys** made this possible. And thank you very much."And we gave the film over. Obviously it was shown, and it was amazing. And then that year, that year, 2008, this ISAF statement from Kabul, Afghanistan, September 17th :”General Stanley McChrystal, commander of **international** security assistance forces in Afghanistan, announced today ISAF will not conduct offensive military operations on the 21st of September.”They were saying they would stop. And then there was this other statement that came out from the U. N. Department of Security and Safety saying that, in Afghanistan, because of this work, the violence was down by 70 percent. 70 percent reduction in violence on this day at least. And that completely blew my mind almost more than anything. And I remember being stuck in New York, this time because of the volcano, which was obviously much less harmful. And I was there thinking about what was going on. And I kept thinking about this 70 percent. 70 percent reduction in violence — in what everyone said was completely impossible and you couldn ’ t do. And that made me think that, if we can get 70 percent in Afghanistan, then surely we can get 70 percent reduction everywhere. We have to go for a global truce. We have to utilize this day of ceasefire and nonviolence and go for a global truce, go for the largest recorded cessation of hostilities, both domestically and internationally, ever recorded. That ’ s exactly what we must do. And on the 21st of September this year, we ’ re going to launch that campaign at the O2 Arena to go for that process, to try and create the largest recorded cessation of hostilities. And we will utilize all kinds of things — have a dance and social media and **visiting** on Facebook and **visit** the website, sign the petition. And it ’ s in the six official languages of the United Nations. And we ’ ll globally link with government, inter-government, non-government, education, unions, sports. And you can see the education box there. We ’ ve got resources at the moment in 174 countries trying to get young people to be the driving force behind the vision of that global truce. And obviously the life-saving is increased, the concepts help. Linking up with the Olympics — I went and saw Seb Coe. I said,”London 2012 is about truce. Ultimately, that ’ s what it ’ s about.”Why don ’ t we all team up? Why don ’ t we bring truce to life? Why don ’ t you **support** the process of the largest ever global truce? We ’ ll make a new film about this process. We ’ ll utilize sport and football. On the Day of Peace, there ’ s thousands of football matches all played, from the favelas of Brazil to wherever it might be. So, utilizing all of these ways to inspire individual action. And ultimately, we have to try that. We have to work together. And when I stand here in front of all of you, and the people who will watch these things, I ’ m excited, on behalf of **everybody** I ’ ve met, that there is a possibility that our world could unite, that we could come together as one, that we could lift the level of consciousness around the fundamental issues, brought about by individuals. I was with Brahimi, Ambassador Brahimi. I think he ’ s one of the most incredible men in relation to **international** politics — in Afghanistan, in Iraq. He ’ s an amazing man. And I sat with him a few weeks ago. And I said to him,”Mr. Brahimi, is this nuts, going for a global truce? Is this possible? Is it really possible that we could do this?”He said,”It ’ s absolutely possible.”I said,”What would you do? Would you go to governments and lobby and use the system?”He said,”No, I ’ d talk to the individuals.”It ’ s all about the individuals. It ’ s all about you and me. It ’ s all about partnerships. It ’ s about your constituencies ; it ’ s about your businesses. Because together, by working together, I seriously think we can start to change things. And there ’ s a wonderful man sitting in this audience, and I don ’ t know where he is, who said to me a few days ago — because I did a little rehearsal — and he said,”I ’ ve been thinking about this day and imagining it as a square with 365 squares, and one of them is white.”And it then made me think about a glass of water, which is clear. If you put one drop, one drop of something, in that water, it ’ ll change it forever. By working together, we can create peace one day. Thank you **TED**. Thank you. Thank you. Thanks a lot.

Thank you very much. Thank you.

Good afternoon, I ’ m proud to be here at TEDxKrakow. I ’ ll try to speak a little bit today about a phenomenon which can, and actually is changing the world, and whose name is people power. I ’ ll start with an anecdote, or for those of you who are Monty Python lovers, a Monty Python type of sketch. Here it is. It is December 15, 2010. Somebody gives you a bet : you will look at a crystal ball, and you will see the future ; the future will be accurate. But you need to share it with the world. OK, curiosity killed the cat, you take the bet, you look at the crystal ball. One hour later, you ’ re sitting in a building of the national TV, in a top show, and you tell the story. Before the end of 2011, Ben Ali, and Mubarak, and Gaddafi would be down, and prosecuted. Saleh of Yemen and Assad of Syria would be either challenged, or already on their knees. Osama bin Laden would be dead, and Ratko Mladic would be in the Hague. Now, the anchor watches you with a strange gaze on his face. And then, on top of it you add :”And thousands of young people from Athens, Madrid and New York will demonstrate for social justice, **claiming** they are inspired by Arabs.”Next thing you know, two **guys** in white appear, they give you the strange t- shirt, take you to the nearest mental institution. So I would like to speak a little bit about the phenomenon which is behind what already seems to be a very bad year for bad **guys**. And this phenomenon is called people power. Well, people power has been there for a while. It helped Gandhi kick the **Brits** from India, it helped Martin Luther King win his historic racial struggle. It helped a local, Lech Walesa, to kick out one million Soviet troops from Poland, and in beginning the end of the Soviet Union as we know it. So what ’ s new in it? What seems to be very new, which is the idea I would like to share with you today, is that there is a set of rules and skills which can be learned and taught in order to perform successful nonviolent struggle. If this is true, we can help these movements. Well, the first one - analytic skills. I ’ ll try where it all started in the Middle East. And for so many years, we were living with a completely wrong perception of the Middle East. It was looking like the frozen region. Literally a refrigerator. And there were only two types of meal there. Steak, which stands for a Mubarak-Ben Ali type of military police dictatorship, or a potato, which stands for a Tehran type of theocracies. And **everybody** was amazed when the refrigerator opened, and millions of young, mainly secular people stepped out to do the change. Guess what - they didn ’ t watch the demographics. What is the average age of an Egyptian? 24. How long was Mubarak in power? 31. So, this system was just obsolete, they expired. And young people of the Arab world have awakened one morning, and understood that power lies in their hands. The rest is the year in front of us. And guess what? The same Generation Y, with their rules, with their tools, with their games, and with their language, which sounds a little bit strange to me. I ’ m 38 now. And can you look at the age of the people on the streets of Europe? It seems that Generation Y is coming. Now, let me set another example. I ’ m meeting different people throughout the world, and they are, you know, academics, and professors, and doctors, and they will always talk conditions. They will say :”People power will work only if the regime is not too oppressive.”They will say :”People power will work, if the annual income of the country is between X and Z.”They will say :”People power will work only if there is a foreign pressure.”They will say :”People power will work only if there is no oil.”And, I mean, there is a set of conditions. Well, the news here is that your skills during the **conflict** seem

to be more important than the conditions. Namely, the skills of unity, planning, and maintaining nonviolent discipline. Let me give you an example. I come from a country called Serbia. It took us 10 years to unite 18 opposition party **leaders**, with their big egos, behind one single candidate against the Balkan dictator Slobodan Milosevic. Guess what? That was the day of his defeat. You look at the Egyptians, they fight on Tahrir Square, they get rid of their individual symbols, they appear on the street only with the flag of Egypt. I will give you a counter-example. You see nine presidential candidates running against Lukashenko, you all know the outcome. So unity is a big thing. And this can be achieved. Same with planning. Somebody has lied to you about the successful and spontaneous nonviolent revolution. That thing doesn ’ t exist in the world. Whenever you see young people in front of the row trying to fraternize with the police or military, somebody was thinking about it before. Now, at the end, nonviolent discipline. And this is probably the game-changer. If you maintain nonviolent discipline, you ’ ll exclusively win. You have 100, 000 people in a nonviolent march, one idiot or agent-provocateur throwing a stone. Guess what takes all the cameras. That one **guy**. One single act of violence can literally destroy your movement. Now, let me move to another place. It ’ s the selection of strategies and tactics. There are certain rules in nonviolent struggle you may follow. First, you start small. Second, you pick the battles you can win. It ’ s only 200 of us in this room. We won ’ t call for the march of a million. But what if we organized the spraying of graffiti throughout the night, all over Krakow. The city will know. So, we pick tactics accommodated to the event, especially this thing we call the small tactics of dispersion. They ’ re very useful in violent oppression. We are actually witnessing the picture of one of the best tactics ever used. It was on Tahrir square, where the **international** community was constantly frightened that, you know, the Islamists will overtake the revolution. What they organized — Christians protecting Muslims where they are praying, a Coptic wedding cheered by thousands of Muslims, the world has just changed the picture, but somebody was thinking about this previously. So there are so many things you can do instead of getting into one place, shouting, and you know, showing off in front of the security forces. Now, there is also another very important dynamic. And this is a dynamic that analysts normally don ’ t see. This is the dynamic between fear and apathy on the one side, and enthusiasm and humor on another side. So, it works like in a video game. You have the fear high, you have status quo. You have the enthusiasm higher, you see the fear is starting to melt. Day two, you see people running towards the police instead of from the police, in Egypt. You can tell that something is happening there. And then, it ’ s about the humor. Humor is such a powerful game-changer, and of course, it was very big in Poland. You know, we were just a small group of crazy students in Serbia when we made this big skit. We put the big petrol barrel with a portrait of Mr. President on it, in the middle of the Main Street. There was a hole in the top. So you could literally come, put a coin in, get a baseball bat, and hit his face. Sounds loud. And within minutes, we were sitting in a nearby caf having coffee, and there was a queue of people waiting to do this lovely thing. Well, that ’ s just the beginning of the show. The real show starts when the police appears.”What will they do?”Arrest us? We were nowhere to be seen. We were like three blocks away, observing it from our espresso bar. Arrest the shoppers, with kids? Doesn ’ t make sense. Of course, you could bet, they did the most **stupid** thing. They arrested the barrel. And now, the picture of the smashed face on the barrel, with the policemen dragging it to the police car, that was the best day for newspaper photographers that they will ever have. So, I mean, these are the things you can do. And you can always use humor. There is also one big thing about humor, it really hurts. Because these **guys** really are taking themselves too seriously. When you start to mock them, it hurts. Now, **everybody** is talking about His Majesty, the Internet, and it is also a very useful skill. But don ’ t rush to label things like”a Facebook Revolution,””Twitter Revolution.”Don ’ t mix the tools with the substance. It is true that the Internet and the new media are very useful in making things faster and cheaper. They also make it a bit **safer** for the participants, because they give partial anonymity. We ’ re watching the great example of something else the Internet can do. It can put the price tag of state-sponsored violence over a nonviolent protester. This is the famous group”We are all Khaled Said,”made by Wael Ghonim in Egypt, and his friend. This is the mutilated face of the **guy** who was beaten by the police. This is how he became known to the public, and this is what probably became the straw that broke the camel ’ s back. But here is also the bad news. The nonviolent struggle is won in the real world, in the streets. You will never change your society towards democracy, or, you know, the economy, if you sit down and click. There are risks to be taken, and there are living people who are winning the struggle. Well, the million-dollar question. What will happen in the Arab world? And though young people from the Arab world were pretty successful in bringing down three dictators, shaking the region, kind of persuading the clever kings from Jordan and Morocco to do substantial reforms, it is yet to be seen what will be the outcome. Whether the Egyptians and Tunisians will make it through the **transition**, or this will end in bloody ethnic and religious **conflicts**, whether the Syrians will maintain nonviolent discipline, faced with a brutal daily violence which kills thousands already, or they will slip into violent struggle and make ugly civil war. Will these revolutions be pushed through the **transitions** and democracy or be overtaken by the military or extremists of all kinds? We cannot tell. The same works for the Western **sector**, where you can see all these excited young people protesting around the world, occupying this, occupying that. Are they going to become the world wave? Are they going to find their skills, their enthusiasm, and their strategy to find what they really want and push for the reform, or will they just stay complaining about the endless list of the things they hate? This is the difference between the two paths. Now, what do the statistics have? My friend Maria Stephan ’ s book talks a lot about violent and nonviolent struggle, and there are some shocking data. If you look at the last 35 years and different social **transitions**, from dictatorship to democracy, you will see that, out of 67 different cases, in 50 of these cases it was nonviolent struggle which was the key power. This is one more reason to look at this phenomenon, this is one more reason to look at Generation Y. Enough for me to give them credit, and hope that they will find their skills and their courage to use nonviolent struggle and thus fix at least a part of the mess our generation is making in this world. Thank you.

Text Sample 576: POS Dim 4 – 2011 – Score 16.00 – 2011/t002473.txt

There ’ s a poem written by a very famous English poet at the end of the 19th century. It was said to echo in Churchill ’ s brain in the 1930s. And the poem goes :”On the idle hill of summer, lazy with the flow of streams, hark I hear a distant drummer, drumming like a sound in dreams, far and near and low and louder on the roads of earth go by, dear to friend and food to powder, soldiers marching, soon to die.”Those who are **interested** in poetry, the poem is”A Shropshire Lad”written by A. E. Housman. But what Housman understood, and you hear it in the symphonies of Nielsen too, was that the long, hot, silvan summers of stability of the 19th century were coming to a close, and that we were about to move into one of those terrifying periods of history when power changes. And these are always periods, ladies and gentlemen, accompanied by turbulence, and all too often by blood. And my message for you is that I believe we are condemned, if you like, to live at just one of those moments in history when the gimbals upon which the established order of power is beginning to change and the new look of the world, the new powers that exist in the world, are beginning to take form. And these are — and we see it very clearly today — nearly always highly turbulent times, highly difficult times, and all too often very bloody times. By the way, it happens about once every century. You might argue that the last time it happened — and that ' s what Housman felt coming and what Churchill felt too — was that when power passed from the old nations, the old powers of Europe, across the Atlantic to the new emerging power of the United States of America — the beginning of the American century. And of course, into the vacuum where the too-old European powers used to be were played the two bloody catastrophes of the last century — the one in the first part and the one in the second part : the two great World Wars. Mao Zedong used to refer to them as the European civil wars, and it ' s probably a more accurate way of describing them. Well, ladies and gentlemen, we live at one of those times. But for us, I want to talk about three factors today. And the first of these, the first two of these, is about a shift in power. And the second is about some new dimension which I want to refer to, which has never quite happened in the way it ' s happening now. But let ' s talk about the shifts of power that are occurring to the world. And what is happening today is, in one sense, frightening because it ' s never happened before. We have seen lateral shifts of power — the power of Greece passed to Rome and the power shifts that occurred during the European civilizations — but we are seeing something slightly different. For power is not just moving laterally from nation to nation. It ' s also moving vertically. What ' s happening today is that the power that was encased, held to accountability, held to the rule of law, within the institution of the nation state has now migrated in very large measure onto the global stage. The globalization of power — we talk about the globalization of markets, but actually it ' s the globalization of real power. And where, at the nation state level that power is held to accountability subject to the rule of law, on the **international** stage it is not. The **international** stage and the global stage where power now resides : the power of the Internet, the power of the satellite broadcasters, the power of the money changers — this vast money-go-round that circulates now 32 times the amount of money necessary for the trade it ' s supposed to be there to finance — the money changers, if you like, the financial speculators that have brought us all to our knees quite recently, the power of the multinational corporations now developing budgets often bigger than medium-sized countries. These live in a global space which is largely unregulated, not subject to the rule of law, and in which people may act free of constraint. Now that suits the powerful up to a moment. It ' s always suitable for those who have the most power to operate in spaces without constraint, but the lesson of history is that, sooner or later, unregulated space — space not subject to the rule of law — becomes populated, not just by the things you wanted — **international** trade, the Internet, etc. — but also by the things you don ' t want — **international** criminality, **international** terrorism. The revelation of 9 / 11 is that even if you are the most powerful nation on earth, nevertheless, those who inhabit that space can attack you even in your most iconic of cities one bright September morning. It ' s said that something like 60 percent of the four million dollars that was taken to fund 9 / 11 actually passed through the institutions of the Twin Towers which 9 / 11 destroyed. You see, our enemies also use this space — the space of mass travel, the Internet, satellite broadcasters — to be able to get around their poison, which is about destroying our systems and our ways. Sooner or later, sooner or later, the rule of history is that where power goes governance must follow. And if it is therefore the case, as I believe it is, that one of the phenomenon of our time is the globalization of power, then it follows that one of the challenges of our time is to bring governance to the global space. And I believe that the decades ahead of us now will be to a greater or lesser extent turbulent the more or less we are able to achieve that aim : to bring governance to the global space. Now notice, I ' m not talking about government. I ' m not talking about setting up some global democratic institution. My own view, by the way, ladies and gentlemen, is that this is unlikely to be done by spawning more U. N. institutions. If we didn ' t have the U. N., we ' d have to invent it. The world needs an **international** forum. It needs a means by which you can legitimize **international** action. But when it comes to governance of the global space, my guess is this won ' t happen through the creation of more U. N. institutions. It will actually happen by the powerful coming together and making treaty-based systems, treaty-based agreements, to govern that global space. And if you look, you can see them happening, already beginning to emerge. The World Trade Organization : treaty-based organization, entirely treaty-based, and yet, powerful enough to hold even the most powerful, the United States, to account if necessary. Kyoto : the beginnings of struggling to create a treaty- based organization. The G20 : we know now that we have to put together an institution which is capable of bringing governance to that financial space for financial speculation. And that ' s what the G20 is, a treaty-based institution. Now there ' s a problem there, and we ' ll come back to it in a minute, which is that if you bring the most powerful together to make the rules in treaty-based institutions, to fill that governance space, then what happens to the weak who are left out? And that ' s a big problem, and we ' ll return to it in just a second. So there ' s my first message, that if you are to pass through these turbulent times more or less turbulently, then our success in doing that will in large measure depend on our capacity to bring sensible governance to the global space. And watch that beginning to happen. My second point is, and I know I don ' t have to talk to an audience like this about such a thing, but power is not just shifting vertically, it ' s also shifting horizontally. You might argue that the story, the history of civilizations, has been civilizations gathered around seas — with the first ones around the Mediterranean, the more recent ones in the ascendents of Western power around the Atlantic. Well it seems to me that we ' re now seeing a fundamental shift of power, broadly speaking, away from nations gathered around the Atlantic [seaboard] to the nations gathered around the Pacific rim. Now that begins with economic power, but that ' s the way it always begins. You already begin to see the development of foreign **policies**, the augmentation of military budgets occurring in the other growing powers in the world. I think actually this is not so much a shift from the **West** to the East ; something different is happening. My guess is, for what it ' s worth, is that the United States will remain the most powerful nation on earth for the next 10 years, 15, but the context in which she holds her power has now radically altered ; it has radically changed. We are coming out of 50 years, most unusual years, of history in which we have had a totally mono-polar world, in which every compass needle for or against has to be referenced by its position to Washington — a world bestrode by a single colossus. But that ' s not a usual case in history. In fact, what ' s now emerging is the much more normal case of history. You ' re beginning to see the emergence of a multi-polar world. Up until now, the United States has been the **dominant** feature of our world. They will remain the most powerful nation, but they will be the most powerful nation in an increasingly multi-polar world. And you begin to see the alternative centers of power building up — in China, of course, though my own guess is that China ' s ascent to greatness is not smooth. It ' s going to be quite grumpy as China begins to democratize her society after liberalizing her economy. But that ' s a subject of a different discussion. You see India, you see Brazil. You see increasingly that the world now looks actually, for us Europeans, much more like Europe in the 19th century. Europe in the 19th century : a great British foreign secretary, Lord Canning, used to describe it as the"European concert of powers."There was a balance, a five-sided balance. Britain always played to the balance. If Paris got together with Berlin, Britain got together with Vienna and Rome to provide a counterbalance. Now notice, in a period which is dominated by a mono-polar world, you have fixed alliances — NATO, the Warsaw Pact. A fixed polarity of power means fixed alliances. But a multiple polarity of power means shifting and changing alliances. And that ' s the world we ' re coming into, in which we will increasingly see that our alliances are not fixed. Canning, the great British foreign secretary once said,"Britain has a common interest, but no common allies."And we will see increasingly that even we in the West will reach out, have to reach out, beyond the cozy circle of the Atlantic powers to make alliances with others if we want to get things done in the world. Note, that when we went into Libya, it was not good enough for the West to do it alone ; we had to bring others in. We had to bring, in this case, the Arab League in. My guess is Iraq and Afghanistan are the last times when the West has tried to do it themselves, and we haven ' t succeeded. My guess is that we ' re reaching the beginning of the end of 400 years — I say 400 years because it ' s the end of the Ottoman Empire — of the hegemony of Western power, Western institutions and Western values. You know, up until now, if the West got its act together, it could propose and dispose in every corner of the world. But that ' s no longer true. Take the last financial **crisis** after the Second World War. The West got together — the Bretton Woods Institution, World Bank, International Monetary Fund — the problem solved. Now we have to call in others. Now we have to create the G20. Now we have to reach beyond the cozy circle of our Western friends. Let me make a prediction for you, which is probably even more startling. I suspect we are now reaching the end of 400 years when Western power was enough. People say to me,"The Chinese, of course, they ' ll never get themselves **involved** in peace-making, multilateral peace-making around the world."Oh yes? Why not? How many Chinese troops are serving under the blue beret, serving under the blue flag, serving under the U. N. command in the world today? 3, 700. How many Americans? 11. What is the largest naval contingent tackling the issue of Somali pirates? The Chinese naval contingent. Of course they are, they are a mercantilist nation. They want to keep the sea lanes open. Increasingly, we are going to have to do business with people with whom we do not share values, but with whom, for the moment, we share common interests. It ' s a whole new different way of looking at the world that is now emerging. And here ' s the third factor, which is totally different. Today in our modern world, because of the Internet, because of the kinds of things people have been talking about here, everything is connected to everything. We are now interdependent. We are now interlocked, as nations, as individuals, in a way which has never been the case before, never been the case before. The interrelationship of nations, well it ' s always existed. Diplomacy is about managing the interrelationship of nations. But now we are intimately locked together. You get swine flu in Mexico, it ' s a problem for Charles de Gaulle Airport 24 hours later. Lehman Brothers goes down, the whole lot collapses. There are fires in the steppes of Russia, food riots in Africa. We are all now deeply, deeply, deeply interconnected. And what that means is the idea of a nation state acting alone, not connected with others, not working with others, is no longer a viable proposition. Because the actions of a nation state are neither confined to itself, nor is it sufficient for the nation state itself to control its own territory, because the effects outside the nation state are now beginning to affect what happens inside them. I was a young soldier in the last of the small empire wars of Britain. At that time, the defense of my country was about one thing and one thing only : how strong was our army, how strong was our **air** force, how strong was our navy and how strong were our allies. That was when the enemy was outside the walls. Now the enemy is inside the walls. Now if I want to talk about the defense of my country, I have to speak to the Minister of Health because **pandemic** disease is a threat to my security, I have to speak to the Minister of Agriculture because food security is a threat to my security, I have to speak to the Minister of Industry because the fragility of our hi-tech infrastructure is now a point of attack for our enemies — as we see from cyber warfare — I have to speak to the Minister of Home Affairs because who has entered my country, who lives in that terraced house in that inner city has a direct effect on what happens in my country — as we in London saw in the 7 / 7 bombings. It ' s no longer the case that the security of a country is simply a matter for its soldiers and its ministry of defense. It ' s its capacity to lock together its institutions. And this tells you something very important. It tells you that, in fact, our governments, vertically constructed, constructed on the economic model of the Industrial Revolution — vertical hierarchy, specialization of tasks, command structures — have got the wrong structures completely. You in business know that the paradigm structure of our time, ladies and gentlemen, is the network. It ' s your capacity to network that matters, both within your governments and externally. So here is Ashdown ' s third law. By the way, don ' t ask me about Ashdown ' s first law and second law because I haven ' t invented those yet ; it always sounds better if there ' s a third law, doesn ' t it? Ashdown ' s third law is that in the modern age, where everything is connected to everything, the most important thing about what you can do is what you can do with others. The most important bit about your structure — whether you ' re a government, whether you ' re an army regiment, whether you ' re a business — is your docking points, your interconnectors, your capacity to network with others. You understand that in industry ; governments don ' t. But now one final thing. If it is the case, ladies and gentlemen — and it is — that we are now locked together in a way that has never been quite the same before, then it ' s also the case that we share a destiny with each other. Suddenly and for the very first time, **collective** defense, the thing that has dominated us as the concept of securing our nations, is no longer enough. It used to be the case that if my tribe was more powerful than their tribe, I was **safe** ; if my country was more powerful than their country, I was **safe** ; my alliance, like NATO, was more powerful than their alliance, I was **safe**. It is no longer the case. The advent of the interconnectedness and of the weapons of mass destruction means that, increasingly, I share a destiny with my enemy. When I was a diplomat **negotiating** the disarmament treaties with the Soviet Union in Geneva in the 1970s, we succeeded because we understood we shared a destiny with them. **Collective** security is not enough. Peace has come to Northern Ireland because both sides realized that the zero-sum game couldn ' t work. They shared a destiny with their enemies. One of the great barriers to peace in the Middle East is that both sides, both Israel and, I think, the Palestinians, do not understand that they share a **collective** destiny. And so suddenly, ladies and gentlemen, what has been the proposition of visionaries and poets down the ages becomes something we have to take seriously as a matter of public **policy**. I started with a poem, I ' ll end with one. The great poem of John Donne ' s."Send not for whom the bell tolls."The poem is called”No Man is an Island.”And it goes :”Every man ’ s death affected me, for I am **involved** in mankind, send not to ask for whom the bell tolls, it tolls for thee.”For John Donne, a recommendation of morality. For us, I think, part of the equation for our survival. Thank you very much.

Democracy is in trouble, no question about that, and it comes in part from a deep dilemma in which it is embedded. It ’ s increasingly irrelevant to the kinds of decisions we face that have to do with global **pandemics**, a cross-border problem ; with HIV, a transnational problem ; with markets and immigration, something that goes beyond national borders ; with terrorism, with war, all now cross-border problems. In fact, we live in a 21st-century world of interdependence, and brutal interdependent problems, and when we look for solutions in politics and in democracy, we are faced with political institutions designed 400 years ago, autonomous, sovereign nation-states with jurisdictions and territories separate from one another, each **claiming** to be able to solve the problem of its own people. Twenty-first-century, transnational world of problems and challenges, 17th-century world of political institutions. In that dilemma lies the central problem of democracy. And like many others, I ’ ve been thinking about what can one do about this, this asymmetry between 21st-century challenges and archaic and increasingly dysfunctional political institutions like nation-states. And my suggestion is that we change the subject, that we stop talking about nations, about bordered states, and we start talking about cities. Because I think you will find, when we talk about cities, we are talking about the political institutions in which civilization and culture were born. We are talking about the cradle of democracy. We are talking about the venues in which those public spaces where we come together to create democracy, and at the same time protest those who would take our freedom, take place. Think of some great names : the Place de la Bastille, Zuccotti Park, Tahrir Square, Taksim Square in today ’ s headlines in Istanbul, or, yes, Tiananmen Square in Beijing. Those are the public spaces where we announce ourselves as citizens, as participants, as people with the right to write our own narratives. Cities are not only the oldest of institutions, they ’ re the most enduring. If you think about it, Constantinople, Istanbul, much older than Turkey. Alexandria, much older than Egypt. Rome, far older than Italy. Cities endure the ages. They are the places where we are born, grow up, are educated, work, marry, pray, play, get old, and in time, die. They are home. Very different than nation-states, which are abstractions. We pay taxes, we vote occasionally, we watch the men and women we choose rule rule more or less without us. Not so in those homes known as our towns and cities where we live. Moreover, today, more than half of the world ’ s population live in cities. In the developed world, it ’ s about 78 percent. More than three out of four people live in urban institutions, urban places, in cities today. So cities are where the action is. Cities are us. Aristotle said in the ancient world, man is a political animal. I say we are an urban animal. We are an urban species, at home in our cities. So to come back to the dilemma, if the dilemma is we have old-fashioned political nation-states unable to govern the world, respond to the global challenges that we face like **climate** change, then maybe it ’ s time for mayors to rule the world, for mayors and the citizens and the peoples they represent to engage in global governance. When I say if mayors ruled the world, when I first came up with that phrase, it occurred to me that actually, they already do. There are scores of **international**, inter-city, cross-border institutions, networks of cities in which cities are already, quite quietly, below the horizon, working together to deal with **climate** change, to deal with security, to deal with immigration, to deal with all of those tough, interdependent problems that we face. They have strange names : UCLG, United Cities and Local Governments ; ICLEI, the International Council for Local Environmental Issues. And the list goes on : Citynet in Asia ; City Protocol, a new organization out of Barcelona that is using the web to share best practices among countries. And then all the things we know a little better, the U. S. **Conference** of Mayors, the Mexican **Conference** of Mayors, the European **Conference** of Mayors. Mayors are where this is happening. And so the question is, how can we create a world in which mayors and the citizens they represent play a more prominent role? Well, to understand that, we need to understand why cities are special, why mayors are so different than prime ministers and presidents, because my premise is that a mayor and a prime minister are at the opposite ends of a political spectrum. To be a prime minister or a president, you have to have an ideology, you have to have a meta- narrative, you have to have a theory of how things work, you have to belong to a party. Independents, on the whole, don ' t get elected to office. But mayors are just the opposite. Mayors are pragmatists, they ' re problem-solvers. Their job is to get things done, and if they don ' t, they ' re out of a job. Mayor Nutter of Philadelphia said, we could never get away here in Philadelphia with the **stuff** that goes on in Washington, the paralysis, the non-action, the inaction. Why? Because potholes have to get filled, because the trains have to run, because kids have to be able to get to school. And that ' s what we have to do, and to do that is about pragmatism in that deep, American sense, reaching outcomes. Washington, Beijing, Paris, as world capitals, are anything but pragmatic, but real city mayors have to be pragmatists. They have to get things done, they have to put ideology and religion and ethnicity aside and draw their cities together. We saw this a couple of decades ago when Teddy Kollek, the great mayor of Jerusalem in the ' 80s and the ' 90s, was besieged one day in his office by religious **leaders** from all of the backgrounds, Christian prelates, rabbis, imams. They were arguing with one another about access to the holy sites. And the squabble went on and on, and Kollek listened and listened, and he finally said,"Gentlemen, spare me your sermons, and I will fix your sewers."That ' s what mayors do. They fix sewers, they get the trains running. There isn ' t a left or a right way of doing. Boris Johnson in London calls himself an anarcho-Tory. Strange term, but in some ways, he is. He ' s a libertarian. He ' s an anarchist. He rides to work on a bike, but at the same time, he ' s in some ways a **conservative**. Bloomberg in New York was a Democrat, then he was a Republican, and finally he was an Independent, and said the party label just gets in the way. Luzhkov, 20 years mayor in Moscow, though he helped found a party, United Party with Putin, in fact **refused** to be defined by the party and finally, in fact, lost his job not under Brezhnev, not under Gorbachev, but under Putin, who wanted a more faithful party follower. So mayors are pragmatists and problem-solvers. They get things done. But the second thing about mayors is they are also what I like to call homeboys, or to include the women mayors, homies. They ' re from the neighborhood. They ' re part of the neighborhood. They ' re known. Ed Koch used to wander around New York City saying,"How am I doing?"Imagine David Cameron wandering around the United Kingdom asking,"How am I doing?"He wouldn ' t like the answer. Or Putin. Or any national **leader**. He could ask that because he knew New Yorkers and they knew him. Mayors are usually from the places they govern. It ' s pretty hard to be a carpetbagger and be a mayor. You can run for the Senate out of a different state, but it ' s hard to do that as a mayor. And as a result, mayors and city councillors and local authorities have a much higher **trust** level, and this is the third feature about mayors, than national governing officials. In the United States, we know the pathetic figures : 18 percent of Americans approve of Congress and what they do. And even with a relatively popular president like Obama, the figures for the Presidency run about 40, 45, sometimes 50 percent at best. The Supreme Court has fallen way down from what it used to be. But when you ask,"Do you **trust** your city councillor, do you **trust** your mayor?"the rates shoot up to 70, 75, even 80 percent, because they ' re from the neighborhood, because the people they work with are their neighbors, because, like Mayor Booker in Newark, a mayor is likely to get out of his car on the way to work and go in and pull people out of a burning building — that happened to Mayor Booker — or intervene in a mugging in the street as he goes to work because he sees it. No head of state would be permitted by their security details to do it, nor be in a position to do it. That ' s the difference, and the difference has to do with the character of cities themselves, because cities are profoundly multicultural, open, participatory, democratic, able to work with one another. When states face each other, China and the U. S., they face each other like this. When cities interact, they interact like this. China and the U. S., despite the recent meta-meeting in California, are locked in all kinds of anger, resentment, and rivalry for number one. We heard more about who will be number one. Cities don ' t worry about number one. They have to work together, and they do work together. They work together in **climate** change, for example. Organizations like the C40, like ICLEI, which I mentioned, have been working together many, many years before Copenhagen. In Copenhagen, four or five years ago, 184 nations came together to explain to one another why their sovereignty didn ' t permit them to deal with the grave, grave **crisis** of **climate** change, but the mayor of Copenhagen had invited 200 mayors to attend. They came, they stayed, and they found ways and are still finding ways to work together, city- to-city, and through inter-city organizations. Eighty percent of carbon emissions come from cities, which means cities are in a position to solve the carbon problem, or most of it, whether or not the states of which they are a part make agreements with one another. And they are doing it. Los Angeles cleaned up its port, which was 40 percent of carbon emissions, and as a result got rid of about 20 percent of carbon. New York has a program to upgrade its old buildings, make them better insulated in the winter, to not leak energy in the summer, not leak **air** conditioning. That ' s having an **impact**. Bogota, where Mayor Mockus, when he was mayor, he introduced a transportation system that saved energy, that allowed surface buses to run in effect like subways, express buses with corridors. It helped unemployment, because people could get across town, and it had a profound **impact** on **climate** as well as many other things there. Singapore, as it developed its high-rises and its remarkable public housing, also developed an island of parks, and if you go there, you ' ll see how much of it is green land and park land. Cities are doing this, but not just one by one. They are doing it together. They are sharing what they do, and they are making a difference by shared best practices. Bike shares, many of you have heard of it, started 20 or 30 years ago in Latin America. Now it ' s in hundreds of cities around the world. Pedestrian zones, congestion fees, emission limits in cities like California cities have, there ' s lots and lots that cities can do even when opaque, stubborn nations **refuse** to act. So what ' s the bottom line here? The bottom line is, we still live politically in a world of borders, a world of boundaries, a world of walls, a world where states **refuse** to act together. Yet we know that the reality we experience day to day is a world without borders, a world of diseases without borders and doctors without borders, maladies sans frontires, Mdecins Sans Frontires, of economics and technology without borders, of education without borders, of terrorism and war without borders. That is the real world, and unless we find a way to globalize democracy or democratize globalization, we will increasingly not only risk the failure to address all of these transnational problems, but we will risk losing democracy itself, locked up in the old nation-state box, unable to address global problems democratically. So where does that leave us? I ’ ll tell you. The road to global democracy doesn ’ t run through states. It runs through cities. Democracy was born in the ancient polis. I believe it can be reborn in the global cosmopolis. In that journey from polis to cosmopolis, we can rediscover the power of democracy on a global level. We can create not a League of Nations, which failed, but a League of Cities, not a United or a dis-United Nations, but United Cities of the World. We can create a global parliament of mayors. That ’ s an idea. It ’ s in my conception of the coming world, but it ’ s also on the table in City Halls in Seoul, Korea, in Amsterdam, in Hamburg, and in New York. Mayors are considering that idea of how you can actually constitute a global parliament of mayors, and I love that idea, because a parliament of mayors is a parliament of citizens and a parliament of citizens is a parliament of us, of you and of me. If ever there were citizens without borders, I think it ’ s the citizens of **TED** who show the promise to be those citizens without borders. I am ready to reach out and embrace a new global democracy, to take back our democracy. And the only question is, are you? Thank you so much, my fellow citizens. Thank you.

Text Sample 578: POS Dim 4 – 2013 – Score 15.00 – 2013/t002037.txt

Good morning. My name is Eric Li, and I was born here. But no, I wasn ’ t born there. This was where I was born : Shanghai, at the height of the Cultural Revolution. My grandmother tells me that she heard the sound of gunfire along with my first cries. When I was growing up, I was told a story that explained all I ever needed to know about humanity. It went like this. All human societies develop in linear progression, beginning with primitive society, then slave society, feudalism, capitalism, socialism, and finally, guess where we end up? Communism! Sooner or later, all of humanity, regardless of culture, language, nationality, will arrive at this final stage of political and social development. The entire world ’ s peoples will be unified in this paradise on Earth and live happily ever after. But before we get there, we ’ re engaged in a struggle between good and evil, the good of socialism against the evil of capitalism, and the good shall triumph. That, of course, was the meta-narrative distilled from the theories of Karl Marx. And the Chinese bought it. We were taught that grand story day in and day out. It became part of us, and we believed in it. The story was a bestseller. About one third of the entire world ’ s population lived under that meta-narrative. Then, the world changed overnight. As for me, disillusioned by the failed religion of my youth, I went to America and became a Berkeley hippie. Now, as I was coming of age, something else happened. As if one big story wasn ’ t enough, I was told another one. This one was just as grand. It also **claims** that all human societies develop in a linear progression towards a singular end. This one went as follows : All societies, regardless of culture, be it Christian, Muslim, Confucian, must progress from traditional societies in which groups are the basic units to modern societies in which atomized individuals are the sovereign units, and all these individuals are, by definition, rational, and they all want one thing : the vote. Because they are all rational, once given the vote, they produce good government and live happily ever after. Paradise on Earth, again. Sooner or later, electoral democracy will be the only political system for all countries and all peoples, with a free market to make them all rich. But before we get there, we ’ re engaged in a struggle between good and evil. The good belongs to those who are democracies and are charged with a mission of spreading it around the globe, sometimes by force, against the evil of those who do not hold elections. George H. W. Bush : A new world order... George W. Bush :... ending tyranny in our world... Barack Obama :... a single standard for all who would hold power. Eric X. Li : Now — This story also became a bestseller. According to Freedom House, the number of democracies went from 45 in 1970 to 115 in 2010. In the last 20 years, Western elites tirelessly trotted around the globe selling this prospectus : Multiple parties fight for political power and everyone voting on them is the only path to salvation to the long-suffering developing world. Those who buy the prospectus are destined for success. Those who do not are doomed to fail. But this time, the Chinese didn ' t buy it. Fool me once... The rest is history. In just 30 years, China went from one of the poorest agricultural countries in the world to its second-largest economy. Six hundred fifty million people were lifted out of poverty. Eighty percent of the entire world ' s poverty alleviation during that period happened in China. In other words, all the new and old democracies put together amounted to a mere fraction of what a single, one-party state did without voting. See, I grew up on this **stuff** : food stamps. Meat was rationed to a few hundred grams per person per month at one point. Needless to say, I ate all my grandmother ' s portions. So I asked myself, what ' s wrong with this picture? Here I am in my hometown, my business growing leaps and bounds. Entrepreneurs are starting companies every day. Middle class is expanding in speed and scale unprecedented in human history. Yet, according to the grand story, none of this should be happening. So I went and did the only thing I could. I studied it. Yes, China is a one-party state run by the Chinese Communist Party, the Party, and they don ' t hold elections. Three assumptions are made by the **dominant** political theories of our time. Such a system is operationally rigid, politically closed, and morally illegitimate. Well, the assumptions are wrong. The opposites are true. Adaptability, meritocracy, and legitimacy are the three defining characteristics of China ' s one-party system. Now, most political scientists will tell us that a one-party system is inherently incapable of self- correction. It won ' t last long because it cannot adapt. Now here are the facts. In 64 years of running the largest country in the world, the range of the Party ' s **policies** has been wider than any other country in recent memory, from radical land collectivization to the Great Leap Forward, then privatization of farmland, then the Cultural Revolution, then Deng Xiaoping ' s market reform, then successor Jiang Zemin took the giant political step of opening up Party **membership** to private businesspeople, something unimaginable during Mao ' s rule. So the Party self-corrects in rather dramatic fashions. Institutionally, new rules get enacted to correct previous **dysfunctions**. For example, term limits. Political **leaders** used to retain their positions for life, and they used that to accumulate power and perpetuate their rules. Mao was the father of modern China, yet his prolonged rule led to disastrous mistakes. So the Party instituted term limits with mandatory retirement age of 68 to 70. One thing we often hear is,"Political reforms have lagged far behind economic reforms,"and"China is in dire need of political reform."But this **claim** is a rhetorical trap hidden behind a political bias. See, some have decided a priori what kinds of changes they want to see, and only such changes can be called political reform. The truth is, political reforms have never stopped. Compared with 30 years ago, 20 years, even 10 years ago, every aspect of Chinese society, how the country is governed, from the most local level to the highest center, are unrecognizable today. Now such changes are simply not possible without political reforms of the most fundamental kind. Now I would venture to suggest the Party is the world ' s leading expert in political reform. The second assumption is that in a one-party state, power gets concentrated in the hands of the few, and bad governance and corruption follow. Indeed, corruption is a big problem, but let ' s first look at the larger context. Now, this may be counterintuitive to you. The Party happens to be one of the most meritocratic political institutions in the world today. China ' s highest ruling body, the Politburo, has 25 members. In the most recent one, only five of them came from a background of privilege, so-called princelings. The other 20, including the president and the premier, came from entirely ordinary backgrounds. In the larger central committee of 300 or more, the percentage of those who were born into power and wealth was even smaller. The vast majority of **senior** Chinese **leaders** worked and competed their way to the top. Compare that with the ruling elites in both developed and developing countries, I think you ' ll find the Party being near the top in upward mobility. The question then is, how could that be possible in a system run by one party? Now we come to a powerful political institution, little-known to Westerners : the Party ' s Organization Department. The department functions like a giant human resource engine that would be the envy of even some of the most successful corporations. It operates a rotating pyramid made up of three components : civil service, state-owned enterprises, and social organizations like a university or a community program. They form separate yet integrated career paths for Chinese officials. They recruit college grads into entry-level positions in all three tracks, and they start from the bottom, called"keyuan"[clerk]. Then they could get promoted through four increasingly elite ranks : fuke [deputy section manager], ke [section manager], fuchu [deputy division manager], and chu [division manger]. Now these are not moves from"Karate Kid,"okay? It ' s serious business. The range of positions is wide, from running health care in a village to foreign investment in a city district to manager in a company. Once a year, the department reviews their performance. They interview their superiors, their peers, their subordinates. They vet their personal conduct. They conduct public opinion surveys. Then they promote the winners. Throughout their careers, these cadres can move through and out of all three tracks. Over time, the good ones move beyond the four base levels to the fuju [deputy bureau chief] and ju [bureau chief] levels. There, they enter high officialdom. By that point, a typical assignment will be to manage a district with a population in the millions or a company with hundreds of millions of dollars in revenue. Just to show you how competitive the system is, in 2012, there were 900, 000 fuke and ke levels, 600, 000 fuchu and chu levels, and only 40, 000 fuju and ju levels. After the ju levels, the best few move further up several more ranks, and eventually make it to the Central Committee. The process takes two to three decades. Does patronage play a role? Yes, of course. But merit remains the fundamental driver. In essence, the Organization Department runs a modernized version of China ' s centuries-old mentoring system. China ' s new president, Xi Jinping, is the son of a former **leader**, which is very unusual, first of his kind to make the top job. Even for him, the career took 30 years. He started as a village manager, and by the time he entered the Politburo, he had managed areas with a total population of 150 million people and combined GDPs of 1. 5 trillion U. S. dollars. Now, please don ' t get me wrong, okay? This is not a put-down of anyone. It ' s just a statement of fact. George W. Bush, remember him? This is not a put-down. Before becoming governor of Texas, or Barack Obama before running for president, could not make even a small county manager in China ' s system. Winston Churchill once said that democracy is a terrible system except for all the rest. Well, apparently he hadn ' t heard of the Organization Department. Now, Westerners always assume that multi-party election with universal suffrage is the only source of political legitimacy. I was asked once,"The Party wasn ' t voted in by election. Where is the source of legitimacy?"I said,"How about competency?"We all know the facts. In 1949, when the Party took power, China was mired in civil wars, dismembered by foreign aggression, average life expectancy at that time, 41 years old. Today, it ' s the second largest economy in the world, an industrial powerhouse, and its people live in increasing prosperity. Pew Research polls Chinese public attitudes, and here are the numbers in recent years. Satisfaction with the direction of the country : 85 percent. Those who think they ' re better off than five years ago : 70 percent. Those who expect the future to be better : a whopping 82 percent. Financial Times polls global youth attitudes, and these numbers, brand new, just came from last week. Ninety-three percent of China ' s Generation Y are optimistic about their country ' s future. Now, if this is not legitimacy, I ' m not sure what is. In contrast, most electoral democracies around the world are suffering from dismal performance. I don ' t need to elaborate for this audience how dysfunctional it is, from Washington to European capitals. With a few exceptions, the vast number of developing countries that have adopted electoral regimes are still suffering from poverty and civil strife. Governments get elected, and then they fall below 50 percent approval in a few months and stay there and get worse until the next election. Democracy is becoming a perpetual cycle of elect and regret. At this rate, I ' m afraid it is democracy, not China ' s one-party system, that is in danger of losing legitimacy. Now, I don ' t want to create the misimpression that China ' s hunky-dory, on the way to some kind of superpowerdom. The country faces enormous challenges. The social and economic problems that come with wrenching change like this are mind-boggling. Pollution is one. Food safety. Population issues. On the political front, the worst problem is corruption. Corruption is widespread and undermines the system and its moral legitimacy. But most analysts misdiagnose the disease. They say that corruption is the result of the one-party system, and therefore, in order to cure it, you have to do away with the entire system. But a more careful look would tell us otherwise. Transparency International ranks China between 70 and 80 in recent years among 170 countries, and it ' s been moving up. India, the largest democracy in the world, 94 and dropping. For the hundred or so countries that are ranked below China, more than half of them are electoral democracies. So if election is the panacea for corruption, how come these countries can ' t fix it? Now, I ' m a venture capitalist. I make bets. It wouldn ' t be fair to end this talk without putting myself on the line and making some predictions. So here they are. In the next 10 years, China will surpass the U. S. and become the largest economy in the world. Income per capita will be near the top of all developing countries. Corruption will be curbed, but not eliminated, and China will move up 10 to 20 notches to above 60 in T. I. ranking. Economic reform will accelerate, political reform will continue, and the one-party system will hold firm. We live in the dusk of an era. Meta-narratives that make universal **claims** failed us in the 20th century and are failing us in the 21st. Meta-narrative is the cancer that is killing democracy from the inside. Now, I want to clarify something. I ' m not here to make an indictment of democracy. On the contrary, I think democracy contributed to the rise of the West and the creation of the modern world. It is the universal **claim** that many Western elites are making about their political system, the hubris, that is at the heart of the West ' s current ills. If they would spend just a little less time on trying to force their way onto others, and a little bit more on political reform at home, they might give their democracy a better chance. China ' s political model will never supplant electoral democracy, because unlike the latter, it doesn ' t pretend to be universal. It cannot be exported. But that is the point precisely. The significance of China ' s example is not that it provides an alternative, but the demonstration that alternatives exist. Let us draw to a close this era of meta- narratives. Communism and democracy may both be laudable ideals, but the era of their dogmatic universalism is over. Let us stop telling people and our children there ’ s only one way to govern ourselves and a singular future towards which all societies must evolve. It is wrong. It is irresponsible. And worst of all, it is boring. Let universality make way for plurality. Perhaps a more **interesting** age is upon us. Are we brave enough to welcome it? Thank you. Thank you. Thank you. Thank you. Thanks. Bruno Giussani : Eric, stay with me for a couple of minutes, because I want to ask you a couple of questions. I think many here, and in general in Western countries, would agree with your statement about analysis of democratic systems becoming dysfunctional, but at the same time, many would kind of find unsettling the thought that there is an unelected authority that, without any form of oversight or consultation, decides what the national interest is. What is the mechanism in the Chinese model that allows people to say, actually, the national interest as you defined it is wrong? EXL : You know, Frank Fukuyama, the political scientist, called the Chinese system”responsive authoritarianism.”It ’ s not exactly right, but I think it comes close. So I know the largest public opinion survey company in China, okay? Do you know who their biggest client is? The Chinese government. Not just from the central government, the city government, the provincial government, to the most local neighborhood districts. They conduct surveys all the time. Are you happy with the garbage collection? Are you happy with the general direction of the country? So there is, in China, there is a different kind of mechanism to be responsive to the **demands** and the thinking of the people. My point is, I think we should get unstuck from the thinking that there ’ s only one political system — election, election, election — that could make it responsive. I ’ m not sure, actually, elections produce responsive government anymore in the world. BG : Many seem to agree. One of the features of a democratic system is a space for civil society to express itself. And you have shown figures about the **support** that the government and the authorities have in China. But then you ’ ve just mentioned other elements like, you know, big challenges, and there are, of course, a lot of other data that go in a different direction : tens of thousands of unrests and protests and environmental protests, etc. So you seem to suggest the Chinese model doesn ’ t have a space outside of the Party for civil society to express itself. EXL : There ’ s a vibrant civil society in China, whether it ’ s environment or what-have-you. But it ’ s different. You wouldn ’ t recognize it. Because, by Western definitions, a so-called civil society has to be separate or even in opposition to the political system, but that concept is alien for Chinese culture. For thousands of years, you have civil society, yet they are consistent and coherent and part of a political order, and I think it ’ s a big cultural difference. BG : Eric, thank you for sharing this with **TED**. EXL : Thank you.

So, why does good sex so often fade, even for couples who continue to love each other as much as ever? And why does good intimacy not guarantee good sex, contrary to popular belief? Or, the next question would be, can we want what we already have? That ’ s the million-dollar question, right? And why is the forbidden so erotic? What is it about transgression that makes desire so potent? And why does sex make babies, and babies spell erotic disaster in couples? It ’ s kind of the fatal erotic blow, isn ’ t it? And when you love, how does it feel? And when you desire, how is it different? These are some of the questions that are at the center of my exploration on the nature of erotic desire and its concomitant dilemmas in modern love. So I travel the globe, and what I ’ m noticing is that everywhere where romanticism has entered, there seems to be a **crisis** of desire. A **crisis** of desire, as in owning the wanting — desire as an expression of our individuality, of our free choice, of our preferences, of our identity — desire that has become a central concept as part of modern love and individualistic societies. You know, this is the first time in the history of humankind where we are trying to experience sexuality in the long term not because we want 14 children, for which we need to have even more because many of them won ’ t make it, and not because it is exclusively a woman ’ s marital duty. This is the first time that we want sex over time about pleasure and connection that is rooted in desire. So what sustains desire, and why is it so difficult? And at the heart of sustaining desire in a committed relationship, I think, is the reconciliation of two fundamental human needs. On the one hand, our need for security, for predictability, for safety, for dependability, for reliability, for permanence. All these anchoring, grounding experiences of our lives that we call home. But we also have an equally strong need — men and women — for adventure, for novelty, for mystery, for risk, for danger, for the unknown, for the unexpected, surprise — you get the gist. For journey, for travel. So reconciling our need for security and our need for adventure into one relationship, or what we today like to call a passionate marriage, used to be a contradiction in terms. Marriage was an economic institution in which you were given a partnership for life in terms of children and social status and succession and companionship. But now we want our partner to still give us all these things, but in addition I want you to be my best friend and my **trusted** confidant and my passionate lover to boot, and we live twice as long. So we come to one person, and we basically are asking them to give us what once an entire village used to provide. Give me belonging, give me identity, give me continuity, but give me transcendence and mystery and awe all in one. Give me comfort, give me edge. Give me novelty, give me familiarity. Give me predictability, give me surprise. And we think it ’ s a given, and toys and lingerie are going to save us with that. So now we get to the existential reality of the story, right? Because I think, in some way — and I ’ ll come back to that — but the **crisis** of desire is often a **crisis** of the imagination. So why does good sex so often fade? What is the relationship between love and desire? How do they relate, and how do they **conflict**? Because therein lies the mystery of eroticism. So if there is a verb, for me, that comes with love, it ’ s”to have.”And if there is a verb that comes with desire, it is”to want.”In love, we want to have, we want to know the beloved. We want to minimize the distance. We want to contract that gap. We want to neutralize the tensions. We want closeness. But in desire, we tend to not really want to go back to the places we ’ ve already gone. Forgone conclusion does not keep our interest. In desire, we want an Other, somebody on the other side that we can go **visit**, that we can go spend some time with, that we can go see what goes on in their red-light district. You know? In desire, we want a bridge to cross. Or in other words, I sometimes say, fire needs **air**. Desire needs space. And when it ’ s said like that, it ’ s often quite abstract. But then I took a question with me. And I ’ ve gone to more than 20 countries in the last few years with”Mating in Captivity,”and I asked people, when do you find yourself most drawn to your partner? Not attracted sexually, per Se, but most drawn. And across culture, across religion, and across **gender** — except for one — there are a few answers that just keep coming back. So the first group is : I am most drawn to my partner when she is away, when we are apart, when we reunite. Basically, when I get back in touch with my **ability** to imagine myself with my partner, when my imagination comes back in the picture, and when I can root it in absence and in longing, which is a major component of desire.

But then the second group is even more **interesting**. I am most drawn to my partner when I see him in the studio, when she is onstage, when he is in his element, when she ’ s doing something she ’ s passionate about, when I see him at a party and other people are really drawn to him, when I see her hold **court**. Basically, when I look at my partner radiant and confident. Probably the biggest turn-on across the board. Radiant, as in self-sustaining. I look at this person — by the way, in desire people rarely talk about it, when we are blended into one, five centimeters from each other. I don ’ t know in inches how much that is. But it ’ s also not when the other person is that far apart that you no longer see them. It ’ s when I ’ m looking at my partner from a comfortable distance, where this person that is already so familiar, so known, is momentarily once again somewhat mysterious, somewhat elusive. And in this space between me and the other lies the erotic lan, lies that movement toward the other. Because sometimes, as Proust says, mystery is not about traveling to new places, but it ’ s about looking with new eyes. And so, when I see my partner on his own or her own, doing something in which they are enveloped, I look at this person and I momentarily get a shift in perception, and I stay open to the mysteries that are living right next to me. And then, more importantly, in this description about the other or myself — it ’ s the same — what is most **interesting** is that there is no neediness in desire. Nobody needs anybody. There is no caretaking in desire. Caretaking is mightily loving. It ’ s a powerful anti-aphrodisiac. I have yet to see somebody who is so turned on by somebody who needs them. Wanting them is one thing. Needing them is a shot down and women have known that forever, because anything that will bring up parenthood will usually decrease the erotic charge. For good reasons, right? And then the third group of answers usually would be : when I ’ m surprised, when we laugh together, as somebody said to me in the office today, when he ’ s in his tux, so I said, you know, it ’ s either the tux or the cowboy boots. But basically it ’ s when there is novelty. But novelty isn ’ t about new positions. It isn ’ t a repertoire of techniques. Novelty is, what parts of you do you bring out? What parts of you are just being seen? Because in some way one could say sex isn ’ t something you do, eh? Sex is a place you go. It ’ s a space you enter inside yourself and with another, or others. So where do you go in sex? What parts of you do you connect to? What do you seek to express there? Is it a place for transcendence and spiritual union? Is it a place for naughtiness and is it a place to be safely aggressive? Is it a place where you can finally surrender and not have to take responsibility for everything? Is it a place where you can express your infantile wishes? What comes out there? It ’ s a language. It isn ’ t just a behavior. And it ’ s the poetic of that language that I ’ m **interested** in, which is why I began to explore this concept of erotic **intelligence**. You know, animals have sex. It ’ s the **pivot**, it ’ s biology, it ’ s the natural instinct. We are the only ones who have an erotic life, which means that it ’ s sexuality transformed by the human imagination. We are the only ones who can make love for hours, have a blissful time, multiple orgasms, and touch nobody, just because we can imagine it. We can hint at it. We don ’ t even have to do it. We can experience that powerful thing called anticipation, which is a mortar to desire. The **ability** to imagine it, as if it ’ s happening, to experience it as if it ’ s happening, while nothing is happening and everything is happening, at the same time. So when I began to think about eroticism, I began to think about the poetics of sex. And if I look at it as an **intelligence**, then it ’ s something that you cultivate. What are the ingredients? Imagination, playfulness, novelty, curiosity, mystery. But the central agent is really that piece called the imagination. But more importantly, for me to begin to understand who are the couples who have an erotic spark, what sustains desire, I had to go back to the original definition of eroticism, the mystical definition, and I went through it through a bifurcation by looking, actually, at trauma, which is the other side. And I looked at it, looking at the community that I had grown up in, which was a community in Belgium, all Holocaust survivors, and in my community, there were two groups : those who didn ' t die, and those who came back to life. And those who didn ' t die lived often very tethered to the ground, could not experience pleasure, could not **trust**, because when you ' re vigilant, worried, anxious, and insecure, you can ' t lift your head to go and take off in space and be playful and **safe** and imaginative. Those who came back to life were those who understood the erotic as an antidote to death. They knew how to keep themselves alive. And when I began to listen to the sexlessness of the couples that I work with, I sometimes would hear people say,"I want more sex,"but generally, people want better sex, and better is to reconnect with that quality of aliveness, of vibrancy, of renewal, of vitality, of Eros, of energy that sex used to afford them, or that they ' ve hoped it would afford them. And so I began to ask a different question."I shut myself off when..."began to be the question."I turn off my desires when..."Which is not the same question as,"What turns me off is..."and"You turn me off when..."And people began to say,"I turn myself off when I feel dead inside, when I don ' t like my body, when I feel old, when I haven ' t had time for myself, when I haven ' t had a chance to even check in with you, when I don ' t perform well at work, when I feel low self esteem, when I don ' t have a sense of self-worth, when I don ' t feel like I have a right to want, to take, to receive pleasure."And then I began to ask the reverse question."I turn myself on when..."Because most of the time, people like to ask the question,"You turn me on, what turns me on,"and I ' m out of the question, you know? Now, if you are dead inside, the other person can do a lot of things for Valentine ' s. It won ' t make a dent. There is nobody at the reception desk. So I turn myself on when, I turn on my desires, I wake up when... Now, in this paradox between love and desire, what seems to be so puzzling is that the very ingredients that nurture love — mutuality, reciprocity, protection, worry, responsibility for the other — are sometimes the very ingredients that stifle desire. Because desire comes with a host of feelings that are not always such favorites of love : jealousy, possessiveness, aggression, power, dominance, naughtiness, mischief. Basically most of us will get turned on at night by the very same things that we will demonstrate against during the day. You know, the erotic mind is not very politically correct. If **everybody** was fantasizing on a bed of roses, we wouldn ' t be having such **interesting** talks about this. But no, in our mind up there are a host of things going on that we don ' t always know how to bring to the person that we love, because we think love comes with selflessness and in fact desire comes with a certain amount of selfishness in the best sense of the word : the **ability** to stay connected to one ' s self in the presence of another. So I want to draw that little image for you, because this need to reconcile these two sets of needs, we are born with that. Our need for connection, our need for separateness, or our need for security and adventure, or our need for togetherness and for autonomy, and if you think about the little kid who sits on your lap and who is cozily nested here and very secure and comfortable, and at some point all of us need to go out into the world to discover and to explore. That ' s the beginning of desire, that exploratory need, curiosity, discovery. And then at some point they turn around and they look at you. And if you tell them,"Hey kiddo, the world ' s a great place. Go for it. There ' s so much fun out there,"then they can turn away and they can experience connection and separateness at the same time. They can go off in their imagination, off in their body, off in their playfulness, all the while knowing that there ' s somebody when they come back. But if on this side there is somebody who says,"I ' m worried. I ' m anxious. I ' m depressed.

My partner hasn ’ t taken care of me in so long. What ’ s so good out there? Don ’ t we have everything you need together, you and I?”then there are a few little **reactions** that all of us can pretty much recognize. Some of us will come back, came back a long time ago, and that little child who comes back is the child who will forgo a part of himself in order not to lose the other. I will lose my freedom in order not to lose connection. And I will learn to love in a certain way that will become burdened with extra worry and extra responsibility and extra protection, and I won ’ t know how to leave you in order to go play, in order to go experience pleasure, in order to discover, to enter inside myself. Translate this into adult language. It starts very young. It continues into our sex lives up to the end. Child number two comes back but looks like that over their shoulder all the time.”Are you going to be there? Are you going to curse me, scold me? Are you going to be angry with me?”And they may be gone, but they ’ re never really away. And those are often the people that will tell you,”In the beginning, it was super hot.”Because in the beginning, the growing intimacy wasn ’ t yet so strong that it actually led to the decrease of desire. The more connected I became, the more responsible I felt, the less I was able to let go in your presence. The third child doesn ’ t really come back. So what happens, if you want to sustain desire, it ’ s that real dialectic piece. On the one hand you want the security in order to be able to go. On the other hand if you can ’ t go, you can ’ t have pleasure, you can ’ t culminate, you don ’ t have an orgasm, you don ’ t get excited because you spend your time in the body and the head of the other and not in your own. So in this dilemma about reconciling these two sets of fundamental needs, there are a few things that I ’ ve come to understand erotic couples do. One, they have a lot of sexual privacy. They understand that there is an erotic space that belongs to each of them. They also understand that foreplay is not something you do five minutes before the real thing. Foreplay pretty much starts at the end of the previous orgasm. They also understand that an erotic space isn ’ t about, you begin to stroke the other. It ’ s about you create a space where you leave Management Inc., maybe where you leave the Agile program — And you actually just enter that place where you stop being the good citizen who is taking care of things and being responsible. Responsibility and desire just butt heads. They don ’ t really do well together. Erotic couples also understand that passion waxes and wanes. It ’ s pretty much like the moon. It has intermittent eclipses. But what they know is they know how to resurrect it. They know how to bring it back. And they know how to bring it back because they have demystified one big myth, which is the myth of spontaneity, which is that it ’ s just going to fall from heaven while you ’ re folding the laundry like a deus ex machina, and in fact they understood that whatever is going to just happen in a long-term relationship, already has. Committed sex is premeditated sex. It ’ s willful. It ’ s intentional. It ’ s focus and presence. Merry Valentine ’ s.

Text Sample 580: POS Dim 4 – 2001 – Score 2.00 – 2001/t000092.txt

I coined my own definition of success in 1934, when I was teaching at a high school in South Bend, Indiana, being a little bit disappointed, and [disillusioned] perhaps, by the way parents of the youngsters in my English classes expected their youngsters to get an A or a B. They thought a C was all right for the neighbors ’ children, because they were all average. But they weren ’ t satisfied when their own — it would make the teacher feel that they had failed, or the youngster had failed. And that ’ s not right. The good Lord in his infinite wisdom didn ’ t create us all equal as far as **intelligence** is concerned, any more than we ’ re equal for size, appearance. Not **everybody** could earn an A or a B, and I didn ’ t like that way of judging, and I did know how the alumni of various schools back in the ’ 30s judged coaches and athletic teams. If you won them all, you were considered to be reasonably successful — not completely. Because I found out — we had a number of years at UCLA where we didn ’ t lose a game. But it seemed that we didn ’ t win each individual game by the margin that some of our alumni had predicted — And quite frequently I really felt that they had backed up their predictions in a more materialistic manner. But that was true back in the 30s, so I understood that. But I didn ’ t like it, I didn ’ t agree with it. I wanted to come up with something I hoped could make me a better teacher, and give the youngsters under my supervision, be it in athletics or the English classroom, something to which to aspire, other than just a higher mark in the classroom, or more points in some athletic contest. I thought about that for quite a spell, and I wanted to come up with my own definition. I thought that might help. And I knew how Mr. Webster defined it, as the accumulation of material possessions or the attainment of a position of power or prestige, or something of that sort, worthy accomplishments perhaps, but in my opinion, not necessarily indicative of success. So I wanted to come up with something of my own. And I recalled — I was raised on a small farm in Southern Indiana, and Dad tried to teach me and my brothers that you should never try to be better than someone else. I ’ m sure at the time he did that, I didn ’ t — it didn ’ t — well, somewhere, I guess in the hidden recesses of the mind, it popped out years later. Never try to be better than someone else, always learn from others. Never cease trying to be the best you can be — that ’ s under your control. If you get too engrossed and **involved** and concerned in regard to the things over which you have no control, it will adversely affect the things over which you have control. Then I ran across this simple verse that said,”At God ’ s footstool to confess, a poor soul knelt, and bowed his head. ’ I failed! ’ he cried. The Master said, ’ Thou didst thy best, that is success. ’”From those things, and one other perhaps, I coined my own definition of success, which is : Peace of mind attained only through self-satisfaction in knowing you made the effort to do the best of which you ’ re capable. I believe that ’ s true. If you make the effort to do the best of which you ’ re capable, trying to improve the situation that exists for you, I think that ’ s success, and I don ’ t think others can judge that ; it ’ s like character and reputation — your reputation is what you ’ re perceived to be ; your character is what you really are. And I think that character is much more important than what you are perceived to be. You ’ d hope they ’ d both be good, but they won ’ t necessarily be the same. Well, that was my idea that I was going to try to get across to the youngsters. I ran across other things. I love to teach, and it was mentioned by the previous speaker that I enjoy poetry, and I dabble in it a bit, and love it. There are some things that helped me, I think, be better than I would have been. I know I ’ m not what I ought to be, what I should be, but I think I ’ m better than I would have been if I hadn ’ t run across certain things. One was just a little verse that said,”No written word, no spoken plea can teach our youth what they should be ; nor all the books on all the shelves — it ’ s what the teachers are themselves.”That made an impression on me in the 1930s. And I tried to use that more or less in my teaching, whether it be in sports, or whether it be in the English classroom. I love poetry and always had an interest in that somehow. Maybe it ’ s because Dad used to read to us at night, by coal oil lamp — we didn ’ t have electricity in our farm home. And Dad would read poetry to us. So I always liked it. And about the same time I ran across this one verse, I ran across another one. Someone asked a lady teacher why she taught, and after some time, she said she wanted to think about that. Then she came up and said,”They ask me why I teach, and I reply,

’ Where could I find such splendid company? ’ There sits a statesman, strong, unbiased, wise ; another Daniel Webster, silver-tongued. A doctor sits beside him, whose quick, steady hand may mend a bone, or stem the life-blood ’ s flow. And there a builder ; upward rise the arch of a church he builds, wherein that minister may speak the word of God, and lead a stumbling soul to touch the Christ. And all about, a gathering of teachers, farmers, merchants, laborers — those who work and vote and build and plan and pray into a great tomorrow. And I may say, I may not see the church, or hear the word, or eat the food their hands may grow, but yet again I may ; And later I may say, I knew him once, and he was weak, or strong, or bold or proud or gay. I knew him once, but then he was a boy. They ask me why I teach and I reply, ’ Where could I find such splendid company? ’”And I believe the teaching profession — it ’ s true, you have so many youngsters, and I ’ ve got to think of my youngsters at UCLA — 30-some attorneys, 11 dentists and doctors, many, many teachers and other professions. And that gives you a great deal of pleasure, to see them go on. I always tried to make the youngsters feel that they ’ re there to get an education, number one ; basketball was second, because it was paying their way, and they do need a little time for social activities, but you let social activities take a little precedence over the other two, and you ’ re not going to have any very long. So that was the idea that I tried to get across to the youngsters under my supervision. I had three rules, pretty much, that I stuck with practically all the time. I ’ d learned these prior to coming to UCLA, and I decided they were very important. One was”Never be late.”Later on I said certain things — the players, if we were leaving for somewhere, had to be neat and clean. There was a time when I made them wear jackets and shirts and ties. Then I saw our chancellor coming to school in denims and turtlenecks, and thought, it ’ s not right for me to keep this other [rule] so I let them just — they had to be neat and clean. I had one of my greatest players that you probably heard of, Bill Walton. He came to catch the bus ; we were leaving for somewhere to play. And he wasn ’ t clean and neat, so I wouldn ’ t let him go. He couldn ’ t get on the bus, he had to go home and get cleaned up to get to the airport. So I was a stickler for that. I believed in that. I believe in time ; very important. I believe you should be on time, but I felt at practice, for example — we start on time, we close on time. The youngsters didn ’ t have to feel that we were going to keep them over. When I speak at coaching clinics, I often tell young coaches — and at coaching clinics, more or less, they ’ ll be the younger coaches getting in the profession. Most of them are young, you know, and probably newly-married. And I tell them,”Don ’ t run practices late, because you ’ ll go home in a bad mood, and that ’ s not good, for a young married man to go home in a bad mood. When you get older, it doesn ’ t make any difference, but —”So I did believe : on time. I believe starting on time, and I believe closing on time. And another one I had was, not one word of profanity. One word of profanity, and you are out of here for the day. If I see it in a game, you ’ re going to come out and sit on the bench. And the third one was, never criticize a teammate. I didn ’ t want that. I used to tell them I was paid to do that. That ’ s my job. I ’ m paid to do it. Pitifully poor, but I am paid to do it. Not like the coaches today, for gracious sakes, no. It ’ s a little different than it was in my day. Those were three things that I stuck with pretty closely all the time. And those actually came from my dad. That ’ s what he tried to teach me and my brothers at one time. I came up with a pyramid eventually, that I don ’ t have the time to go on that. But that helped me, I think, become a better teacher. It ’ s something like this : And I had blocks in the pyramid, and the cornerstones being industriousness and enthusiasm, working hard and enjoying what you ’ re doing, coming up to the apex, according to my definition of success. And right at the top, faith and patience. And I say to you, in whatever you ’ re doing, you must be patient. You have to have patience to — we want things to happen. We talk about our youth being impatient a lot, and they are. They want to change everything. They think all change is progress. And we get a little older — we sort of let things go. And we forget there is no progress without change. So you must have patience, and I believe that we must have faith. I believe that we must believe, truly believe. Not just give it word service, believe that things will work out as they should, providing we do what we should. I think our tendency is to hope things will turn out the way we want them to much of the time, but we don ’ t do the things that are necessary to make those things become reality. I worked on this for some 14 years, and I think it helped me become a better teacher. But it all revolved around that original definition of success. You know, a number of years ago, there was a Major League Baseball umpire by the name of George Moriarty. He spelled Moriarty with only one ’ i ’. I ’ d never seen that before, but he did. Big league baseball players — they ’ re very perceptive about those things, and they noticed he had only one ’ i ’ in his name. You ’ d be surprised how many also told him that that was one more than he had in his head at various times. But he wrote something where I think he did what I tried to do in this pyramid. He called it”The Road Ahead, or the Road Behind.”He said,”Sometimes I think the Fates must grin as we denounce them and insist the only reason we can ’ t win, is the Fates themselves have missed. Yet there lives on the ancient **claim** : we win or lose within ourselves. The shining trophies on our shelves can never win tomorrow ’ s game. You and I know deeper down, there ’ s always a chance to win the crown. But when we fail to give our best, we simply haven ’ t met the test, of giving all and saving none until the game is really won ; of showing what is meant by grit ; of playing through when others quit ; of playing through, not letting up. It ’ s bearing down that wins the cup. Of dreaming there ’ s a goal ahead ; of hoping when our dreams are dead ; of praying when our hopes have fled ; yet losing, not afraid to fall, if, bravely, we have given all. For who can ask more of a man than giving all within his span. Giving all, it seems to me, is not so far from victory. And so the Fates are seldom wrong, no matter how they twist and wind. It ’ s you and I who make our fates — we open up or close the gates on the road ahead or the road behind.”Reminds me of another set of threes that my dad tried to get across to us : Don ’ t whine. Don ’ t complain. Don ’ t make excuses. Just get out there, and whatever you ’ re doing, do it to the best of your **ability**. And no one can do more than that. I tried to get across, too, that — my opponents will tell you — you never heard me mention winning. Never mention winning. My idea is that you can lose when you outscore somebody in a game, and you can win when you ’ re outscored. I ’ ve felt that way on certain occasions, at various times. And I just wanted them to be able to hold their head up after a game. I used to say that when a game is over, and you see somebody that didn ’ t know the outcome, I hope they couldn ’ t tell by your actions whether you outscored an opponent or the opponent outscored you. That ’ s what really matters : if you make an effort to do the best you can regularly, the results will be about what they should be. Not necessarily what you ’ d want them to be but they ’ ll be about what they should ; only you will know whether you can do that. And that ’ s what I wanted from them more than anything else. And as time went by, and I learned more about other things, I think it worked a little better, as far as the results. But I wanted the score of a game to be the byproduct of these other things, and not the end itself. I believe it was one great philosopher who said — no, no — Cervantes. Cervantes said,”The journey is better than the end.”And I like that. I think that it is — it ’ s getting there. Sometimes when you get there, there ’ s almost a let down. But it ’ s the getting there that ’ s the fun. As a basketball coach at UCLA, I liked our practices to be the journey, and the game would be the end, the end result. I liked to go up and sit in the stands and watch the players play, and see whether I ' d done a decent job during the week. There again, it ' s getting the players to get that self-satisfaction, in knowing that they ' d made the effort to do the best of which they are capable. Sometimes I ' m asked who was the best player I had, or the best teams. I can never answer that. As far as the individuals are concerned — I was asked one time about that, and they said,"Suppose that you, in some way, could make the perfect player. What would you want?"And I said,"Well, I ' d want one that knew why he was at UCLA : to get an education, he was a good student, really knew why he was there in the first place. But I ' d want one that could play, too. I ' d want one to realize that defense usually wins championships, and who would work hard on defense. But I ' d want one who would play offense, too. I ' d want him to be unselfish, and look for the pass first and not shoot all the time. And I ' d want one that could pass and would pass. I ' ve had some that could and wouldn ' t, and I ' ve had some that would and could. So, yeah, I ' d want that. And I wanted them to be able to shoot from the outside. I wanted them to be good inside too. I ' d want them to be able to rebound well at both ends, too. Why not just take someone like Keith Wilkes and let it go at that. He had the qualifications. Not the only one, but he was one that I used in that particular category, because I think he made the effort to become the best. There was a couple. I mention in my book,"They Call Me Coach,"two players that gave me great satisfaction, that came as close as I think anyone I ever had to reach their full potential : one was Conrad Burke, and one was Doug McIntosh. When I saw them as freshmen, on our freshmen team — freshmen couldn ' t play varsity when I taught. I thought,"Oh gracious, if these two players, either one of them"— they were different years, but I thought about each one at the time he was there —"Oh, if he ever makes the varsity, our varsity must be pretty miserable, if he ' s good enough to make it."And you know, one of them was a starting player for a season and a half. The other one, his next year, played 32 minutes in a national championship game, Did a tremendous job for us. The next year, he was a starting player on the national championship team, and here I thought he ' d never play a minute, when he was — so those are the things that give you great joy, and great satisfaction to see. Neither one of those youngsters could shoot very well. But they had outstanding shooting percentages, because they didn ' t force it. And neither one could jump very well, but they kept good position, and so they did well rebounding. They remembered that every shot that ' s taken, they assumed would be missed. I ' ve had too many stand around and wait to see if it ' s missed, then they go and it ' s too late, somebody else is in there ahead of them. They weren ' t very quick, but they played good position, kept in good balance. And so they played pretty good defense for us. So they had qualities that — they came close to — as close to reaching possibly their full potential as any players I ever had. So I consider them to be as successful as Lewis Alcindor or Bill Walton, or many of the others that we had ; there were some outstanding players. Have I rambled enough? I was told that when he makes his appearance, I was supposed to shut up.

So I understand that this meeting was planned, and the slogan was From Was to Still. And I am illustrating Still. Which, of course, I am not agreeing with be-cause, although I am 94, I am not still working. And anybody who asks me,"Are you still doing this or that?"I don ' t answer because I ' m not doing things still, I ’ m doing it like I always did. I still have — or did I use the word still? I didn ’ t mean that. I have my file which is called To Do. I have my plans. I have my clients. I am doing my work like I always did. So this takes care of my age. I want to show you my work so you know what I am doing and why I am here. This was about 1925. All of these things were made during the last 75 years. But, of course, I ’ m working since 25, doing more or less what you see here. This is Castleton China. This was an exhibition at the Museum of Modern Art. This is now for sale at the Metropolitan Museum. This is still at the Metropolitan Museum now for sale. This is a portrait of my daughter and myself. These were just some of the things I ’ ve made. I made hundreds of them for the last 75 years. I call myself a maker of things. I don ’ t call myself an industrial designer because I ’ m other things. Industrial designers want to make novel things. Novelty is a concept of commerce, not an aesthetic concept. The industrial design magazine, I believe, is called”Innovation.”Innovation is not part of the aim of my work. Well, makers of things : they make things more beautiful, more elegant, more comfortable than just the craftsmen do. I have so much to say. I have to think what I am going to say. Well, to describe our profession otherwise, we are actually concerned with the playful search for beauty. That means the playful search for beauty was called the first activity of Man. Sarah Smith, who was a mathematics professor at MIT, wrote,”The playful search for beauty was Man ’ s first activity — that all useful qualities and all material qualities were developed from the playful search for beauty.”These are tiles. The word,”playful”is a necessary aspect of our work because, actually, one of our problems is that we have to make, produce, lovely things throughout all of life, and this for me is now 75 years. So how can you, without drying up, make things with the same pleasure, as a gift to others, for so long? The playful is therefore an important part of our quality as designer. Let me tell you some about my life. As I said, I started to do these things 75 years ago. My first exhibition in the United States was at the Sesquicentennial exhibition in 1926 — that the Hungarian government sent one of my hand-drawn pieces as part of the exhibit. My work actually took me through many countries, and showed me a great part of the world. This is not that they took me — the work didn ’ t take me — I made the things particularly because I wanted to use them to see the world. I was incredibly curious to see the world, and I made all these things, which then finally did take me to see many countries and many cultures. I started as an apprentice to a Hungarian craftsman, and this taught me what the guild system was in Middle Ages. The guild system : that means when I was an apprentice, I had to apprentice myself in order to become a pottery master. In my shop where I studied, or learned, there was a traditional hierarchy of master, journeyman and learned worker, and apprentice, and I worked as the apprentice. The work as an apprentice was very primitive. That means I had to actually learn every aspect of making pottery by hand. We mashed the clay with our feet when it came from the hillside. After that, it had to be kneaded. It had to then go in, kind of, a mangle. And then finally it was prepared for the throwing. And there I really worked as an apprentice. My master took me to set ovens because this was part of oven-making, oven-setting, in the time. And finally, I had received a **document** that I had accomplished my apprenticeship successfully, that I had behaved morally, and this **document** was given to me by the Guild of Roof- Coverers, Rail-Diggers, Oven-Setters, Chimney Sweeps and Potters. I also got at the time a workbook which explained my rights and my working conditions, and I still have that workbook. First I set up a shop in my own garden, and made pottery which I sold on the marketplace in Budapest. And there I was sitting, and my then-boyfriend — I didn ’ t mean it was a boyfriend like it is meant today — but my boyfriend and I sat at the market and sold the pots. My mother thought that this was not very proper, so she sat with us to add propriety to this activity. However, after a while there was a new factory being built in Budapest, a pottery factory, a large one. And I **visited** it with several ladies, and asked all sorts of questions of the director. Then the director asked me, why do you ask all these questions? I said, I also have a pottery. So he asked me, could he please **visit** me, and then finally he did, and explained to me that what I did now in my shop was an anachronism, that the industrial revolution had broken out, and that I rather should join the factory. There he made an art department for me where I worked for several months. However, **everybody** in the factory spent his time at the art department. The director there said there were several women casting and producing my designs now in molds, and this was sold also to America. I remember that it was quite successful. However, the director, the chemist, model maker — **everybody** — concerned himself much more with the art department — that means, with my work — than making toilets, so finally they got a letter from the center, from the bank who owned the factory, saying, make toilet-setting behind the art department, and that was my end. So this gave me the possibility because now I was a journeyman, and journeymen also take their satchel and go to see the world. So as a journeyman, I put an ad into the paper that I had studied, that I was a down-to-earth potter ’ s journeyman and I was looking for a job as a journeyman. And I got several answers, and I accepted the one which was farthest from home and practically, I thought, halfway to America. And that was in Hamburg. Then I first took this job in Hamburg, at an art pottery where everything was done on the wheel, and so I worked in a shop where there were several potters. And the first day, I was coming to take my place at the turntable — there were three or four turntables — and one of them, behind where I was sitting, was a hunchback, a deaf-mute hunchback, who smelled very bad. So I doused him in cologne every day, which he thought was very nice, and therefore he brought bread and butter every day, which I had to eat out of courtesy. The first day I came to work in this shop there was on my wheel a surprise for me. My colleagues had thoughtfully put on the wheel where I was supposed to work a very nicely modeled natural man ’ s organs. After I brushed them off with a hand motion, they were very — I finally was now accepted, and worked there for some six months. This was my first job. If I go on like this, you will be here till midnight. So I will try speed it up a little Moderator : Eva, we have about five minutes. Eva Zeisel : Are you sure? Moderator : Yes, I am sure. EZ : Well, if you are sure, I have to tell you that within five minutes I will talk very fast. And actually, my work took me to many countries because I used my work to fill my curiosity. And among other things, other countries I worked, was in the Soviet Union, where I worked from ’ 32 to ’ 37 — actually, to ’ 36. I was finally there, although I had nothing to do — I was a foreign expert. I became art director of the china and glass industry, and eventually under Stalin ’ s purges — at the beginning of Stalin ’ s purges, I didn ’ t know that hundreds of thousands of innocent people were arrested. So I was arrested quite early in Stalin ’ s purges, and spent 16 months in a Russian prison. The accusation was that I had successfully prepared an Attentat on Stalin ’ s life. This was a very dangerous accusation. And if this is the end of my five minutes, I want to tell you that I actually did survive, which was a surprise. But since I survived and I ’ m here, and since this is the end of the five minutes, I will — Moderator : Tell me when your last trip to Russia was. Weren ’ t you there recently? EZ : Oh, this summer, in fact, the Lomonosov factory was bought by an American company, invited me. They found out that I had worked in ’ 33 at this factory, and they came to my studio in Rockland County, and brought the 15 of their artists to **visit** me here. And they invited myself to come to the Russian factory last summer, in July, to make some dishes, design some dishes. And since I don ’ t like to travel alone, they also invited my daughter, son-in-law and granddaughter, so we had a lovely trip to see Russia today, which is not a very pleasant and happy view. Here I am now, if this is the end? Thank you.

I ’ d like to do pretty much what I did the first time, which is to choose a lighthearted theme. Last time, I talked about death and dying. This time, I ’ m going to talk about mental illness. But it has to be technological, so I ’ ll talk about electroshock therapy. You know, ever since man had any notion that some of his other people, his colleagues, could be different, could be strange, could be severely depressed or what we now recognize as schizophrenia, he was certain that this kind of illness had to come from evil spirits getting into the body. So, the way of treating these diseases in early times was to, in some way or other, exorcise those evil spirits, and this is still going on, as you know. But it wasn ’ t enough to use the priests. When medicine became somewhat scientific, in about 450 BC, with Hippocrates and those boys, they tried to look for herbs, plants that would literally shake the bad spirits out. So, they found certain plants that could cause convulsions. And the herbals, the botanical books of up to the late Middle Ages, the Renaissance are filled with prescriptions for causing convulsions to shake the evil spirits out. Finally, in about the sixteenth century, a physician whose name was Theophrastus Bombastus Aureolus von Hohenheim, called Paracelsus, a name probably familiar to some people here — — good, old Paracelsus found that he could predict the degree of convulsion by using a measured amount of camphor to produce the convulsion. Can you imagine going to your closet, pulling out a mothball, and chewing on it if you ’ re feeling depressed? It ’ s better than Prozac, but I wouldn ’ t recommend it. So what we see in the seventeenth, eighteenth century is the continued search for medications other than camphor that ’ ll do the trick. Well, along comes Benjamin Franklin, and he comes close to convulsing himself with a bolt of electricity off the end of his kite. And so people begin thinking in terms of electricity to produce convulsions. And then, we fast-forward to about 1932, when three Italian psychiatrists, who were largely treating depression, began to notice among their patients, who were also epileptics, that if they had an epileptic — a series of epileptic fits, a lot of them in a row — the depression would very frequently lift. Not only would it lift, but it might never return. So they got very **interested** in producing convulsions, measured types of convulsions. And they thought,”Well, we ’ ve got electricity, we ’ ll plug somebody into the wall. That always makes hair stand up and people shake a lot.”So, they tried it on a few pigs, and none of the pigs were killed. So, they went to the police and they said,”We know that at the Rome railroad station, there are all these lost souls wandering around, muttering gibberish. Can you bring one of them to us?”Someone who is, as the Italians say,”cagoots.”So they found this”cagoots”**guy**, a 39-year-old man who was really hopelessly schizophrenic, who was known, had been known for months, to be literally defecating on himself, talking nothing that made any sense, and they brought him into the hospital. So these three psychiatrists, after about two or three weeks of observation, laid him down on a table, connected his temples to a very small source of current. They thought,”Well, we ’ ll try 55 volts, two-tenths of a second. That ’ s not going to do anything terrible to him.”So they did that. Well, I have the following from a firsthand observer, who told me this about 35 years ago, when I was thinking about these things for some research project of mine. He said,”This

fellow"— remember, he wasn ' t even put to sleep —"after this major grand mal convulsion, sat right up, looked at these three fellas and said, ' What the fuck are you assholes trying to do? '"If I could only say that in Italian. Well, they were happy as could be, because he hadn ' t said a rational word in the weeks of observation. So they plugged him in again, and this time they used 110 volts for half a second. And to their amazement, after it was over, he began speaking like he was perfectly well. He relapsed a little bit, they gave him a series of treatments, and he was essentially cured. But of course, having schizophrenia, within a few months, it returned. But they wrote a paper about this, and **everybody** in the Western world began using electricity to convulse people who were either schizophrenic or severely depressed. It didn ' t work very well on the schizophrenics, but it was pretty clear in the ' 30s and by the middle of the ' 40s that electroconvulsive therapy was very, very effective in the treatment of depression. And of course, in those days, there were no antidepressant drugs, and it became very, very popular. They would anesthetize people, convulse them, but the real difficulty was that there was no way to paralyze muscles. So people would have a real grand mal seizure. Bones were broken. Especially in old, fragile people, you couldn ' t use it. And then in the 1950s, late 1950s, the so-called muscle relaxants were developed by pharmacologists, and it got so that you could induce a complete convulsion, an electroencephalographic convulsion — you could see it on the brain waves — without causing any convulsion in the body except a little bit of twitching of the toes. So again, it was very, very popular and very, very useful. Well, you know, in the middle ' 60s, the first antidepressants came out. Tofranil was the first. In the late ' 70s, early ' 80s, there were others, and they were very effective. And patients ' rights groups seemed to get very upset about the kinds of things that they would witness. And so the whole idea of electroconvulsive, electroshock therapy disappeared, but has had a renaissance in the last 10 years. And the reason that it has had a renaissance is that probably about 10 percent of the people, severe depressives, do not respond, regardless of what is done for them. Now, why am I telling you this story at this meeting? I ' m telling you this story, because actually ever since Richard called me and asked me to talk about — as he asked all of his speakers — to talk about something that would be new to this audience, that we had never talked about, never written about, I ' ve been planning this moment. This reason really is that I am a man who, almost 30 years ago, had his life saved by two long courses of electroshock therapy. And let me tell you this story. I was, in the 1960s, in a marriage. To use the word bad would be perhaps the understatement of the year. It was dreadful. There are, I ' m sure, enough divorced people in this room to know about the hostility, the anger, who knows what. Being someone who had had a very difficult childhood, a very difficult adolescence — it had to do with not quite poverty but close. It had to do with being brought up in a family where no one spoke English, no one could read or write English. It had to do with death and disease and lots of other things. I was a little prone to depression. So, as things got worse, as we really began to hate each other, I became progressively depressed over a period of a couple of years, trying to save this marriage, which was inevitably not to be saved. Finally, I would schedule — all my major surgical cases, I was scheduling them for 12, one o ' clock in the afternoon, because I couldn ' t get out of bed before about 11 o ' clock. And anybody who ' s been depressed here knows what that ' s like. I couldn ' t even pull the covers off myself. Well, you ' re in a university medical center, where **everybody** knows **everybody**, and it ' s perfectly clear to my colleagues, so my referrals began to decrease. As my referrals began to decrease, I clearly became increasingly depressed until I thought, my God, I can ' t work anymore. And, in fact, it didn ' t make any difference because I didn

’ t have any patients anymore. So, with the advice of my physician, I had myself admitted to the acute care psychiatric unit of our university hospital. And my colleagues, who had known me since medical school in that place, said,”Don ’ t worry, chap. Six weeks, you ’ re back in the operating room. Everything ’ s going to be great.”Well, you know what bovine stercus is? That proved to be a lot of bovine stercus. I know some people who got tenure in that place with lies like that. So I was one of their failures. But it wasn ’ t that simple. Because by the time I got out of that unit, I was not functional at all. I could hardly see five feet in front of myself. I shuffled when I walked. I was bowed over. I rarely bathed. I sometimes didn ’ t shave. It was dreadful. And it was clear — not to me, because nothing was clear to me at that time anymore — that I would need long-term hospitalization in that awful place called a mental hospital. So I was admitted, in 1973, in the spring of 1973, to the Institute of Living, which used to be called the Hartford Retreat. It was founded in the eighteenth century, the largest psychiatric hospital in the state of Connecticut, other than the huge public hospitals that existed at that time. And they tried everything they had. They tried the usual psychotherapy. They tried every medication available in those days. And they did have Tofranil and other things — Mellaril, who knows what. Nothing happened except that I got jaundiced from one of these things. And finally, because I was well known in Connecticut, they decided they better have a meeting of the **senior** staff. All the **senior** staff got together, and I later found out what happened. They put all their heads together and they decided that there was nothing that could be done for this surgeon who had essentially separated himself from the world, who by that time had become so overwhelmed, not just with depression and feelings of worthlessness and inadequacy, but with obsessional thinking, obsessional thinking about coincidences. And there were particular numbers that every time I saw them, just got me dreadfully upset — all kinds of ritualistic observances, just awful, awful **stuff**. Remember when you were a kid, and you had to step on every line? Well, I was a grown man who had all of these rituals, and it got so there was a throbbing, there was a ferocious fear in my head. You ’ ve seen this painting by Edvard Munch, The Scream. Every moment was a scream. It was impossible. So they decided there was no therapy, there was no treatment. But there was one treatment, which actually had been pioneered at the Hartford hospital in the early 1940s, and you can imagine what it was. It was pre-frontal lobotomy. So they decided — I didn ’ t know this, again, I found this out later — that the only thing that could be done was for this 43-year-old man to have a pre-frontal lobotomy. Well, as in all hospitals, there was a resident assigned to my case. He was 27 years old, and he would meet with me two or three times a week. And of course, I had been there, what, three or four months at the time. And he asked to meet with the **senior** staff, and they agreed to meet with him because he was very well thought of in that place. They thought he had a really extraordinary future. And he dug in his heels and said,”No. I know this man better than any of you. I have met with him over and over again. You ’ ve just seen him from time to time. You ’ ve read reports and so forth. I really honestly believe that the basic problem here is pure depression, and all of the obsessional thinking comes out of it. And you know, of course, what ’ ll happen if you do a pre- frontal lobotomy. Any of the results along the spectrum, from pretty bad to terrible, terrible, terrible is going to happen. If he does the best he can, he will have no further obsessions, probably no depression, but his affect will be dulled, he will never go back to surgery, he will never be the loving father that he was to his two children, his life will be changed. If he has the usual result, he will end up like ’ One Flew Over the Cuckoo ’ s Nest. ’ And you know about that, just essentially in a stupor the rest of his life.”Well, he said,”Can ’ t we try a course of electroshock therapy?”And you know why they agreed? They agreed to humor him. They just thought,”Well, we ’ ll give a course of 10. And so we ’ ll lose a little time. Big deal. It doesn ’ t make any difference.”So they gave the course of 10, and the first — the usual course, incidentally, was six to eight and still is six to eight. Plugged me into the wires, put me to sleep, gave me the muscle relaxant. Six didn ’ t work. Seven didn ’ t work. Eight didn ’ t work. At nine, I noticed — and it ’ s wonderful that I could notice anything — I noticed a change. And at 10, I noticed a real change. And he went back to them, and they agreed to do another 10. Again, not a single one of them — I think there are about seven or eight of them — thought this would do any good. They thought this was a temporary change. But, lo and behold, by 16, by 17, there were demonstrable differences in the way I felt. By 18 and 19, I was sleeping through the night. And by 20, I had the sense, I really had the sense that I could overcome this, that I was now strong enough that by an act of will, I could blow the obsessional thinking away. I could blow the depression away. And I ’ ve never forgotten — I never will forget — standing in the kitchen of the unit, it was a Sunday morning in January of 1974, standing in the kitchen by myself and thinking,”I ’ ve got the strength now to do this.”It was as though those tightly coiled wires in my head had been disconnected and I could think clearly. But I need a formula. I need some thing to say to myself when I begin thinking obsessionally, obsessively. Well, the Gilbert and Sullivan fans in this room will remember”Ruddigore,”and they will remember Mad Margaret, and they will remember that she was married to a fellow named Sir Despard Murgatroyd. And she used to go nuts, every five minutes or so in the play, and he said to her,”We must have a word to bring you back to reality, and the word, my dear, will be ’ Basingstoke. ’”So every time she got a little nuts, he would say,”Basingstoke!”And she would say,”Basingstoke, it is.”And she would be fine for a little while. Well, you know, I ’ m from the Bronx. I can ’ t say”Basingstoke.”But I had something better. And it was very simple. It was,”Ah, fuck it!”Much better than”Basingstoke,”at least for me. And it worked — my God, it worked. Every time I would begin thinking obsessionally — again, once more, after 20 shock treatments — I would say,”Ah, fuck it.”And things got better and better, and within three or four months, I was discharged from that hospital, and I joined a group of surgeons where I could work with other people in the community, not in New Haven, but fairly close by. I stayed there for three years. At the end of three years, I went back to New Haven, had remarried by that time. I brought my wife with me, actually, to make sure I could get through this. My children came back to live with us. We had two more children after that. Resuscitated the career, even better than it had been before. Went right back into the university and began to write books. Well, you know, it ’ s been a wonderful life. It ’ s been, as I said, close to 30 years. I stopped doing surgery about six years ago and became a full-time writer, as many people know. But it ’ s been very exciting. It ’ s been very happy. Every once in a while, I have to say,”Ah, fuck it.”Every once in a while, I get somewhat depressed and a little obsessional. So, I ’ m not free of all of this. But it ’ s worked. It ’ s always worked. Why have I chosen, after never, ever talking about this, to talk about it now? Well, those of you who know some of these books know that one is about death and dying, one is about the human body and the human spirit, one is about the way mystical thoughts are constantly in our minds, and they have always to do with my own personal experiences. One might think reading these books — and I ’ ve gotten thousands of letters about them by people who do think this — that based on my life ’ s history as I ’ ve portrayed in the books, my early life ’ s history, I am someone who has overcome adversity. That I am someone who has drunk, drank, drunk of the bitter dregs of near-disaster in childhood and emerged not just unscathed but strengthened. I really have it figured out, so that I can advise people about death and dying, so that I can talk about mysticism and the human spirit. And I ’ ve always felt guilty about that. I ’ ve always felt that somehow I was an impostor because my readers don ’ t know what I have just told you. It ’ s known by some people in New Haven, obviously, but it is not generally known. So one of the reasons that I have come here to talk about this today is to — frankly, selfishly — unburden myself and let it be known that this is not an untroubled mind that has written all of these books. But more importantly, I think, is the fact that a very significant proportion of people in this audience are under 30, and there are many, of course, who are well over 30. For people under 30, and it looks to me like almost all of you — I would say all of you — are either on the cusp of a magnificent and exciting career or right into a magnificent and exciting career : anything can happen to you. Things change. Accidents happen. Something from childhood comes back to haunt you. You can be thrown off the track. I hope it happens to none of you, but it will probably happen to a small percentage of you. To those to whom it doesn ’ t happen, there will be adversities. If I, with the bleakness of spirit, with no spirit, that I had in the 1970s and no possibility of recovery, as far as that group of very experienced psychiatrists thought, if I can find my way back from this, believe me, anybody can find their way back from any adversity that exists in their lives. And for those who are older, who have lived through perhaps not something as bad as this, but who have lived through difficult times, perhaps where they lost everything, as I did, and started out all over again, some of these things will seem very familiar. There is recovery. There is redemption. And there is resurrection. There are resurrection themes in every society that has ever been studied, and it is because not just only do we fantasize about the possibility of resurrection and recovery, but it actually happens. And it happens a lot. Perhaps the most popular resurrection theme, outside of specifically religious ones, is the one about the phoenix, the ancient story of the phoenix, who, every 500 years, resurrects itself from its own ashes to go on to live a life that is even more beautiful than it was before. Richard, thanks very much.

I thought I would read poems I have that relate to the subject of youth and age. I was sort of astonished to find out how many I have actually. The first one is dedicated to Spencer, and his grandmother, who was shocked by his work. My poem is called”Dirt.”My grandmother is washing my mouth out with soap ; half a long century gone and still she comes at me with that thick cruel yellow bar. All because of a word I said, not even said really, only repeated. But”Open,”she says,”open up!”her hand clawing at my head. I know now her life was hard ; she lost three children as babies, then her husband died too, leaving young sons, and no money. She ’ d stand me in the sink to pee because there was never room in the toilet. But oh, her soap! Might its bitter burning have been what made me a poet? The street she lived on was **unpaved**, her flat, two cramped rooms and a fetid kitchen where she stalked and caught me. Dare I admit that after she did it I never really loved her again? She lived to a hundred, even then. All along it was the sadness, the squalor, but I never, until now loved her again. When that was published in a magazine I got an irate letter from my uncle."You have maligned a great woman."It took some diplomacy. This is called"The Dress."It ' s a longer poem. In those days, those days which exist for me only as the most elusive memory now, when often the first sound you ' d hear in the morning would be a storm of birdsong, then the soft clop of the hooves of the horse hauling a milk wagon down your block, and the last sound at night as likely as not would be your father pulling up in his car, having worked late again, always late, and going heavily down to the cellar, to the furnace, to shake out the ashes and damp the draft before he came upstairs to fall into bed — in those long-ago days, women, my mother, my friends ' mothers, our neighbors, all the women I knew — wore, often much of the day, what were called housedresses, cheap, printed, **pulpy**, seemingly purposefully **shapeless** light cotton shifts that you wore over your nightgown and, when you had to go look for a child, hang wash on the line, or run down to the grocery store on the corner, under a coat, the twisted hem of the nightgown always lank and yellowed, dangling beneath. More than the curlers some of the women seemed constantly to have in their hair in preparation for some great event — a ball, one would think — that never came to pass ; more than the way most women ' s faces not only were never made up during the day, but seemed scraped, bleached, and, with their plucked eyebrows, scarily masklike ; more than all that it was those dresses that made women so unknowable and forbidding, adepts of enigmas to which men could have no access, and boys no conception. Only later would I see the dresses also as a proclamation : that in your **dim** kitchen, your laundry, your bleak concrete yard, what you revealed of yourself was a fabulation ; your real sensual nature, veiled in those **sexless** vestments, was utterly your dominion. In those days, one hid much else as well : grown men didn ' t embrace one another, unless someone had died, and not always then ; you shook hands or, at a ball game, thumped your friend ' s back and exchanged blows meant to be codes for affection ; once out of childhood you ' d never again know the shock of your father ' s whiskers on your cheek, not until mores at last had evolved, and you could hug another man, then hold on for a moment, then even kiss. What release finally, the embrace : though we were wary — it seemed so audacious — how much unspoken joy there was in that affirmation of equality and communion, no matter how much misunderstanding and pain had passed between you by then. We knew so little in those days, as little as now, I suppose about healing those hurts : even the women, in their best dresses, with beads and sequins sewn on the **bodices**, even in lipstick and mascara, their hair aflow, could only stand wringing their hands, begging for peace, while father and son, like thugs, like thieves, like Romans, simmered and hissed and hated, inflicting sorrows that endured, the worst anyway, through the kiss and embrace, bleeding from brother to brother, into the generations. In those days there was still countryside close to the city, farms, cornfields, cows ; even not far from our building with its blurred brick and long shadowy hallway you could find tracts with hills and trees you could pretend were mountains and forests. Or you could go out by yourself even to a half-block-long empty lot, into the bushes : like a creature of leaves you ' d lurk, crouched, **crawling**, simplified, savage, alone ; already there was wanting to be simpler, wanting, when they called you, never to go back. This is another longish one, about the old and the young. It actually happened right at the time we met. Part of the poem takes place in space we shared and time we shared. It ' s called"The Neighbor."Her five horrid, deformed little dogs who incessantly yap on the roof under my window. Her cats, God knows how many, who must piss on her rugs — her landing ' s a sickening **reek**. Her shadow once, fumbling the chain on her door, then the door slamming fearfully shut, only the barking and the music — jazz

— filtering as it does, day and night into the hall. The time it was Chris Connor singing”Lush Life”— how it brought back my college sweetheart, my first real love, who — till I left her — played the same record. And head on my shoulder, hand on my thigh, sang sweetly along, of regrets and depletions she was too young for, as I was too young, later, to believe in her pain. It startled, then bored, then repelled me. My starting to fancy she ’ d ended up in this fire-trap in the Village, that my neighbor was her. My thinking we ’ d meet, recognize one another, become friends, that I ’ d accomplish a penance. My seeing her, it wasn ’ t her, at the mailbox. Gray-yellow hair, army pants under a nightgown, her turning away, hiding her ravaged face in her hands, **muttering** an inappropriate”Hi.”Sometimes there are frightening **goings-on** in the stairwell. A man shouting,”Shut up!”The dogs frantically snarling, claws scrabbling, then her — her voice hoarse, harsh, hollow, almost only a tone, incoherent, a note, a squawk, bone on metal, metal gone molten, calling them back,”Come back darlings, come back dear ones. My sweet angels, come back.”Medea she was, next time I saw her. Sorceress, tranced, ecstatic, stock-still on the sidewalk **ragged** coat hanging agape, passersby flowing around her, her mouth torn suddenly open as though in a scream, silently though, as though only in her **brain** or breast had it erupted. A cry so pure, practiced, detached, it had no need of a voice, or could no longer bear one. These invisible links that allure, these transfigurations, even of anguish, that hold us. The girl, my old love, the last lost time I saw her when she came to find me at a party, her drunkenly **stumbling**, falling, sprawling, skirt hiked, eyes veined red, swollen with tears, her shame, her dishonor. My ignorant, arrogant coarseness, my secret pride, my turning away. Still life on a rooftop, dead trees in barrels, a bench broken, dogs, excrement, sky. What pathways through pain, what junctures of vulnerability, what crossings and counterings? Too many lives in our lives already, too many chances for sorrow, too many unaccounted-for pasts.”**Behold** me,”the god of frenzied, inexhaustible love says, rising in bloody splendor,”**Behold** me.”Her making her way down the littered vestibule stairs, one agonized step at a time. My holding the door. Her crossing the fragmented **tiles**, faltering at the step to the street, droning, not looking at me,”Can you help me?”Taking my arm, leaning lightly against me. Her wavering step into the world. Her whispering,”Thanks love.”Lightly, lightly against me. I think I ’ ll lighten up a little. Another, different kind of poem of youth and age. It ’ s called”Gas.”Wouldn ’ t it be nice, I think, when the blue-haired lady in the doctor ’ s waiting room bends over the magazine table and farts, just a little, and violently blushes. Wouldn ’ t it be nice if intestinal gas came embodied in visible clouds, so she could see that her really quite **inoffensive pop** had only barely grazed my face before it drifted away. Besides, for this to have happened now is a nice coincidence. Because not an hour ago, while we were on our walk, my dog was startled by a backfire and jumped straight up like a horse bucking. And that brought back to me the stable I worked on weekends when I was 12, and a **splendid piebald stallion**, who whenever he was mounted would buck just like that, though more hugely of course, enormous, gleaming, **resplendent**. And the woman, her face abashedly buried in her”Elle”now, reminded me — I ’ d forgotten that not the least part of my awe consisted of the fact that with every jump he took the horse would powerfully fart. Phwap! Phwap! Phwap! Something never mentioned in the dozens of books about horses and their riders I devoured in those days. All that savage grandeur, the **steely** glinting hooves, the eruptions driven from the creature ’ s mighty **innards**, breath stopped, heart stopped, nostrils madly flared, I didn ’ t know if I wanted to break him, or be him. This is called”Thirst.”Many — most of my poems actually are urban poems. I happen to be reading a bunch that aren ’ t.”Thirst.”Here was my relation with the woman who lived all last autumn and winter, day and night, on a bench in the 103rd Street subway station, until finally one day she vanished. We regarded each other, scrutinized one another. Me shyly, obliquely, trying not to be furtive. She boldly, unblinkingly, even pugnaciously, wrathfully even, when her bottle was empty. I was frightened of her. I felt like a child. I was afraid some repressed part of myself would go out of control, and I ’ d be forever entrapped in the shocking seethe of her stench. Not excrement merely, not merely surface and orifice going unwashed, rediffusion of rum, there was will in it, and intention, power and purpose — a social, ethical rage and rebellion — despair too, though, grief, loss. Sometimes I ’ d think I should take her home with me, bathe her, comfort her, dress her. She wouldn ’ t have wanted me to, I would think. Instead, I ’ d step into my train. How rich I would think, is the lexicon of our self-absolving. How enduring, our bland fatal assurance that reflection is righteousness being accomplished. The dance of our glances, the clash, pulling each other through our perceptual punctures, then holocaust, holocaust, host on host of ill, injured presences, squandered, consumed. Her vigil somewhere I know continues. Her **occupancy**, her absolute, faithful attendance. The dance of our glances, challenge, **abdication**, **effacement**, the perfume of our consternation. This is a newer poem, a brand new poem. The title is”This Happened.”A student, a young woman in a fourth-floor hallway of her lycee, perched on the ledge of an open window chatting with friends between classes ; a teacher passes and chides her,”Be careful, you might fall,”almost banteringly chides her,”You might fall,”and the young woman, 18, a girl really, though she wouldn ’ t think that, as brilliant as she is, first in her class, and”Beautiful, too,”she ’ s often told, smiles back, and leans into the open window, which wouldn ’ t even be open if it were winter — if it were winter someone would have closed it — leans into the window, farther, still smiling, farther and farther, though it takes less time than this, really an instant, and lets herself fall. Herself fall. A casual impulse, a fancy, never thought of until now, hardly thought of even now... No, more than impulse or fancy, the girl knows what she ’ s doing, the girl means something, the girl means to mean, because it occurs to her in that instant, that beautiful or not, bright yes or no, she ’ s not who she is, she ’ s not the person she is, and the reason, she suddenly knows, is that there ’ s been so much premeditation where she is, so much plotting and planning, there ’ s hardly a person where she is, or if there is, it ’ s not her, or not wholly her, it ’ s a self inhabited, lived in by her, and seemingly even as she thinks it she knows what ’ s been missing : grace, not premeditation but grace, a kind of being in the world spontaneously, with grace. Weightfully upon me was the world. Weightfully this self which graced the world yet never wholly itself. Weightfully this self which weighed upon me, the release from which is what I desire and what I achieve. And the girl remembers, in this infinite instant already now so many times divided, the sadness she felt once, hardly knowing she felt it, to merely inhabit herself. Yes, the girl falls, absurd to fall, even the earth with its compulsion to take unto itself all that falls must know that falling is absurd, yet the girl falling isn ’ t myself, or she is myself, but a self I took of my own volition unto myself. Forever. With grace. This happened. I ’ ll read just one more. I don ’ t usually say that. I like to just end. But I ’ m afraid that Ricky will come out here and shake his fist at me. This is called”Old Man,”appropriately enough.”Special : big tits,”Says the advertisement for a soft-core magazine on our neighborhood newsstand. But forget her breasts. A lush, fresh-lipped blond, skin glowing gold, sprawls there, **resplendent**. 60 nearly, yet these hardly tangible, hardly better than harlots, can still stir me. Maybe a coming of age in the American sensual darkness, never seeing an unsmudged nipple, an uncensored vagina, has left me forever infected with an unquenchable lust of the eye. Always that erotic murmur, I ' m hardly myself if I ' m not in a state of incipient desire. God knows though, there are worse twists your obsessions can take. Last year in Israel, a young ultra-orthodox Rabbi guiding some teenage girls through the Shrine of the Shoah forbade them to look in one room. Because there were images in it he said were licentious. The display was a photo. Men and women stripped naked, some trying to cover their genitals, others too frightened to bother, lined up in snow waiting to be shot and thrown into a ditch. The girls, to my horror, averted their gaze. What carnal mistrust had their teacher taught them. Even that though. Another confession : Once in a book on pre-war Poland, a studio portrait, an absolute angel, an absolute angel with tormented, tormenting eyes. I kept finding myself at her page. That she died in the camps made her — I didn ' t dare wonder why — more present, more precious. Died in the camps, that too people — or Jews anyway — kept from their children back then. But it was like sex, you didn ' t have to be told. Sex and death, how close they can seem. So constantly conscious now of death moving towards me, sometimes I think I confound them. My wife ' s loveliness almost consumes me. My passion for her goes beyond reasonable bounds. When we make love, her holding me everywhere all around me, I ' m there and not there. My mind teems, jumbles of faces, voices, impressions, I live my life over, as though I were drowning. Then I am drowning, in despair at having to leave her, this, everything, all, unbearable, awful. Still, to be able to die with no special contrition, not having been slaughtered, or enslaved. And not having to know history ' s next mad rage or regression, it might be a relief. No. Again, no. I don ' t mean that for a moment. What I mean is the world holds me so tightly — the good and the bad — my own **follies** and weakness that even this counterfeit Venus with her sham heat, and her bosom probably plumped with gel, so moves me my breath catches. Vamp. Siren. Seductress. How much more she reveals in her glare of **ink** than she knows. How she incarnates our desperate human need for regard, our passion to live in beauty, to be beauty, to be cherished by glances, if by no more, of something like love, or love. Thank you.

So I understand that this meeting was planned, and the slogan was From Was to Still. And I am illustrating Still. Which, of course, I am not agreeing with because, although I am 94, I am not still working. And anybody who asks me,"Are you still doing this or that?"I don ' t answer because I ' m not doing things still, I ' m doing it like I always did. I still have — or did I use the word still? I didn ' t mean that. I have my file which is called To Do. I have my plans. I have my clients. I am doing my work like I always did. So this takes care of my age. I want to show you my work so you know what I am doing and why I am here. This was about 1925. All of these things were made during the last 75 years. But, of course, I ' m working since 25, doing more or less what you see here. This is Castleton China. This was an exhibition at the Museum of Modern Art. This is now for sale at the Metropolitan Museum. This is still at the Metropolitan Museum now for sale. This is a portrait of my daughter and myself. These were just some of the things I ' ve made. I made hundreds of them for the last 75 years. I call myself a maker of things. I don ' t call myself an industrial designer because I ' m other things. Industrial designers want to make novel things. Novelty is a concept of commerce, not an aesthetic concept. The industrial design magazine, I believe, is called"Innovation."Innovation is not part of the aim of my work. Well, makers of things : they make things more beautiful, more elegant, more comfortable than just the craftsmen do. I have so much to say. I have to think what I am going to say. Well, to describe our profession otherwise, we are actually concerned with the playful search for beauty. That means the playful search for beauty was called the first activity of Man. Sarah Smith, who was a mathematics professor at MIT, wrote,"The playful search for beauty was Man ' s first activity — that all useful qualities and all material qualities were developed from the playful search for beauty."These are **tiles**. The word,"playful"is a necessary aspect of our work because, actually, one of our problems is that we have to make, produce, lovely things throughout all of life, and this for me is now 75 years. So how can you, without drying up, make things with the same pleasure, as a gift to others, for so long? The playful is therefore an important part of our quality as designer. Let me tell you some about my life. As I said, I started to do these things 75 years ago. My first exhibition in the United States was at the Sesquicentennial exhibition in 1926 — that the Hungarian government sent one of my hand-drawn pieces as part of the exhibit. My work actually took me through many countries, and showed me a great part of the world. This is not that they took me — the work didn ' t take me — I made the things particularly because I wanted to use them to see the world. I was incredibly curious to see the world, and I made all these things, which then finally did take me to see many countries and many cultures. I started as an apprentice to a Hungarian craftsman, and this taught me what the guild system was in Middle Ages. The guild system : that means when I was an apprentice, I had to apprentice myself in order to become a pottery master. In my shop where I studied, or learned, there was a traditional hierarchy of master, journeyman and learned worker, and apprentice, and I worked as the apprentice. The work as an apprentice was very primitive. That means I had to actually learn every aspect of making pottery by hand. We mashed the clay with our feet when it came from the hillside. After that, it had to be kneaded. It had to then go in, kind of, a mangle. And then finally it was prepared for the throwing. And there I really worked as an apprentice. My master took me to set ovens because this was part of oven-making, oven-setting, in the time. And finally, I had received a document that I had accomplished my apprenticeship successfully, that I had behaved morally, and this document was given to me by the Guild of Roof- Coverers, Rail-Diggers, Oven-Setters, Chimney Sweeps and Potters. I also got at the time a workbook which explained my rights and my working conditions, and I still have that workbook. First I set up a shop in my own garden, and made pottery which I sold on the marketplace in Budapest. And there I was sitting, and my then-boyfriend — I didn ' t mean it was a boyfriend like it is meant today — but my boyfriend and I sat at the market and sold the pots. My mother thought that this was not very proper, so she sat with us to add propriety to this activity. However, after a while there was a new factory being built in Budapest, a pottery factory, a large one. And I visited it with several ladies, and asked all sorts of questions of the director. Then the director asked me, why do you ask all these questions? I said, I also have a pottery. So he asked me, could he please visit me, and then finally he did, and explained to me that what I did now in my shop was an anachronism, that the industrial revolution had broken out, and that I rather should join the factory. There he made an art department for me where I worked for several months. However, everybody in the factory spent his time at the art department. The director there said there were several women casting and producing my designs now in molds, and this was sold also to America. I remember that it was quite successful. However, the director, the chemist, model maker — everybody — concerned himself much more with the art department — that means, with my work — than making toilets, so finally they got a letter from the center, from the bank who owned the factory, saying, make toilet-setting behind the art department, and that was my end. So this gave me the possibility because now I was a journeyman, and journeymen also take their satchel and go to see the world. So as a journeyman, I put an ad into the paper that I had studied, that I was a down-to-earth potter ’ s journeyman and I was looking for a job as a journeyman. And I got several answers, and I accepted the one which was farthest from home and practically, I thought, halfway to America. And that was in Hamburg. Then I first took this job in Hamburg, at an art pottery where everything was done on the wheel, and so I worked in a shop where there were several potters. And the first day, I was coming to take my place at the turntable — there were three or four turntables — and one of them, behind where I was sitting, was a hunchback, a deaf-mute hunchback, who smelled very bad. So I doused him in cologne every day, which he thought was very nice, and therefore he brought bread and butter every day, which I had to eat out of courtesy. The first day I came to work in this shop there was on my wheel a surprise for me. My colleagues had thoughtfully put on the wheel where I was supposed to work a very nicely modeled natural man ’ s organs. After I brushed them off with a hand motion, they were very — I finally was now accepted, and worked there for some six months. This was my first job. If I go on like this, you will be here till midnight. So I will try speed it up a little Moderator : Eva, we have about five minutes. Eva Zeisel : Are you sure? Moderator : Yes, I am sure. EZ : Well, if you are sure, I have to tell you that within five minutes I will talk very fast. And actually, my work took me to many countries because I used my work to fill my curiosity. And among other things, other countries I worked, was in the Soviet Union, where I worked from ’ 32 to ’ 37 — actually, to ’ 36. I was finally there, although I had nothing to do — I was a foreign expert. I became art director of the china and glass industry, and eventually under Stalin ’ s purges — at the beginning of Stalin ’ s purges, I didn ’ t know that hundreds of thousands of innocent people were arrested. So I was arrested quite early in Stalin ’ s purges, and spent 16 months in a Russian prison. The accusation was that I had successfully prepared an Attentat on Stalin ’ s life. This was a very dangerous accusation. And if this is the end of my five minutes, I want to tell you that I actually did survive, which was a surprise. But since I survived and I ’ m here, and since this is the end of the five minutes, I will — Moderator : Tell me when your last trip to Russia was. Weren ’ t you there recently? EZ : Oh, this summer, in fact, the Lomonosov factory was bought by an American company, invited me. They found out that I had worked in ’ 33 at this factory, and they came to my studio in Rockland County, and brought the 15 of their artists to visit me here. And they invited myself to come to the Russian factory last summer, in July, to make some dishes, design some dishes. And since I don ’ t like to travel alone, they also invited my daughter, son-in-law and granddaughter, so we had a lovely trip to see Russia today, which is not a very pleasant and happy view. Here I am now, if this is the end? Thank you.

I coined my own definition of success in 1934, when I was teaching at a high school in South Bend, Indiana, being a little bit disappointed, and [disillusioned] perhaps, by the way parents of the youngsters in my English classes expected their youngsters to get an A or a B. They thought a C was all right for the neighbors ’ children, because they were all average. But they weren ’ t satisfied when their own — it would make the teacher feel that they had failed, or the youngster had failed. And that ’ s not right. The good Lord in his infinite wisdom didn ’ t create us all equal as far as intelligence is concerned, any more than we ’ re equal for size, appearance. Not everybody could earn an A or a B, and I didn ’ t like that way of judging, and I did know how the alumni of various schools back in the ’ 30s judged coaches and athletic teams. If you won them all, you were considered to be reasonably successful — not completely. Because I found out — we had a number of years at UCLA where we didn ’ t lose a game. But it seemed that we didn ’ t win each individual game by the margin that some of our alumni had predicted — And quite frequently I really felt that they had backed up their predictions in a more materialistic manner. But that was true back in the 30s, so I understood that. But I didn ’ t like it, I didn ’ t agree with it. I wanted to come up with something I hoped could make me a better teacher, and give the youngsters under my supervision, be it in athletics or the English classroom, something to which to aspire, other than just a higher mark in the classroom, or more points in some athletic contest. I thought about that for quite a spell, and I wanted to come up with my own definition. I thought that might help. And I knew how Mr. Webster defined it, as the accumulation of material possessions or the attainment of a position of power or prestige, or something of that sort, worthy accomplishments perhaps, but in my opinion, not necessarily indicative of success. So I wanted to come up with something of my own. And I recalled — I was raised on a small farm in Southern Indiana, and Dad tried to teach me and my brothers that you should never try to be better than someone else. I ’ m sure at the time he did that, I didn ’ t — it didn ’ t — well, somewhere, I guess in the hidden recesses of the mind, it **popped** out years later. Never try to be better than someone else, always learn from others. Never cease trying to be the best you can be — that ’ s under your control. If you get too engrossed and involved and concerned in regard to the things over which you have no control, it will adversely affect the things over which you have control. Then I ran across this simple verse that said,”At God ’ s footstool to confess, a poor soul knelt, and bowed his head. ’ I failed! ’ he cried. The Master said, ’ Thou didst thy best, that is success. ’”From those things, and one other perhaps, I coined my own definition of success, which is : Peace of mind attained only through self-satisfaction in knowing you made the effort to do the best of which you ’ re capable. I believe that ’ s true. If you make the effort to do the best of which you ’ re capable, trying to improve the situation that exists for you, I think that ’ s success, and I don ’ t think others can judge that ; it ’ s like character and reputation — your reputation is what you ’ re perceived to be ; your character is what you really are. And I think that character is much more important than what you are perceived to be. You ’ d hope they ’ d both be good, but they won ’ t necessarily be the same. Well, that was my idea that I was going to try to get across to the youngsters. I ran across other things. I love to teach, and it was mentioned by the previous speaker that I enjoy poetry, and I dabble in it a bit, and love it. There are some things that helped me, I think, be better than I would have been. I know I ’ m not what I ought to be, what I should be, but I think I ’ m better than I would have been if I hadn ’ t run across certain things. One was just a little verse that said,”No written word, no spoken plea can teach our youth what they should be ; nor all the books on all the shelves — it ’ s what the teachers are themselves.”That made an impression on me in the 1930s. And I tried to use that more or less in my teaching, whether it be in sports, or whether it be in the English classroom. I love poetry and always had an interest in that somehow. Maybe it ’ s because Dad used to read to us at night, by coal oil lamp — we didn ’ t have electricity in our farm home. And Dad would read poetry to us. So I always liked it. And about the same time I ran across this one verse, I ran across another one. Someone asked a lady teacher why she taught, and after some time, she said she wanted to think about that. Then she came up and said,”They ask me why I teach, and I reply, ’ Where could I find such **splendid** company? ’ There sits a statesman, strong, unbiased, wise ; another Daniel Webster, silver-tongued. A doctor sits beside him, whose quick, steady hand may mend a bone, or stem the life-blood ’ s flow. And there a builder ; upward rise the arch of a church he builds, wherein that minister may speak the word of God, and lead a **stumbling** soul to touch the Christ. And all about, a gathering of teachers, farmers, merchants, laborers — those who work and vote and build and plan and pray into a great tomorrow. And I may say, I may not see the church, or hear the word, or eat the food their hands may grow, but yet again I may ; And later I may say, I knew him once, and he was weak, or strong, or bold or proud or gay. I knew him once, but then he was a boy. They ask me why I teach and I reply, ’ Where could I find such **splendid** company? ’”And I believe the teaching profession — it ’ s true, you have so many youngsters, and I ’ ve got to think of my youngsters at UCLA — 30-some attorneys, 11 dentists and doctors, many, many teachers and other professions. And that gives you a great deal of pleasure, to see them go on. I always tried to make the youngsters feel that they ’ re there to get an education, number one ; basketball was second, because it was paying their way, and they do need a little time for social activities, but you let social activities take a little precedence over the other two, and you ’ re not going to have any very long. So that was the idea that I tried to get across to the youngsters under my supervision. I had three rules, pretty much, that I stuck with practically all the time. I ’ d learned these prior to coming to UCLA, and I decided they were very important. One was”Never be late.”Later on I said certain things — the players, if we were leaving for somewhere, had to be neat and clean. There was a time when I made them wear jackets and shirts and ties. Then I saw our chancellor coming to school in denims and turtlenecks, and thought, it ’ s not right for me to keep this other [rule] so I let them just — they had to be neat and clean. I had one of my greatest players that you probably heard of, Bill Walton. He came to catch the bus ; we were leaving for somewhere to play. And he wasn ’ t clean and neat, so I wouldn ’ t let him go. He couldn ’ t get on the bus, he had to go home and get cleaned up to get to the airport. So I was a stickler for that. I believed in that. I believe in time ; very important. I believe you should be on time, but I felt at practice, for example — we start on time, we close on time. The youngsters didn ’ t have to feel that we were going to keep them over. When I speak at coaching clinics, I often tell young coaches — and at coaching clinics, more or less, they ’ ll be the younger coaches getting in the profession. Most of them are young, you know, and probably newly-married. And I tell them,”Don ’ t run practices late, because you ’ ll go home in a bad mood, and that ’ s not good, for a young married man to go home in a bad mood. When you get older, it doesn ’ t make any difference, but —”So I did believe : on time. I believe starting on time, and I believe closing on time. And another one I had was, not one word of profanity. One word of profanity, and you are out of here for the day. If I see it in a game, you ’ re going to come out and sit on the bench. And the third one was, never criticize a teammate. I didn ’ t want that. I used to tell them I was paid to do that. That ’ s my job. I ’ m paid to do it. Pitifully poor, but I am paid to do it. Not like the coaches today, for gracious sakes, no. It ’ s a little different than it was in my day. Those were three things that I stuck with pretty closely all the time. And those actually came from my dad. That ’ s what he tried to teach me and my brothers at one time. I came up with a pyramid eventually, that I don ’ t have the time to go on that. But that helped me, I think, become a better teacher. It ’ s something like this : And I had blocks in the pyramid, and the cornerstones being industriousness and enthusiasm, working hard and enjoying what you ’ re doing, coming up to the apex, according to my definition of success. And right at the top, faith and patience. And I say to you, in whatever you ' re doing, you must be patient. You have to have patience to — we want things to happen. We talk about our youth being impatient a lot, and they are. They want to change everything. They think all change is progress. And we get a little older — we sort of let things go. And we forget there is no progress without change. So you must have patience, and I believe that we must have faith. I believe that we must believe, truly believe. Not just give it word service, believe that things will work out as they should, providing we do what we should. I think our tendency is to hope things will turn out the way we want them to much of the time, but we don ' t do the things that are necessary to make those things become reality. I worked on this for some 14 years, and I think it helped me become a better teacher. But it all revolved around that original definition of success. You know, a number of years ago, there was a Major League Baseball umpire by the name of George Moriarty. He spelled Moriarty with only one ' i '. I ' d never seen that before, but he did. Big league baseball players — they ' re very perceptive about those things, and they noticed he had only one ' i ' in his name. You ' d be surprised how many also told him that that was one more than he had in his head at various times. But he wrote something where I think he did what I tried to do in this pyramid. He called it"The Road Ahead, or the Road Behind."He said,"Sometimes I think the Fates must grin as we denounce them and insist the only reason we can ' t win, is the Fates themselves have missed. Yet there lives on the ancient claim : we win or lose within ourselves. The shining trophies on our shelves can never win tomorrow ' s game. You and I know deeper down, there ' s always a chance to win the crown. But when we fail to give our best, we simply haven ' t met the test, of giving all and saving none until the game is really won ; of showing what is meant by grit ; of playing through when others quit ; of playing through, not letting up. It ' s bearing down that wins the cup. Of dreaming there ' s a goal ahead ; of hoping when our dreams are dead ; of praying when our hopes have fled ; yet losing, not afraid to fall, if, bravely, we have given all. For who can ask more of a man than giving all within his span. Giving all, it seems to me, is not so far from victory. And so the Fates are seldom wrong, no matter how they twist and wind. It ' s you and I who make our fates — we open up or close the gates on the road ahead or the road behind."Reminds me of another set of threes that my dad tried to get across to us : Don ' t whine. Don ' t complain. Don ' t make excuses. Just get out there, and whatever you ' re doing, do it to the best of your ability. And no one can do more than that. I tried to get across, too, that — my opponents will tell you — you never heard me mention winning. Never mention winning. My idea is that you can lose when you outscore somebody in a game, and you can win when you ' re outscored. I ' ve felt that way on certain occasions, at various times. And I just wanted them to be able to hold their head up after a game. I used to say that when a game is over, and you see somebody that didn ' t know the outcome, I hope they couldn ' t tell by your actions whether you outscored an opponent or the opponent outscored you. That ' s what really matters : if you make an effort to do the best you can regularly, the results will be about what they should be. Not necessarily what you ' d want them to be but they ' ll be about what they should ; only you will know whether you can do that. And that ' s what I wanted from them more than anything else. And as time went by, and I learned more about other things, I think it worked a little better, as far as the results. But I wanted the score of a game to be the byproduct of these other things, and not the end itself. I believe it was one great philosopher who said — no, no — Cervantes. Cervantes said,"The journey is better than the end."And I like that. I think that it is — it ' s getting there. Sometimes when you get there,

there ’ s almost a let down. But it ’ s the getting there that ’ s the fun. As a basketball coach at UCLA, I liked our practices to be the journey, and the game would be the end, the end result. I liked to go up and sit in the stands and watch the players play, and see whether I ’ d done a decent job during the week. There again, it ’ s getting the players to get that self-satisfaction, in knowing that they ’ d made the effort to do the best of which they are capable. Sometimes I ’ m asked who was the best player I had, or the best teams. I can never answer that. As far as the individuals are concerned — I was asked one time about that, and they said,”Suppose that you, in some way, could make the perfect player. What would you want?”And I said,”Well, I ’ d want one that knew why he was at UCLA : to get an education, he was a good student, really knew why he was there in the first place. But I ’ d want one that could play, too. I ’ d want one to realize that defense usually wins championships, and who would work hard on defense. But I ’ d want one who would play offense, too. I ’ d want him to be unselfish, and look for the pass first and not shoot all the time. And I ’ d want one that could pass and would pass. I ’ ve had some that could and wouldn ’ t, and I ’ ve had some that would and could. So, yeah, I ’ d want that. And I wanted them to be able to shoot from the outside. I wanted them to be good inside too. I ’ d want them to be able to rebound well at both ends, too. Why not just take someone like Keith Wilkes and let it go at that. He had the qualifications. Not the only one, but he was one that I used in that particular category, because I think he made the effort to become the best. There was a couple. I mention in my book,”They Call Me Coach,”two players that gave me great satisfaction, that came as close as I think anyone I ever had to reach their full potential : one was Conrad Burke, and one was Doug McIntosh. When I saw them as freshmen, on our freshmen team — freshmen couldn ’ t play varsity when I taught. I thought,”Oh gracious, if these two players, either one of them”— they were different years, but I thought about each one at the time he was there —”Oh, if he ever makes the varsity, our varsity must be pretty miserable, if he ’ s good enough to make it.”And you know, one of them was a starting player for a season and a half. The other one, his next year, played 32 minutes in a national championship game, Did a tremendous job for us. The next year, he was a starting player on the national championship team, and here I thought he ’ d never play a minute, when he was — so those are the things that give you great joy, and great satisfaction to see. Neither one of those youngsters could shoot very well. But they had outstanding shooting percentages, because they didn ’ t force it. And neither one could jump very well, but they kept good position, and so they did well rebounding. They remembered that every shot that ’ s taken, they assumed would be missed. I ’ ve had too many stand around and wait to see if it ’ s missed, then they go and it ’ s too late, somebody else is in there ahead of them. They weren ’ t very quick, but they played good position, kept in good balance. And so they played pretty good defense for us. So they had qualities that — they came close to — as close to reaching possibly their full potential as any players I ever had. So I consider them to be as successful as Lewis Alcindor or Bill Walton, or many of the others that we had ; there were some outstanding players. Have I rambled enough? I was told that when he makes his appearance, I was supposed to shut up.

Text Sample 586: NEG Dim 4 – 2001 – Score 2.00 – 2001/t000367.txt

I ’ d like to do pretty much what I did the first time, which is to choose a light-hearted theme. Last time, I talked about death and dying. This time, I ’ m going to talk about mental illness. But it has to be technological, so I ’ ll talk about electroshock therapy. You know, ever since man had any notion that some of his other people, his colleagues, could be different, could be strange, could be severely depressed or what we now recognize as schizophrenia, he was certain that this kind of illness had to come from evil spirits getting into the body. So, the way of treating these diseases in early times was to, in some way or other, exorcise those evil spirits, and this is still going on, as you know. But it wasn ' t enough to use the priests. When medicine became somewhat scientific, in about 450 BC, with Hippocrates and those boys, they tried to look for herbs, plants that would literally shake the bad spirits out. So, they found certain plants that could cause convulsions. And the herbals, the botanical books of up to the late Middle Ages, the Renaissance are filled with prescriptions for causing convulsions to shake the evil spirits out. Finally, in about the sixteenth century, a physician whose name was Theophrastus Bombastus Aureolus von Hohenheim, called Paracelsus, a name probably familiar to some people here — — good, old Paracelsus found that he could predict the degree of convulsion by using a measured amount of camphor to produce the convulsion. Can you imagine going to your closet, pulling out a mothball, and chewing on it if you ' re feeling depressed? It ' s better than Prozac, but I wouldn ' t recommend it. So what we see in the seventeenth, eighteenth century is the continued search for medications other than camphor that ' ll do the trick. Well, along comes Benjamin Franklin, and he comes close to convulsing himself with a bolt of electricity off the end of his kite. And so people begin thinking in terms of electricity to produce convulsions. And then, we fast-forward to about 1932, when three Italian psychiatrists, who were largely treating depression, began to notice among their patients, who were also epileptics, that if they had an epileptic — a series of epileptic fits, a lot of them in a row — the depression would very frequently lift. Not only would it lift, but it might never return. So they got very interested in producing convulsions, measured types of convulsions. And they thought,"Well, we ' ve got electricity, we ' ll plug somebody into the wall. That always makes hair stand up and people shake a lot."So, they tried it on a few pigs, and none of the pigs were killed. So, they went to the police and they said,"We know that at the Rome railroad station, there are all these lost souls wandering around, **muttering** gibberish. Can you bring one of them to us?"Someone who is, as the Italians say,"cagoots."So they found this"cagoots"guy, a 39-year-old man who was really hopelessly schizophrenic, who was known, had been known for months, to be literally defecating on himself, talking nothing that made any sense, and they brought him into the hospital. So these three psychiatrists, after about two or three weeks of observation, laid him down on a table, connected his temples to a very small source of current. They thought,"Well, we ' ll try 55 volts, two-tenths of a second. That ' s not going to do anything terrible to him."So they did that. Well, I have the following from a firsthand observer, who told me this about 35 years ago, when I was thinking about these things for some research project of mine. He said,"This fellow"— remember, he wasn ' t even put to sleep —"after this major grand mal convulsion, sat right up, looked at these three fellas and said, ' What the fuck are you assholes trying to do? '"If I could only say that in Italian. Well, they were happy as could be, because he hadn ' t said a rational word in the weeks of observation. So they plugged him in again, and this time they used 110 volts for half a second. And to their amazement, after it was over, he began speaking like he was perfectly well. He relapsed a little bit, they gave him a series of treatments, and he was essentially cured. But of course, having schizophrenia, within a few months, it returned. But they wrote a paper about this, and everybody in the Western world began using electricity to convulse people who were either schizophrenic or severely depressed. It didn ' t work very well on the schizophrenics, but it was pretty clear in the ’ 30s and by the middle of the ’ 40s that electroconvulsive therapy was very, very effective in the treatment of depression. And of course, in those days, there were no antidepressant drugs, and it became very, very popular. They would anesthetize people, convulse them, but the real difficulty was that there was no way to paralyze muscles. So people would have a real grand mal seizure. Bones were broken. Especially in old, fragile people, you couldn ’ t use it. And then in the 1950s, late 1950s, the so-called muscle relaxants were developed by pharmacologists, and it got so that you could induce a complete convulsion, an electroencephalographic convulsion — you could see it on the **brain** waves — without causing any convulsion in the body except a little bit of twitching of the toes. So again, it was very, very popular and very, very useful. Well, you know, in the middle ’ 60s, the first antidepressants came out. Tofranil was the first. In the late ’ 70s, early ’ 80s, there were others, and they were very effective. And patients ’ rights groups seemed to get very upset about the kinds of things that they would witness. And so the whole idea of electroconvulsive, electroshock therapy disappeared, but has had a renaissance in the last 10 years. And the reason that it has had a renaissance is that probably about 10 percent of the people, severe depressives, do not respond, regardless of what is done for them. Now, why am I telling you this story at this meeting? I ’ m telling you this story, because actually ever since Richard called me and asked me to talk about — as he asked all of his speakers — to talk about something that would be new to this audience, that we had never talked about, never written about, I ’ ve been planning this moment. This reason really is that I am a man who, almost 30 years ago, had his life saved by two long courses of electroshock therapy. And let me tell you this story. I was, in the 1960s, in a marriage. To use the word bad would be perhaps the understatement of the year. It was dreadful. There are, I ’ m sure, enough divorced people in this room to know about the hostility, the anger, who knows what. Being someone who had had a very difficult childhood, a very difficult adolescence — it had to do with not quite poverty but close. It had to do with being brought up in a family where no one spoke English, no one could read or write English. It had to do with death and disease and lots of other things. I was a little prone to depression. So, as things got worse, as we really began to hate each other, I became progressively depressed over a period of a couple of years, trying to save this marriage, which was inevitably not to be saved. Finally, I would schedule — all my major surgical cases, I was scheduling them for 12, one o ’ clock in the afternoon, because I couldn ’ t get out of bed before about 11 o ’ clock. And anybody who ’ s been depressed here knows what that ’ s like. I couldn ’ t even pull the covers off myself. Well, you ’ re in a university medical center, where everybody knows everybody, and it ’ s perfectly clear to my colleagues, so my referrals began to decrease. As my referrals began to decrease, I clearly became increasingly depressed until I thought, my God, I can ’ t work anymore. And, in fact, it didn ’ t make any difference because I didn ’ t have any patients anymore. So, with the advice of my physician, I had myself admitted to the acute care psychiatric unit of our university hospital. And my colleagues, who had known me since medical school in that place, said,”Don ’ t worry, chap. Six weeks, you ’ re back in the operating room. Everything ’ s going to be great.”Well, you know what bovine stercus is? That proved to be a lot of bovine stercus. I know some people who got tenure in that place with lies like that. So I was one of their failures. But it wasn ’ t that simple. Because by the time I got out of that unit, I was not functional at all. I could hardly see five feet in front of myself. I shuffled when I walked. I was bowed over. I rarely bathed. I sometimes didn ’ t shave. It was dreadful. And it was clear — not to me, because nothing was clear to me at that time anymore — that I would need long-term hospitalization in that awful place called a mental hospital. So I was admitted, in 1973, in the spring of 1973, to the Institute of Living, which used to be called the Hartford Retreat. It was founded in the eighteenth century, the largest psychiatric hospital in the state of Connecticut, other than the huge public hospitals that existed at that time. And they tried everything they had. They tried the usual psychotherapy. They tried every medication available in those days. And they did have Tofranil and other things — Mellaril, who knows what. Nothing happened except that I got jaundiced from one of these things. And finally, because I was well known in Connecticut, they decided they better have a meeting of the senior staff. All the senior staff got together, and I later found out what happened. They put all their heads together and they decided that there was nothing that could be done for this surgeon who had essentially separated himself from the world, who by that time had become so overwhelmed, not just with depression and feelings of worthlessness and inadequacy, but with obsessional thinking, obsessional thinking about coincidences. And there were particular numbers that every time I saw them, just got me dreadfully upset — all kinds of ritualistic observances, just awful, awful stuff. Remember when you were a kid, and you had to step on every line? Well, I was a grown man who had all of these rituals, and it got so there was a throbbing, there was a ferocious fear in my head. You ' ve seen this painting by Edvard Munch, The Scream. Every moment was a scream. It was impossible. So they decided there was no therapy, there was no treatment. But there was one treatment, which actually had been pioneered at the Hartford hospital in the early 1940s, and you can imagine what it was. It was pre-frontal lobotomy. So they decided — I didn ' t know this, again, I found this out later — that the only thing that could be done was for this 43-year-old man to have a pre-frontal lobotomy. Well, as in all hospitals, there was a resident assigned to my case. He was 27 years old, and he would meet with me two or three times a week. And of course, I had been there, what, three or four months at the time. And he asked to meet with the senior staff, and they agreed to meet with him because he was very well thought of in that place. They thought he had a really extraordinary future. And he dug in his heels and said,"No. I know this man better than any of you. I have met with him over and over again. You ' ve just seen him from time to time. You ' ve read reports and so forth. I really honestly believe that the basic problem here is pure depression, and all of the obsessional thinking comes out of it. And you know, of course, what ' ll happen if you do a pre- frontal lobotomy. Any of the results along the spectrum, from pretty bad to terrible, terrible, terrible is going to happen. If he does the best he can, he will have no further obsessions, probably no depression, but his affect will be dulled, he will never go back to surgery, he will never be the loving father that he was to his two children, his life will be changed. If he has the usual result, he will end up like ' One Flew Over the Cuckoo ' s Nest. ' And you know about that, just essentially in a stupor the rest of his life."Well, he said,"Can ' t we try a course of electroshock therapy?"And you know why they agreed? They agreed to humor him. They just thought,"Well, we ' ll give a course of 10. And so we ' ll lose a little time. Big deal. It doesn ' t make any difference."So they gave the course of 10, and the first — the usual course, incidentally, was six to eight and still is six to eight. Plugged me into the wires, put me to sleep, gave me the muscle relaxant. Six didn ' t work. Seven didn ' t work. Eight didn ' t work. At nine, I noticed — and it ' s wonderful that I could notice anything — I noticed a change. And at 10, I noticed a real change. And he went back to them, and they agreed to do another 10. Again, not a single one of them — I think there are about seven or eight of them — thought this would do any good. They thought this was a temporary change. But, lo and **behold**, by 16, by 17, there were demonstrable differences in the way I felt. By 18 and 19, I was sleeping through the night. And by 20, I had the sense, I really had the sense that I could overcome this, that I was now strong enough that by an act of will, I could blow the obsessional thinking away. I could blow the depression away. And I ' ve never forgotten — I never will forget — standing in the kitchen of the unit, it was a Sunday morning in January of 1974, standing in the kitchen by myself and thinking,"I ' ve got the strength now to do this."It was as though those tightly coiled wires in my head had been disconnected and I could think clearly. But I need a formula. I need some thing to say to myself when I begin thinking obsessionally, obsessively. Well, the Gilbert and Sullivan fans in this room will remember"Ruddigore,"and they will remember Mad Margaret, and they will remember that she was married to a fellow named Sir Despard Murgatroyd. And she used to go nuts, every five minutes or so in the play, and he said to her,"We must have a word to bring you back to reality, and the word, my dear, will be ' Basingstoke. '"So every time she got a little nuts, he would say,"Basingstoke!"And she would say,"Basingstoke, it is."And she would be fine for a little while. Well, you know, I ' m from the Bronx. I can ' t say"Basingstoke."But I had something better. And it was very simple. It was,"Ah, fuck it!"Much better than"Basingstoke,"at least for me. And it worked — my God, it worked. Every time I would begin thinking obsessionally — again, once more, after 20 shock treatments — I would say,"Ah, fuck it."And things got better and better, and within three or four months, I was discharged from that hospital, and I joined a group of surgeons where I could work with other people in the community, not in New Haven, but fairly close by. I stayed there for three years. At the end of three years, I went back to New Haven, had remarried by that time. I brought my wife with me, actually, to make sure I could get through this. My children came back to live with us. We had two more children after that. Resuscitated the career, even better than it had been before. Went right back into the university and began to write books. Well, you know, it ' s been a wonderful life. It ' s been, as I said, close to 30 years. I stopped doing surgery about six years ago and became a full-time writer, as many people know. But it ' s been very exciting. It ' s been very happy. Every once in a while, I have to say,"Ah, fuck it."Every once in a while, I get somewhat depressed and a little obsessional. So, I ' m not free of all of this. But it ' s worked. It ' s always worked. Why have I chosen, after never, ever talking about this, to talk about it now? Well, those of you who know some of these books know that one is about death and dying, one is about the human body and the human spirit, one is about the way mystical thoughts are constantly in our minds, and they have always to do with my own personal experiences. One might think reading these books — and I ' ve gotten thousands of letters about them by people who do think this — that based on my life ' s history as I ' ve portrayed in the books, my early life ' s history, I am someone who has overcome adversity. That I am someone who has drunk, drank, drunk of the bitter dregs of near-disaster in childhood and emerged not just unscathed but strengthened. I really have it figured out, so that I can advise people about death and dying, so that I can talk about mysticism and the human spirit. And I ' ve always felt guilty about that. I ' ve always felt that somehow I was an impostor because my readers don ' t know what I have just told you. It ' s known by some people in New Haven, obviously, but it is not generally known. So one of the reasons that I have come here to talk about this today is to — frankly, selfishly — unburden myself and let it be known that this is not an untroubled mind that has written all of these books. But more importantly, I think, is the fact that a very significant proportion of people in this audience are under 30, and there are many, of course, who are well over 30. For people under 30, and it looks to me like almost all of you — I would say all of you — are either on the cusp of a magnificent and exciting career or right into a magnificent and exciting career : anything can happen to you. Things change. Accidents happen. Something from childhood comes back to haunt you. You can be thrown off the track. I hope it happens to none of you, but it will probably happen to a small percentage of you. To those to whom it doesn ’ t happen, there will be adversities. If I, with the bleakness of spirit, with no spirit, that I had in the 1970s and no possibility of recovery, as far as that group of very experienced psychiatrists thought, if I can find my way back from this, believe me, anybody can find their way back from any adversity that exists in their lives. And for those who are older, who have lived through perhaps not something as bad as this, but who have lived through difficult times, perhaps where they lost everything, as I did, and started out all over again, some of these things will seem very familiar. There is recovery. There is redemption. And there is resurrection. There are resurrection themes in every society that has ever been studied, and it is because not just only do we fantasize about the possibility of resurrection and recovery, but it actually happens. And it happens a lot. Perhaps the most popular resurrection theme, outside of specifically religious ones, is the one about the phoenix, the ancient story of the phoenix, who, every 500 years, resurrects itself from its own ashes to go on to live a life that is even more beautiful than it was before. Richard, thanks very much.

Today I ’ m going to show you an electric vehicle that weighs less than a bicycle, that you can carry with you anywhere, that you can charge off a normal wall outlet in 15 minutes, and you can run it for 1, 000 kilometers on about a dollar of electricity. But when I say the word electric vehicle, people think about vehicles. They think about cars and motorcycles and bicycles, and the vehicles that you use every day. But if you come about it from a different perspective, you can create some more interesting, more novel concepts. So we built something. I ’ ve got some of the pieces in my pocket here. So this is the motor. This motor has enough power to take you up the hills of San Francisco at about 20 miles per hour, about 30 kilometers an hour, and this battery, this battery right here has about six miles of range, or 10 kilometers, which is enough to cover about half of the car trips in the U. S. alone. But the best part about these components is that we bought them at a toy store. These are from remote control airplanes. And the performance of these things has gotten so good that if you think about vehicles a little bit differently, you can really change things. So today we ’ re going to show you one example of how you can use this. Pay attention to not only how fun this thing is, but also how the portability that comes with this can totally change the way you interact with a city like San Francisco. [6 Mile Range] [Top Speed Near 20mph] [Uphill Climbing] [Regenerative Braking] So we ’ re going to show you what this thing can do. It ’ s really maneuverable. You have a hand-held remote, so you can pretty easily control acceleration, braking, go in reverse if you like, also have braking. It ’ s incredible just how light this thing is. I mean, this is something you can pick up and carry with you anywhere you go. So I ’ ll leave you with one of the most compelling facts about this technology and these kinds of vehicles. This uses 20 times less energy for every mile or kilometer that you travel than a car, which means not only is this thing fast to charge and really cheap to build, but it also reduces the footprint of your energy use in terms of your transportation. So instead of looking at large amounts of energy needed for each person in this room to get around in a city, now you can look at much smaller amounts and more sustainable transportation. So next time you think about a vehicle, I hope, like us, you ’ re thinking about something new. Thank you.

I live in South Central. This is South Central : liquor stores, fast food, vacant lots. So the city planners, they get together and they figure they ’ re going to change the name South Central to make it represent something else, so they change it to South Los Angeles, like this is going to fix what ’ s really going wrong in the city. This is South Los Angeles. Liquor stores, fast food, vacant lots. Just like 26. 5 million other Americans, I live in a food desert, South Central Los Angeles, home of the drive-thru and the drive-by. Funny thing is, the drive-thrus are killing more people than the drive-bys. People are dying from curable diseases in South Central Los Angeles. For instance, the obesity rate in my neighborhood is five times higher than, say, Beverly Hills, which is probably eight, 10 miles away. I got tired of seeing this happening. And I was wondering, how would you feel if you had no access to healthy food, if every time you walk out your door you see the ill effects that the present food system has on your neighborhood? I see wheelchairs bought and sold like used cars. I see dialysis centers **popping** up like Starbucks. And I figured, this has to stop. So I figured that the problem is the solution. Food is the problem and food is the solution. Plus I got tired of driving 45 minutes round trip to get an apple that wasn ’ t impregnated with pesticides. So what I did, I planted a food forest in front of my house. It was on a strip of land that we call a parkway. It ’ s 150 feet by 10 feet. Thing is, it ’ s owned by the city. But you have to maintain it. So I ’ m like,”Cool. I can do whatever the hell I want, since it ’ s my responsibility and I gotta maintain it.”And this is how I decided to maintain it. So me and my group, L. A. Green Grounds, we got together and we started planting my food forest, fruit trees, you know, the whole nine, vegetables. What we do, we ’ re a pay-it-forward kind of group, where it ’ s composed of gardeners from all walks of life, from all over the city, and it ’ s completely volunteer, and everything we do is free. And the garden, it was beautiful. And then somebody complained. The city came down on me, and basically gave me a citation saying that I had to remove my garden, which this citation was turning into a warrant. And I ’ m like,”Come on, really? A warrant for planting food on a piece of land that you could care less about?”And I was like,”Cool. Bring it.”Because this time it wasn ’ t coming up. So L. A. Times got ahold of it. Steve Lopez did a story on it and talked to the councilman, and one of the Green Grounds members, they put up a petition on Change. org, and with 900 signatures, we were a success. We had a victory on our hands. My councilman even called in and said how they endorse and love what we ’ re doing. I mean, come on, why wouldn ’ t they? L. A. leads the United States in vacant lots that the city actually owns. They own 26 square miles of vacant lots. That ’ s 20 Central Parks. That ’ s enough space to plant 725 million tomato plants. Why in the hell would they not okay this? Growing one plant will give you 1, 000, 10, 000 seeds. When one dollar ’ s worth of green beans will give you 75 dollars ’ worth of produce. It ’ s my gospel, when I ’ m telling people, grow your own food. Growing your own food is like printing your own money. See, I have a legacy in South Central. I grew up there. I raised my sons there. And I refuse to be a part of this manufactured reality that was manufactured for me by some other people, and I ’ m manufacturing my own reality. See, I ’ m an artist. Gardening is my graffiti. I grow my art. Just like a graffiti artist, where they beautify walls, me, I beautify lawns, parkways. I

use the garden, the soil, like it ' s a piece of cloth, and the plants and the trees, that ' s my embellishment for that cloth. You ' d be surprised what the soil could do if you let it be your canvas. You just couldn ' t imagine how amazing a sunflower is and how it affects people. So what happened? I have witnessed my garden become a tool for the education, a tool for the transformation of my neighborhood. To change the community, you have to change the composition of the soil. We are the soil. You ' d be surprised how kids are affected by this. Gardening is the most therapeutic and defiant act you can do, especially in the inner city. Plus you get strawberries. I remember this time, there was this mother and a daughter came, it was, like, 10:30 at night, and they were in my yard, and I came out and they looked so ashamed. So I ' m like, man, it made me feel bad that they were there, and I told them, you know, you don ' t have to do this like this. This is on the street for a reason. It made me feel ashamed to see people that were this close to me that were hungry, and this only reinforced why I do this, and people asked me,"Fin, aren ' t you afraid people are going to steal your food?"And I ' m like,"Hell no, I ain ' t afraid they ' re gonna steal it. That ' s why it ' s on the street. That ' s the whole idea. I want them to take it, but at the same time, I want them to take back their health."There ' s another time when I put a garden in this homeless shelter in downtown Los Angeles. These are the guys, they helped me unload the truck. It was cool, and they just shared the stories about how this affected them and how they used to plant with their mother and their grandmother, and it was just cool to see how this changed them, if it was only for that one moment. So Green Grounds has gone on to plant maybe 20 gardens. We ' ve had, like, 50 people come to our dig-ins and participate, and it ' s all volunteers. If kids grow kale, kids eat kale. If they grow tomatoes, they eat tomatoes. But when none of this is presented to them, if they ' re not shown how food affects the mind and the body, they blindly eat whatever the hell you put in front of them. I see young people and they want to work, but they ' re in this thing where they ' re caught up — I see kids of color and they ' re just on this track that ' s designed for them, that leads them to nowhere. So with gardening, I see an opportunity where we can train these kids to take over their communities, to have a sustainable life. And when we do this, who knows? We might produce the next George Washington Carver. but if we don ' t change the composition of the soil, we will never do this. Now this is one of my plans. This is what I want to do. I want to plant a whole block of gardens where people can share in the food in the same block. I want to take shipping containers and turn them into healthy cafes. Now don ' t get me wrong. I ' m not talking about no free shit, because free is not sustainable. The funny thing about sustainability, you have to sustain it. What I ' m talking about is putting people to work, and getting kids off the street, and letting them know the joy, the pride and the honor in growing your own food, opening farmer ' s markets. So what I want to do here, we gotta make this sexy. So I want us all to become ecolutionary renegades, gangstas, gangsta gardeners. We gotta flip the script on what a gangsta is. If you ain ' t a gardener, you ain ' t gangsta. Get gangsta with your shovel, okay? And let that be your weapon of choice. So basically, if you want to meet with me, you know, if you want to meet, don ' t call me if you want to sit around in cushy chairs and have meetings where you talk about doing some shit — where you talk about doing some shit. If you want to meet with me, come to the garden with your shovel so we can plant some shit. Peace. Thank you. Thank you.

Growing up in Taiwan as the daughter of a calligrapher, one of my most treasured memories was my mother showing me the beauty, the shape and the form of Chinese characters. Ever since then, I was fascinated by this incredible language. But to an outsider, it seems to be as impenetrable as the Great Wall of China. Over the past few years, I ’ ve been wondering if I can break down this wall, so anyone who wants to understand and appreciate the beauty of this sophisticated language could do so. I started thinking about how a new, fast method of learning Chinese might be useful. Since the age of five, I started to learn how to draw every single stroke for each character in the correct sequence. I learned new characters every day during the course of the next 15 years. Since we only have five minutes, it ’ s better that we have a fast and simpler way. A Chinese scholar would understand 20, 000 characters. You only need 1, 000 to understand the basic literacy. The top 200 will allow you to comprehend 40 percent of basic literature — enough to read road signs, restaurant menus, to understand the basic idea of the web pages or the newspapers. Today I ’ m going to start with eight to show you how the method works. You are ready? Open your mouth as wide as possible until it ’ s square. You get a mouth. This is a person going for a walk. Person. If the shape of the fire is a person with two arms on both sides, as if she was yelling frantically,”Help! I ’ m on fire!”— This symbol actually is originally from the shape of the flame, but I like to think that way. Whichever works for you. This is a tree. Tree. This is a mountain. The sun. The moon. The symbol of the door looks like a pair of saloon doors in the wild west. I call these eight characters radicals. They are the building blocks for you to create lots more characters. A person. If someone walks behind, that is”to follow.”As the old saying goes, two is company, three is a crowd. If a person stretched their arms wide, this person is saying,”It was this big.”The person inside the mouth, the person is trapped. He ’ s a prisoner, just like Jonah inside the whale. One tree is a tree. Two trees together, we have the woods. Three trees together, we create the forest. Put a plank underneath the tree, we have the foundation. Put a mouth on the top of the tree, that ’ s”idiot.”Easy to remember, since a talking tree is pretty idiotic. Remember fire? Two fires together, I get really hot. Three fires together, that ’ s a lot of flames. Set the fire underneath the two trees, it ’ s burning. For us, the sun is the source of prosperity. Two suns together, prosperous. Three together, that ’ s sparkles. Put the sun and the moon shining together, it ’ s brightness. It also means tomorrow, after a day and a night. The sun is coming up above the horizon. Sunrise. A door. Put a plank inside the door, it ’ s a door bolt. Put a mouth inside the door, asking questions. Knock knock. Is anyone home? This person is sneaking out of a door, escaping, evading. On the left, we have a woman. Two women together, they have an argument. Three women together, be careful, it ’ s adultery. So we have gone through almost 30 characters. By using this method, the first eight radicals will allow you to build 32. The next group of eight characters will build an extra 32. So with very little effort, you will be able to learn a couple hundred characters, which is the same as a Chinese eight-year-old. So after we know the characters, we start building phrases. For example, the mountain and the fire together, we have fire mountain. It ’ s a volcano. We know Japan is the land of the rising sun. This is a sun placed with the origin, because Japan lies to the east of China. So a sun, origin together, we build Japan. A person behind Japan, what do we get? A Japanese person. The character on the left is two mountains stacked on top of each other. In ancient China, that means in exile, because Chinese emperors, they put their political enemies in exile beyond mountains. Nowadays, exile has turned into getting out. A mouth which tells you where to get out is an exit. This is a slide to remind me that I should stop talking and get off of the stage. Thank you.

I ’ m here to share my photography. Or is it photography? Because, of course, this is a photograph that you can ’ t take with your camera. Yet, my interest in photography started as I got my first digital camera at the age of 15. It mixed with my earlier passion for drawing, but it was a bit different, because using the camera, the process was in the planning instead. And when you take a photograph with a camera, the process ends when you press the trigger. So to me it felt like photography was more about being at the right place and the right time. I felt like anyone could do that. So I wanted to create something different, something where the process starts when you press the trigger. Photos like this : construction going on along a busy road. But it has an unexpected twist. And despite that, it retains a level of realism. Or photos like these — both dark and colorful, but all with a common goal of retaining the level of realism. When I say realism, I mean photo-realism. Because, of course, it ’ s not something you can capture really, but I always want it to look like it could have been captured somehow as a photograph. Photos where you will need a brief moment to think to figure out the trick. So it ’ s more about capturing an idea than about capturing a moment really. But what ’ s the trick that makes it look realistic? Is it something about the details or the colors? Is it something about the light? What creates the illusion? Sometimes the perspective is the illusion. But in the end, it comes down to how we interpret the world and how it can be realized on a two- dimensional surface. It ’ s not really what is realistic, it ’ s what we think looks realistic really. So I think the basics are quite simple. I just see it as a puzzle of reality where you can take different pieces of reality and put it together to create alternate reality. And let me show you a simple example. Here we have three perfectly imaginable physical objects, something we all can relate to living in a three-dimensional world. But combined in a certain way, they can create something that still looks three-dimensional, like it could exist. But at the same time, we know it can ’ t. So we trick our **brains**, because our **brain** simply doesn ’ t accept the fact that it doesn ’ t really make sense. And I see the same process with combining photographs. It ’ s just really about combining different realities. So the things that make a photograph look realistic, I think it ’ s the things that we don ’ t even think about, the things all around us in our daily lives. But when combining photographs, this is really important to consider, because otherwise it just looks wrong somehow. So I would like to say that there are three simple rules to follow to achieve a realistic result. As you can see, these images aren ’ t really special. But combined, they can create something like this. So the first rule is that photos combined should have the same perspective. Secondly, photos combined should have the same type of light. And these two images both fulfill these two requirements — shot at the same height and in the same type of light. The third one is about making it impossible to distinguish where the different images begin and end by making it seamless. Make it impossible to say how the image actually was composed. So by matching color, contrast and brightness in the borders between the different images, adding photographic defects like depth of field, desaturated colors and noise, we erase the borders between the different images and make it look like one single image, despite the fact that one image can contain hundreds of layers basically. So here ’ s another example. One might think that this is just an image of a landscape and the lower part is what ’ s manipulated. But this image is actually entirely composed of photographs from different locations. I

personally think that it ’ s easier to actually create a place than to find a place, because then you don ’ t need to compromise with the ideas in your head. But it does require a lot of planning. And getting this idea during winter, I knew that I had several months to plan it, to find the different locations for the pieces of the puzzle basically. So for example, the fish was captured on a fishing trip. The shores are from a different location. The underwater part was captured in a stone pit. And yeah, I even turned the house on top of the island red to make it look more Swedish. So to achieve a realistic result, I think it comes down to planning. It always starts with a sketch, an idea. Then it ’ s about combining the different photographs. And here every piece is very well planned. And if you do a good job capturing the photos, the result can be quite beautiful and also quite realistic. So all the tools are out there, and the only thing that limits us is our imagination. Thank you.

Text Sample 591: NEG Dim 4 – 2011 – Score -1.00 – 2011/t002625.txt

I ’ m a huge believer in hands-on education. But you have to have the right tools. If I ’ m going to teach my daughter about electronics, I ’ m not going to give her a soldering iron. And similarly, she finds prototyping boards really frustrating for her little hands. So my wonderful student Sam and I decided to look at the most tangible thing we could think of : Play-Doh. And so we spent a summer looking at different Play-Doh recipes. And these recipes probably look really familiar to any of you who have made homemade play-dough — pretty standard ingredients you probably have in your kitchen. We have two favorite recipes — one that has these ingredients and a second that had sugar instead of salt. And they ’ re great. We can make great little sculptures with these. But the really cool thing about them is when we put them together. You see that really salty Play-Doh? Well, it conducts electricity. And this is nothing new. It turns out that regular Play-Doh that you buy at the store conducts electricity, and high school physics teachers have used that for years. But our homemade play-dough actually has half the resistance of commercial Play-Doh. And that sugar dough? Well it ’ s 150 times more resistant to electric current than that salt dough. So what does that mean? Well it means if you them together you suddenly have circuits — circuits that the most creative, tiny, little hands can build on their own. And so I want to do a little demo for you. So if I take this salt dough, again, it ’ s like the play-dough you probably made as kids, and I plug it in — it ’ s a two-lead battery pack, simple battery pack, you can buy them at Radio Shack and pretty much anywhere else — we can actually then light things up. But if any of you have studied electrical engineering, we can also create a short circuit. If I push these together, the light turns off. Right, the current wants to run through the play-dough, not through that LED. If I separate them again, I have some light. Well now if I take that sugar dough, the sugar dough doesn ’ t want to conduct electricity. It ’ s like a wall to the electricity. If I place that between, now all the dough is touching, but if I stick that light back in, I have light. In fact, I could even add some movement to my sculptures. If I want a spinning tail, let ’ s grab a motor, put some play-dough on it, stick it on and we have spinning. And once you have the basics, we can make a slightly more complicated circuit. We call this our sushi circuit. It ’ s very popular with kids. I plug in again the power to it. And now I can start talking about parallel and series circuits. I can start plugging in lots of lights. And we can start talking about things like electrical load. What happens if I put in lots of lights and then add a motor? It ’ ll **dim**. We can even add microprocessors and have this as an input and create squishy sound music that we ’ ve done.

You could do parallel and series circuits for kids using this. So this is all in your home kitchen. We ’ ve actually tried to turn it into an electrical engineering lab. We have a website, it ’ s all there. These are the home recipes. We ’ ve got some videos. You can make them yourselves. And it ’ s been really fun since we put them up to see where these have gone. We ’ ve had a mom in Utah who used them with her kids, to a science researcher in the U. K., and curriculum developers in Hawaii. So I would encourage you all to grab some Play-Doh, grab some salt, grab some sugar and start playing. We don ’ t usually think of our kitchen as an electrical engineering lab or little kids as circuit designers, but maybe we should. Have fun. Thank you.

Space, we all know what it looks like. We ’ ve been surrounded by images of space our whole lives, from the speculative images of science fiction to the inspirational visions of artists to the increasingly beautiful pictures made possible by complex technologies. But whilst we have an overwhelmingly vivid visual understanding of space, we have no sense of what space sounds like. And indeed, most people associate space with silence. But the story of how we came to understand the universe is just as much a story of listening as it is by looking. And yet despite this, hardly any of us have ever heard space. How many of you here could describe the sound of a single planet or star? Well in case you ’ ve ever wondered, this is what the Sun sounds like. This is the planet Jupiter. And this is the space probe Cassini pirouetting through the ice rings of Saturn. This is a a highly condensed clump of neutral matter, spinning in the distant universe. So my artistic practice is all about listening to the weird and wonderful noises emitted by the magnificent celestial objects that make up our universe. And you may wonder, how do we know what these sounds are? How can we tell the difference between the sound of the Sun and the sound of a pulsar? Well the answer is the science of radio astronomy. Radio astronomers study radio waves from space using sensitive antennas and receivers, which give them precise information about what an astronomical object is and where it is in our night sky. And just like the signals that we send and receive here on Earth, we can convert these transmissions into sound using simple analog techniques. And therefore, it ’ s through listening that we ’ ve come to uncover some of the universe ’ s most important secrets — its scale, what it ’ s made of and even how old it is. So today, I ’ m going to tell you a short story of the history of the universe through listening. It ’ s punctuated by three quick anecdotes, which show how accidental encounters with strange noises gave us some of the most important information we have about space. Now this story doesn ’ t start with vast telescopes or futuristic spacecraft, but a rather more humble technology — and in fact, the very medium which gave us the telecommunications revolution that we ’ re all part of today : the telephone. It ’ s 1876, it ’ s in Boston, and this is Alexander Graham Bell who was working with Thomas Watson on the invention of the telephone. A key part of their technical set up was a half-mile long length of wire, which was thrown across the rooftops of several houses in Boston. The line carried the telephone signals that would later make Bell a household name. But like any long length of charged wire, it also inadvertently became an antenna. Thomas Watson spent hours listening to the strange crackles and hisses and chirps and whistles that his accidental antenna detected. Now you have to remember, this is 10 years before Heinrich Hertz proved the existence of radio waves — 15 years before Nikola Tesla ’ s four-tuned circuit — nearly 20 years before Marconi ’ s first broadcast. So

Thomas Watson wasn ’ t listening to us. We didn ’ t have the technology to transmit. So what were these strange noises? Watson was in fact listening to very low- frequency radio emissions caused by nature. Some of the crackles and **pops** were lightning, but the eerie whistles and curiously melodious chirps had a rather more exotic origin. Using the very first telephone, Watson was in fact dialed into the heavens. As he correctly guessed, some of these sounds were caused by activity on the surface of the Sun. It was a solar wind interacting with our ionosphere that he was listening to — a phenomena which we can see at the extreme northern and southern latitudes of our planet as the aurora. So whilst inventing the technology that would usher in the telecommunications revolution, Watson had discovered that the star at the center of our solar system emitted powerful radio waves. He had accidentally been the first person to tune in to them. Fast-forward 50 years, and Bell and Watson ’ s technology has completely transformed global communications. But going from slinging some wire across rooftops in Boston to laying thousands and thousands of miles of cable on the Atlantic Ocean seabed is no easy matter. And so before long, Bell were looking to new technologies to optimize their revolution. Radio could carry sound without wires. But the medium is lossy — it ’ s subject to a lot of noise and interference. So Bell employed an engineer to study those noises, to try and find out where they came from, with a view towards building the perfect hardware codec, which would get rid of them so they could think about using radio for the purposes of telephony. Most of the noises that the engineer, Karl Jansky, investigated were fairly prosaic in origin. They turned out to be lightning or sources of electrical power. But there was one persistent noise that Jansky couldn ’ t identify, and it seemed to appear in his radio headset four minutes earlier each day. Now any astronomer will tell you, this is the telltale sign of something that doesn ’ t originate from Earth. Jansky had made a historic discovery, that celestial objects could emit radio waves as well as light waves. Fifty years on from Watson ’ s accidental encounter with the Sun, Jansky ’ s careful listening ushered in a new age of space exploration : the radio astronomy age. Over the next few years, astronomers connected up their antennas to loudspeakers and learned about our radio sky, about Jupiter and the Sun, by listening. Let ’ s jump ahead again. It ’ s 1964, and we ’ re back at Bell Labs. And once again, two scientists have got a problem with noise. Arno Penzias and Robert Wilson were using the horn antenna at Bell ’ s Holmdel laboratory to study the Milky Way with extraordinary precision. They were really listening to the galaxy in high fidelity. There was a glitch in their soundtrack. A mysterious persistent noise was disrupting their research. It was in the microwave range, and it appeared to be coming from all directions simultaneously. Now this didn ’ t make any sense, and like any reasonable engineer or scientist, they assumed that the problem must be the technology itself, it must be the dish. There were pigeons roosting in the dish. And so perhaps once they cleaned up the pigeon droppings, get the disk kind of operational again, normal operations would resume. But the noise didn ’ t disappear. The mysterious noise that Penzias and Wilson were listening to turned out to be the oldest and most significant sound that anyone had ever heard. It was cosmic radiation left over from the very birth of the universe. This was the first experimental evidence that the Big Bang existed and the universe was born at a precise moment some 14. 7 billion years ago. So our story ends at the beginning — the beginning of all things, the Big Bang. This is the noise that Penzias and Wilson heard — the oldest sound that you ’ re ever going to hear, the cosmic microwave background radiation left over from the Big Bang. Thanks.

I call myself a body architect. I trained in classical ballet and have a background in architecture and fashion. As a body architect, I fascinate with the human body and explore how I can transform it. I worked at Philips Electronics in the far-future design research lab, looking 20 years into the future. I explored the human skin, and how technology can transform the body. I worked on concepts like an electronic tattoo, which is augmented by touch, or dresses that blushed and shivered with light. I started my own experiments. These were the low-tech approaches to the high-tech conversations I was having. These are Q-tips stuck to my roommate with wig glue. I started a collaboration with a friend of mine, Bart Hess — he doesn ’ t normally look like this — and we used ourselves as models. We transformed our apartments into our laboratories, and worked in a very spontaneous and immediate way. We were creating visual imagery provoking human evolution. Whilst I was at Philips, we discussed this idea of a maybe technology, something that wasn ’ t either switched on or off, but in between. A maybe that could take the form of a gas or a liquid. And I became obsessed with this idea of blurring the perimeter of the body, so you couldn ’ t see where the skin ended and the near environment started. I set up my studio in the red-light district and obsessively wrapped myself in plumbing tubing, and found a way to redefine the skin and create this dynamic textile. I was introduced to Robyn, the Swedish **pop** star, and she was also exploring how technology coexists with raw human emotion. And she talked about how technology with these new feathers, this new face paint, this punk, the way that we identify with the world, and we made this music video. I ’ m fascinated with the idea of what happens when you merge biology with technology, and I remember reading about this idea of being able to reprogram biology, in the future, away from disease and aging. And I thought about this concept of, imagine if we could reprogram our own body odor, modify and biologically enhance it, and how would that change the way that we communicate with each other? Or the way that we attract sexual partners? And would we revert back to being more like animals, more primal modes of communication? I worked with a synthetic biologist, and I created a swallowable perfume, which is a cosmetic pill that you eat and the fragrance comes out through the skin ’ s surface when you perspire. It completely blows apart the way that perfume is, and provides a whole new format. It ’ s perfume coming from the inside out. It redefines the role of skin, and our bodies become an atomizer. I ’ ve learned that there ’ s no boundaries, and if I look at the evolution of my work i can see threads and connections that make sense. But when I look towards the future, the next project is completely unknown and wide open. I feel like I have all these ideas existing embedded inside of me, and it ’ s these conversations and these experiences that connect these ideas, and they kind of instinctively come out. As a body architect, I ’ ve created this limitless and boundless platform for me to discover whatever I want. And I feel like I ’ ve just got started. So here ’ s to another day at the office. Thank you! Thank you!

Organic chemists make molecules, very complicated molecules, by chopping up a big molecule into small molecules and reverse engineering. And as a chemist, one of the things I wanted to ask my research group a couple of years ago is, could we make a really cool universal chemistry set? In essence, could we”app”chemistry? Now what would this mean, and how would we do it? Well to start to do this, we took a 3D printer and we started to print our beakers and our test tubes on one side and then print the molecule at the same time on the other side and combine them together in what we call reactionware. And so by printing the vessel and doing the chemistry at the same time, we may start to access this universal toolkit of chemistry. Now what could this mean? Well if we can embed biological and chemical networks like a search engine, so if you have a cell that ’ s ill that you need to cure or bacteria that you want to kill, if you have this embedded in your device at the same time, and you do the chemistry, you may be able to make drugs in a new way. So how are we doing this in the lab? Well it requires software, it requires hardware and it requires chemical **inks**. And so the really cool bit is, the idea is that we want to have a universal set of **inks** that we put out with the printer, and you download the blueprint, the organic chemistry for that molecule and you make it in the device. And so you can make your molecule in the printer using this software. So what could this mean? Well, ultimately, it could mean that you could print your own medicine. And this is what we ’ re doing in the lab at the moment. But to take baby steps to get there, first of all we want to look at drug design and production, or drug discovery and manufacturing. Because if we can manufacture it after we ’ ve discovered it, we could deploy it anywhere. You don ’ t need to go to the chemist anymore. We can print drugs at point of need. We can download new diagnostics. Say a new super bug has emerged. You put it in your search engine, and you create the drug to treat the threat. So this allows you on-the-fly molecular assembly. But perhaps for me the core bit going into the future is this idea of taking your own stem cells, with your genes and your environment, and you print your own personal medicine. And if that doesn ’ t seem fanciful enough, where do you think we ’ re going to go? Well, you ’ re going to have your own personal matter fabricator. Beam me up, Scotty.

Five years ago, I experienced a bit of what it must have been like to be Alice in Wonderland. Penn State asked me, a communications teacher, to teach a communications class for engineering students. And I was scared. Really scared. Scared of these students with their big **brains** and their big books and their big, unfamiliar words. But as these conversations unfolded, I experienced what Alice must have when she went down that rabbit hole and saw that door to a whole new world. That ’ s just how I felt as I had those conversations with the students. I was amazed at the ideas that they had, and I wanted others to experience this wonderland as well. And I believe the key to opening that door is great communication. We desperately need great communication from our scientists and engineers in order to change the world. Our scientists and engineers are the ones that are tackling our grandest challenges, from energy to environment to health care, among others, and if we don ’ t know about it and understand it, then the work isn ’ t done, and I believe it ’ s our responsibility as non-scientists to have these interactions. But these great conversations can ’ t occur if our scientists and engineers don ’ t invite us in to see their wonderland. So scientists and engineers, please, talk nerdy to us. I want to share a few keys on how you can do that to make sure that we can see that your science is sexy and that your engineering is engaging. First question to answer for us : so what? Tell us why your science is relevant to us. Don ’ t just tell me that you study trabeculae, but tell me that you study trabeculae, which is the mesh-like structure of our bones because it ’ s important to understanding and treating osteoporosis. And when you ’ re describing your science, beware

of jargon. Jargon is a barrier to our understanding of your ideas. Sure, you can say”spatial and temporal,”but why not just say”space and time,”which is so much more accessible to us? And making your ideas accessible is not the same as dumbing it down. Instead, as Einstein said, make everything as simple as possible, but no simpler. You can clearly communicate your science without compromising the ideas. A few things to consider are having examples, stories and analogies. Those are ways to engage and excite us about your content. And when presenting your work, drop the bullet points. Have you ever wondered why they ’ re called bullet points? What do bullets do? Bullets kill, and they will kill your presentation. A slide like this is not only boring, but it relies too much on the language area of our **brain**, and causes us to become overwhelmed. Instead, this example slide by Genevieve Brown is much more effective. It ’ s showing that the special structure of trabeculae are so strong that they actually inspired the unique design of the Eiffel Tower. And the trick here is to use a single, readable sentence that the audience can key into if they get a bit lost, and then provide visuals which appeal to our other senses and create a deeper sense of understanding of what ’ s being described. So I think these are just a few keys that can help the rest of us to open that door and see the wonderland that is science and engineering. And because the engineers that I ’ ve worked with have taught me to become really in touch with my inner nerd, I want to summarize with an equation. Take your science, subtract your bullet points and your jargon, divide by relevance, meaning share what ’ s relevant to the audience, and multiply it by the passion that you have for this incredible work that you ’ re doing, and that is going to equal incredible interactions that are full of understanding. And so, scientists and engineers, when you ’ ve solved this equation, by all means, talk nerdy to me. Thank you.

What ’ s the fastest growing threat to Americans ’ health? Cancer? Heart attacks? Diabetes? The answer is actually none of these ; it ’ s Alzheimer ’ s disease. Every 67 seconds, someone in the United States is diagnosed with Alzheimer ’ s. As the number of Alzheimer ’ s patients triples by the year 2050, caring for them, as well as the rest of the aging population, will become an overwhelming societal challenge. My family has experienced firsthand the struggles of caring for an Alzheimer ’ s patient. Growing up in a family with three generations, I ’ ve always been very close to my grandfather. When I was four years old, my grandfather and I were walking in a park in Japan when he suddenly got lost. It was one of the scariest moments I ’ ve ever experienced in my life, and it was also the first instance that informed us that my grandfather had Alzheimer ’ s disease. Over the past 12 years, his condition got worse and worse, and his wandering in particular caused my family a lot of stress. My aunt, his primary caregiver, really struggled to stay awake at night to keep an eye on him, and even then often failed to catch him leaving the bed. I became really concerned about my aunt ’ s well-being as well as my grandfather ’ s safety. I searched extensively for a solution that could help my family ’ s problems, but couldn ’ t find one. Then, one night about two years ago, I was looking after my grandfather and I saw him stepping out of the bed. The moment his foot landed on the floor, I thought, why don ’ t I put a pressure sensor on the heel of his foot? Once he stepped onto the floor and out of the bed, the pressure sensor would detect an increase in pressure caused by body weight and then wirelessly send an audible alert to the caregiver ’ s smartphone. That way, my aunt could sleep much better at night without having to worry about my grandfather ’ s wandering. So now I ’ d like to perform a demonstration of this sock. Could I please have my sock model on the stage? Great. So once the patient steps onto the floor — — an alert is sent to the caregiver ’ s smartphone. Thank you. Thank you, sock model. So this is a drawing of my preliminary design. My desire to create a sensor-based technology perhaps stemmed from my lifelong love for sensors and technology. When I was six years old, an elderly family friend fell down in the bathroom and suffered severe injuries. I became concerned about my own grandparents and decided to invent a smart bathroom system. Motion sensors would be installed inside the **tiles** of bathroom floors to detect the falls of elderly patients whenever they fell down in the bathroom. Since I was only six years old at the time and I hadn ’ t graduated from kindergarten yet, I didn ’ t have the necessary resources and tools to translate my idea into reality, but nonetheless, my research experience really implanted in me a firm desire to use sensors to help the elderly people. I really believe that sensors can improve the quality of life of the elderly. When I laid out my plan, I realized that I faced three main challenges : first, creating a sensor ; second, designing a circuit ; and third, coding a smartphone app. This made me realize that my project was actually much harder to realize than I initially had thought it to be. First, I had to create a wearable sensor that was thin and flexible enough to be worn comfortably on the bottom of the patient ’ s foot. After extensive research and testing of different materials like rubber, which I realized was too thick to be worn snugly on the bottom of the foot, I decided to print a film sensor with electrically conductive pressure-sensitive **ink** particles. Once pressure is applied, the connectivity between the particles increases. Therefore, I could design a circuit that would measure pressure by measuring electrical resistance. Next, I had to design a wearable wireless circuit, but wireless signal transmission consumes lots of power and requires heavy, bulky batteries. Thankfully, I was able to find out about the Bluetooth low energy technology, which consumes very little power and can be driven by a coin-sized battery. This prevented the system from dying in the middle of the night. Lastly, I had to code a smartphone app that would essentially transform the care-giver ’ s smartphone into a remote monitor. For this, I had to expand upon my knowledge of coding with Java and XCode and I also had to learn about how to code for Bluetooth low energy devices by watching YouTube tutorials and reading various textbooks. Integrating these components, I was able to successfully create two prototypes, one in which the sensor is embedded inside a sock, and another that ’ s a re- attachable sensor assembly that can be adhered anywhere that makes contact with the bottom of the patient ’ s foot. I ’ ve tested the device on my grandfather for about a year now, and it ’ s had a 100 percent success rate in detecting the over 900 known cases of his wandering. Last summer, I was able to beta test my device at several residential care facilities in California, and I ’ m currently incorporating the feedback to further improve the device into a marketable product. Testing the device on a number of patients made me realize that I needed to invent solutions for people who didn ’ t want to wear socks to sleep at night. So sensor data, collected on a vast number of patients, can be useful for improving patient care and also leading to a cure for the disease, possibly. For example, I ’ m currently examining correlations between the frequency of a patient ’ s nightly wandering and his or her daily activities and diet. One thing I ’ ll never forget is when my device first caught my grandfather ’ s wandering out of bed at night. At that moment, I was really struck by the power of technology to change lives for the better. People living happily and healthfully — that ’ s the world that I imagine. Thank you very much.

I know a man who soars above the city every night. In his dreams, he twirls and swirls with his toes kissing the Earth. Everything has motion, he claims, even a body as paralyzed as his own. This man is my father. Three years ago, when I found out that my father had suffered a severe stroke in his **brain** stem, I walked into his room in the ICU at the Montreal Neurological Institute and found him lying deathly still, tethered to a breathing machine. Paralysis had closed over his body slowly, beginning in his toes, then legs, torso, fingers and arms. It made its way up his neck, cutting off his ability to breathe, and stopped just beneath the eyes. He never lost consciousness. Rather, he watched from within as his body shut down, limb by limb, muscle by muscle. In that ICU room, I walked up to my father ' s body, and with a quivering voice and through tears, I began reciting the alphabet. A, B, C, D, E, F, G, H, I, J, K. At K, he blinked his eyes. I began again. A, B, C, D, E, F, G, H, I. He blinked again at the letter I, then at T, then at R, and A : Kitra. He said"Kitra, my beauty, don ' t cry. This is a blessing."There was no audible voice, but my father called out my name powerfully. Just 72 hours after his stroke, he had already embraced the totality of his condition. Despite his extreme physical state, he was completely present with me, guiding, nurturing, and being my father as much if not more than ever before. Locked-in syndrome is many people ' s worst nightmare. In French, it ' s sometimes called"maladie de l ' emmur vivant."Literally,"walled-in-alive disease."For many people, perhaps most, paralysis is an unspeakable horror, but my father ' s experience losing every system of his body was not an experience of feeling trapped, but rather of turning the psyche inwards, **dimming** down the external chatter, facing the recesses of his own mind, and in that place, falling in love with life and body anew. As a rabbi and spiritual man dangling between mind and body, life and death, the paralysis opened up a new awareness for him. He realized he no longer needed to look beyond the corporeal world in order to find the divine."Paradise is in this body. It ' s in this world,"he said. I slept by my father ' s side for the first four months, tending as much as I could to his every discomfort, understanding the deep human psychological fear of not being able to call out for help. My mother, sisters, brother and I, we surrounded him in a cocoon of healing. We became his mouthpiece, spending hours each day reciting the alphabet as he whispered back sermons and poetry with blinks of his eye. His room, it became our temple of healing. His bedside became a site for those seeking advice and spiritual counsel, and through us, my father was able to speak and uplift, letter by letter, blink by blink. Everything in our world became slow and tender as the din, drama and death of the hospital ward faded into the background. I want to read to you one of the first things that we transcribed in the week following the stroke. He composed a letter, addressing his synagogue congregation, and ended it with the following lines :"When my nape exploded, I entered another dimension : inchoate, sub-planetary, protozoan. Universes are opened and closed continually. There are many when low, who stop growing. Last week, I was brought so low, but I felt the hand of my father around me, and my father brought me back."When we weren ' t his voice, we were his legs and arms. I moved them like I know I would have wanted my own arms and legs to be moved were they still for all the hours of the day. I remember I ' d hold his fingers near my face, bending each joint to keep it soft and limber. I ' d ask him again and again to visualize the motion, to watch from within as the finger curled and extended, and to move along with it in his mind. Then, one day, from the corner of my eye, I saw his body slither like a snake, an involuntary spasm passing through the course of his limbs. At first, I thought it was my own hallucination, having spent so much time tending to this one body, so desperate to see anything react on its own. But he told me he felt tingles, sparks of electricity flickering on and off just beneath the surface of the skin. The following week, he began ever so slightly to show muscle resistance. Connections were being made. Body was slowly and gently reawakening, limb by limb, muscle by muscle, twitch by twitch. As a documentary photographer, I felt the need to photograph each of his first movements like a mother with her newborn. I photographed him taking his first unaided breath, the celebratory moment after he showed muscle resistance for the very first time, the new adapted technologies that allowed him to gain more and more independence. I photographed the care and the love that surrounded him. But my photographs only told the outside story of a man lying in a hospital bed attached to a breathing machine. I wasn ’ t able to portray his story from within, and so I began to search for a new visual language, one which strived to express the ephemeral quality of his spiritual experience. Finally, I want to share with you a video from a series that I ’ ve been working on that tries to express the slow, in-between existence that my father has experienced. As he began to regain his ability to breathe, I started recording his thoughts, and so the voice that you hear in this video is his voice. Ronnie Cahana : You have to believe you ’ re paralyzed to play the part of a quadriplegic. I don ’ t. In my mind, and in my dreams every night I Chagall-man float over the city twirl and swirl with my toes kissing the floor. I know nothing about the statement of man without motion. Everything has motion. The heart pumps. The body heaves. The mouth moves. We never stagnate. Life triumphs up and down. Kitra Cahana : For most of us, our muscles begin to twitch and move long before we are conscious, but my father tells me his privilege is living on the far periphery of the human experience. Like an astronaut who sees a perspective that very few of us will ever get to share, he wonders and watches as he takes his first breaths and dreams about **crawling** back home. So begins life at 57, he says. A toddler has no attitude in its being, but a man insists on his world every day. Few of us will ever have to face physical limitations to the degree that my father has, but we will all have moments of paralysis in our lives. I know I frequently confront walls that feel completely unscalable, but my father insists that there are no dead ends. Instead, he invites me into his space of co-healing to give the very best of myself, and for him to give the very best of himself to me. Paralysis was an opening for him. It was an opportunity to emerge, to rekindle life force, to sit still long enough with himself so as to fall in love with the full continuum of creation. Today, my father is no longer locked in. He moves his neck with ease, has had his feeding peg removed, breathes with his own lungs, speaks slowly with his own quiet voice, and works every day to gain more movement in his paralyzed body. But the work will never be finished. As he says,”I ’ m living in a broken world, and there is holy work to do.”Thank you.

The universe is teeming with planets. I want us, in the next decade, to build a space telescope that ’ ll be able to image an Earth about another star and figure out whether it can harbor life. My colleagues at the NASA Jet Propulsion Laboratory at Princeton and I are working on technology that will be able to do just that in the coming years. Astronomers now believe that every star in the galaxy has a planet, and they speculate that up to one fifth of them have an Earth-like planet that might be able to harbor life, but we haven ’ t seen any of them. We ’ ve only detected them indirectly. This is NASA ’ s famous picture of the pale blue dot. It was taken by the Voyager spacecraft in 1990, when they turned it around as it was exiting the solar system to take a picture of the Earth from six billion kilometers away. I want to take that of an Earth-like planet about another star. Why haven ' t we done that? Why is that hard? Well to see, let ' s imagine we take the Hubble Space Telescope and we turn it around and we move it out to the orbit of Mars. We ' ll see something like that, a slightly blurry picture of the Earth, because we ' re a fairly small telescope out at the orbit of Mars. Now let ' s move ten times further away. Here we are at the orbit of Uranus. It ' s gotten smaller, it ' s got less detail, less resolve. We can still see the little moon, but let ' s go ten times further away again. Here we are at the edge of the solar system, out at the Kuiper Belt. Now it ' s not resolved at all. It ' s that pale blue dot of Carl Sagan ' s. But let ' s move yet again ten times further away. Here we are out at the Oort Cloud, outside the solar system, and we ' re starting to see the sun move into the field of view and get into where the planet is. One more time, ten times further away. Now we ' re at Alpha Centauri, our nearest neighbor star, and the planet is gone. All we ' re seeing is the big beaming image of the star that ' s ten billion times brighter than the planet, which should be in that little red circle. That ' s what we want to see. That ' s why it ' s hard. The light from the star is diffracting. It ' s scattering inside the telescope, creating that very bright image that washes out the planet. So to see the planet, we have to do something about all of that light. We have to get rid of it. I have a lot of colleagues working on really amazing technologies to do that, but I want to tell you about one today that I think is the coolest, and probably the most likely to get us an Earth in the next decade. It was first suggested by Lyman Spitzer, the father of the space telescope, in 1962, and he took his inspiration from an eclipse. You ' ve all seen that. That ' s a solar eclipse. The moon has moved in front of the sun. It blocks out most of the light so we can see that **dim** corona around it. It would be the same thing if I put my thumb up and blocked that spotlight that ' s getting right in my eye, I can see you in the back row. Well, what ' s going on? Well the moon is casting a shadow down on the Earth. We put a telescope or a camera in that shadow, we look back at the sun, and most of the light ' s been removed and we can see that **dim**, fine structure in the corona. Spitzer ' s suggestion was we do this in space. We build a big screen, we fly it in space, we put it up in front of the star, we block out most of the light, we fly a space telescope in that shadow that ' s created, and boom, we get to see planets. Well that would look something like this. So there ' s that big screen, and there ' s no planets, because unfortunately it doesn ' t actually work very well, because the light waves of the light and waves diffracts around that screen the same way it did in the telescope. It ' s like water bending around a rock in a stream, and all that light just destroys the shadow. It ' s a terrible shadow. And we can ' t see planets. But Spitzer actually knew the answer. If we can feather the edges, soften those edges so we can control diffraction, well then we can see a planet, and in the last 10 years or so we ' ve come up with optimal solutions for doing that. It looks something like that. We call that our flower petal starshade. If we make the edges of those petals exactly right, if we control their shape, we can control diffraction, and now we have a great shadow. It ' s about 10 billion times **dimmer** than it was before, and we can see the planets beam out just like that. That, of course, has to be bigger than my thumb. That starshade is about the size of half a football field and it has to fly 50, 000 kilometers away from the telescope that has to be held right in its shadow, and then we can see those planets. This sounds formidable, but brilliant engineers, colleagues of mine at JPL, came up with a fabulous design for how to do that and it looks like this. It starts wrapped around a hub. It separates from the telescope. The petals unfurl, they open up, the telescope turns around. Then you ’ ll see it flip and fly out that 50, 000 kilometers away from the telescope. It ’ s going to move in front of the star just like that, creates a wonderful shadow. Boom, we get planets orbiting about it. Thank you. That ’ s not science fiction. We ’ ve been working on this for the last five or six years. Last summer, we did a really cool test out in California at Northrop Grumman. So those are four petals. This is a sub-scale star shade. It ’ s about half the size of the one you just saw. You ’ ll see the petals unfurl. Those four petals were built by four undergraduates doing a summer internship at JPL. Now you ’ re seeing it deploy. Those petals have to rotate into place. The base of those petals has to go to the same place every time to within a tenth of a millimeter. We ran this test 16 times, and 16 times it went into the exact same place to a tenth of a millimeter. This has to be done very precisely, but if we can do this, if we can build this technology, if we can get it into space, you might see something like this. That ’ s a picture of one our nearest neighbor stars taken with the Hubble Space Telescope. If we can take a similar space telescope, slightly larger, put it out there, fly an occulter in front of it, what we might see is something like that — that ’ s a family portrait of our solar system — but not ours. We ’ re hoping it ’ ll be someone else ’ s solar system as seen through an occulter, through a starshade like that. You can see Jupiter, you can see Saturn, Uranus, Neptune, and right there in the center, next to the residual light is that pale blue dot. That ’ s Earth. We want to see that, see if there ’ s water, oxygen, ozone, the things that might tell us that it could harbor life. I think this is the coolest possible science. That ’ s why I got into doing this, because I think that will change the world. That will change everything when we see that. Thank you.

Text Sample 599: NEG Dim 4 – 1994 – Score 6.00 – 1994/t002458.txt

Because I usually take the role of trying to explain to people how wonderful the new technologies that are coming along are going to be, and I thought that, since I was among friends here, I would tell you what I really think and try to look back and try to understand what is really going on here with these amazing jumps in technology that seem so fast that we can barely keep on top of it. So I ’ m going to start out by showing just one very boring technology slide. And then, so if you can just turn on the slide that ’ s on. This is just a random slide that I picked out of my file. What I want to show you is not so much the details of the slide, but the general form of it. This happens to be a slide of some analysis that we were doing about the power of RISC microprocessors versus the power of local area networks. And the interesting thing about it is that this slide, like so many technology slides that we ’ re used to, is a sort of a straight line on a semi-log curve. In other words, every step here represents an order of magnitude in performance scale. And this is a new thing that we talk about technology on semi-log curves. Something really weird is going on here. And that ’ s basically what I ’ m going to be talking about. So, if you could bring up the lights. If you could bring up the lights higher, because I ’ m just going to use a piece of paper here. Now why do we draw technology curves in semi-log curves? Well the answer is, if I drew it on a normal curve where, let ’ s say, this is years, this is time of some sort, and this is whatever measure of the technology that I ’ m trying to graph, the graphs look sort of silly. They sort of go like this. And they don ’ t tell us much. Now if I graph, for instance, some other technology, say transportation technology, on a semi-log curve, it would look very stupid, it would look like a flat line. But when something like this happens, things are qualitatively changing. So if transportation technology was moving along as fast as microprocessor technology, then the day after tomorrow, I would be able to get in a taxi cab and be in Tokyo in 30 seconds. It ’ s not moving like that. And there ’ s nothing precedented in the history of technology development of this kind of self- feeding growth where you go by orders of magnitude every few years. Now the question that I ’ d like to ask is, if you look at these exponential curves, they don ’ t go on forever. Things just can ’ t possibly keep changing as fast as they are. One of two things is going to happen. Either it ’ s going to turn into a sort of classical S-curve like this, until something totally different comes along, or maybe it ’ s going to do this. That ’ s about all it can do. Now I ’ m an optimist, so I sort of think it ’ s probably going to do something like that. If so, that means that what we ’ re in the middle of right now is a transition. We ’ re sort of on this line in a transition from the way the world used to be to some new way that the world is. And so what I ’ m trying to ask, what I ’ ve been asking myself, is what ’ s this new way that the world is? What ’ s that new state that the world is heading toward? Because the transition seems very, very confusing when we ’ re right in the middle of it. Now when I was a kid growing up, the future was kind of the year 2000, and people used to talk about what would happen in the year 2000. Now here ’ s a conference in which people talk about the future, and you notice that the future is still at about the year 2000. It ’ s about as far as we go out. So in other words, the future has kind of been shrinking one year per year for my whole lifetime. Now I think that the reason is because we all feel that something ’ s happening there. That transition is happening. We can all sense it. And we know that it just doesn ’ t make too much sense to think out 30, 50 years because everything ’ s going to be so different that a simple extrapolation of what we ’ re doing just doesn ’ t make any sense at all. So what I would like to talk about is what that could be, what that transition could be that we ’ re going through. Now in order to do that I ’ m going to have to talk about a bunch of stuff that really has nothing to do with technology and computers. Because I think the only way to understand this is to really step back and take a long time scale look at things. So the time scale that I would like to look at this on is the time scale of life on Earth. So I think this picture makes sense if you look at it a few billion years at a time. So if you go back about two and a half billion years, the Earth was this big, sterile hunk of rock with a lot of chemicals floating around on it. And if you look at the way that the chemicals got organized, we begin to get a pretty good idea of how they do it. And I think that there ’ s theories that are beginning to understand about how it started with RNA, but I ’ m going to tell a sort of simple story of it, which is that, at that time, there were little drops of oil floating around with all kinds of different recipes of chemicals in them. And some of those drops of oil had a particular combination of chemicals in them which caused them to incorporate chemicals from the outside and grow the drops of oil. And those that were like that started to split and divide. And those were the most primitive forms of cells in a sense, those little drops of oil. But now those drops of oil weren ’ t really alive, as we say it now, because every one of them was a little random recipe of chemicals. And every time it divided, they got sort of unequal division of the chemicals within them. And so every drop was a little bit different. In fact, the drops that were different in a way that caused them to be better at incorporating chemicals around them, grew more and incorporated more chemicals and divided more. So those tended to live longer, get expressed more. Now that ’ s sort of just a very simple chemical form of life, but when things got interesting was when these drops learned a trick about abstraction. Somehow by ways that we don ’ t quite understand, these little drops learned to write down information. They learned to record the information that was the recipe of the cell onto a particular kind of chemical called DNA. So in other words, they worked out, in this mindless sort of evolutionary way, a form of writing that let them write down what they were, so that that way of writing it down could get copied. The amazing thing is that that way of writing seems to have stayed steady since it evolved two and a half billion years ago. In fact the recipe for us, our genes, is exactly that same code and that same way of writing. In fact, every living creature is written in exactly the same set of letters and the same code. In fact, one of the things that I did just for amusement purposes is we can now write things in this code. And I ' ve got here a little 100 micrograms of white powder, which I try not to let the security people see at airports. But this has in it — what I did is I took this code — the code has standard letters that we use for symbolizing it — and I wrote my business card onto a piece of DNA and amplified it 10 to the 22 times. So if anyone would like a hundred million copies of my business card, I have plenty for everyone in the room, and, in fact, everyone in the world, and it ' s right here. If I had really been a egotist, I would have put it into a virus and released it in the room. So what was the next step? Writing down the DNA was an interesting step. And that caused these cells — that kept them happy for another billion years. But then there was another really interesting step where things became completely different, which is these cells started exchanging and communicating information, so that they began to get communities of cells. I don ' t know if you know this, but bacteria can actually exchange DNA. Now that ' s why, for instance, antibiotic resistance has evolved. Some bacteria figured out how to stay away from penicillin, and it went around sort of creating its little DNA information with other bacteria, and now we have a lot of bacteria that are resistant to penicillin, because bacteria communicate. Now what this communication allowed was communities to form that, in some sense, were in the same boat together ; they were synergistic. So they survived or they failed together, which means that if a community was very successful, all the individuals in that community were repeated more and they were favored by evolution. Now the transition point happened when these communities got so close that, in fact, they got together and decided to write down the whole recipe for the community together on one string of DNA. And so the next stage that ' s interesting in life took about another billion years. And at that stage, we have multi-cellular communities, communities of lots of different types of cells, working together as a single organism. And in fact, we ' re such a multi- cellular community. We have lots of cells that are not out for themselves anymore. Your skin cell is really useless without a heart cell, muscle cell, a **brain** cell and so on. So these communities began to evolve so that the interesting level on which evolution was taking place was no longer a cell, but a community which we call an organism. Now the next step that happened is within these communities. These communities of cells, again, began to abstract information. And they began building very special structures that did nothing but process information within the community. And those are the neural structures. So neurons are the information processing apparatus that those communities of cells built up. And in fact, they began to get specialists in the community and special structures that were responsible for recording, understanding, learning information. And that was the **brains** and the nervous system of those communities. And that gave them an evolutionary advantage. Because at that point, an individual — learning could happen within the time span of a single organism, instead of over this evolutionary time span. So an organism could, for instance, learn not to eat a certain kind of fruit because it tasted bad and it got sick last time it ate it. That could happen within the lifetime of a single organism, whereas before they ' d built these special information processing structures, that would have had to be learned evolutionarily over hundreds of thousands of years by the individuals dying off that ate that kind of fruit. So that nervous system, the fact that they built these special information structures, tremendously sped up the whole process of evolution. Because evolution could now happen within an individual. It could happen in learning time scales. But then what happened was the individuals worked out, of course, tricks of communicating. And for example, the most sophisticated version that we ’ re aware of is human language. It ’ s really a pretty amazing invention if you think about it. Here I have a very complicated, messy, confused idea in my head. I ’ m sitting here making grunting sounds basically, and hopefully constructing a similar messy, confused idea in your head that bears some analogy to it. But we ’ re taking something very complicated, turning it into sound, sequences of sounds, and producing something very complicated in your **brain**. So this allows us now to begin to start functioning as a single organism. And so, in fact, what we ’ ve done is we, humanity, have started abstracting out. We ’ re going through the same levels that multi-cellular organisms have gone through — abstracting out our methods of recording, presenting, processing information. So for example, the invention of language was a tiny step in that direction. Telephony, computers, videotapes, CD-ROMs and so on are all our specialized mechanisms that we ’ ve now built within our society for handling that information. And it all connects us together into something that is much bigger and much faster and able to evolve than what we were before. So now, evolution can take place on a scale of microseconds. And you saw Ty ’ s little evolutionary example where he sort of did a little bit of evolution on the Convolution program right before your eyes. So now we ’ ve speeded up the time scales once again. So the first steps of the story that I told you about took a billion years a piece. And the next steps, like nervous systems and **brains**, took a few hundred million years. Then the next steps, like language and so on, took less than a million years. And these next steps, like electronics, seem to be taking only a few decades. The process is feeding on itself and becoming, I guess, autocatalytic is the word for it — when something reinforces its rate of change. The more it changes, the faster it changes. And I think that that ’ s what we ’ re seeing here in this explosion of curve. We ’ re seeing this process feeding back on itself. Now I design computers for a living, and I know that the mechanisms that I use to design computers would be impossible without recent advances in computers. So right now, what I do is I design objects at such complexity that it ’ s really impossible for me to design them in the traditional sense. I don ’ t know what every transistor in the connection machine does. There are billions of them. Instead, what I do and what the designers at Thinking Machines do is we think at some level of abstraction and then we hand it to the machine and the machine takes it beyond what we could ever do, much farther and faster than we could ever do. And in fact, sometimes it takes it by methods that we don ’ t quite even understand. One method that ’ s particularly interesting that I ’ ve been using a lot lately is evolution itself. So what we do is we put inside the machine a process of evolution that takes place on the microsecond time scale. So for example, in the most extreme cases, we can actually evolve a program by starting out with random sequences of instructions. Say,”Computer, would you please make a hundred million random sequences of instructions. Now would you please run all of those random sequences of instructions, run all of those programs, and pick out the ones that came closest to doing what I wanted.”So in other words, I define what I wanted. Let ’ s say I want to sort numbers, as a simple example I ’ ve done it with. So find the programs that come closest to sorting numbers. So of course, random sequences of instructions are very unlikely to sort numbers, so none of them will really do it. But one of them, by luck, may put two numbers in the right order. And I say,”Computer, would you please now take the 10 percent of those random sequences that did the best job. Save those. Kill off the rest. And now let ’ s reproduce the ones that sorted numbers the best. And let ’ s reproduce them by a process of recombination analogous to sex.”Take two programs and they produce children by exchanging their subroutines, and the children inherit the traits of the subroutines of the two programs. So I ’ ve got now a new generation of programs that are produced by combinations of the programs that did a little bit better job. Say,”Please repeat that process.”Score them again. Introduce some mutations perhaps. And try that again and do that for another generation. Well every one of those generations just takes a few milliseconds. So I can do the equivalent of millions of years of evolution on that within the computer in a few minutes, or in the complicated cases, in a few hours. At the end of that, I end up with programs that are absolutely perfect at sorting numbers. In fact, they are programs that are much more efficient than programs I could have ever written by hand. Now if I look at those programs, I can ’ t tell you how they work. I ’ ve tried looking at them and telling you how they work. They ’ re obscure, weird programs. But they do the job. And in fact, I know, I ’ m very confident that they do the job because they come from a line of hundreds of thousands of programs that did the job. In fact, their life depended on doing the job. I was riding in a 747 with Marvin Minsky once, and he pulls out this card and says,”Oh look. Look at this. It says, ’ This plane has hundreds of thousands of tiny parts working together to make you a safe flight. ’ Doesn ’ t that make you feel confident?”In fact, we know that the engineering process doesn ’ t work very well when it gets complicated. So we ’ re beginning to depend on computers to do a process that ’ s very different than engineering. And it lets us produce things of much more complexity than normal engineering lets us produce. And yet, we don ’ t quite understand the options of it. So in a sense, it ’ s getting ahead of us. We ’ re now using those programs to make much faster computers so that we ’ ll be able to run this process much faster. So it ’ s feeding back on itself. The thing is becoming faster and that ’ s why I think it seems so confusing. Because all of these technologies are feeding back on themselves. We ’ re taking off. And what we are is we ’ re at a point in time which is analogous to when single- celled organisms were turning into multi-celled organisms. So we ’ re the amoebas and we can ’ t quite figure out what the hell this thing is we ’ re creating. We ’ re right at that point of transition. But I think that there really is something coming along after us. I think it ’ s very haughty of us to think that we ’ re the end product of evolution. And I think all of us here are a part of producing whatever that next thing is. So lunch is coming along, and I think I will stop at that point, before I get selected out.

Greg Gage : If I asked you to think of a ferocious killer animal, you ’ d probably think of a lion, and for all the wonderful predatory skills that a lion has, it still only has about a 20 percent success rate at catching a meal. Now, one of the most successful hunters in the entire animal kingdom is surprising : the dragonfly. Now, dragonflies are killer flies, and when they see a smaller fly, they have about a 97 percent chance of catching it for a meal. And this is in mid-flight. But how can such a small insect be so precise? In this episode, we ’ re going to see how the dragonfly ’ s **brain** is highly specialized to be a deadly killer. [DIY Neuroscience] So what makes the dragonfly one of the most successful predators in the animal kingdom? One, it ’ s the eyes. It has near 360-degree vision. Two, the wings. With individual control of its wings, the dragonfly can move precisely in any direction. But the real secret to the dragonfly ’ s success is how its **brain** coordinates this complex information between the eyes and the wings and turns hunting into a simple reflex. To study this, Jaimie ’ s been spending a lot of time socializing with dragonflies. What do you need to do your experiments? Jaimie Spahr : First of all, you need dragonflies. Oliver : I have a mesh cage to catch the dragonflies. JS : The more I worked with them, the more terrified I got of them. They ’ re actually very scary, especially under a microscope. They have really sharp mandibles, are generally pretty aggressive, which I guess also helps them to be really good predators. GG : In order to learn what ’ s going on inside the dragonfly ’ s **brain** when it sees a prey, we ’ re going to eavesdrop in on a conversation between the eyes and the wings, and to do that, we need to anesthetize the dragonfly on ice and make sure we protect its wings so that we can release it afterwards. Now, the dragonfly ’ s **brain** is made up of specialized cells called neurons and these neurons are what allow the dragonfly to see and move so quickly. The individual neurons form circuits by connecting to each other via long, tiny threads called axons and the neurons communicate over these axons using electricity. In the dragonfly, we ’ re going to place little metal wires, or electrodes, along the axon tracks, and this is what ’ s really cool. In the dragonfly, there ’ s only 16 neurons ; that ’ s eight per eye that tell the wings exactly where the target is. We ’ ve placed the electrodes so that we can record from these neurons that connect the eyes to the wings. Whenever a message is being passed from the eye to the wing, our electrode intercepts that conversation in the form of an electrical current, and it amplifies it. Now, we can both hear it and see it in the form of a spike, which we also call an action potential. Now let ’ s listen in. Right now, we have the dragonfly flipped upside down, so he ’ s looking down towards the ground. We ’ re going to take a prey, or what we sometimes call a target. In this case, the target ’ s going to be a fake fly. We ’ re going to move it into the dragonfly ’ s sights. Oh! Oh, look at that. Look at that, but it ’ s only in one direction. Oh, yes! You don ’ t see any spikes when I go forward, but they ’ re all when I come back. In our experiments, we were able to see that the neurons of the dragonfly fired when we moved the target in one direction but not the other. Now, why is that? Remember when I said that the dragonfly had near 360-degree vision. Well, there ’ s a section of the eye called the fovea and this is the part that has the sharpest visual acuity, and you can think of it as its crosshairs. Remember when I told you the dragonfly had individual precise control of its wings? When a dragonfly sees its prey, it trains its crosshairs on it and along its axons it sends messages only to the neurons that control the parts of the wings that are needed to keep that dragonfly on target. So if the prey is on the left of the dragonfly, only the neurons that are tugging the wings to the left are fired. And if the prey moves to the right of the dragonfly, those same neurons are not needed, so they ’ re going to remain quiet. And the dragonfly speeds toward the prey at a fixed angle that ’ s communicated by this crosshairs to the wings, and then boom, dinner. Now, all this happens in a split second, and it ’ s effortless for the dragonfly. It ’ s almost like a reflex. And this whole incredibly efficient process is called fixation. But there ’ s one more story to this process. We saw how the neurons respond to movements, but how does the dragonfly know that something really is prey? This is where size matters. Let ’ s show the dragonfly a series of dots. Oh, yeah! JS : Yeah, it prefers that one. GG : Out of all the sizes, we found that the dragonfly responded to smaller targets over larger ones. In other words, the dragonfly was programmed to go after smaller flies versus something much larger, like a bird. And as soon as it recognizes something as prey, that poor little fly only has seconds to live. Today we got to see how the dragonfly ’ s **brain** works to make it a very efficient killer. And let ’ s be thankful that we didn ’ t live 300 million years ago when dragonflies were the size of cats.

I ’ d like you all to close your eyes, please... and imagine yourself sitting in the middle of a large, open field with the sun setting on your right. And as the sun sets, imagine that tonight you don ’ t just see the stars appear, but you ’ re able to hear the stars appear with the brightest stars being the loudest notes and the hotter, bluer stars producing the higher-pitched notes. And since each constellation is made up of different types of stars, they ’ ll each produce their own unique melody, such as Aries, the ram. Or Orion, the hunter. Or even Taurus, the bull. We live in a musical universe, and we can use that to experience it from a new perspective, and to share that perspective with a wider range of people. Let me show you what I mean. Now, when I tell people I ’ m an astrophysicist, they ’ re usually pretty impressed. And then I say I ’ m also a musician — they ’ re like,”Yeah, we know.”So everyone seems to know that there ’ s this deep connection between music and astronomy. And it ’ s actually a very old idea ; it goes back over 2, 000 years to Pythagoras. You might remember Pythagoras from such theorems as the Pythagorean theorem — And he said :”There is geometry in the humming of the strings, there is music in the spacing of the spheres.”And so he literally thought that the motions of the planets along the celestial sphere created harmonious music. And if you asked him,”Why don ’ t we hear anything?”he ’ d say you can ’ t hear it because you don ’ t know what it ’ s like to not hear it ; you don ’ t know what true silence is. It ’ s like how you have to wait for your power to go out to hear how annoying your refrigerator was. Maybe you buy that, but not everybody else was buying it, including such names as Aristotle. Exact words. So I ’ ll paraphrase his exact words. He said it ’ s a nice idea, but if something as large and vast as the heavens themselves were moving and making sounds, it wouldn ’ t just be audible, it would be earth-shatteringly loud. We exist, therefore there is no music of the spheres. He also thought that the **brain** ’ s only purpose was to cool down the blood, so there ’ s that... But I ’ d like to show you that in some way they were actually both right. And we ’ re going to start by understanding what makes music musical. It may sound like a silly question, but have you ever wondered why it is that certain notes, when played together, sound relatively pleasing or consonant, such as these two — while others are a lot more tense or dissonant, such as these two. Right? Why is that? Why are there notes at all? Why can you be in or out of tune? Well, the answer to that question was actually solved by Pythagoras himself. Take a look at the string on the far left. If you bow that string, it will produce a note as it oscillates very fast back and forth. But now if you cut the string in half, you ’ ll get two strings, each oscillating twice as fast. And that will produce a related note. Or three times as fast, or four times — And so the secret to musical harmony really is simple ratios : the simpler the ratio, the more pleasing or consonant those two notes will sound together. And the more complex the ratio, the more dissonant they will sound. And it ’ s this interplay between tension and release, or consonance and dissonance, that makes what we call music. Thank you. But there ’ s more. So the two features of music we like to think of as pitch and rhythms, they ’ re actually two versions of the same thing, and I can show you. That ’ s a rhythm right? Watch what happens when we speed it up. So once a rhythm starts happening more than about 20 times per second, your **brain** flips. It stops hearing it as a rhythm and starts hearing it as a pitch. So what does this have to do with astronomy? Well, that ’ s when we get to the TRAPPIST-1 system. This is an exoplanetary system discovered last February of 2017, and it got everyone excited because it is seven Earth-sized planets all orbiting a very near red dwarf star. And we think that three of the planets have the right temperature for liquid water. It ’ s also so close that in the next few years, we should be able to detect elements in their atmospheres such as oxygen and methane — potential signs of life. But one thing about the TRAPPIST system is that it is tiny. So here we have the orbits of the inner rocky planets in our solar system : Mercury, Venus, Earth and Mars, and all seven Earth-sized planets of TRAPPIST-1 are tucked well inside the orbit of Mercury. I have to expand this by 25 times for you to see the orbits of the TRAPPIST-1 planets. It ’ s actually much more similar in size to our planet Jupiter and its moons, even though it ’ s seven Earth-size planets orbiting a star. Another reason this got everyone excited was artist renderings like this. You got some liquid water, some ice, maybe some land, maybe you can go for a dive in this amazing orange sunset. It got everyone excited, and then a few months later, some other papers came out that said, actually, it probably looks more like this. So there were signs that some of the surfaces might actually be molten lava and that there were very damaging X-rays coming from the central star — X-rays that will sterilize the surface of life and even strip off atmospheres. Luckily, just a few months ago in 2018, some new papers came out with more refined measurements, and they found actually it does look something like that. So we now know that several of them have huge supplies of water — global oceans — and several of them have thick atmospheres, so it ’ s the right place to look for potential life. But there ’ s something even more exciting about this system, especially for me. And that ’ s that TRAPPIST-1 is a resonant chain. And so that means for every two orbits of the outer planet, the next one in orbits three times, and the next one in four, and then six, nine, 15 and 24. So you see a lot of very simple ratios among the orbits of these planets. Clearly, if you speed up their motion, you can get rhythms, right? One beat, say, for every time a planet goes around. But now we know if you speed that motion up even more, you ’ ll actually produce musical pitches, and in this case alone, those pitches will work together, making harmonious, even human-like harmony. So let ’ s hear TRAPPIST-1. The first thing you ’ ll hear will be a note for every orbit of each planet, and just keep in mind, this music is coming from the system itself. I ’ m not creating the pitches or rhythms, I ’ m just bringing them into the human hearing range. And after all seven planets have entered, you ’ re going to see — well, you ’ re going to hear a drum for every time two planets align. That ’ s when they kind of get close to each other and give each other a gravitational tug. And that ’ s the sound of the star itself — its light converted into sound. So you may wonder how this is even possible. And it ’ s good to think of the analogy of an orchestra. When everyone gets together to start playing in an orchestra, they can ’ t just dive into it, right? They have to all get in tune ; they have to make sure their instruments resonate with their neighbors ’ instruments, and something very similar happened to TRAPPIST-1 early in its existence. When the planets were first forming, they were orbiting within a disc of gas, and while inside that disc, they can actually slide around and adjust their orbits to their neighbors until they ’ re perfectly in tune. And it ’ s a good thing they did because this system is so compact — a lot of mass in a tight space — if every aspect of their orbits wasn ’ t very finely tuned, they would very quickly disrupt each other ’ s orbits, destroying the whole system. So it ’ s really music that is keeping this system alive — and any of its potential inhabitants. But what does our solar system sound like? I hate to be the one to show you this, but it ’ s not pretty. So for one thing, our solar system is on a much, much larger scale, and so to hear all eight planets, we have to start with Neptune near the bottom of our hearing range, and then Mercury ' s going to be all the way up near the very top of our hearing range. But also, since our planets are not very compact — they ' re very spread out — they didn ' t have to adjust their orbits to each other, so they ' re kind of just all playing their own random note at random times. So, I ' m sorry, but here it is. That ' s Neptune. Uranus. Saturn. Jupiter. And then tucked in, that ' s Mars. Earth. Venus. And that ' s Mercury — OK, OK, I ' ll stop. So this was actually Kepler ' s dream. Johannes Kepler is the person that figured out the laws of planetary motion. He was completely fascinated by this idea that there ' s a connection between music, astronomy and geometry. And so he actually spent an entire book just searching for any kind of musical harmony amongst the solar system ' s planets and it was really, really hard. It would have been much easier had he lived on TRAPPIST-1, or for that matter... K2- 138. This is a new system discovered in January of 2018 with five planets, and just like TRAPPIST, early on in their existence, they were all finely tuned. They were actually tuned into a tuning structure proposed by Pythagoras himself, over 2, 000 years before. But the system ' s actually named after Kepler, discovered by the Kepler space telescope. And so, in the last few billion years, they ' ve actually lost their tuning, quite a bit more than TRAPPIST has, and so what we ' re going to do is go back in time and imagine what they would ' ve sounded like just as they were forming. Thank you. Now, you may be wondering : How far does this go? How much music actually is out there? And that ' s what I was wondering last fall when I was working at U of T ' s planetarium, and I was contacted by an artist named Robyn Rennie and her daughter Erin. Robyn loves the night sky, but she hasn ' t been able to fully see it for 13 years because of vision loss. And so they wondered if there was anything I could do. So I collected all the sounds I could think of from the universe and packaged them into what became"Our Musical Universe."This is a sound-based planetarium show exploring the rhythm and harmony of the cosmos. And Robyn was so moved by this presentation that when she went home, she painted this gorgeous representation of her experience. And then I defaced it by putting Jupiter on it for the poster. So... in this show, I take people of all vision levels and bring them on an audio tour of the universe, from the night sky all the way out to the edge of the observable universe. But even this is just the start of a musical odyssey to experience the universe with new eyes and with new ears, and I hope you ' ll join me. Thank you.

Hi. My name is Aparna. I am a shopaholic â and I ' m addicted to online returns. Well, at least I was. At one time, I had two or three packages of clothing delivered to me every other day. I would intentionally buy the same item in a couple different sizes and many colors, because I did not know what I really wanted. So I overordered, I tried things on, and then I sent what didn ' t work back. Once my daughter was watching me return some of those packages back, and she said,"Mom, I think you have a problem."I didn ' t think so. I mean, it ' s free shipping and free returns, right? I didn ' t even think twice about it, until I heard a statistic at work that shocked me. You see, I ' m a global solutions director for top-tier retail, and we were in a meeting with one of my largest customers, discussing how to streamline costs. One of their biggest concerns was managing returns. Just this past holiday season alone, they had 7. 5 million pieces of clothing returned to them. I could not stop thinking about it. What happens to all these returned clothes? So I came home and researched. And I learned that every year, four billion pounds of returned clothing ends up in the landfill. That ’ s like every resident in the US did a load of laundry last night and decided to throw it in the trash today. I was horrified. I ’ m like,”Of all people, I should be able to help prevent this.”My job is to find solutions to logistical issues like these â not create them. So this issue became very personal to me. I said,”You know what? We have to solve this.”And we can, with some of the existing systems we already have in place. And then I started to wonder : How did we get here? I mean, it was only like six years ago when a study recommended that offering free online returns would drive customers to spend more. We started seeing companies offering free online returns to drive more sales and provide a better experience. What we didn ’ t realize is that this would lead to more items being returned as well. In the US, companies lost $351 billion in sales in 2017 alone. Retailers are scrambling to recover their losses. They try to place that returned item online to be sold again, or they ’ ll sell it to a discount partner or a liquidator. Basically, if companies cannot find a place for this item quickly and economically, its place becomes the trash. Suddenly, I felt very guilty for being that shopper, somebody who contributes to this. Who would have thought my innocent shopping behavior would be hurting not only me, but our planet as well? And as I thought about what to do, I kept thinking : Why does the item have to be returned to the retailer in the first place? What if there was another way, a win-win for everyone? What if when a person is trying to return something, it could go to the next shopper who wants it, and not the retailer? What if, instead of a return, they could do what I call a”green turn”? Consumers could use an app to take pictures of the item and verify the condition while returning it. Artificial intelligence systems could then sort these clothes by condition â mint condition or slightly used â and direct it to the next appropriate person. Mint-condition clothes could automatically go to the next buyer, while slightly used clothes could be marked down and offered online again. The retailer can decide the business rules on the number of times a particular item can be resold. All that the consumer would need to do is obtain a mobile code, take it to the nearest shipping place to be packed and shipped, and off it goes from one buyer to the next, not the landfill. Now you will ask,”Would people really go through all this trouble?”I think they would if they had incentives, like loyalty points or cash back. Let ’ s call it”green cash.”There would be a whole new opportunity to make money from this new customer base looking to buy these returns. This system would make a fun thing like shopping a spiritual experience that helps save our planet. This is doable and would probably take six months to weave some of our existing systems and run a pilot. Even before any of these logistical systems are in place, each of us shoppers can act now, if every single adult in the US made a few small changes to our shopping behavior. Take the extra time to research and think â Do I really need this item? No : Do I really want this item? â before making a purchase. And if every one of us adults in the US returned five less items this year, we would keep 240 million pounds of clothes out of the landfill. Six percent reduction, just like that. This environmental problem that we have created is not thousands of years away ; it ’ s happening today, and must stop now to prevent growing landfills across the globe. I want to leave my daughter and my daughter ’ s daughter a better and cleaner place than I found it, so I have not only stopped overordering, I recycle religiously as well. And you can, too. It ’ s not difficult. Before we fill our shopping carts and our landfills with extra items that we don ’ t want, let ’ s pause next time we are shopping online and think twice about what we all hopefully really do want : a beautiful Earth to call home. Thank you.

We are drowning in news. Reuters alone puts out three and a half million news stories a year. That ' s just one source. My question is : How many of those stories are actually going to matter in the long run? That ' s the idea behind The Long News. It ' s a project by The Long Now Foundation, which was founded by TEDsters including Kevin Kelly and Stewart Brand. And what we ' re looking for is news stories that might still matter 50 or 100 or 10, 000 years from now. And when you look at the news through that filter, a lot falls by the wayside. To take the top stories from the A. P. this last year, is this going to matter in a decade? Or this? Or this? Really? Is this going to matter in 50 or 100 years? Okay, that was kind of cool. But the top story of this past year was the economy, and I ' m just betting that, sooner or later, this particular recession is going to be old news. So, what kind of stories might make a difference for the future? Well, let ' s take science. Someday, little robots will go through our bloodstreams fixing things. That someday is already here if you ' re a mouse. Some recent stories : nanobees zap tumors with real bee venom ; they ' re sending genes into the **brain** ; a robot they built that can **crawl** through the human body. What about resources? How are we going to feed nine billion people? We ' re having trouble feeding six billion today. As we heard yesterday, there ' s over a billion people hungry. Britain will starve without genetically modified crops. Bill Gates, fortunately, has bet a billion on [agricultural] research. What about global politics? The world ' s going to be very different when and if China sets the agenda, and they may. They ' ve overtaken the U. S. as the world ' s biggest car market, they ' ve overtaken Germany as the largest exporter, and they ' ve started doing DNA tests on kids to choose their careers. We ' re finding all kinds of ways to push back the limits of what we know. Some recent discoveries : There ' s an ant colony from Argentina that has now spread to every continent but Antarctica ; there ' s a self-directed robot scientist that ' s made a discovery — soon, science may no longer need us, and life may no longer need us either ; a microbe wakes up after 120, 000 years. It seems that with or without us, life will go on. But my pick for the top Long News story of this past year was this one : water found on the moon. Makes it a lot easier to put a colony up there. And if NASA doesn ' t do it, China might, or somebody in this room might write a big check. My point is this : In the long run, some news stories are more important than others.

Why grow homes? Because we can. Right now, America is in an unremitting state of trauma. And there ' s a cause for that, all right. We ' ve got McPeople, McCars, McHouses. As an architect, I have to confront something like this. So what ' s a technology that will allow us to make ginormous houses? Well, it ' s been around for 2, 500 years. It ' s called pleaching, or grafting trees together, or grafting inosculate matter into one contiguous, vascular system. And we do something different than what we did in the past ; we add kind of a modicum of intelligence to that. We use CNC to make scaffolding to train semi-epithetic matter, plants, into a specific geometry that makes a home that we call a Fab Tree Hab. It fits into the environment. It is the environment. It is the landscape, right? And you can have a hundred million of these homes, and it ' s great because they suck carbon. They ' re perfect. You can have 100 million families, or take things out of the suburbs, because these are homes that are a part of the environment. Imagine pre-growing a village — it takes about seven to 10 years — and everything is green. So not only do we do the veggie house, we also do the in-vitro meat habitat, or homes that we ’ re doing research on now in Brooklyn, where, as an architecture office, we ’ re for the first of its kind to put in a molecular cell biology lab and start experimenting with regenerative medicine and tissue engineering and start thinking about what the future would be if architecture and biology became one. So we ’ ve been doing this for a couple of years, and that ’ s our lab. And what we do is we grow extracellular matrix from pigs. We use a modified inkjet printer, and we print geometry. We print geometry where we can make industrial design objects like, you know, shoes, leather belts, handbags, etc., where no sentient creature is harmed. It ’ s victimless. It ’ s meat from a test tube. So our theory is that eventually we should be doing this with homes. So here is a typical stud wall, an architectural construction, and this is a section of our proposal for a meat house, where you can see we use fatty cells as insulation, cilia for dealing with wind loads and sphincter muscles for the doors and windows. And we know it ’ s incredibly ugly. It could have been an English Tudor or Spanish Colonial, but we kind of chose this shape. And there it is kind of grown, at least one particular section of it. We had a big show in Prague, and we decided to put it in front of the cathedral so religion can confront the house of meat. That ’ s why we grow homes. Thanks very much.

Today, I want you to look at children who become suicide bombers through a completely different lens. In 2009, there were 500 bomb blasts across Pakistan. I spent the year working with children who were training to become suicide bombers and with Taliban recruiters, trying to understand how the Taliban were converting these children into live ammunition and why these children were actively signing up to their cause. I want you to watch a short video from my latest documentary film,”Children of the Taliban.”The Taliban now run their own schools. They target poor families and convince the parents to send their children. In return, they provide free food and shelter and sometimes pay the families a monthly stipend. We ’ ve obtained a propaganda video made by the Taliban. Young boys are taught justifications for suicide attacks and the execution of spies. I made contact with a child from Swat who studied in a madrassa like this. Hazrat Ali is from a poor farming family in Swat. He joined the Taliban a year ago when he was 13. How do the Taliban in your area get people to join them? Hazrat Ali : They first call us to the mosque and preach to us. Then they take us to a madrassa and teach us things from the Koran. Sharmeen Obaid Chinoy : He tells me that children are then given months of military training. HA : They teach us to use machine guns, Kalashnikov, rocket launchers, grenades, bombs. They ask us to use them only against the infidels. Then they teach us to do a suicide attack. SOC : Would you like to carry out a suicide attack? HA : If God gives me strength. SOC : I, in my research, have seen that the Taliban have perfected the way in which they recruit and train children, and I think it ’ s a five-step process. Step one is that the Taliban prey on families that are large, that are poor, that live in rural areas. They separate the parents from the children by promising to provide food, clothing, shelter to these children. Then they ship them off, hundreds of miles away to hard-line schools that run along the Taliban agenda. Step two : They teach the children the Koran, which is Islam ’ s holiest book, in Arabic, a language these children do not understand and cannot speak. They rely very heavily on teachers, who I have personally seen distort the message to these children as and when it suits their purpose to. These children are explicitly forbidden from reading newspapers, listening to radio, reading any books that the teachers do not prescribe them. If any child is found violating these rules, he is severely reprimanded. Effectively, the Taliban create a complete blackout of any other source of information for these children. Step three : The Taliban want these children to hate the world that they currently live in. So they beat these children — I have seen it ; they feed them twice a day dried bread and water ; they rarely allow them to play games ; they tell them that, for eight hours at a time, all they have to do is read the Koran. The children are virtual prisoners ; they cannot leave, they cannot go home. Their parents are so poor, they have no resources to get them back. Step four : The older members of the Taliban, the fighters, start talking to the younger boys about the glories of martyrdom. They talk to them about how when they die, they will be received up with lakes of honey and milk, how there will be 72 virgins waiting for them in paradise, how there will be unlimited food, and how this glory is going to propel them to become heroes in their neighborhoods. Effectively, this is the brainwashing process that has begun. Step five : I believe the Taliban have one of the most effective means of propaganda. Their videos that they use are intercut with photographs of men and women and children dying in Iraq and Afghanistan and in Pakistan. And the basic message is that the Western powers do not care about civilian deaths, so those people who live in areas and support governments that work with Western powers are fair game. That ’ s why Pakistani civilians, over 6, 000 of whom have been killed in the last two years alone, are fair game. Now these children are primed to become suicide bombers. They ’ re ready to go out and fight because they ’ ve been told that this is effectively their only way to glorify Islam. I want you to watch another excerpt from the film. This boy is called Zenola. He blew himself up, killing six. This boy is called Sadik. He killed 22. This boy is called Messoud. He killed 28. The Taliban are running suicide schools, preparing a generation of boys for atrocities against civilians. Do you want to carry out a suicide attack? Boy : I would love to. But only if I get permission from my dad. When I look at suicide bombers younger than me, or my age, I get so inspired by their terrific attacks. SOC : What blessing would you get from carrying out a suicide attack? Boy : On the day of judgment, God will ask me,”Why did you do that?”I will answer,”My Lord! Only to make you happy! I have laid down my life fighting the infidels.”Then God will look at my intention. If my intention was to eradicate evil for Islam, then I will be rewarded with paradise. Singer : On the day of judgment My God will call me My body will be put back together And God will ask me why I did this SOC : I leave you all with this thought : If you grew up in these circumstances, faced with these choices, would you choose to live in this world or in the glorious afterlife? As one Taliban recruiter told me,”There will always be sacrificial lambs in this war.”Thank you.

Imagine spending seven years at MIT and research laboratories, only to find out that you ’ re a performance artist. I ’ m also a software engineer, and I make lots of different kinds of art with the computer. And I think the main thing that I ’ m interested in is trying to find a way of making the computer into a personal mode of expression. And many of you out there are the heads of Macromedia and Microsoft, and in a way those are my bane : I think there ’ s a great homogenizing force that software imposes on people and limits the way they think about what ’ s possible on the computer. Of course, it ’ s also a great liberating force that makes possible, you know, publishing and so forth, and standards, and so on. But, in a way, the computer makes possible much more than what most people think, and my art has just been about trying to find a personal way of using the computer, and so I end up writing software to do that. Chris has asked me to do a short performance, and so I ’ m going to take just this time — maybe 10 minutes — to do that, and hopefully at the end have just a moment to show you a couple of my other projects in video form. Thank you. We ’ ve got about a minute left. I ’ d just like to show a clip from a most recent project. I did a performance with two singers who specialize in making strange noises with their mouths. And this just came off last September at ARS Electronica ; we repeated it in England. And the idea is to visualize their speech and song behind them with a large screen. We used a computer vision tracking system in order to know where they were. And since we know where their heads are, and we have a wireless mic on them that we ’ re processing the sound from, we ’ re able to create visualizations which are linked very tightly to what they ’ re doing with their speech. This will take about 30 seconds or so. He ’ s making a, kind of, cheek-flapping sound. Well, suffice it to say it ’ s not all like that, but that ’ s part of it. Thanks very much. There ’ s always lots more. I ’ m overtime, so I just wanted to say you can, if you ’ re in New York, you can check out my work at the Whitney Biennial next week, and also at Bitforms Gallery in Chelsea. And with that, I think I should give up the stage, so, thank you so much.

A few words about how I got started, and it has a lot to do with happiness, actually. When I was a very young child, I was extremely introverted and very much to myself. And, kind of as a way of surviving, I would go into my own very personal space, and I would make things. I would make things for people as a way of, you know, giving, showing them my love. I would go into these private places, and I would put my ideas and my passions into objects — and sort of learning how to speak with my hands. So, the whole activity of working with my hands and creating objects is very much connected with not only the idea realm, but also with very much the feeling realm. And the ideas are very disparate. I ’ m going to show you many different kinds of pieces, and there ’ s no real connection between one or the other, except that they sort of come out of my **brain**, and they ’ re all different sort of thoughts that are triggered by looking at life, and seeing nature and seeing objects, and just having kind of playful random thoughts about things. When I was a child, I started to explore motion. I fell in love with the way things moved, so I started to explore motion by making little flipbooks. And this is one that I did, probably like when I was around seventh grade, and I remember when I was doing this, I was thinking about that little rock there, and the pathway of the vehicles as they would fly through the air, and how the characters — — would come shooting out of the car, so, on my mind, I was thinking about the trajectory of the vehicles. And of course, when you ’ re a little kid, there ’ s always destruction. So, it has to end with this — — gratuitous violence. So that was how I first started to explore the way things moved, and expressed it. Now, when I went to college, I found myself making fairly complicated, fragile machines. And this really came about from having many different kinds of interests. When I was in high school, I loved to program computers, so I sort of liked the logical flow of events. I was also very interested in perhaps going into surgery and becoming a surgeon, because it meant working with my hands in a very focused, intense way. So, I started taking art courses, and I found a way to make sculpture that brought together my love for being very precise with my hands, with coming up with different kinds of logical flows of energy through a system. And also, working with wire — everything that I did was both a visual and a mechanical engineering decision at the same time. So, I was able to sort of exercise all of that. Now, this kind of machine is as close as I can get to painting. And it ' s full of many little trivial end points, like there ' s a little foot here that just drags around in circles and it doesn ' t really mean anything. It ' s really just for the sort of joy of its own triviality. The connection I have with engineering is the same as any other engineer, in that I love to solve problems. I love to figure things out, but the end result of what I ' m doing is really completely ambiguous. That ' s pretty ambiguous. The next piece that is going to come up is an example of a kind of machine that is fairly complex. I gave myself the problem. Since I ' m always liking to solve problems, I gave myself the problem of turning a crank in one direction, and solving all of the mechanical problems for getting this little man to walk back and forth. So, when I started this, I didn ' t have an overall plan for the machine, but I did have a sense of the gesture, and a sense of the shape and how it would occupy space. And then it was a matter of starting from one point and sort of building to that final point. That little gear there switches back and forth to change direction. And that ' s a little found object. So a lot of the pieces that I ' ve made, they involve found objects. And it really — it ' s almost like doing visual puns all the time. When I see objects, I imagine them in motion. I imagine what can be said with them. This next one here,"Machine with Wishbone,"it came about from playing with this wishbone after dinner. You know, they say, never play with your food — but I always play with things. So, I had this wishbone, and I thought, it ' s kind of like a cowboy who ' s been on his horse for too long. And I started to make him walk across the table, and I thought,"Oh, I can make a little machine that will do that."So, I made this device, linked it up, and the wishbone walks. And because the wishbone is bone — it ' s animal — it ' s sort of a point where I think we can enter into it. And that ' s the whole piece. That ' s about that big. This kind of work is also very much like puppetry, where the found object is, in a sense, the puppet, and I ' m the puppeteer at first, because I ' m playing with an object. But then I make the machine, which is sort of the stand-in for me, and it is able to achieve the action that I want. The next piece I ' ll show you is a much more conceptual thought, and it ' s a little piece called"Cory ' s Yellow Chair."I had this image in my mind, when I saw my son ' s little chair, and I saw it explode up and out. And — so the way I saw this in my mind at first, was that the pieces would explode up and out with infinite speed, and the pieces would move far out, and then they would begin to be pulled back with a kind of a gravitational feel, to the point where they would approach infinite speed back to the center. And they would coalesce for just a moment, so you could perceive that there was a chair there. For me, it ' s kind of a feeling about the fleetingness of the present moment, and I wanted to express that. Now, the machine is — in this case, it ' s a real approximation of that, because obviously you can ' t move physical matter infinitely with infinite speed and have it stop instantaneously. This whole thing is about four feet wide, and the chair itself is only about a few inches. Now, this is a funny sort of conceptual thing, and yesterday we were talking about Danny Hillis '"10, 000 Year Clock."So, we have a motor here on the left, and it goes through a gear train. There are 12 pairs of 50:1 reductions, so that means that the final speed of that gear on the end is so slow that it would take two trillion years to turn once. So I ' ve invented it in concrete, because it doesn ' t really matter. Because it could run all the time. Now, a completely different thought. I ' m always imagining myself in different situations. I ’ m imagining myself as a machine. What would I love? I would love to be bathed in oil. So, this machine does nothing but just bathe itself in oil. And it ’ s really, just sort of — for me, it was just really about the lusciousness of oil. And then, I got a call from a friend who wanted to have a show of erotic art, and I didn ’ t have any pieces. But when she suggested to be in the show, this piece came to mind. So, it ’ s sort of related, but you can see it ’ s much more overtly erotic. And this one I call”Machine with Grease.”It ’ s just continually ejaculating, and it ’ s — — this is a happy machine, I ’ ll tell you. It ’ s definitely happy. From an engineering point of view, this is just a little four-bar linkage. And then again, this is a found object, a little fan that I found. And I thought, what about the gesture of opening the fan, and how simply could I state something. And, in a case like this, I ’ m trying to make something which is clear but also not suggestive of any particular kind of animal or plant. For me, the process is very important, because I ’ m inventing machines, but I ’ m also inventing tools to make machines, and the whole thing is all sort of wrapped up from the beginning. So this is a little wire-bending tool. After many years of bending gears with a pair of pliers, I made that tool, and then I made this other tool for sort of centering gears very quickly — sort of developing my own little world of technology. My life completely changed when I found a spot welder. And that was that tool. It completely changed what I could do. Now here, I ’ m going to do a very poor job of silver soldering. This is not the way they teach you to silver solder when you ’ re in school. I just like, throw it in. I mean, real jewelers put little bits of solder in. So, that ’ s a finished gear. When I moved to Boston, I joined a group called the World Sculpture Racing Society. And the idea, their premise was that we wanted to show pieces of sculpture on the street, and there ’ d be no subjective decision about what was the best. It would be — whatever came across the finish line first would be the winner. So I made — this is my first racing sculpture, and I thought,”Oh, I ’ m going to make a cart, and I ’ m going to have it — I ’ m going to have my hand writing ’ faster, ’ so as I run down the street, the cart ’ s going to talk to me and it ’ s going to go, ’ Faster, faster! ’”So, that ’ s what it does. But then in the end, what I decided was every time you finish writing the word, I would stop and I would give the card to somebody on the side of the road. So I would never win the race because I ’ m always stopping. But I had a lot of fun. Now, I only have two and a half minutes — I ’ m going to play this. This is a piece that, for me, is in some ways the most complete kind of piece. Because when I was a kid, I also played a lot of guitar. And when I had this thought, I was imagining that I would make — I would have a whole machine theater evening, where I would — you would have an audience, the curtain would open, and you ’ d be entertained by machines on stage. So, I imagined a very simple gestural dance that would be between a machine and just a very simple chair, and... When I ’ m making these pieces, I ’ m always trying to find a point where I ’ m saying something very clearly and it ’ s very simple, but also at the same time it ’ s very ambiguous. And I think there ’ s a point between simplicity and ambiguity which can allow a viewer to perhaps take something from it. And that leads me to the thought that all of these pieces start off in my own mind, in my heart, and I do my best at finding ways to express them with materials, and it always feels really crude. It ’ s always a struggle, but somehow I manage to sort of get this thought out into an object, and then it ’ s there, OK. It means nothing at all. The object itself just means nothing. Once it ’ s perceived, and someone brings it into their own mind, then there ’ s a cycle that has been completed. And to me, that ’ s the most important thing because, ever since being a kid, I ’ ve wanted to communicate my passion and love. And that means the complete cycle of coming from inside, out to the physical, to someone perceiving it. So I

’ ll just let this chair come down. Thank you.

Text Sample 608: NEG Dim 4 – 2004 – Score 3.00 – 2004/t000064.txt

This is called Hooked on a Feeling : The Pursuit of Happiness and Human Design. I put up a somewhat dour Darwin, but a very happy chimp up there. My first point is that the pursuit of happiness is obligatory. Man wishes to be happy, only wishes to be happy, and cannot wish not to be so. We are wired to pursue happiness, not only to enjoy it, but to want more and more of it. So given that that ’ s true, how good are we at increasing our happiness? Well, we certainly try. If you look on the Amazon site, there are over 2, 000 titles with advice on the seven habits, the nine choices, the 10 secrets, the 14, 000 thoughts that are supposed to bring happiness. Now another way we try to increase our happiness is we medicate ourselves. And so there ’ s over 120 million prescriptions out there for antidepressants. Prozac was really the first absolute blockbuster drug. It was clean, efficient, there was no high, there was really no danger, it had no street value. In 1995, illegal drugs were a $400 billion business, representing eight percent of world trade, roughly the same as gas and oil. These routes to happiness haven ’ t really increased happiness very much. One problem that ’ s happening now is, although the rates of happiness are about as flat as the surface of the moon, depression and anxiety are rising. Some people say this is because we have better diagnosis, and more people are being found out. It isn ’ t just that. We ’ re seeing it all over the world. In the United States right now there are more suicides than homicides. There is a rash of suicide in China. And the World Health Organization predicts by the year 2020 that depression will be the second largest cause of disability. Now the good news here is that if you take surveys from around the world, we see that about three quarters of people will say they are at least pretty happy. But this does not follow any of the usual trends. For example, these two show great growth in income, absolutely flat happiness curves. My field, the field of psychology, hasn ’ t done a whole lot to help us move forward in understanding human happiness. In part, we have the legacy of Freud, who was a pessimist, who said that pursuit of happiness is a doomed quest, is propelled by infantile aspects of the individual that can never be met in reality. He said,”One feels inclined to say that the intention that man should be happy is not included in the plan of creation.”So the ultimate goal of psychoanalytic psychotherapy was really what Freud called ordinary misery. And Freud in part reflects the anatomy of the human emotion system — which is that we have both a positive and a negative system, and our negative system is extremely sensitive. So for example, we ’ re born loving the taste of something sweet and reacting aversively to the taste of something bitter. We also find that people are more averse to losing than they are happy to gain. The formula for a happy marriage is five positive remarks, or interactions, for every one negative. And that ’ s how powerful the one negative is. Especially expressions of contempt or disgust, well you really need a lot of positives to upset that. I also put in here the stress response. We ’ re wired for dangers that are immediate, that are physical, that are imminent, and so our body goes into an incredible reaction where endogenous opioids come in. We have a system that is really ancient, and really there for physical danger. And so over time, this becomes a stress response, which has enormous effects on the body. Cortisol floods the **brain** ; it destroys hippocampal cells and memory, and can lead to all kinds of health problems. But unfortunately, we need this system in part. If we were only governed by pleasure we would not survive. We really have two command posts. Emotions are short-lived intense responses to challenge and to opportunity. And each one of them allows us to click into alternate selves that tune in, turn on, drop out thoughts, perceptions, feelings and memories. We tend to think of emotions as just feelings. But in fact, emotions are an all-systems alert that change what we remember, what kind of decisions we make, and how we perceive things. So let me go forward to the new science of happiness. We ’ ve come away from the Freudian gloom, and people are now actively studying this. And one of the key points in the science of happiness is that happiness and unhappiness are not endpoints of a single continuum. The Freudian model is really one continuum that, as you get less miserable, you get happier. And that isn ’ t true — when you get less miserable, you get less miserable. And that happiness is a whole other end of the equation. And it ’ s been missing. It ’ s been missing from psychotherapy. So when people ’ s symptoms go away, they tend to recur, because there isn ’ t a sense of the other half — of what pleasure, happiness, compassion, gratitude, what are the positive emotions. And of course we know this intuitively, that happiness is not just the absence of misery. But somehow it was not put forward until very recently, seeing these as two parallel systems. So that the body can both look for opportunity and also protect itself from danger, at the same time. And they ’ re sort of two reciprocal and dynamically interacting systems. People have also wanted to deconstruct. We use this word”happy,”and it ’ s this very large umbrella of a term. And then three emotions for which there are no English words : fiero, which is the pride in accomplishment of a challenge ; schadenfreude, which is happiness in another ’ s misfortune, a malicious pleasure ; and naches, which is a pride and joy in one ’ s children. Absent from this list, and absent from any discussions of happiness, are happiness in another ’ s happiness. We don ’ t seem to have a word for that. We are very sensitive to the negative, but it is in part offset by the fact that we have a positivity. We ’ re also born pleasure-seekers. Babies love the taste of sweet and hate the taste of bitter. They love to touch smooth surfaces rather than rough ones. They like to look at beautiful faces rather than plain faces. They like to listen to consonant melodies instead of dissonant melodies. Babies really are born with a lot of innate pleasures. There was once a statement made by a psychologist that said that 80 percent of the pursuit of happiness is really just about the genes, and it ’ s as difficult to become happier as it is to become taller. That ’ s nonsense. There is a decent contribution to happiness from the genes — about 50 percent — but there is still that 50 percent that is unaccounted for. Let ’ s just go into the **brain** for a moment, and see where does happiness arise from in evolution. We have basically at least two systems here, and they both are very ancient. One is the reward system, and that ’ s fed by the chemical dopamine. And it starts in the ventral tegmental area. It goes to the nucleus accumbens, all the way up to the prefrontal cortex, orbital frontal cortex, where decisions are made, high level. This was originally seen as a system that was the pleasure system of the **brain**. In the 1950s, Olds and Milner put electrodes into the **brain** of a rat. And the rat would just keep pressing that bar thousands and thousands and thousands of times. It wouldn ’ t eat. It wouldn ’ t sleep. It wouldn ’ t have sex. It wouldn ’ t do anything but press this bar. So they assumed this must be, you know, the **brain** ’ s orgasmatron. It turned out that it wasn ’ t, that it really is a system of motivation, a system of wanting. It gives objects what ’ s called incentive salience. It makes something look so attractive that you just have to go after it. That ’ s something different from the system that is the pleasure system, which simply says,”I like this.”The pleasure system, as you see, which is the internal opiates, there is a hormone oxytocin, is widely spread throughout the **brain**. Dopamine system, the wanting system, is much more centralized. The other thing about positive emotions is that they have a universal signal. And we see here the smile. And the universal signal is not just raising the corner of the lips to the zygomatic major. It ' s also crinkling the outer corner of the eye, the orbicularis oculi. So you see, even 10-month-old babies, when they see their mother, will show this particular kind of smile. Extroverts use it more than introverts. People who are relieved of depression show it more after than before. So if you want to unmask a true look of happiness, you will look for this expression. Our pleasures are really ancient. And we learn, of course, many, many pleasures, but many of them are base. And one of them, of course, is biophilia — that we have a response to the natural world that ' s very profound. Very interesting studies done on people recovering from surgery, who found that people who faced a brick wall versus people who looked out on trees and nature, the people who looked out on the brick wall were in the hospital longer, needed more medication, and had more medical complications. There is something very restorative about nature, and it ' s part of how we are tuned. Humans, particularly so, we ' re very imitative creatures. And we imitate from almost the second we are born. Here is a three-week-old baby. And if you stick your tongue out at this baby, the baby will do the same. We are social beings from the beginning. And even studies of cooperation show that cooperation between individuals lights up reward centers of the **brain**. One problem that psychology has had is instead of looking at this intersubjectivity — or the importance of the social **brain** to humans who come into the world helpless and need each other tremendously — is that they focus instead on the self and self-esteem, and not self-other. It ' s sort of"me,"not"we."And I think this has been a really tremendous problem that goes against our biology and nature, and hasn ' t made us any happier at all. Because when you think about it, people are happiest when in flow, when they ' re absorbed in something out in the world, when they ' re with other people, when they ' re active, engaged in sports, focusing on a loved one, learning, having sex, whatever. They ' re not sitting in front of the mirror trying to figure themselves out, or thinking about themselves. These are not the periods when you feel happiest. The other thing is, that a piece of evidence is, is if you look at computerized text analysis of people who commit suicide, what you find there, and it ' s quite interesting, is use of the first person singular —"I,""me,""my,"not"we"and"us"— and the letters are less hopeless than they are really alone. And being alone is very unnatural to the human. There is a profound need to belong. But there are ways in which our evolutionary history can really trip us up. Because, for example, the genes don ' t care whether we ' re happy, they care that we replicate, that we pass our genes on. So for example we have three systems that underlie reproduction, because it ' s so important. There ' s lust, which is just wanting to have sex. And that ' s really mediated by the sex hormones. Romantic attraction, that gets into the desire system. And that ' s dopamine-fed. And that ' s,"I must have this one person."There ' s attachment, which is oxytocin, and the opiates, which says,"This is a long-term bond."See the problem is that, as humans, these three can separate. So a person can be in a long term attachment, become romantically infatuated with someone else, and want to have sex with a third person. The other way in which our genes can sometimes lead us astray is in social status. We are very acutely aware of our social status and always seek to further and increase it. Now in the animal world, there is only one way to increase status, and that ' s dominance. I seize command by physical prowess, and I keep it by beating my chest, and you make submissive gestures. Now, the human has a whole other way to rise to the top, and that is a prestige route, which is freely conferred. Someone has expertise and knowledge, and knows how to do things, and we give that person status. And that ' s clearly the way for us to create many more niches of status so that people don ' t have to be lower on the status hierarchy as they are in the animal world. The data isn ’ t terribly supportive of money buying happiness. But it ’ s not irrelevant. So if you look at questions like this, life satisfaction, you see life satisfaction going up with each rung of income. You see mental distress going up with lower income. So clearly there is some effect. But the effect is relatively small. And one of the problems with money is materialism. What happens when people pursue money too avidly, is they forget about the real basic pleasures of life. So we have here, this couple.”Do you think the less- fortunate are having better sex?”And then this kid over here is saying,”Leave me alone with my toys.”So one of the things is that it really takes over. That whole dopamine-wanting system takes over and derails from any of the pleasure system. Maslow had this idea back in the 1950s that as people rise above their biological needs, as the world becomes safer and we don ’ t have to worry about basic needs being met — our biological system, whatever motivates us, is being satisfied — we can rise above them, to think beyond ourselves toward self-actualization or transcendence, and rise above the materialist. So to just quickly conclude with some brief data that suggests this might be so. One is people who underwent what is called a quantum change : they felt their life and their whole values had changed. And sure enough, if you look at the kinds of values that come in, you see wealth, adventure, achievement, pleasure, fun, be respected, before the change, and much more post-materialist values after. Women had a whole different set of value shifts. But very similarly, the only one that survived there was happiness. They went from attractiveness and happiness and wealth and self-control to generosity and forgiveness. I end with a few quotes.”There is only one question : How to love this world?”And Rilke,”If your daily life seems poor, do not blame it ; blame yourself. Tell yourself that you are not poet enough to call forth its riches.””First, say to yourself what you would be. Then do what you have to do.”Thank you.

Text Sample 609: NEG Dim 4 – 2008 – Score -1.00 – 2008/t000158.txt

Unless we do something to prevent it, over the next 40 years weâ□□re facing an epidemic of neurologic diseases on a global scale. A cheery thought. On this map, every country thatâ□□s colored blue has more than 20 percent of its population over the age of 65. This is the world we live in. And this is the world your children will live in. For 12, 000 years, the distribution of ages in the human population has looked like a pyramid, with the oldest on top. Itâ□□s already flattening out. By 2050, itâ□□s going to be a column and will start to invert. This is why itâ□□s happening. The average lifespanâ□□s more than doubled since 1840, and itâ□□s increasing currently at the rate of about five hours every day. And this is why thatâ□□s not entirely a good thing : because over the age of 65, your risk of getting Alzheimerâ□□s or Parkinsonâ□□s disease will increase exponentially. By 2050, thereâ□□ll be about 32 million people in the United States over the age of 80, and unless we do something about it, half of them will have Alzheimerâ□□s disease and three million more will have Parkinsonâ□□s disease. Right now, those and other neurologic diseases â□□ for which we have no cure or prevention â□□ cost about a third of a trillion dollars a year. It will be well over a trillion dollars by 2050. Alzheimerâ□□s disease starts when a protein that should be folded up properly misfolds into a kind of demented origami. So one approach weâ□□re taking is to try to design drugs that function like molecular Scotch tape, to hold the protein into its proper shape. That would keep it from forming the tangles that seem to kill large sections of the **brain** when they do. Interestingly enough, other neurologic diseases which affect very different parts of the **brain** also show tangles of misfolded protein, which suggests that the approach might be a general one, and might be used to cure many neurologic diseases, not just Alzheimerâs disease. Thereâs also a fascinating connection to cancer here, because people with neurologic diseases have a very low incidence of most cancers. And this is a connection that most people arenât pursuing right now, but which weâre fascinated by. Most of the important and all of the creative work in this area is being funded by private philanthropies. And thereâs tremendous scope for additional private help here, because the government has dropped the ball on much of this, Iâm afraid. In the meantime, while weâre waiting for all these things to happen, hereâs what you can do for yourself. If you want to lower your risk of Parkinsonâs disease, caffeine is protective to some extent ; nobody knows why. Head injuries are bad for you. They lead to Parkinsonâs disease. And the Avian Flu is also not a good idea. As far as protecting yourself against Alzheimerâs disease, well, it turns out that fish oil has the effect of reducing your risk for Alzheimerâs disease. You should also keep your blood pressure down, because chronic high blood pressure is the biggest single risk factor for Alzheimerâs disease. Itâs also the biggest risk factor for glaucoma, which is just Alzheimerâs disease of the eye. And of course, when it comes to cognitive effects,"use it or lose it"applies, so you want to stay mentally stimulated. But hey, youâre listening to me. So youâve got that covered. And one final thing. Wish people like me luck, okay? Because the clock is ticking for all of us. Thank you.

I was here about four years ago, talking about the relationship of design and happiness. At the very end of it, I showed a list under that title. I learned very few things in addition since â but made a whole number of them into projects since. These are inflatable monkeys in every city in Scotland :"Everybody always thinks they are right."They were combined in the media."Drugs are fun in the beginning but become a drag later on."We ' re doing changing media. This is a projection that can see the viewer as the viewer walks by. You can ' t help but actually ripping that spider web apart. All of these things are pieces of graphic design. We do them for our clients. They are commissioned. I would never have the money to actually pay for the installment or pay for all the billboards or the production of these, so there ' s always a client attached to them. These are 65, 000 coat hangers in a street that ' s lined with fashion stores."Worrying solves nothing.""Money does not make me happy"appeared first as double-page spreads in a magazine. The printer lost the file, didn ' t tell us. When the magazine â actually, when I got the subscription â it was 12 following pages. It said,"Money does does make me happy."And a friend of mine in Austria felt so sorry for me that he talked the largest casino owner in Linz into letting us wrap his building. So this is the big pedestrian zone in Linz. It just says"Money,"and if you look down the side street, it says,"does not make me happy."We had a show that just came down last week in New York. We steamed up the windows permanently, and every hour we had a different designer come in and write these things that they ' ve learned into the steam in the window. Everybody participated â Milton Glaser, Massimo Vignelli. Singapore was quite in discussion. This is a little spot that we filmed there that ' s to be displayed on the large JumboTrons in Singapore. And, of course, it ' s one that ' s dear to my heart, because all of these sentiments â some banal, some a bit more profound â all originally had come out of my diary. And I do go often into the diary and check if I wanted to change something about the situation. If it ’ s â see it for a long enough time, I actually do something about it. And the very last one is a billboard. This is our roof in New York, the roof of the studio. This is newsprint plus stencils that lie on the newsprint. We let that lie around in the sun. As you all know, newsprint yellows significantly in the sun. After a week, we took the stencils and the leaves off, shipped the newsprints to Lisbon to a very sunny spot, so on day one the billboard said,”Complaining is silly. Either act or forget.”Three days later it faded, and a week later, no more complaining anywhere. Thank you so much.

Good morning. Let ’ s look for a minute at the greatest icon of all, Leonardo da Vinci. We ’ re all familiar with his fantastic work â his drawings, his paintings, his inventions, his writings. But we do not know his face. Thousands of books have been written about him, but there ’ s controversy, and it remains, about his looks. Even this well-known portrait is not accepted by many art historians. So, what do you think? Is this the face of Leonardo da Vinci or isn ’ t it? Let ’ s find out. Leonardo was a man that drew everything around him. He drew people, anatomy, plants, animals, landscapes, buildings, water, everything. But no faces? I find that hard to believe. His contemporaries made faces, like the ones you see here â en face or three-quarters. So, surely a passionate drawer like Leonardo must have made self-portraits from time to time. So let ’ s try to find them. I think that if we were to scan all of his work and look for self-portraits, we would find his face looking at us. So I looked at all of his drawings, more than 700, and looked for male portraits. There are about 120, you see them here. Which ones of these could be self-portraits? Well, for that they have to be done as we just saw, en face or three-quarters. So we can eliminate all the profiles. It also has to be sufficiently detailed. So we can also eliminate the ones that are very vague or very stylized. And we know from his contemporaries that Leonardo was a very handsome, even beautiful man. So we can also eliminate the ugly ones or the caricatures. And look what happens â only three candidates remain that fit the bill. And here they are. Yes, indeed, the old man is there, as is this famous pen drawing of the Homo Vitruvianus. And lastly, the only portrait of a male that Leonardo painted,”The Musician.”Before we go into these faces, I should explain why I have some right to talk about them. I ’ ve made more than 1, 100 portraits myself for newspapers, over the course of 300 â 30 years, sorry, 30 years only. But there are 1, 100, and very few artists have drawn so many faces. So I know a little about drawing and analyzing faces. OK, now let ’ s look at these three portraits. And hold onto your seats, because if we zoom in on those faces, remark how they have the same broad forehead, the horizontal eyebrows, the long nose, the curved lips and the small, well-developed chin. I couldn ’ t believe my eyes when I first saw that. There is no reason why these portraits should look alike. All we did was look for portraits that had the characteristics of a self-portrait, and look, they are very similar. Now, are they made in the right order? The young man should be made first. And as you see here from the years that they were created, it is indeed the case. They are made in the right order. What was the age of Leonardo at the time? Does that fit? Yes, it does. He was 33, 38 and 63 when these were made. So we have three pictures, potentially of the same person of the same age as Leonardo at the time. But how do we know it ’ s him, and not someone else? Well, we need a reference. And here ’ s the only picture of Leonardo that ’ s widely accepted. It ’ s a statue made by Verrocchio,

of David, for which Leonardo posed as a boy of 15. And if we now compare the face of the statue, with the face of the musician, you see the very same features again. The statue is the reference, and it connects the identity of Leonardo to those three faces. Ladies and gentlemen, this story has not yet been published. It ' s only proper that you here at TED hear and see it first. The icon of icons finally has a face. Here he is : Leonardo da Vinci.

Text Sample 612: NEG Dim 4 – 2015 – Score -3.00 – 2015/t001484.txt
As a singer-songwriter, people often ask me about my influences or, as I like to call them, my sonic lineages. And I could easily tell you that I was shaped by the jazz and hip hop that I grew up with, by the Ethiopian heritage of my ancestors, or by the 1980s **pop** on my childhood radio stations. But beyond genre, there is another question : how do the sounds we hear every day influence the music that we make? I believe that everyday soundscape can be the most unexpected inspiration for songwriting, and to look at this idea a little bit more closely, I ' m going to talk today about three things : nature, language and silence — or rather, the impossibility of true silence. And through this I hope to give you a sense of a world already alive with musical expression, with each of us serving as active participants, whether we know it or not. I ' m going to start today with nature, but before we do that, let ' s quickly listen to this snippet of an opera singer warming up. Here it is. It ' s beautiful, isn ' t it? Gotcha! That is actually not the sound of an opera singer warming up. That is the sound of a bird slowed down to a pace that the human ear mistakenly recognizes as its own. It was released as part of Peter Szke ' s 1987 Hungarian recording”The Unknown Music of Birds,”where he records many birds and slows down their pitches to reveal what ' s underneath. Let ' s listen to the full-speed recording. Now, let ' s hear the two of them together so your **brain** can juxtapose them. It ' s incredible. Perhaps the techniques of opera singing were inspired by birdsong. As humans, we intuitively understand birds to be our musical teachers. In Ethiopia, birds are considered an integral part of the origin of music itself. The story goes like this : 1, 500 years ago, a young man was born in the Empire of Aksum, a major trading center of the ancient world. His name was Yared. When Yared was seven years old his father died, and his mother sent him to go live with an uncle, who was a priest of the Ethiopian Orthodox tradition, one of the oldest churches in the world. Now, this tradition has an enormous amount of scholarship and learning, and Yared had to study and study and study and study, and one day he was studying under a tree, when three birds came to him. One by one, these birds became his teachers. They taught him music — scales, in fact. And Yared, eventually recognized as Saint Yared, used these scales to compose five volumes of chants and hymns for worship and celebration. And he used these scales to compose and to create an indigenous musical notation system. And these scales evolved into what is known as kiit, the unique, pentatonic, five-note, modal system that is very much alive and thriving and still evolving in Ethiopia today. Now, I love this story because it ' s true at multiple levels. Saint Yared was a real, historical figure, and the natural world can be our musical teacher. And we have so many examples of this : the Pygmies of the Congo tune their instruments to the pitches of the birds in the forest around them. Musician and natural soundscape expert Bernie Krause describes how a healthy environment has animals and insects taking up low, medium and high-frequency bands, in exactly the same way as a symphony does. And countless works of music were inspired by bird and forest song. Yes, the natural world can be our cultural teacher. So let ' s go now to the

uniquely human world of language. Every language communicates with pitch to varying degrees, whether it ’ s Mandarin Chinese, where a shift in melodic inflection gives the same phonetic syllable an entirely different meaning, to a language like English, where a raised pitch at the end of a sentence... implies a question? As an Ethiopian-American woman, I grew up around the language of Amharic, Amharia. It was my first language, the language of my parents, one of the main languages of Ethiopia. And there are a million reasons to fall in love with this language : its depth of poetics, its double entendres, its wax and gold, its humor, its proverbs that illuminate the wisdom and **follies** of life. But there ’ s also this melodicism, a musicality built right in. And I find this distilled most clearly in what I like to call emphatic language — language that ’ s meant to highlight or underline or that springs from surprise. Take, for example, the word :”indey.”Now, if there are Ethiopians in the audience, they ’ re probably chuckling to themselves, because the word means something like”No!”or”How could he?”or”No, he didn ’ t.”It kind of depends on the situation. But when I was a kid, this was my very favorite word, and I think it ’ s because it has a pitch. It has a melody. You can almost see the shape as it springs from someone ’ s mouth.”Indey”— it dips, and then raises again. And as a musician and composer, when I hear that word, something like this is floating through my mind. Or take, for example, the phrase for”It is right”or”It is correct”—”Lickih nehu... Lickih nehu.”It ’ s an affirmation, an agreement.”Lickih nehu.”When I hear that phrase, something like this starts rolling through my mind. And in both of those cases, what I did was I took the melody and the phrasing of those words and phrases and I turned them into musical parts to use in these short compositions. And I like to write bass lines, so they both ended up kind of as bass lines. Now, this is based on the work of Jason Moran and others who work intimately with music and language, but it ’ s also something I ’ ve had in my head since I was a kid, how musical my parents sounded when they were speaking to each other and to us. It was from them and from Amharia that I learned that we are awash in musical expression with every word, every sentence that we speak, every word, every sentence that we receive. Perhaps you can hear it in the words I ’ m speaking even now. Finally, we go to the 1950s United States and the most seminal work of 20th century avant-garde composition : John Cage ’ s”4:33,”written for any instrument or combination of instruments. The musician or musicians are invited to walk onto the stage with a stopwatch and open the score, which was actually purchased by the Museum of Modern Art — the score, that is. And this score has not a single note written and there is not a single note played for four minutes and 33 seconds. And, at once enraging and enrapturing, Cage shows us that even when there are no strings being plucked by fingers or hands hammering piano keys, still there is music, still there is music, still there is music. And what is this music? It was that sneeze in the back. It is the everyday soundscape that arises from the audience themselves : their coughs, their sighs, their rustles, their whispers, their sneezes, the room, the wood of the floors and the walls expanding and contracting, creaking and groaning with the heat and the cold, the pipes clanking and contributing. And controversial though it was, and even controversial though it remains, Cage ’ s point is that there is no such thing as true silence. Even in the most silent environments, we still hear and feel the sound of our own heartbeats. The world is alive with musical expression. We are already immersed. Now, I had my own moment of, let ’ s say, remixing John Cage a couple of months ago when I was standing in front of the stove cooking lentils. And it was late one night and it was time to stir, so I lifted the lid off the cooking pot, and I placed it onto the kitchen counter next to me, and it started to roll back and forth making this sound. And it stopped me cold. I thought,”What a weird, cool swing that cooking pan lid has.”So when the lentils were ready and eaten, I hightailed it to my backyard studio, and I made this. Now, John Cage wasn ’ t instructing musicians to mine the soundscape for sonic textures to turn into music. He was saying that on its own, the environment is musically generative, that it is generous, that it is fertile, that we are already immersed. Musician, music researcher, surgeon and human hearing expert Charles Limb is a professor at Johns Hopkins University and he studies music and the **brain**. And he has a theory that it is possible — it is possible — that the human auditory system actually evolved to hear music, because it is so much more complex than it needs to be for language alone. And if that ’ s true, it means that we ’ re hard-wired for music, that we can find it anywhere, that there is no such thing as a musical desert, that we are permanently hanging out at the oasis, and that is marvelous. We can add to the soundtrack, but it ’ s already playing. And it doesn ’ t mean don ’ t study music. Study music, trace your sonic lineages and enjoy that exploration. But there is a kind of sonic lineage to which we all belong. So the next time you are seeking percussion inspiration, look no further than your tires, as they roll over the unusual grooves of the freeway, or the top-right burner of your stove and that strange way that it clicks as it is preparing to light. When seeking melodic inspiration, look no further than dawn and dusk avian orchestras or to the natural lilt of emphatic language. We are the audience and we are the composers and we take from these pieces we are given. We make, we make, we make, we make, knowing that when it comes to nature or language or soundscape, there is no end to the inspiration — if we are listening. Thank you.

Text Sample 613: NEG Dim 4 – 2015 – Score 1.00 – 2015/t001604.txt

My first love was for the night sky. Love is complicated. You ’ re looking at a fly-through of the Hubble Space Telescope Ultra-Deep Field, one of the most distant images of our universe ever observed. Everything you see here is a galaxy, comprised of billions of stars each. And the farthest galaxy is a trillion, trillion kilometers away. As an astrophysicist, I have the awesome privilege of studying some of the most exotic objects in our universe. The objects that have captivated me from first crush throughout my career are supermassive, hyperactive black holes. Weighing one to 10 billion times the mass of our own sun, these galactic black holes are devouring material, at a rate of upwards of 1, 000 times more than your”average”supermassive black hole. These two characteristics, with a few others, make them quasars. At the same time, the objects I study are producing some of the most powerful particle streams ever observed. These narrow streams, called jets, are moving at 99. 99 percent of the speed of light, and are pointed directly at the Earth. These jetted, Earth-pointed, hyperactive and supermassive black holes are called blazars, or blazing quasars. What makes blazars so special is that they ’ re some of the universe ’ s most efficient particle accelerators, transporting incredible amounts of energy throughout a galaxy. Here, I ’ m showing an artist ’ s conception of a blazar. The dinner plate by which material falls onto the black hole is called the accretion disc, shown here in blue. Some of that material is slingshotted around the black hole and accelerated to insanely high speeds in the jet, shown here in white. Although the blazar system is rare, the process by which nature pulls in material via a disk, and then flings some of it out via a jet, is more common. We ’ ll eventually zoom out of the blazar system to show its approximate relationship to the larger galactic context. Beyond the cosmic accounting of what goes in to what goes out, one of the hot topics in blazar astrophysics right now is where the highest-energy jet emission comes from. In this image, I ’ m interested in where this white blob forms and if, as a result, there ’ s any relationship between the jet and the accretion disc material. Clear answers to this question were almost completely inaccessible until 2008, when NASA launched a new telescope that better detects gamma ray light — that is, light with energies a million times higher than your standard x-ray scan. I simultaneously compare variations between the gamma ray light data and the visible light data from day to day and year to year, to better localize these gamma ray blobs. My research shows that in some instances, these blobs form much closer to the black hole than we initially thought. As we more confidently localize where these gamma ray blobs are forming, we can better understand how jets are being accelerated, and ultimately reveal the dynamic processes by which some of the most fascinating objects in our universe are formed. This all started as a love story. And it still is. This love transformed me from a curious, stargazing young girl to a professional astrophysicist, hot on the heels of celestial discovery. Who knew that chasing after the universe would ground me so deeply to my mission here on Earth. Then again, when do we ever know where love ’ s first flutter will truly take us. Thank you.

Text Sample 614: NEG Dim 4 – 2015 – Score 1.00 – 2015/t001603.txt
The **brain** is an amazing and complex organ. And while many people are fascinated by the **brain**, they can ’ t really tell you that much about the properties about how the **brain** works because we don ’ t teach neuroscience in schools. And one of the reasons why is that the equipment is so complex and so expensive that it ’ s really only done at major universities and large institutions. And so in order to be able to access the **brain**, you really need to dedicate your life and spend six and a half years as a graduate student just to become a neuroscientist to get access to these tools. And that ’ s a shame because one out of five of us, that ’ s 20 percent of the entire world, will have a neurological disorder. And there are zero cures for these diseases. And so it seems that what we should be doing is reaching back earlier in the eduction process and teaching students about neuroscience so that in the future, they may be thinking about possibly becoming a **brain** scientist. When I was a graduate student, my lab mate Tim Marzullo and myself, decided that what if we took this complex equipment that we have for studying the **brain** and made it simple enough and affordable enough that anyone that you know, an amateur or a high school student, could learn and actually participate in the discovery of neuroscience. And so we did just that. A few years ago, we started a company called Backyard **Brains** and we make DIY neuroscience equipment and I brought some here tonight, and I want to do some demonstrations. You guys want to see some? So I need a volunteer. So right before — what is your name? Sam Kelly : Sam. Greg Gage : All right, Sam, I ’ m going to record from your **brain**. Have you had this before? SK : No. GG : I need you to stick out your arm for science, roll up your sleeve a bit, So what I ’ m going to do, I ’ m putting electrodes on your arm, and you ’ re probably wondering, I just said I ’ m going to record from your **brain**, what am I doing with your arm? Well, you have about 80 billion neurons inside your **brain** right now. They ’ re sending electrical messages back and forth, and chemical messages. But some of your neurons right here in your motor cortex are going to send messages down when you move your arm like this. They ’ re going to go down across your corpus callosum, down onto your spinal cord to your lower motor neuron out to your muscles here, and that electrical discharge is going to be picked up by these electrodes right here and we ’ re

going to be able to listen to exactly what your **brain** is going to be doing. So I ’ m going to turn this on for a second. Have you ever heard what your **brain** sounds like? SK : No. GG : Let ’ s try it out. So go ahead and squeeze your hand. So what you ’ re listening to, so this is your motor units happening right here. Let ’ s take a look at it as well. So I ’ m going to stand over here, and I ’ m going to open up our app here. So now I want you to squeeze. So right here, these are the motor units that are happening from her spinal cord out to her muscle right here, and as she ’ s doing it, you ’ re seeing the electrical activity that ’ s happening here. You can even click here and try to see one of them. So keep doing it really hard. So now we ’ ve paused on one motor action potential that ’ s happening right now inside of your **brain**. Do you guys want to see some more? That ’ s interesting, but let ’ s get it better. I need one more volunteer. What is your name, sir? Miguel Goncalves : Miguel. GG : Miguel, all right. You ’ re going to stand right here. So when you ’ re moving your arm like this, your **brain** is sending a signal down to your muscles right here. I want you to move your arm as well. So your **brain** is going to send a signal down to your muscles. And so it turns out that there is a nerve that ’ s right here that runs up here that innervates these three fingers, and it ’ s close enough to the skin that we might be able to stimulate that so that what we can do is copy your **brain** signals going out to your hand and inject it into your hand, so that your hand will move when your **brain** tells your hand to move. So in a sense, she will take away your free will and you will no longer have any control over this hand. You with me? So I just need to hook you up. So I ’ m going to find your ulnar nerve, which is probably right around here. You don ’ t know what you ’ re signing up for when you come up. So now I ’ m going to move away and we ’ re going to plug it in to our human-to-human interface over here. Okay, so Sam, I want you to squeeze your hand again. Do it again. Perfect. So now I ’ m going to hook you up over here so that you get the — It ’ s going to feel a little bit weird at first, this is going to feel like a — You know, when you lose your free will, and someone else becomes your agent, it does feel a bit strange. Now I want you to relax your hand. Sam, you ’ re with me? So you ’ re going to squeeze. I ’ m not going to turn it on yet, so go ahead and give it a squeeze. So now, are you ready, Miguel? MG : Ready as I ’ ll ever be. GG : I ’ ve turned it on, so go ahead and turn your hand. Do you feel that a little bit? MG : Nope. GG : Okay, do it again? MG : A little bit. GG : A little bit? So relax. So hit it again. Oh, perfect, perfect. So relax, do it again. All right, so right now, your **brain** is controlling your arm and it ’ s also controlling his arm, so go ahead and just do it one more time. All right, so it ’ s perfect. So now, what would happen if I took over my control of your hand? And so, just relax your hand. What happens? Ah, nothing. Why not? Because the **brain** has to do it. So you do it again. All right, that ’ s perfect. Thank you guys for being such a good sport. This is what ’ s happening all across the world — electrophysiology! We ’ re going to bring on the neuro-revolution. Thank you.

Text Sample 615: NEG Dim 4 – 2019 – Score 1.00 – 2019/t002074.txt

Chris Anderson : Shep, thank you so much for coming. I think your plane landed literally two hours ago in Vancouver. Such a treat to have you. So, talk us through how do you get from Einstein ’ s equation to a black hole? Sheperd Doeleman : Over 100 years ago, Einstein came up with this geometric theory of gravity which deforms space-time. So, matter deforms space-time, and then space-time tells matter in turn how to move around it. And you can get enough matter into a small enough region that it punctures space-time, and that even light can ’ t escape, the force of gravity keeps even light inside. CA : And so, before that, the reason the Earth moves around the Sun is not because the Sun is pulling the Earth as we think, but it ’ s literally changed the shape of space so that we just sort of fall around the Sun. SD : Exactly, the geometry of space-time tells the Earth how to move around the Sun. You ’ re almost seeing a black hole puncture through space-time, and when it goes so deeply in, then there ’ s a point at which light orbits the black hole. CA : And so that ’ s, I guess, is what ’ s happening here. This is not an image, this is a computer simulation of what we always thought, like, the event horizon around the black hole. SD : Until last week, we had no idea what a black hole really looked like. The best we could do were simulations like this in supercomputers, but even here you see this ring of light, which is the orbit of photons. That ’ s where photons literally move around the black hole, and around that is this hot gas that ’ s drawn to the black hole, and it ’ s hot because of friction. All this gas is trying to get into a very small volume, so it heats up. CA : A few years ago, you embarked on this mission to try and actually image one of these things. And I guess you took — you focused on this galaxy way out there. Tell us about this galaxy. SD : This is the galaxy — we ’ re going to zoom into the galaxy M87, it ’ s 55 million light-years away. CA : Fifty-five million. SD : Which is a long way. And at its heart, there ’ s a six-and-a-half-billion- solar-mass black hole. That ’ s hard for us to really fathom, right? Six and a half billion suns compressed into a single point. And it ’ s governing some of the energetics of the center of this galaxy. CA : But even though that thing is so huge, because it ’ s so far away, to actually dream of getting an image of it, that ’ s incredibly hard. The resolution would be incredible that you need. SD : Black holes are the smallest objects in the known universe. But they have these outsize effects on whole galaxies. But to see one, you would need to build a telescope as large as the Earth, because the black hole that we ’ re looking at gives off copious radio waves. It ’ s emitting all the time. CA : And that ’ s exactly what you did. SD : Exactly. What you ’ re seeing here is we used telescopes all around the world, we synchronized them perfectly with atomic clocks, so they received the light waves from this black hole, and then we stitched all of that data together to make an image. CA : To do that the weather had to be right in all of those locations at the same time, so you could actually get a clear view. SD : We had to get lucky in a lot of different ways. And sometimes, it ’ s better to be lucky than good. In this case, we were both, I like to think. But light had to come from the black hole. It had to come through intergalactic space, through the Earth ’ s atmosphere, where water vapor can absorb it, and everything worked out perfectly, the size of the Earth at that wavelength of light, one millimeter wavelength, was just right to resolve that black hole, 55 million light-years away. The universe was telling us what to do. CA : So you started capturing huge amounts of data. I think this is like half the data from just one telescope. SD : Yeah, this is one of the members of our team, Lindy Blackburn, and he ’ s sitting with half the data recorded at the Large Millimeter Telescope, which is atop a 15, 000-foot mountain in Mexico. And what he ’ s holding there is about half a petabyte. Which, to put it in terms that we might understand, it ’ s about 5, 000 people ’ s lifetime selfie budget. CA : It ’ s a lot of data. So this was all shipped, you couldn ’ t send this over the internet. All this data was shipped to one place and the massive computer effort began to try and analyze it. And you didn ’ t really know what you were going to see coming out of this. SD : The way this technique works that we used — imagine taking an optical mirror and smashing it and putting all the shards in different places. The way a normal mirror works is the light rays bounce off the surface, which is perfect, and they focus in a certain point at the same time. We take all these recordings, and with atomic clock precision we align them perfectly, later in a supercomputer. And we recreate kind of an Earth-sized lens. And the only way to do that is to bring the data back by plane. You can ’ t beat the bandwidth of a 747 filled with hard discs. CA : And so, I guess a few weeks or a few months ago, on a computer screen somewhere, this started to come into view. This moment. SD : Well, it took a long time. CA : I mean, look at this. That was it. That was the first image. So tell us what we ’ re really looking at there. SD : I still love it. So what you ’ re seeing is that last orbit of photons. You ’ re seeing Einstein ’ s geometry laid bare. The puncture in space-time is so deep that light moves around in orbit, so that light behind the black hole, as I think we ’ ll see soon, moves around and comes to us on these parallel lines at exactly that orbit. It turns out, that orbit is the square root of 27 times just a handful of fundamental constants. It ’ s extraordinary when you think about it. CA : When... In my head, initially, when I thought of black holes, I ’ m thinking that is the event horizon, there ’ s lots of matter and light whirling around in that shape. But it ’ s actually more complicated than that. Well, talk us through this animation, because it ’ s light being lensed around it. SD : You ’ ll see here that some light from behind it gets lensed, and some light does a loop-the-loop around the entire orbit of the black hole. But when you get enough light from all this hot gas swirling around the black hole, then you wind up seeing all of these light rays come together on this screen, which is a stand-in for where you and I are. And you see the definition of this ring begin to come into shape. And that ’ s what Einstein predicted over 100 years ago. CA : Yeah, that is amazing. So tell us more about what we ’ re actually looking at here. First of all, why is part of it brighter than the rest? SD : So what ’ s happening is that the black hole is spinning. And you wind up with some of the gas moving towards us below and receding from us on the top. And just as the train whistle has a higher pitch when it ’ s coming towards you, there ’ s more energy from the gas coming towards us than going away from us. You see the bottom part brighter because the light is actually being boosted in our direction. CA : And how physically big is that? SD : Our entire solar system would fit well within that dark region. And if I may, that dark region is the signature of the event horizon. The reason we don ’ t see light from there, is that the light that would come to us from that place was swallowed by the event horizon. So that — that ’ s it. CA : And so when we think of a black hole, you think of these huge rays jetting out of it, which are pointed directly in our direction. Why don ’ t we see them? SD : This is a very powerful black hole. Not by universal standards, it ’ s still powerful, and from the north and south poles of this black hole we think that jets are coming. Now, we ’ re too close to really see all the jet structure, but it ’ s the base of those jets that are illuminating the space-time. And that ’ s what ’ s being bent around the black hole. CA : And if you were in a spaceship whirling around that thing somehow, how long would it take to actually go around it? SD : First, I would give anything to be in that spaceship. Sign me up. There—s something called the — if I can get wonky for one moment — the innermost stable circular orbit, that ’ s the innermost orbit at which matter can move around a black hole before it spirals in. And for this black hole, it ’ s going to be between three days and about a month. CA : It ’ s so powerful, it ’ s weirdly slow at one level. I mean, you wouldn ’ t even notice falling into that event horizon if you were there. SD : So you may have heard of”spaghettification,”where you fall into a black hole and the gravitational field on your feet is much stronger than on your head, so you ’ re ripped apart. This black hole is so big that you ’ re not going to become a spaghetti noodle. You ’ re just going to drift right through that event horizon. CA : So, it ’ s like a giant tornado. When Dorothy was whipped by a tornado, she ended up in Oz. Where do you end up if you fall into a black hole? SD : Vancouver. CA : Oh, my God. It

’ s the red circle, that ’ s terrifying. No, really. SD : Black holes really are the central mystery of our age, because that ’ s where the quantum world and the gravitational world come together. What ’ s inside is a singularity. And that ’ s where all the forces become unified, because gravity finally is strong enough to compete with all the other forces. But it ’ s hidden from us, the universe has cloaked it in the ultimate invisibility cloak. So we don ’ t know what happens in there. CA : So there ’ s a smaller one of these in our own galaxy. Can we go back to our own beautiful galaxy? This is the Milky Way, this is home. And somewhere in the middle of that there ’ s another one, which you ’ re trying to find as well. SD : We already know it ’ s there, and we ’ ve already taken data on it. And we ’ re working on those data right now. So we hope to have something in the near future, I can ’ t say when. CA : It ’ s way closer but also a lot smaller, maybe the similar kind of size to what we saw? SD : Right. So it turns out that the black hole in M87, that we saw before, is six and a half billion solar masses. But it ’ s so far away that it appears a certain size. The black hole in the center of our galaxy is a thousand times less massive, but also a thousand times closer. So it looks the same angular size on the sky. CA : Finally, I guess, a nod to a remarkable group of people. Who are these guys? SD : So these are only some of the team. We marveled at the resonance that this image has had. If you told me that it would be above the fold in all of these newspapers, I ’ m not sure I would have believed you, but it was. Because this is a great mystery, and it ’ s inspiring for us, and I hope it ’ s inspiring to everyone. But the more important thing is that this is just a small number of the team. We ’ re 200 people strong with 60 institutes and 20 countries and regions. If you want to build a global telescope you need a global team. And this technique that we use of linking telescopes around the world kind of effortlessly sidesteps some of the issues that divide us. And as scientists, we naturally come together to do something like this. CA : Wow, boy, that ’ s inspiring for our whole team this week. Shep, thank you so much for what you did and for coming here. SD : Thank you.

I ’ m an astronomer who builds telescopes. I build telescopes because, number one, they are awesome. But number two, I believe if you want to discover a new thing about the universe, you have to look at the universe in a new way. New technologies in astronomy â things like lenses, photographic plates, all the way up to space telescopes â each gave us new ways to see the universe and directly led to a new understanding of our place in it. But those discoveries come with a cost. It took thousands of people and 44 years to get the Hubble Space Telescope from an idea into orbit. It takes time, it takes a tolerance for failure, it takes individual people choosing every day not to give up. I know how hard that choice is because I live it. The reality of my job is that I fail almost all the time and still keep going, because that ’ s how telescopes get built. The telescope I helped build is called the faint intergalactic-medium red- shifted emission balloon, which is a mouthful, so we call it”FIREBall.”And don ’ t worry, it is not going to explode at the end of this story. I ’ ve been working on FIREBall for more than 10 years and now lead the team of incredible people who built it. FIREBall is designed to observe some of the faintest structures known : huge clouds of hydrogen gas. These clouds are giant. They are even bigger than whatever you ’ re thinking of. They are huge, huge clouds of hydrogen that we think flow into and out of galaxies. I work on FIREBall because what I really want is to take our view of the universe from one with just light from stars to one where we can see and measure every atom that exists. That ’ s all that I want to do. But observing at least some of those atoms is crucial to our understanding of why galaxies look the way they do. I want to know how that hydrogen gas gets into a galaxy and creates a star. My work on FIREBall started in 2008, working not on the telescope but on the light sensor, which is the heart of any telescope. This new sensor was being developed by a team that I joined at NASA ’ s Jet Propulsion Laboratory. And our goal was to prove that this sensor would work really well to detect that hydrogen gas. In my work on this, I destroyed several very, very, very expensive sensors before realizing that the machine I was using created a plasma that shorted out anything electrical that we put in it. We used a different machine, there were other challenges, and it took years to get it right. But when that first sensor worked, it was glorious. And our sensors are now 10 times better than the previous state of the art and are getting put into all kinds of new telescopes. Our sensors will give us a new way to see the universe and our place in it. So, sensors done, time to build a telescope. And FIREBall is weird as far as telescopes go, because it ’ s not in space, and it ’ s not on the ground. Instead, it hangs on a cable from a giant balloon and observes for one night only from 130, 000 feet in the stratosphere, at the very edge of space. This is partly because the edge of space is much cheaper than actual space. So building it, of course, more failures : mirrors that failed, scratched mirrors that had to be remade ; cooling system failures, an entire system that had to be remade ; calibration failures, we ran tests again and again and again and again ; failures when you literally least expect them : we had an adorable but super angry baby falcon that landed on our spectrograph tank one day. Although to be fair, this was the greatest day in the history of this project. I really loved that falcon. But falcon damage fixed, we got it built for an August 2017 launch attempt â and then failed to launch, due to six weeks of continuous rain in the New Mexico desert. Our spirits dampened, we showed up again, August 2018, year 10. And on the morning of September 22nd, we finally got the telescope launched. I have put so much of myself â my whole life â into this project, and I, like, still can ’ t believe that that happened. And I have this picture that ’ s taken right around sunset on that day of our balloon, FIREBall hanging from it, and the nearly full moon. And I love this picture. God, I love it. But I look at it, and it makes me want to cry, because when fully inflated, these balloons are spherical, and this one isn ’ t. It ’ s shaped like a teardrop. And that ’ s because there is a hole in it. Sometimes balloons fail, too. FIREBall crash-landed in the New Mexico desert, and we didn ’ t get the data that we wanted. And at the end of that day, I thought to myself,”Why am I doing this?”And I ’ ve thought a lot about why since that day. And I ’ ve realized that all of my work has been full of things that break and fail, that we don ’ t understand and they fail, that we just get wrong the first time, and so they fail. I think about the thousands of people who built Hubble and how many failures they endured. There were countless failures, heartbreaking failures, even when it was in space. And none of those failures were a reason for them to give up. I think about why I love my job. I want to know what is happening in the universe. You all want to know what ’ s happening in the universe, too. I want to know what ’ s going on with that hydrogen. And so I ’ ve realized that discovery is mostly a process of finding things that don ’ t work, and failure is inevitable when you ’ re pushing the limits of knowledge. And that ’ s what I want to do. So I ’ m choosing to keep going. And our team is going to do what everyone who has ever built anything before us has done : we ’ re going to try again, in 2020. And it might feel like a failure today â and it really does â but it ’ s only going to stay a failure if I give up. Thank you very much.

Preparing for this talk has been scarier for me than preparing for LSD therapy.”Psychedelics are to the study of the mind what the microscope is to biology and the telescope is to astronomy.”Dr. Stanislav Grof spoke those words. He ’ s one of the leading psychedelic researchers in the world, and he ’ s also been my mentor. Today, I ’ d like to share with you how psychedelics, when used wisely, have the potential to help heal us, help inspire us, and perhaps even to help save us. In the 1950s and 60s, psychedelic research flourished all over the world and showed great promise for the fields of psychiatry, psychology and psychotherapy, neuroscience and the study of mystical experiences. But psychedelics leaked out of the research settings and began to be used by the counterculture, and by the anti-Vietnam War movement. And there was unwise use. And so there was a backlash. And in 1970, the US government criminalized all uses of psychedelics, and they began shutting down all psychedelic research. And this ban spread all over the world and lasted for decades. and it was tragic, since psychedelics are really just tools, and whether their outcomes are beneficial or harmful depends on how they ’ re used. Psychedelic means”mind-manifesting,”and it relates to drugs like LSD, psilocybin, mescaline, iboga and other drugs. When I was 18 years old, I was a college freshman, I was experimenting with LSD and mescaline, and these experiences brought me in touch with my emotions. And they helped me have a spiritual connection that unfortunately, my bar mitzvah did not produce. When I wanted to tease my parents, I would tell them that they drove me to psychedelics because my bar mitzvah had failed to turn me into a man. But most importantly, psychedelics gave me this feeling of our shared humanity, of our unity with all life. And other people reported that same thing as well. And I felt that these experiences had the potential to help be an antidote to tribalism, to fundamentalism, to genocide and environmental destruction. And so I decided to focus my life on changing the laws and becoming a legal psychedelic psychotherapist. Now, half a century after the ban, we ’ re in the midst of a global renaissance of psychedelic research. Psychedelic psychotherapy is showing great promise for the treatment of post-traumatic stress disorder, or PTSD, depression, social anxiety, substance abuse and alcoholism and suicide. Psychedelic psychotherapy is an attempt to go after the root causes of the problems, with just relatively few administrations, as contrasted to most of the psychiatric drugs used today that are mostly just reducing symptoms and are meant to be taken on a daily basis. Psychedelics are now also being used as tools for neuroscience to study **brain** function and to study the enduring mystery of human consciousness. And psychedelics and the mystical experiences they produce are being explored for their connections between meditation and mindfulness, including a paper just recently published about lifelong zen meditators taking psilocybin in the midst of a meditation retreat and showing long-term benefits and **brain** changes. Now, how do these drugs work? Modern neuroscience research has demonstrated that psychedelics reduce activity in what ’ s known as the **brain** ’ s default mode network. This is where we create our sense of self. It ’ s our equivalent to the ego, and it filters all incoming information according to our personal needs and priorities. When activity is reduced in the default mode network, our ego shifts from the foreground to the background, and we see that it ’ s just part of a larger field of awareness. It ’ s similar to the shift that Copernicus and Galileo were able to produce in humanity using the telescope to show that the earth was no longer the center of the universe, but was actually something that revolved around the sun, something bigger than itself. For some people, this shift in awareness is the most important and among the most important experiences of their lives. They feel more connected to the world bigger than themselves. They feel more altruistic, and they lose some of their fear of death. Not all drugs work this way. MDMA, also known as Ecstasy, or Molly, works fundamentally different. And I ’ ll be able to share with you the story of Marcela, who suffered from post-traumatic stress disorder from a violent sexual assault. Marcela and I were introduced in 1984, when MDMA was still legal, but it was beginning also to leak out of therapeutic circles. Marcela had tried MDMA in a recreational setting, and during that, her past trauma flooded her awareness and it intensified her suicidal feelings. During our first conversation, I shared that when MDMA is taken therapeutically, it can reduce the fear of difficult emotions, and she could help move forward past her trauma. I asked her to promise not to commit suicide if we were to work together. She agreed and made that promise. During her therapeutic sessions, Marcela was able to process her trauma more fluidly, more easily. And yet, she was able to tell that the rapist had told her that if she ever shared her story, he would kill her. And she realized that that was keeping her a prisoner in her own mind. So being able to share the story and experience the feelings and the thoughts in her mind freed her, and she was able to decide that she wanted to move forward with her life. And in that moment, I realized that MDMA could be very effective for treating PTSD. Now, 35 years later, after Marcela ’ s treatment, she ’ s actually a therapist, training other therapists to help people overcome PTSD with MDMA. Now, how does MDMA work? How did MDMA help Marcela? People who have PTSD have **brains** that are different from those of us who don ’ t have PTSD. They have a hyperactive amygdala, where we process fear. They have reduced activity in the prefrontal cortex, where we think logically. And they have reduced activity in the hippocampus, where we store memories into long-term storage. MDMA changes the **brain** in the opposite way. MDMA reduces activity in the amygdala, increases activity in the prefrontal cortex and increases connectivity between the amygdala and the hippocampus to remit traumatic memories to move into long-term storage. Recently, researchers at Johns Hopkins published a paper in”Nature,”in which they demonstrated that MDMA releases oxytocin, the hormone of love and nurturing. The same researchers also did studies in octopuses, who are normally asocial, unless it ’ s mating season. But lo and **behold**, you give them MDMA, and they become prosocial. Several months after Marcela and I worked together, the Drug Enforcement Administration moved to criminalize Ecstasy, having no knowledge of its therapeutic use. So I went to Washington, and I went into the headquarters of the Drug Enforcement Administration, and I filed a lawsuit demanding a hearing, at which psychiatrists and psychotherapists would be able to present information about therapeutic use of MDMA to try to keep it legal. And in the middle of the hearing, the DEA freaked out, declared an emergency and criminalized all uses of MDMA. And so the only way that I could see to bring it back was through science, through medicine and through the FDA drug development process. So in 1986, I started MAPS as a nonprofit psychedelic pharmaceutical company. It took us 30 years, till 2016, to develop the data that we needed to present to FDA to request permission to move into the large-scale Phase 3 studies that are required to prove safety and efficacy before you get approval for prescription use. Tony was a veteran in one of our pilot studies. According to the Veterans Administration, there ’ s over a million veterans now disabled with PTSD. And at least 20 veterans a day are committing suicide, many of them from PTSD. The treatment that Tony was to receive was three and a half months long. But during that period of time, he would only get MDMA on three occasions, separated by 12, 90-minute non-drug psychotherapy sessions, three before the first MDMA session for preparation and three after each MDMA session for integration. We call our treatment approach"inner-directed therapy,"in that we support the patient to experience whatever ' s emerging within their minds or their bodies. Even with MDMA, this is hard work. And a lot of our subjects have said,"I don ' t know why they call this Ecstasy."During Tony ' s first MDMA session, he lay on the couch, he had eyeshades on, he listened to music, and he would speak to the therapists, who were a male-female co-therapy team, whenever he felt that he needed to. After several hours, in a moment of calmness and clarity, Tony shared that he had realized his PTSD was a way of connecting him to his friends. It was a way of honoring the memory of his friends who had died. But he was able to shift and see himself through the eyes of his dead friends. And he realized that they would not want him to suffer, to squander his life. They would want him to live more fully, which they were unable to do. And so he realized that there was a new way to honor their memory, which was to live as fully as possible. He also realized that he was telling himself a story that he was taking opiates for pain. But actually, he realized, he was taking them for escape. So he decided he didn ' t need the opiates anymore, he didn ' t need the MDMA anymore, and he was dropping out of the study. That was seven years ago. Tony is still free of PTSD, has never returned to opiates and is helping others less fortunate than himself in Cambodia. The data that we presented to FDA from 107 people in our pilot studies, including Tony, showed that 23 percent of the people that received therapy without active MDMA no longer had PTSD at the end of treatment. This is really pretty good for this patient population. However, when you add MDMA, the results more than double, to 56 percent no longer having PTSD. But most importantly, once people learn that if they don ' t need to suppress their trauma, but they can process it, they keep getting better on their own. So at the 12-month follow-up one year after the last treatment session, two- thirds no longer have PTSD. And of the one-third that do, many have clinically significant reductions in symptoms. On the basis of this data, the FDA has declared MDMA-assisted psychotherapy for PTSD a breakthrough therapy. FDA has also declared psilocybin a breakthrough therapy for treatment-resistant depression and just recently approved esketamine for depression. I ' m proud to say that we have now initiated our Phase 3 studies. And if the results are as we hope, and if they ' re similar to the Phase 2 studies, by the end of 2021, FDA will approve MDMA-assisted psychotherapy for PTSD. If approved, the only therapists who will be able to directly administer it to patients are going to be therapists that have been through our training program, and they will only be able to administer MDMA under direct supervision in clinic settings. We anticipate that over the next several decades, there will be thousands of psychedelic clinics established, at which, therapists will be able to administer MDMA, psilocybin, ketamine and other psychedelics to potentially millions of patients. These clinics can also evolve into centers where people can come for psychedelic psychotherapy for personal growth, for couples therapy or for spiritual, mystical experiences. Humanity now is in a race between catastrophe and consciousness. The psychedelic renaissance is here to help consciousness triumph. And now, if you all just look under your seats... Just joking! Thank you. Thank you. Corey Hajim : You ' ve got to stay up here for a minute. Thank you so much, Rick. I guess it ' s a supportive audience. Rick Doblin : Yes, very. Many of them have also been to Burning Man. CH : There ' s some synergy. RD : CH : So, in your talk, you talked about using these drugs to address some pretty serious traumas. So what about some more common mental illnesses like anxiety and depression, and is that where microdosing comes in? RD : Well, microdosing can be helpful for depression, I do know someone that has been using it. But in general, for therapeutic purposes, we prefer macro-dosing rather than microdosing, in order to really help people deal with the root causes. Microdosing is more for creativity, for artistic inspiration, for focus... And it also does have a mood-elevation lift. But I think for serious illnesses, we ' d rather not get people thinking that they need a daily drug, but do more deeper, intense work. CH : And what about outside the United States and North America, is this research being done there? RD : Oh yeah, we ' re globalizing. Our Phase 3 studies are actually being done in Israel, Canada and the United States. So once we get approval in FDA, it will also become approved in Israel and in Canada. We ' re just starting research in Europe. And we ' re actually going to be training some therapists from China. CH : That ' s great. We were going to do an audience vote to see if people felt like this was a good idea to move forward with this research or not, but I have a feeling I know the answer to that, so... Thank you so much, Rick. RD : Thank you. Thank you all.

So I am a pediatric cancer doctor and stem-cell researcher at Stanford University where my clinical focus has been bone marrow transplantation. Now, inspired by Jill Bolte Taylor last year, I didn ' t bring a human **brain**, but I did bring a liter of bone marrow. And bone marrow is actually what we use to save the lives of tens of thousands of patients, most of whom have advanced malignancies like leukemia and lymphoma and some other diseases. So, a few years ago, I ' m doing my transplant fellowship at Stanford. I ' m in the operating room. We have Bob here, who is a volunteer donor. We ' re sending his marrow across the country to save the life of a child with leukemia. So actually how do we harvest this bone marrow? Well we have a whole O. R. team, general anesthesia, nurses, and another doctor across from me. Bob ' s on the table, and we take this sort of small needle, you know, not too big. And the way we do this is we basically place this through the soft tissue, and kind of punch it into the hard bone, into the tuchus — that ' s a technical term — and aspirate about 10 mls of bone marrow out, each time, with a syringe. And hand it off to the nurse. She squirts it into a tin. Hands it back to me. And we do that again and again. About 200 times usually. And by the end of this my arm is sore, I ' ve got a callus on my hand, let alone Bob, whose rear end looks something more like this, like Swiss cheese. So I ' m thinking, you know, this procedure hasn ' t changed in about 40 years. And there is probably a better way to do this. So I thought of a minimally invasive approach, and a new device that we call the Marrow Miner. This is it. And the Marrow Miner, the way it works is shown here. Our standard see-through patient. Instead of entering the bone dozens of times, we enter just once, into the front of the hip or the back of the hip. And we have a flexible, powered catheter with a special wire loop tip that stays inside the crunchy part of the marrow and follows the contours of the hip, as it moves around. So it enables you to very rapidly aspirate, or suck out, rich bone marrow very quickly through one hole. We can do multiple passes through that same entry. No robots required. And, so, very quickly, Bob can just get one puncture, local anesthesia, and do this harvest as an outpatient. So I did a few prototypes. I got a small little grant at Stanford. And played around with this a little bit. And our team members developed this technology. And eventually we got two large animals, and pig studies. And we found, to our surprise, that we not only got bone marrow out, but we got 10 times the stem cell activity in the marrow from the Marrow Miner, compared to the normal device. This device was just FDA approved in the last year. Here is a live patient. You can see it following the flexible curves around. There will be two passes here, in the same patient, from the same hole. This was done under local anesthesia, as an outpatient. And we got, again, about three to six times more stem cells than the standard approach done on the same patient. So why should you care? Bone marrow is a very rich source of adult stem cells. You all know about embryonic stem cells. They ' ve got great potential but haven ' t yet entered clinical trials. Adult stem cells are throughout our body, including the blood-forming stem cells in our bone marrow, which we ' ve been using as a form of stem-cell therapy for over 40 years. In the last decade there ' s been an explosion of use of bone marrow stem cells to treat the patient ' s other diseases such as heart disease, vascular disease, orthopedics, tissue engineering, even in neurology to treat Parkinson ' s and diabetes. We ' ve just come out, we ' re commercializing, this year, generation 2. 0 of the Marrow Miner. The hope is that this gets more stem cells out, which translates to better outcomes. It may encourage more people to sign up to be potential live-saving bone marrow donors. It may even enable you to bank your own marrow stem cells, when you ' re younger and healthier, to use in the future should you need it. And ultimately — and here ' s a picture of our bone marrow transplant survivors, who come together for a reunion each year at Stanford. Hopefully this technology will let us have more of these survivors in the future. Thanks.

My journey to coming here today started in 1974. That ' s me with the funny gloves. I was 17 and going on a peace walk. What I didn ' t know though, was most of those people, standing there with me, were Moonies. And within a week I had come to believe that the second coming of Christ had occurred, that it was Sun Myung Moon, and that I had been specially chosen and prepared by God to be his disciple. Now as cool as that sounds, my family was not that thrilled with this. And they tried everything they could to get me out of there. There was an underground railroad of sorts that was going on during those years. Maybe some of you remember it. They were called deprogrammers. And after about five long years my family had me deprogrammed. And I then became a deprogrammer. I started going out on cases. And after about five years of doing this, I was arrested for kidnapping. Most of the cases I went out on were called involuntary. What happened was that the family had to get their loved ones some safe place somehow. And so they took them to some safe place. And we would come in and talk to them, usually for about a week. And so after this happened, I decided it was a good time to turn my back on this work. And about 20 years went by. There was a burning question though that would not leave me. And that was,”How did this happen to me?”And in fact, what did happen to my **brain**? Because something did. And so I decided to write a book, a memoir, about this decade of my life. And toward the end of writing that book there was a documentary that came out. It was on Jonestown. And it had a chilling effect on me. These are the dead in Jonestown. About 900 people died that day, most of them taking their own lives. Women gave poison to their babies, and watched foam come from their mouths as they died. The top picture is a group of Moonies that have been blessed by their messiah. Their mates were chosen for them. The bottom picture is Hitler youth. This is the leg of a suicide bomber. The thing I had to admit to myself, with great repulsion, was that I get it. I understand how this could happen. I understand how someone ' s **brain**, how someone ' s mind can come to the place where it makes sense — in fact it would be wrong, when your **brain** is working like that — not to try to save the world through genocide. And so what is this? How does this work? And how I ’ ve come to view what happened to me is a viral, memetic infection. For those of you who aren ’ t familiar with memetics, a meme has been defined as an idea that replicates in the human **brain** and moves from **brain** to **brain** like a virus, much like a virus. The way a virus works is — it can infect and do the most damage to someone who has a compromised immune system. In 1974, I was young, I was naive, and I was pretty lost in my world. I was really idealistic. These easy ideas to complex questions are very appealing when you are emotionally vulnerable. What happens is that circular logic takes over.”Moon is one with God. God is going to fix all the problems in the world. All I have to do is humbly follow. Because God is going to stop war and hunger — all these things I wanted to do — all I have to do is humbly follow. Because after all, God is [working through] the messiah. He ’ s going to fix all this.”It becomes impenetrable. And the most dangerous part of this is that is creates”us”and”them,””right”and”wrong,””good”and”evil.”And it makes anything possible, makes anything rationalizable. And the thing is, though, if you looked at my **brain** during those years in the Moonies — neuroscience is expanding exponentially, as Ray Kurzweil said yesterday. Science is expanding. We ’ re beginning to look inside the **brain**. And so if you looked at my **brain**, or any **brain** that ’ s infected with a viral memetic infection like this, and compared it to anyone in this room, or anyone who uses critical thinking on a regular basis, I am convinced it would look very, very different. And that, strange as it may sound, gives me hope. And the reason that gives me hope is that the first thing is to admit that we have a problem. But it ’ s a human problem. It ’ s a scientific problem, if you will. It happens in the human **brain**. There is no evil force out there to get us. And so this is something that, through research and education, I believe that we can solve. And so the first step is to realize that we can do this together, and that there is no”us”and”them.”Thank you very much.

So, I am indeed going to talk about the spaces men create for themselves, but first I want to tell you why I ’ m here. I ’ m here for two reasons. These two guys are my two sons Ford and Wren. When Ford was about three years old, we shared a very small room together, in a very small space. My office was on one half of the bedroom, and his bedroom was on the other half. And you can imagine, if you ’ re a writer, that things would get really crowded around deadlines. So when Wren was on the way, I realized I needed to find a space of my own. There was no more space in the house. So I went out to the backyard, and without any previous building experience, and about 3, 000 dollars and some recycled materials, I built this space. It had everything I needed. It was quiet. There was enough space. And I had control, which was very important. As I was building this space, I thought to myself,”Surely I ’ m not the only guy to have to have carved out a space for his own.”So I did some research. And I found that there was an historic precedence. Hemingway had his writing space. Elvis had two or three manspaces, which is pretty unique because he lived with both his wife and his mother in Graceland. In the popular culture, Superman had the Fortress of Solitude, and there was, of course, the Batcave. So I realized then that I wanted to go out on a journey and see what guys were creating for themselves now. Here is one of the first spaces I found. It is in Austin, Texas, which is where I ’ m from. On the outside it looks like a very typical garage, a nice garage. But on the inside, it ’ s anything but. And this, to me, is a pretty classic manspace. It has neon concert posters, a bar and, of course, the leg lamp, which is very important. I soon realized that manspaces didn ’ t have to be only inside. This guy built a bowling alley in his backyard, out of landscaping timbers, astroturf. And he found the scoreboard in the trash. Here ’ s another outdoor space, a little bit more sophisticated. This a 1923 wooden tugboat, made completely out of Douglas fir. The guy did it all himself. And there is about 1, 000 square feet of hanging-out space inside. So, pretty early on in my investigations I realized what I was finding was not what I expected to find, which was, quite frankly, a lot of beer can pyramids and overstuffed couches and flat-screen TVs. There were definitely hang-out spots. But some were for working, some were for playing, some were for guys to collect their things. Most of all, I was just surprised with what I was finding. Take this place for example. On the outside it looks like a typical northeastern garage. This is in Long Island, New York. The only thing that might tip you off is the round window. On the inside it ’ s a recreation of a 16th century Japanese tea house. The man imported all the materials from Japan, and he hired a Japanese carpenter to build it in the traditional style. It has no nails or screws. All the joints are hand-carved and hand-scribed. Here is another pretty typical scene. This is a suburban Las Vegas neighborhood. But you open one of the garage doors and there is a professional- size boxing ring inside. And so there is a good reason for this. It was built by this man who is Wayne McCullough. He won the silver medal for Ireland in the 1992 Olympics, and he trains in this space. He trains other people. And right off the garage he has his own trophy room where he can sort of bask in his accomplishments, which is another sort of important part about a manspace. So, while this space represents someone ’ s profession, this one certainly represents a passion. It ’ s made to look like the inside of an English sailing ship. It ’ s a collection of nautical antiques from the 1700s and 1800s. Museum quality. So, as I came to the end of my journey, I found over 50 spaces. And they were unexpected and they were surprising. But they were also — I was really impressed by how personalized they were, and how much work went into them. And I realized that ’ s because the guys that I met were all very passionate about what they did. And they really loved their professions. And they were very passionate about their collections and their hobbies. And so they created these spaces to reflect what they love to do, and who they were. So if you don ’ t have a space of your own, I highly recommend finding one, and getting into it. Thank you very much.

Cancer. Many of us have lost family, friends or loved ones to this horrible disease. I know there are some of you in the audience who are cancer survivors, or who are fighting cancer at this moment. My heart goes out to you. While this word often conjures up emotions of sadness and anger and fear, I bring you good news from the front lines of cancer research. The fact is, we are starting to win the war on cancer. In fact, we lie at the intersection of the three of the most exciting developments within cancer research. The first is cancer genomics. The genome is a composition of all the genetic information encoded by DNA in an organism. In cancers, changes in the DNA called mutations are what drive these cancers to go out of control. Around 10 years ago, I was part of the team at Johns Hopkins that first mapped the mutations of cancers. We did this first for colorectal, breast, pancreatic and **brain** cancers. And since then, there have been over 90 projects in 70 countries all over the world, working to understand the genetic basis of these diseases. Today, tens of thousands of cancers are understood down to exquisite molecular detail. The second revolution is precision medicine, also known as”personalized medicine.”Instead of one-size-fits-all methods to be able to treat cancers, there is a whole new class of drugs that are able to target cancers based on their unique genetic profile. Today, there are a host of these tailor-made drugs, called targeted therapies, available to physicians even today to be able to personalize their therapy for their patients, and many others are in development. The third exciting revolution is immunotherapy, and this is really exciting. Scientists have been able to leverage the immune system in the fight against cancer. For example, there have been ways where we find the off switches of cancer, and new drugs have been able to turn the immune system back on, to be able to fight cancer. In addition, there are ways where you can take away immune cells from the body, train them, engineer them and put them back into the body to fight cancer. Almost sounds like science fiction, doesn ’ t it? While I was a researcher at the National Cancer Institute, I had the privilege of working with some of the pioneers of this field and watched the development firsthand. It ’ s been pretty amazing. Today, over 600 clinical trials are open, actively recruiting patients to explore all aspects in immunotherapy. While these three exciting revolutions are ongoing, unfortunately, this is only the beginning, and there are still many, many challenges. Let me illustrate with a patient. Here is a patient with a skin cancer called melanoma. It ’ s horrible ; the cancer has gone everywhere. However, scientists were able to map the mutations of this cancer and give a specific treatment that targets one of the mutations. And the result is almost miraculous. Tumors almost seem to melt away. Unfortunately, this is not the end of the story. A few months later, this picture is taken. The tumor has come back. The question is : Why? The answer is tumor heterogeneity. Let me explain. Even a cancer as small as one centimeter in diameter harbors over a hundred million different cells. While genetically similar, there are small differences in these different cancers that make them differently prone to different drugs. So even if you have a drug that ’ s highly effective, that kills almost all the cells, there is a chance that there ’ s a small population that ’ s resistant to the drug. This ultimately is the population that comes back, and takes over the patient. So then the question is : What do we do with this information? Well, the key, then, is to apply all these exciting advancements in cancer therapy earlier, as soon as we can, before these resistance clones emerge. The key to cancer and curing cancer is early detection. And we intuitively know this. Finding cancer early results in better outcomes, and the numbers show this as well. For example, in ovarian cancer, if you detect cancer in stage four, only 17 percent of the women survive at five years. However, if you are able to detect this cancer as early as stage one, over 92 percent of women will survive. But the sad fact is, only 15 percent of women are detected at stage one, whereas the vast majority, 70 percent, are detected in stages three and four. We desperately need better detection mechanisms for cancers. The current best ways to screen cancer fall into one of three categories. First is medical procedures, which is like colonoscopy for colon cancer. Second is protein biomarkers, like PSA for prostate cancer. Or third, imaging techniques, such as mammography for breast cancer. Medical procedures are the gold standard ; however, they are highly invasive and require a large infrastructure to implement. Protein markers, while effective in some populations, are not very specific in some circumstances, resulting in high numbers of false positives, which then results in unnecessary work-ups and unnecessary procedures. Imaging methods, while useful in some populations, expose patients to harmful radiation. In addition, it is not applicable to all patients. For example, mammography has problems in women with dense breasts. So what we need is a method that is noninvasive, that is light in infrastructure, that is highly specific, that also does not have false positives, does not use any radiation and is applicable to large populations. Even more importantly, we need a method to be able to detect cancers before they ’ re 100 million cells in size. Does such a technology exist? Well, I wouldn ’ t be up here giving a talk if it didn ’ t. I ’ m excited to tell you about this latest technology we ’ ve developed. Central to our technology is a simple blood test. The blood circulatory system, while seemingly mundane, is essential for you to survive, providing oxygen and nutrients to your cells, and removing waste and carbon dioxide. Here ’ s a key biological insight : Cancer cells grow and die faster than normal cells, and when they die, DNA is shed into the blood system. Since we know the signatures of these cancer cells from all the different cancer genome sequencing projects, we can look for those signals in the blood to be able to detect these cancers early. So instead of waiting for cancers to be large enough to cause symptoms, or for them to be dense enough to show up on imaging, or for them to be prominent enough for you to be able to visualize on medical procedures, we can start looking for cancers while they are relatively pretty small, by looking for these small amounts of DNA in the blood. So let me tell you how we do this. First, like I said, we start off with a simple blood test — no radiation, no complicated equipment — a simple blood test. Then the blood is shipped to us, and what we do is extract the DNA out of it. While your body is mostly healthy cells, most of the DNA that ’ s detected will be from healthy cells. However, there will be a small amount, less than one percent, that comes from the cancer cells. Then we use molecular biology methods to be able to enrich this DNA for areas of the genome which are known to be associated with cancer, based on the information from the cancer genomics projects. We ’ re able to then put this DNA into DNA-sequencing machines and are able to digitize the DNA into A ’ s, C ’ s, T ’ s and G ’ s and have this final readout. Ultimately, we have information of billions of letters that output from this run. We then apply statistical and computational methods to be able to find the small signal that ’ s present, indicative of the small amount of cancer DNA in the blood. So does this actually work in patients? Well, because there ’ s no way of really predicting right now which patients will get cancer, we use the next best population : cancers in remission ; specifically, lung cancer. The sad fact is, even with the best drugs that we have today, most lung cancers come back. The key, then, is to see whether we ’ re able to detect these recurrences of cancers earlier than with standard methods. We just finished a major trial with Professor Charles Swanton at University College London, examining this. Let me walk you through an example of one patient. Here ’ s an example of one patient who undergoes surgery at time point zero, and then undergoes chemotherapy. Then the patient is under remission. He is monitored using clinical exams and imaging methods. Around day 450, unfortunately, the cancer comes back. The question is : Are we able to catch this earlier? During this whole time, we ’ ve been collecting blood serially to be able to measure the amount of ctDNA in the blood. So at the initial time point, as expected, there ’ s a high level of cancer DNA in the blood. However, this goes away to zero in subsequent time points and remains negligible after subsequent points. However, around day 340, we see the rise of cancer DNA in the blood, and eventually, it goes up higher for days 400 and 450. Here ’ s the key, if you ’ ve missed it : At day 340, we see the rise in the cancer DNA in the blood. That means we are catching this cancer over a hundred days earlier than traditional methods. This is a hundred days earlier where we can give therapies, a hundred days earlier where we can do surgical interventions, or even a hundred days less for the cancer to grow or a hundred days less for resistance to occur. For some patients, this hundred days means the matter of life and death.

We ’ re really excited about this information. Because of this assignment, we ’ ve done additional studies now in other cancers, including breast cancer, lung cancer and ovarian cancer, and I can ’ t wait to see how much earlier we can find these cancers. Ultimately, I have a dream, a dream of two vials of blood, and that, in the future, as part of all of our standard physical exams, we ’ ll have two vials of blood drawn. And from these two vials of blood we will be able to compare the DNA from all known signatures of cancer, and hopefully then detect cancers months to even years earlier. Even with the therapies we have currently, this could mean that millions of lives could be saved. And if you add on to that recent advancements in immunotherapy and targeted therapies, the end of cancer is in sight. The next time you hear the word”cancer,”I want you to add to the emotions : hope. Hold on. Cancer researchers all around the world are working feverishly to beat this disease, and tremendous progress is being made. This is the beginning of the end. We will win the war on cancer. And to me, this is amazing news. Thank you.

Text Sample 622: NEG Dim 4 – 2017 – Score 1.00 – 2017/t000748.txt
Words matter. They can heal and they can kill... yet, they have a limit. When I was in eighth grade, my teacher gave me a vocabulary sheet with the word”genocide.”I hated it. The word genocide is clinical... overgeneral... bloodless... dehumanizing. No word can describe what this does to a nation. You need to know, in this kind of war, husbands kills wives, wives kill husbands, neighbors and friends kill each other. Someone in power says,”Those over there... they don ’ t belong. They ’ re not human.”And people believe it. I don ’ t want words to describe this kind of behavior. I want words to stop it. But where are the words to stop this? And how do we find the words? But I believe, truly, we have to keep trying. I was born in Kigali, Rwanda. I felt loved by my entire family and my neighbors. I was constantly being teased by everybody, especially my two older siblings. When I lost my front tooth, my brother looked at me and said,”Oh, it has happened to you, too? It will never grow back.”I enjoyed playing everywhere, especially my mother ’ s garden and my neighbor ’ s. I loved my kindergarten. We sang songs, we played everywhere and ate lunch. I had a childhood that I would wish for anyone. But when I was six, the adults in my family began to speak in whispers and shushed me any time that I asked a question. One night, my mom and dad came. They had this strange look when they woke us. They sent my older sister Claire and I to our grandparent ’ s, hoping whatever was happening would blow away. Soon we had to escape from there, too. We hid, we **crawled**, we sometimes ran. Sometimes I heard laughter and then screaming and crying and then noise that I had never heard. You see, I did not know what those noises were. They were neither human — and also at the same time, they were human. I saw people who were not breathing. I thought they were asleep. I still didn ’ t understand what death was, or killing in itself. When we would stop to rest for a little bit or search for food, I would close my eyes, hoping when I opened them, I would be awake. I had no idea which direction was home. Days were for hiding and night for walking. You go from a person who ’ s away from home to a person with no home. The place that is supposed to want you has pushed you out, and no one takes you in. You are unwanted by anyone. You are a refugee. From age six to 12, I lived in seven different countries, moving from one refugee camp to another, hoping we would be wanted. My older sister Claire, she became a young mother... and a master at getting things done. When I was 12, I came to America with Claire and her family on refugee status. And that ’ s only the beginning, because even though

I was 12 years old, sometimes I felt like three years old and sometimes 50 years old. My past receded, grew jumbled, distorted. Everything was too much and nothing. Time seemed like pages torn out of a book and scattered everywhere. This still happens to me standing right here. After I got to America, Claire and I did not talk about our past. In 2006, after 12 years being separated away from my family, and then seven years knowing that they were dead and them thinking that we were dead, we reunited... in the most dramatic, American way possible. Live, on television — on"The Oprah Show."I told you, I told you. But after the show, as I spent time with my mom and dad and my little sister and my two new siblings that I never met, I felt anger. I felt every deep pain in me. And I know that there is absolutely nothing, nothing, that could restore the time we lost with each other and the relationship we could ’ ve had. Soon, my parents moved to the United States, but like Claire, they don ’ t talk about our past. They live in never-ending present. Not asking too many questions, not allowing themselves to feel — moving in small steps. None of us, of course, can make sense of what happened to us. Though my family is alive — yes, we were broken, and yes, we are numb and we were silenced by our own experience. It ’ s not just my family. Rwanda is not the only country where people have turned on each other and murdered each other. The entire human race, in many ways, is like my family. Not dead ; yes, broken, numb and silenced by the violence of the world that has taken over. You see, the chaos of the violence continues inside in the words we use and the stories we create every single day. But also on the labels that we impose on ourselves and each other. Once we call someone"other,""less than,""one of them"or"better than,"believe me... under the right condition, it ’ s a short path to more destruction. More chaos and more noise that we will not understand. Words will never be enough to quantify and qualify the many magnitudes of human-caused destruction. In order for us to stop the violence that goes on in the world, I hope — at least I beg you — to pause. Let ’ s ask ourselves : Who are we without words? Who are we without labels? Who are we in our breath? Who are we in our heartbeat?

Text Sample 623: NEG Dim 4 – 2017 – Score 1.00 – 2017/t000380.txt

Almost 50 years ago, psychiatrists Richard Rahe and Thomas Holmes developed an inventory of the most distressing human experiences that we could have. Number one on the list? Death of a spouse. Number two, divorce. Three, marital separation. Now, generally, but not always, for those three to occur, we need what comes in number seven on the list, which is marriage. Fourth on the list is imprisonment in an institution. Now, some say number seven has been counted twice. I don ’ t believe that. When the life stress inventory was built, back then, a long-term relationship pretty much equated to a marriage. Not so now. So for the purposes of this talk, I ’ m going to be including de facto relationships, common-law marriages and same-sex marriages, or same-sex relationships soon hopefully to become marriages. And I can say from my work with same-sex couples, the principles I ’ m about to talk about are no different. They ’ re the same across all relationships. So in a modern society, we know that prevention is better than cure. We vaccinate against polio, diphtheria, tetanus, whooping cough, measles. We have awareness campaigns for melanoma, stroke, diabetes — all important campaigns. But none of those conditions come close to affecting 45 percent of us. Forty- five percent : that ’ s our current divorce rate. Why no prevention campaign for divorce? Well, I think it ’ s because our policymakers don ’ t believe that things like attraction and the way relationships are built is changeable or educable. Why? Well, our policymakers currently are Generation X. They ' re in their 30s to 50s. And when I ' m talking to these guys about these issues, I see their eyes glaze over, and I can see them thinking,"Doesn ' t this crazy psychiatrist get it? You can ' t control the way in which people attract other people and build relationships."Not so, our dear millennials. This is the most information- connected, analytical and skeptical generation, making the most informed decisions of any generation before them. And when I talk to millennials, I get a very different reaction. They actually want to hear about this. They want to know about how do we have relationships that last? So for those of you who want to embrace the post-"romantic destiny"era with me, let me talk about my three life hacks for preventing divorce. Now, we can intervene to prevent divorce at two points : later, once the cracks begin to appear in an established relationship ; or earlier, before we commit, before we have children. And that ' s where I ' m going to take us now. So my first life hack : millennials spend seven-plus hours on their devices a day. That ' s American data. And some say, probably not unreasonably, this has probably affected their face-to-face relationships. Indeed, and add to that the hookup culture, ergo apps like Tinder, and it ' s no great surprise that the 20-somethings that I work with will often talk to me about how it is often easier for them to have sex with somebody that they ' ve met than have a meaningful conversation. Now, some say this is a bad thing. I say this is a really good thing. It ' s a particularly good thing to be having sex outside of the institution of marriage. Now, before you go out and get all moral on me, remember that Generation X, in the American Public Report, they found that 91 percent of women had had premarital sex by the age of 30. Ninety-one percent. It ' s a particularly good thing that these relationships are happening later. See, boomers in the ' 60s — they were getting married at an average age for women of 20 and 23 for men. 2015 in Australia? That is now 30 for women and 32 for men. That ' s a good thing, because the older you are when you get married, the lower your divorce rate. Why? Why is it helpful to get married later? Three reasons. Firstly, getting married later allows the other two preventers of divorce to come into play. They are tertiary education and a higher income, which tends to go with tertiary education. So these three factors all kind of get mixed up together. Number two, neuroplasticity research tell us that the human **brain** is still growing until at least the age of 25. So that means how you ' re thinking and what you ' re thinking is still changing up until 25. And thirdly, and most importantly to my mind, is personality. Your personality at the age of 20 does not correlate with your personality at the age of 50. But your personality at the age of 30 does correlate with your personality at the age of 50. So when I ask somebody who got married young why they broke up, and they say,"We grew apart,"they ' re being surprisingly accurate, because the 20s is a decade of rapid change and maturation. So the first thing you want to get before you get married is older. Number two, John Gottman, psychologist and relationship researcher, can tell us many factors that correlate with a happy, successful marriage. But the one that I want to talk about is a big one : 81 percent of marriages implode, self- destruct, if this problem is present. And the second reason why I want to talk about it here is because it ' s something you can evaluate while you ' re dating. Gottman found that the relationships that were the most stable and happy over the longer term were relationships in which the couple shared power. They were influenceable : big decisions, like buying a house, overseas trips, buying a car, having children. But when Gottman drilled down on this data, what he found was that women were generally pretty influenceable. Guess where the problem lay? Yeah, there ' s only two options here, isn ' t there? Yeah, we men were to blame. The other thing that Gottman found is that men who are influenceable also tended to be"outstanding fathers."So women : How influenceable is your man? Men : you ' re with her because you respect her. Make sure that respect plays out in the decision-making process. Number three. I ' m often intrigued by why couples come in to see me after they ' ve been married for 30 or 40 years. This is a time when they ' re approaching the infirmities and illness of old age. It ' s a time when they ' re particularly focused on caring for each other. They ' ll forgive things that have bugged them for years. They ' ll forgive all betrayals, even infidelities, because they ' re focused on caring for each other. So what pulls them apart? The best word I have for this is reliability, or the lack thereof. Does your partner have your back? It takes two forms. Firstly, can you rely on your partner to do what they say they ' re going to do? Do they follow through? Secondly, if, for example, you ' re out and you ' re being verbally attacked by somebody, or you ' re suffering from a really disabling illness, does your partner step up and do what needs to be done to leave you feeling cared for and protected? And here ' s the rub : if you ' re facing old age, and your partner isn ' t doing that for you — in fact, you ' re having to do that for them — then in an already-fragile relationship, it can look a bit like you might be better off out of it rather than in it. So is your partner there for you when it really matters? Not all the time, 80 percent of the time, but particularly if it ' s important to you. On your side, think carefully before you commit to do something for your partner. It is much better to commit to as much as you can follow through than to commit to more sound-good-in-the-moment and then let them down. And if it ' s really important to your partner, and you commit to it, make sure you move hell and high water to follow through. Now, these are things that I ' m saying you can look for. Don ' t worry, these are also things that can be built in existing relationships. I believe that the most important decision that you can make is who you choose as a life partner, who you choose as the other parent of your children. And of course, romance has to be there. Romance is a grand and beautiful and quirky thing. But we need to add to a romantic, loving heart an informed, thoughtful mind, as we make the most important decision of our life. Thank you.

Text Sample 624: NEG Dim 4 – 2016 – Score 1.00 – 2016/t001137.txt

I am holding something remarkably old. It is older than any human artifact, older than life on Earth, older than the continents and the oceans between them. This was formed over four billion years ago in the earliest days of the solar system while the planets were still forming. This rusty lump of nickel and iron may not appear special, but when it is cut open... you can see that it is different from earthly metals. This pattern reveals metallic crystals that can only form out in space where molten metal can cool extremely slowly, a few degrees every million years. This was once part of a much larger object, one of millions left over after the planets formed. We call these objects asteroids. Asteroids are our oldest and most numerous cosmic neighbors. This graphic shows near-Earth asteroids orbiting around the Sun, shown in yellow, and swinging close to the Earth ' s orbit, shown in blue. The sizes of the Earth, Sun and asteroids have been greatly exaggerated so you can see them clearly. Teams of scientists across the globe are searching for these objects, discovering new ones every day, steadily mapping near-Earth space. Much of this work is funded by NASA. I think of the search for these asteroids as a giant public works project, but instead of building a highway, we ' re charting outer space, building an archive that will last for generations. These are the 1, 556 near-Earth asteroids discovered just last year. And these are all of the known near-Earth asteroids, which at last count was 13, 733. Each one has been imaged, cataloged and had its path around the Sun determined. Although it varies from asteroid to asteroid, the paths of most asteroids can be predicted for dozens of years. And the paths of some asteroids can be predicted with incredible precision. For example, scientists at the Jet Propulsion Laboratory predicted where the asteroid Toutatis was going to be four years in advance to within 30 kilometers. In those four years, Toutatis traveled 8. 5 billion kilometers. That ’ s a fractional precision of 0. 000000004. Now, the reason I have this beautiful asteroid fragment is because, like all neighbors, asteroids sometimes drop by unexpectedly. Three years ago today, a small asteroid exploded over the city of Chelyabinsk, Russia. That object was about 19 meters across, or about as big as a convenience store. Objects of this size hit the Earth every 50 years or so. 66 million years ago, a much larger object hit the Earth, causing a massive extinction. 75 percent of plant and animal species were lost, including, sadly, the dinosaurs. That object was about 10 kilometers across, and 10 kilometers is roughly the cruising altitude of a 747 jet. So the next time you ’ re in an airplane, snag a window seat, look out and imagine a rock so enormous that resting on the ground, it just grazes your wingtip. It ’ s so wide that it takes your plane one full minute to fly past it. That ’ s the size of the asteroid that hit the Earth. It has only been within my lifetime that asteroids have been considered a credible threat to our planet. And since then, there ’ s been a focused effort underway to discover and catalog these objects. I am lucky enough to be part of this effort. I ’ m part of a team of scientists that use NASA ’ s NEOWISE telescope. Now, NEOWISE was not designed to find asteroids. It was designed to orbit the earth and look far beyond our solar system to seek out the coldest stars and the most luminous galaxies. And it did that very well for its designed lifetime of seven months. But today, six years later, it ’ s still going. We ’ ve repurposed it to discover and study asteroids. And although it ’ s a wonderful little space robot, these days it ’ s kind of like a used car. The cryogen that used to refrigerate its sensors is long gone, so we joke that its air-conditioning is broken. It ’ s got 920 million miles on the odometer, but it still runs great and reliably takes a photograph of the sky every 11 seconds. It ’ s taken 23 photos since I began speaking to you. One of the reasons NEOWISE is so valuable is that it sees the sky in the thermal infrared. That means that instead of seeing the sunlight that asteroids reflect, NEOWISE sees the heat that they emit. This is a vital capability since some asteroids are as dark as coal and can be difficult or impossible to spot with other telescopes. But all asteroids, light or dark, shine brightly for NEOWISE. Astronomers are using every technique at their disposal to discover and study asteroids. In 2010, a historic milestone was reached. The community, together, discovered over 90 percent of asteroids bigger than one kilometer across — objects capable of massive destruction to Earth. But the job ’ s not done yet. An object 140 meters or bigger could decimate a medium-sized country. So far, we ’ ve only found 25 percent of those. We must keep searching the sky for near-Earth asteroids. We are the only species able to understand calculus or build telescopes. We know how to find these objects. This is our responsibility. If we found a hazardous asteroid with significant early warning, we could nudge it out of the way. Unlike earthquakes, hurricanes or volcanic eruptions, an asteroid impact can be precisely predicted and prevented. What we need to do now is map near-Earth space. We must keep searching the sky. Thank you.

Today I want to talk about the meaning of words, how we define them and how they, almost as revenge, define us. The English language is a magnificent sponge. I love the English language. I ’ m glad that I speak it. But for all that, it has a lot of holes. In Greek, there ’ s a word,”lachesism”which is the hunger for disaster. You know, when you see a thunderstorm on the horizon and you just find yourself rooting for the storm. In Mandarin, they have a word”y y”— I ’ m not pronouncing that correctly — which means the longing to feel intensely again the way you did when you were a kid. In Polish, they have a word”jouska”which is the kind of hypothetical conversation that you compulsively play out in your head. And finally, in German, of course in German, they have a word called”zielschmerz”which is the dread of getting what you want. Finally fulfilling a lifelong dream. I ’ m German myself, so I know exactly what that feels like. Now, I ’ m not sure if I would use any of these words as I go about my day, but I ’ m really glad they exist. But the only reason they exist is because I made them up. I am the author of”The Dictionary of Obscure Sorrows,”which I ’ ve been writing for the last seven years. And the whole mission of the project is to find holes in the language of emotion and try to fill them so that we have a way of talking about all those human peccadilloes and quirks of the human condition that we all feel but may not think to talk about because we don ’ t have the words to do it. And about halfway through this project, I defined”sonder,”the idea that we all think of ourselves as the main character and everyone else is just extras. But in reality, we ’ re all the main character, and you yourself are an extra in someone else ’ s story. And so as soon as I published that, I got a lot of response from people saying,”Thank you for giving voice to something I had felt all my life but there was no word for that.”So it made them feel less alone. That ’ s the power of words, to make us feel less alone. And it was not long after that that I started to notice sonder being used earnestly in conversations online, and not long after I actually noticed it, I caught it next to me in an actual conversation in person. There is no stranger feeling than making up a word and then seeing it take on a mind of its own. I don ’ t have a word for that yet, but I will. I ’ m working on it. I started to think about what makes words real, because a lot of people ask me, the most common thing I got from people is,”Well, are these words made up? I don ’ t really understand.”And I didn ’ t really know what to tell them because once sonder started to take off, who am I to say what words are real and what aren ’ t. And so I sort of felt like Steve Jobs, who described his epiphany as when he realized that most of us, as we go through the day, we just try to avoid bouncing against the walls too much and just sort of get on with things. But once you realize that people — that this world was built by people no smarter than you, then you can reach out and touch those walls and even put your hand through them and realize that you have the power to change it. And when people ask me,”Are these words real?”I had a variety of answers that I tried out. Some of them made sense. Some of them didn ’ t. But one of them I tried out was,”Well, a word is real if you want it to be real.”The way that this path is real because people wanted it to be there. It happens on college campuses all the time. It ’ s called a”desire path.”But then I decided, what people are really asking when they ’ re asking if a word is real, they ’ re really asking,”Well, how many **brains** will this give me access to?”Because I think that ’ s a lot of how we look at language. A word is essentially a key that gets us into certain people ’ s heads. And if it gets us into one **brain**, it ’ s not really worth it, not really worth knowing. Two **brains**, eh, it depends on who it is. A million **brains**, OK, now we ’ re talking. And so a real word is one that gets you access to as many **brains** as you can. That ’ s what makes it worth knowing. Incidentally, the realest word of all by this measure is this. [O. K.] That ’ s it. The realest word we have. That is the closest thing we have to a master key. That ’ s the most commonly understood word in the world, no matter where you are. The problem with that is, no one seems to know what those two letters stand for. Which is kind of weird, right? I mean, it could be a misspelling of”all correct,”I guess, or”old kinderhook.”No one really seems to know, but the fact that it doesn ’ t matter says something about how we add meaning to words. The meaning is not in the words themselves. We ’ re the ones that pour ourselves into it. And I think, when we ’ re all searching for meaning in our lives, and searching for the meaning of life, I think words have something to do with that. And I think if you ’ re looking for the meaning of something, the dictionary is a decent place to start. It brings a sense of order to a very chaotic universe. Our view of things is so limited that we have to come up with patterns and shorthands and try to figure out a way to interpret it and be able to get on with our day. We need words to contain us, to define ourselves. I think a lot of us feel boxed in by how we use these words. We forget that words are made up. It ’ s not just my words. All words are made up, but not all of them mean something. We ’ re all just sort of trapped in our own lexicons that don ’ t necessarily correlate with people who aren ’ t already like us, and so I think I feel us drifting apart a little more every year, the more seriously we take words. Because remember, words are not real. They don ’ t have meaning. We do. And I ’ d like to leave you with a reading from one of my favorite philosophers, Bill Watterson, who created”Calvin and Hobbes.”He said,”Creating a life that reflects your values and satisfies your soul is a rare achievement. To invent your own life ’ s meaning is not easy, but it is still allowed, and I think you ’ ll be happier for the trouble.”Thank you.

By raising your hand, how many of you know at least one person on the screen? Wow, it ’ s almost a full house. It ’ s true, they are very famous in their fields. And do you know what all of them have in common? They all died of pancreatic cancer. However, although it ’ s very, very sad this news, it ’ s also thanks to their personal stories that we have raised awareness of how lethal this disease can be. It ’ s become the third cause of cancer deaths, and only eight percent of the patients will survive beyond five years. That ’ s a very tiny number, especially if you compare it with breast cancer, where the survival rate is almost 90 percent. So it doesn ’ t really come as a surprise that being diagnosed with pancreatic cancer means facing an almost certain death sentence. What ’ s shocking, though, is that in the last 40 years, this number hasn ’ t changed a bit, while much more progress has been made with other types of tumors. So how can we make pancreatic cancer treatment more effective? As a biomedical entrepreneur, I like to work on problems that seem impossible, understanding their limitations and trying to find new, innovative solutions that can change their outcome. The first piece of bad news with pancreatic cancer is that your pancreas is in the middle of your belly, literally. It ’ s depicted in orange on the screen. But you can barely see it until I remove all the other organs in front. It ’ s also surrounded by many other vital organs, like the liver, the stomach, the bile duct. And the ability of the tumor to grow into those organs is the reason why pancreatic cancer is one of the most painful tumor types. The hard-to-reach location also prevents the doctor from surgically removing it, as is routinely done for breast cancer, for example. So all of these reasons leave chemotherapy as the only option for the pancreatic cancer patient. This brings us to the second piece of bad news. Pancreatic cancer tumors have very few blood vessels. Why should we care about the blood vessel of a tumor? Let ’ s think for a second how chemotherapy works. The drug is injected in the vein and it navigates throughout the body until it reaches the tumor site. It ’ s like driving on a highway, trying to reach a destination. But what if your destination doesn ’ t have an exit on the highway? You will never get there. And that ’ s exactly the same problem for chemotherapy and pancreatic cancer. The drugs navigate throughout all of your body. They will reach healthy organs, resulting in high toxic effect for the patients overall, but very little will go to the tumor. Therefore, the efficacy is very limited. To me, it seems very counterintuitive to have a whole-body treatment to target a specific organ. However, in the last 40 years, a lot of money, research and effort have gone towards finding new, powerful drugs to treat pancreatic cancer, but nothing has been done in changing the way we deliver them to the patient. So after two pieces of bad news, I ’ m going to give you good news, hopefully. With a collaborator at MIT and the Massachusetts General Hospital in Boston, we have revolutionized the way we treat cancer by making localized drug delivery a reality. We are basically parachuting you on top of your destination, avoiding your having to drive all around the highway. We have embedded the drug into devices that look like this one. They are flexible enough that they can be folded to fit into the catheter, so the doctor can implant it directly on top of the tumor with minimally invasive surgery. But they are solid enough that once they are positioned on top of the tumor, they will act as a cage. They will actually physically prevent the tumor from entering other organs, controlling the metastasis. The devices are also biodegradable. That means that once in the body, they start dissolving, delivering the drug only locally, slowly and more effectively than what is done with the current whole-body treatment. In pre-clinical study, we have demonstrated that this localized approach is able to improve by 12 times the response to treatment. So we took a drug that is already known and by just delivering it locally where it ’ s needed the most, we allow a response that is 12 times more powerful, reducing the systemic toxic effect. We are working relentlessly to bring this technology to the next level. We are finalizing the pre-clinical testing and the animal model required prior to asking the FDA for approval for clinical trials. Currently, the majority of patients will die from pancreatic cancer. We are hoping that one day, we can reduce their pain, extend their life and potentially make pancreatic cancer a curable disease. By rethinking the way we deliver the drug, we don ’ t only make it more powerful and less toxic, we are also opening the door to finding new innovative solutions for almost all other impossible problems in pancreatic cancer patients and beyond. Thank you very much.

In this rather long sort of marathon presentation, I ’ ve tried to break it up into three parts : the first being a whole lot of examples on how it can be a little bit more pleasurable to deal with a computer and really address the qualities of the human interface. And these will be some simple design qualities and they will also be some qualities of, if you will, the intelligence of interaction. Then the second part will really just be examples of new technologies — new media falling very much into that mold. Again, I will go through them as fast as possible. And then the last one will be some examples I ’ ve been able to collect, which I think illustrate this at least as best I can, in the world of entertainment. People have this belief — and I share most of it — that we will be using the TV screens or their equivalents for electronic books of the future. But then you think,”My God! What a terrible image you get when you look at still pictures on TV.”Well, it doesn ’ t have to be terrible. And that is a slide taken from a

TV set and it was pre- processed to be very sympathetic to the TV medium, and it absolutely looks beautiful. Well, what ' s happened? How did people get into this mess? Where you are now, all of a sudden, sitting in front of personal computers and video text — teletext systems, and somewhat horrified by what you see on the screen? Well, you have to remember that TV was designed to be looked at eight times the distance of the diagonal. So you get a 13-inch, 19-inch, whatever, TV, and then you should multiply that by eight and that ' s the distance you should sit away from the TV set. Now we ' ve put people 18 inches in front of a TV, and all the artifacts that none of the original designers expected to be seen, all of a sudden, are staring you in the face : the shadow mask, the scan lines, all of that. And they can be treated very easily ; there are actually ways of getting rid of them, there are actually ways of just making absolutely beautiful pictures. I ' m talking here a little bit about display technologies. Let me talk about how you might input information. And my favorite example is always fingers. I ' m very interested in touch-sensitive displays. High-tech, high-touch. Isn ' t that what some of you said? It ' s certainly a very important medium for input, and a lot of people think that fingers are a very low- resolution sort of stylus for inputting to a display. In fact, they ' re not : it ' s really a very, very high-resolution input medium — you have to just do it twice, you have to touch the screen and then rotate your finger slightly — and you can move a cursor with great accuracy. And so when you see on the market these systems that have just a few light emitting diodes on the side and are very low resolution, it ' s nice that they exist because it still is better than nothing. But it, in some sense, misses the point : namely, that fingers are a very, very high-resolution input medium. Now, what are some of the other advantages? Well, the one advantage is that you don ' t have to pick them up, and people don ' t realize how important that is — not having to pick up your fingers to use them. When you think for a second of the mouse on Macintosh — and I will not criticize the mouse too much — when you ' re typing — what you have — you want to now put something — first of all, you ' ve got to find the mouse. You have to probably stop. Maybe not come to a grinding halt, but you ' ve got to sort of find that mouse. Then you find the mouse, and you ' re going to have to wiggle it a little bit to see where the cursor is on the screen. And then when you finally see where it is, then you ' ve got to move it to get the cursor over there, and then —"Bang"— you ' ve got to hit a button or do whatever. That ' s four separate steps versus typing and then touching and typing and just doing it all in one motion — or one-and-a-half, depending on how you want to count. Again, what I ' m trying to do is just illustrate the kinds of problems that I think face the designers of new computer systems and entertainment systems and educational systems from the perspective of the quality of that interface. And another advantage, of course, of using fingers is you have 10 of them. And we have never known how to do this technically, so this slide is a fake slide. We never succeeded in using ten fingers, but there are certain things you can do, obviously, with more than one-finger input, which is rather fascinating. What we did stumble across was something... Again, which is typical of the computer field, is when you have a bug that you can ' t get rid of you turn it into a feature. And maybe... maybe a mouse is a new kind of bug. But the bug in our case was in touch-sensitive displays : we wanted to be able to draw — you know, rub your finger across the screen to input continuous points — and there was just too much friction created between your finger and the glass — if glass was the substrate, which it usually is. So we found that that actually was a feature in the sense you could build a pressure-sensitive display. And when you touch it with your finger, you can actually, then, introduce all the forces on the face of that screen, and that actually has a certain amount of value. Let me see if I can load another disc and show you, quickly, an example. Now, imagine a screen, which is not only touch-sensitive now, it ’ s pressure-sensitive. And it ’ s pressure-sensitive to the forces both in the plane of the screen — X, Y, and Z at least in one direction ; we couldn ’ t figure out how to come in the other direction. But let me get rid of the slide, and let ’ s see if this comes on. OK. So there is the pressure-sensitive display in operation. The person ’ s just, if you will, pushing on the screen to make a curve. But this is the interesting part. I want to stop it for a second because the movie is very badly made. And the particular display was built about six years ago, and when we moved from one room to another room, a rather large person sat on it and it got destroyed. So all we have is this record. But imagine that screen having lots of objects on it and the person has touched an object — one of N — like he did there, and then pushed on it. Now, imagine a program where some of those objects are physically heavy and some are light : one is an anvil on a fuzzy rug and the other one is a ping-pong ball on a sheet of glass. And when you touch it, you have to really push very hard to move that anvil across the screen, and yet you touch the ping-pong ball very lightly and it just scoots across the screen. And what you can do — oops, I didn ’ t mean to do that — what you can do is actually feed back to the user the feeling of the physical properties. So again, they don ’ t have to be weight ; they could be a general trying to move troops, and he ’ s got to move an aircraft carrier versus a little boat. In fact, they funded it for that very reason. The whole notion, then, is one that at the interface there are physical properties in that transducer — in this case it ’ s pressure and touches — that allow you to present things to the user that you could never present before. So it ’ s not simply looking at the quality or, if you will, the luxury of that interface, but it ’ s actually looking at the idea of presenting things that previously couldn ’ t be presented before. I want to move on to another example, which is one of a different sort, where we ’ re trying to use computer and video disc technology now to come up with a new kind of book. Here, the idea is that you ’ re going to take this book, if you will, and it ’ s going to come alive. You ’ re going to sort of breathe life into it. We are so used to doing monologues. Filmmakers, for example, are the experts in monologue making : you make a film and it has a well-formed beginning, middle and end, and in some sense the art of it is that. And you then say,”There ’ s an opportunity for making conversational movies.”Well, what does that mean? And it sort of nibbles at the core of the whole profession and all the assumptions of that medium. So, book writing is the same thing. What I ’ ll show you very quickly is a new kind of book where it is mixed now with... all sorts of things live in there, but you have to keep a few things in mind. One is that this book knows about itself. Each frame of the movie has information about itself. So it knows, or at least there is computer-readable information in the medium itself. It ’ s just not a static movie frame. That ’ s one thing. The other is that you have to realize that it is a random access medium, and you can, in fact, branch and expand and elaborate and shrink. And here — again, my favorite example — is the cookbook, the”Larousse Gastronomique.”And I think I use the example all too often, but it ’ s a great one because there is a classic ending in that little encyclopedia-style cookbook that tells you how to do something like penguin, and you get to the end of the recipe and it says,”Cook until done.”Now, that would be, if you will, the top green track, which doesn ’ t mean too much. But you might have to elaborate for me or for somebody who isn ’ t an expert, and say,”Cook at 380 degrees for 45 minutes.”And then for a real beginner, you would go down even further and elaborate more — say,”Open the oven, preheat, wait for the light to go out, open the door, don ’ t leave it open too long, put the penguin in and shut the door...”whatever. And that ’ s a much more elaborate one than you dribble back. That ’ s one kind of use of random access. And the other is where you want to explain the same thing in different ways. If you ’ re in a classroom situation and somebody asks a question, the last thing you do is repeat what you just said. You try and think of a different way of saying the same thing, or if you know the particular student and that student ’ s cognitive style, then you might say it in a way that you think would have a good impedance match with that student. There are all sorts of techniques you will use — and again, this is a different kind of branching. So, what I will show you is... it ’ s a rather boring book, but I ’ m afraid sometimes you have to do boring books because your sponsors aren ’ t necessarily interested in fiction and entertainment. And this is a book on how to repair a transmission. Now, I don ’ t even know what vintage the transmission is, but let me just show you very quickly some of it, and we ’ ll move on. Narrator : And continue to get descriptions for each of these chapters. Nicholas Negroponte : Now, this is his table of contents. Just a picture of the transmission, and as you rub your finger across the transmission it highlights the various parts. Narrator : When I find a chapter that I want to see, I just touch the text and the system will format pages for me to read. The words or phrases that are lit up in red are glossary words, so I can get a different definition by just touching the word, and the definition appears, superimposed over the illustration. NN : This is about the oil pan, or the oil filter and all that. This is relatively important because it sets the page... Narrator : This is another example of a page with glossary words highlighted in red. I can get a definition of these words just by touching them, and the definition will appear in the illustration corner. I can get back to the illustration, but in this case it ’ s not a single frame, but it ’ s actually a movie of someone coming into the frame and doing the repair that ’ s described in the text. The two-headed slider is a speed control that allows me to watch the movie at various speeds, in forward or reverse. And the movie is displayed as a full frame movie. I can go back to the beginning... and play the movie at full speed. Here ’ s another step-by-step procedure, only in this case — NN : Okay, this movie is... Everybody ’ s heard of sound-sync movies — this is text-sync movies, so as the movie plays, the text gets highlighted. We highlight the text as we go through the movie. Repairman :... Not too far out. Front poles, preferably. Don ’ t loosen them too far. If you loosen them too far, you ’ ll have a big mess. NN : I suspect that some of you might not even understand that language. OK. I ’ m at the third and last part of this, which I said I would make an attempt to at least give you some examples that may be more directly related to the world of entertainment. And of course, good education has got to be good entertainment, so my first example will be drawn from a very recent experiment that we ’ ve been doing — in this case, in Senegal — where we have tried to use personal computers as a pedagogical medium. But not as teaching machines at all ; the whole notion is to use this as an instrument where there is a complete reversal of roles — the child is, if you will, the teacher and the machine is the student — and the art of computer programming is a vehicle that sort of approximates thinking about thinking. But teaching kids programming per se is utterly irrelevant. And there are just a few slides I want to go through, but there ’ s a story I ’ d like to tell. And that was when, before we did this in any developing countries — we ’ re doing it, in fact, in three developing countries right now : Pakistan, Colombia and Senegal — we did it in some pretty rough areas of New York City. And one child, whose name I ’ ve forgotten, was about seven or eight years old, absolutely considered mentally handicapped — couldn ’ t read, didn ’ t even make it in the lowest section of the school ’ s classes — and was pretty much not in school, though physically there. But did hang around the, quote,”computer room,”where there were quite a few computers, and learned this particular language called Logo — and learned it with great ease and found it a lot of fun, it was very interesting. And one day, by chance, some visitors from the NIE came by in their double-breasted suits looking at this setup, and none of the children who were normally there, except for this one child, were there. He was, and he said,"Let me show you how this works,"and they got an absolutely ingenuous, wonderful description of Logo. And the child was just zipping right through it, showing them all sorts of things until they asked him how to do something which he couldn ' t explain and so he flipped through the manual, found the explanation and typed the command and got it to do what they asked. They were delighted, and by the time it was time to go see the principal, whom they ' d actually come to see — not the computer room — they went upstairs and they said,"This is absolutely remarkable! That child was very articulate and showed us and even dealt with the things he couldn ' t do automatically with that manual. It was just absolutely fantastic."The principal said,"There ' s a dreadful mistake, because that child can ' t read. And you obviously have been hoodwinked or you ' ve talked about somebody else."And they all got up and they all went downstairs and the child was still there. And they did something very intelligent : they asked the child,"Can you read?"And the child said,"No, I can ' t."And then they said,"But wait a minute. You just looked through that manual and you found..."and he said,"Oh, but that ' s not reading."And so they said,"Well, what ' s reading then?"He says,"Well, reading is this junk they give me in little books to read. It ' s absolutely irrelevant, and I get nothing for it. But here, with a little bit of effort I get a lot of return."And it really meant something to the child. The child read beautifully, it turned out, and was really very competent. So it actually meant something. And that story has many other anecdotes that are similar, but wow. The key to the future of computers in education is right there, and it is : when does it mean something to a child? There is a myth, and it truly is a myth : we believe — and I ' m sure a lot of you believe in this room — that it is harder to read and write than it is to learn how to speak. And it ' s not, but we think speech —"My God, little children pick it up somehow, and by the age of two they ' re doing a mediocre job, and by three and four they ' re speaking reasonably well. And yet you ' ve got to go to school to learn how to read, and you have to sit in a classroom and somebody has to teach you. Hence, it must be harder."Well, it ' s not harder. What the truth is is that speaking has great value to a child ; the child can get a great deal by talking to you. Reading and writing is utterly useless. There is no reason for a child to read and write except blind faith, and that it ' s going to help you. So what happens is you go to school and people say,"Just believe me, you ' re going to like it. You ' re going to like reading,"and just read and read. On the other hand, you give a kid — a three-year-old kid — a computer and they type a little command and — Poof! — something happens. And all of a sudden... You may not call that reading and writing, but a certain bit of typing and reading stuff on the screen has a huge payoff, and it ' s a lot of fun. And in fact, it ' s a powerful educational instrument. Well, in Senegal we found that this was the traditional classroom : 120 kids — three per desk — one teacher, a little bit of chalk. This student was one of our first students, and it ' s the girl on the left leaning with her chalkboard, and she came... within two days — I want to show you the program she wrote, and remember her hairstyle. And that is the program she made. That ' s what meant something to her, is doing the hair pattern, and actually did it within two days — an hour each day — and found it was, to her, absolutely the most meaningful piece... But rooted in that, little did she know how much knowledge she was acquiring about geometry and just math and logic and all the rest. And again, I could talk for three hours about this subject. I will come to my last example and then quit. And my last example

— as some of my former colleagues, whom I see in the room, can imagine what it will be. Yes, it is. It ’ s our work — that was a while ago, and it still is my favorite project — of teleconferencing. And the reason it remains a favorite project is that we were asked to do a teleconferencing system where you had the following situation : you had five people at five different sites — they were known people — and you had to have these people in teleconference, such that each one was utterly convinced that the other four were physically present. Now, that is sufficiently zany that we would, obviously, jump to the bait, and we did. And the fact that we knew the people — we had to take a page out of the history of Walt Disney — we actually went so far as to build CRTs in the shapes of the people ’ s faces. So if I wanted to call my friend Peter Sprague on the phone, my secretary would get his head out and bring it and set it on the desk, and that would be the TV used for the occasion. And it ’ s uncanny : there ’ s no way I can explain to you the amount of eye contact you get with that physical face projected on a 3D CRT of that sort. The next thing that we had to do is to persuade them that there needed to be spatial correspondence, which is straightforward, but again, it ’ s something that didn ’ t fall naturally out of a telecommunications or computing style of thinking ; it was a very, if you will, architectural or spatial concept. And that was to recognize that when you sit around the table, the actual location of the people becomes rather important. And when somebody gets up, in fact, to go answer a phone or use a bathroom or something, the empty seat becomes, if you will, that person. And you point frequently to the empty seat and you say,”He or she wouldn ’ t agree,”and the empty chair is that person and the spatiality is crucial. So we said,”Well, these will be on round tables and the order around the table had to be the same, so that at my site, I would be, if you will, real and then at each other ’ s site you ’ d have these plastic heads. And the plastic heads, sometimes you want to project them. And there are a number of schemes, which I don ’ t want to dwell on, but this is the one that we finally used where we projected onto rear screen material that was molded in the face — literally in the face of the person. And I ’ ll show you one more slide, where this is actually made from something called a solid photograph and is the screen. Now, we track, on the person ’ s head, the head motions — so we transmit with a video the head positions — and so this head moves in about two axes. So if I, all of a sudden, turn to the person to my left and start talking to that person, then at the person to my right ’ s site, he ’ ll see these two plastic heads talking to each other. And then if that person interrupts, then those two heads may turn. And it really is reconstructing, quite accurately, teleconferencing.

When I first arrived in beautiful Zimbabwe, it was difficult to understand that 35 percent of the population is HIV positive. It really wasn ’ t until I was invited to the homes of people that I started to understand the human toll of the epidemic. For instance, this is Herbert with his grandmother. When I first met him, he was sitting on his grandmother ’ s lap. He has been orphaned, as both of his parents died of AIDS, and his grandmother took care of him until he too died of AIDS. He liked to sit on her lap because he said that it was painful for him to lie in his own bed. When she got up to make tea, she placed him in my own lap and I had never felt a child that was that emaciated. Before I left, I actually asked him if I could get him something. I thought he would ask for a toy, or candy, and he asked me for slippers, because he said that his feet were cold. This is Joyce who ’ s — in this picture — 21. Single mother, HIV positive. I photographed

her before and after the birth of her beautiful baby girl, Issa. And I was last week walking on Lafayette Street in Manhattan and got a call from a woman who I didn ’ t know, but she called to tell me that Joyce had passed away at the age of 23. Joyce ’ s mother is now taking care of her daughter, like so many other Zimbabwean children who ’ ve been orphaned by the epidemic. So a few of the stories. With every picture, there are individuals who have full lives and stories that deserve to be told. All these pictures are from Zimbabwe. Chris Anderson : Kirsten, will you just take one minute, just to tell your own story of how you got to Africa? Kirsten Ashburn : Mmm, gosh. CA : Just — KA : Actually, I was working at the time, doing production for a fashion photographer. And I was constantly reading the New York Times, and stunned by the statistics, the numbers. It was just frightening. So I quit my job and decided that that ’ s the subject that I wanted to tackle. And I first actually went to Botswana, where I spent a month — this is in December 2000 — then went to Zimbabwe for a month and a half, and then went back again this March 2002 for another month and a half in Zimbabwe. CA : That ’ s an amazing story, thank you. KB : Thanks for letting me show these.

Text Sample 629: NEG Dim 4 – 2003 – Score 3.00 – 2003/t000110.txt

This is a sculpture I made, which is a way of, kind of, freeing a form into an object that has different degrees of freedom. So, it can balance on a point. This is a bronze ball, an aluminum arm here, and then this wooden disk. And the wooden disk was really thought about as something that you ’ d want to hold on to, and that would glide easily through your hands. The aluminum is because it ’ s very light. The bronze is nice hard, durable material that could roll on the ground. Inside of the bronze ball there ’ s a lead weight that is free-swinging on an axle that ’ s on two bearings that pass in between, across it, like this, that counterbalance this weight. So it allows it to roll. And the sphere has that balance property that it always sort of stays still and looks the same from every direction. But if you put something on top of it, it disbalances it. And so it would tip over. But in this case because the interior is free-swinging in relation to the sphere, it can stand up on one point. And then there was a second level to this object, which is that it — I wanted it to convey some proportions that I was interested in, which is the diameter of the Moon and the diameter of the Earth in proportion to each other. I was exploring, really early on, wanting to make things float in the air. And I thought up a lot of ideas. This is sculpture that I made that — it ’ s magnetically levitated. The thing is, is that it ’ s slightly dangerous. Normally it ’ s sort of cordoned off when it ’ s in a museum. But it ’ s uh — let ’ s see if I can manipulate it a little bit without, um — oops. So this is just floating, floating on a permanent magnetic field, which stabilizes it in all directions. Except there is a slight tether here, which keeps it from going over the top of its field. It ’ s sort of surfing on a magnetic field at the crest of a wave. And that ’ s what supports the object and keeps it stable. I think we could roll the tape, admin. I have a sort of a collection of videos that I took of different installations, which I could narrate. This is a sculpture of the Sun and the Earth, in proportion. Representing that eight and a half minutes that it takes light and gravity to connect the two. So here is the Earth. It ’ s a little less than a millimeter that was turned of solid bronze. And here is a similar sculpture. That ’ s the Sun at that end. And then in a series of 55 balls, it reduces, proportionately — each ball and the spaces between them reduce proportionately, until they get down to this little Earth. This is in a sculpture park in Taejon. This one is about the Moon and then the distance to the Earth, in proportion also. This is a little stone ball, floating. As you can see the little tether, that it ’ s also magnetically levitated. And then this is the first part of — this is 109 spheres, since the Sun is 109 times the diameter of the Earth. And so this is the size of the Sun. And then each of these little spheres is the size of the Earth in proportion to the Sun. It ’ s made up of 16 concentric shells. Each one has 92 spheres. This is in the courtyard of a twelfth-century alchemist. I was thinking that the Sun is kind of the ultimate alchemist. So this, again, is on the subject — a slice from the equator of the Earth. And then the Moon in the center, and it ’ s floating. And this is in France. This is in Sapporo. It ’ s balancing on a shaft and a ball, right at the center of gravity, or just slightly above the center of gravity, which means that the lower half of the object is just a little bit more weighty. So you can see it rotating here. It weighs about a ton or over a ton. It ’ s made of stainless steel, quite thick. But it ’ s being balanced like that in equilibrium. It ’ s susceptible to motion by the air currents. This is another species of work that I do. These are these arrays. These spheres are all suspended, but they have magnets horizontally in them that make them all like compasses. So all the red sides, for example, face one direction : south. And the blue side, the compliment, faces the other way. So as you turn around you ’ re seeing different colors. This is based on the structure of a diamond. It was a diamond cell structure was the point of departure. And then there were kind of large spaces in the hollows between the atoms. And so I placed one more element of each one of them. These were white spheres. Then I had video projectors that were projecting intermittently onto the spheres. So they would catch parts of the images, and make sort of three-dimensional color volumes, as you walk through it, through the object. This is something I did of a tactile communication system. It was the idea of isolating the tactile component of sculpture, and then putting it into a communication system. This is an idea of moving a sculpture, a ball, that would be directed around the room by a computer. This is a clock I designed. It has Buckminster Fuller ’ s Dymaxion Map edited here. It turns once per day in synchrony with the Earth. And then, this is like projects that are harder to build. This has a diamond-bottomed lake. So it ’ s a floating island with water, fresh water, that can fly from place to place. This would be grown, I suppose, with nanotechnology in the future sometime. In the course of doing my work I sort of have a broad range of interests. And some of it is just the idea of creating media — media as a sculpture, something that would keep the sculpture fresh and ever-changing, by just creating the media that the sculpture is made of. And I had a lot of — always interested in the concept of a crystal ball. And the idea that you could see things inside of a crystal ball and predict the future — or a television set, where it ’ s sort of like a magic box where anything can appear. I had thought about, a long time ago, in the late ’ 60s — when I was just starting out, I was under the influence of thinking about Buckminster Fuller ’ s grand project for an electric globe across from the United Nations — and other things that were happening, the space program at that time, and Whole Earth Catalog, things like that. I was thinking about mass produced spherical television sets that could be linked to orbiting camera satellites. So if we could roll the next film here. This has evolved over the years in a lot of different iterations. But this the current version of it, is a flying airship that is about 35 meters in diameter, about 110 feet in diameter. The whole surface of it is covered with 60 million diodes, red, blue, and green, that allow you to have a high-resolution picture, visible in daylight. I came with a plan. I brought it to Paul MacCready ’ s company AeroVironment to do a feasibility study, and they analyzed it, and came up with a lot of innovative ideas about how to propel it. So we have a physical plan of how to make this actually happen. This is the control room inside of the ship. The idea of this air genie is, it ’ s something that can just transform and become anything. It ’ s like a traveling show. It has speakers on it. And it has cameras over the surface of it. So it can see its environment, and then it can mimic its environment and disappear. Here the legs are retracting. The cabin is open or closed, as you like. It weighs about 20 tons. It has on-board generators. It can generate about a million kilowatts, in order to be bright enough to be visible in daylight. The idea of it is to make a kind of a traveling show. It really would be dedicated to the arts and to interacting. There would be on board a crew of artists, musicians, that would allow the thing to become actually kind of a conscious object that would respond to the moment, and to interact as an entity that was aware, that could communicate. It ’ s completely silent and nonpolluting. It has electric motors with a novel propulsion system. It could be interacted with large crowds in different ways. Primarily I would be interested in how it would interact with, say, going to a college campus, and then being used as a way of talking about the earth sciences, the world, the situation of the globe. The default image on the object would probably be a high-resolution Earth image. But then one could interact with that and show plate tectonics or global warming issues, or migrations — all of the things that we ’ re concerned with today. And then at night the idea is that it would be used as kind of a rave situation, where the people could cut loose, and the music and the lights, and everything. So it could land in a park, for example. Or this could represent a college green. And then it would have a corresponding website that would show the itinerary of this. And so interacting with the same kind of imagery. It would also be able to be an open code, so people could interact with it. It would be forum for people ’ s ideas about what they would like to see on a giant screen of this type. So that ’ s pretty much it. Okay. Thank you.

Text Sample 630: NEG Dim 4 – 2003 – Score 4.00 – 2003/t000124.txt
The new me is beauty. Yeah, people used to say,”Norman ’ s OK, but if you followed what he said, everything would be usable but it would be ugly.”Well, I didn ’ t have that in mind, so... This is neat. Thank you for setting up my display. I mean, it ’ s just wonderful. And I haven ’ t the slightest idea of what it does or what it ’ s good for, but I want it. And that ’ s my new life. My new life is trying to understand what beauty is about, and”pretty,”and”emotions.”The new me is all about making things kind of neat and fun. And so this is a Philippe Starck juicer, produced by Alessi. It ’ s just neat ; it ’ s fun. It ’ s so much fun I have it in my house — but I have it in the entryway, I don ’ t use it to make juice. In fact, I bought the gold-plated special edition and it comes with a little slip of paper that says,”Don ’ t use this juicer to make juice.”The acid will ruin the gold plating. So actually, I took a carton of orange juice and I poured it in the glass to take this picture. Beneath it is a wonderful knife. It ’ s a Global cutting knife made in Japan. First of all, look at the shape — it ’ s just wonderful to look at. Second of all, it ’ s really beautifully balanced : it holds well, it feels well. And third of all, it ’ s so sharp, it just cuts. It ’ s a delight to use. And so it ’ s got everything, right? It ’ s beautiful and it ’ s functional. And I can tell you stories about it, which makes it reflective, and so you ’ ll see I have a theory of emotion. And those are the three components. Hiroshi Ishii and his group at the MIT Media Lab took a ping-pong table and placed a projector above it, and on the ping-pong table they projected an image of water with fish swimming in it. And as you play ping-pong, whenever the ball hits part of the table, the ripples spread out and the fish run away. But of course, then the ball hits the other side, the ripples hit the — poor fish, they can ’ t find any peace and quiet.

Is that a good way to play ping-pong? No. But is it fun? Yeah! Yeah. Or look at Google. If you type in, oh say,"emotion and design,"you get 10 pages of results. So Google just took their logo and they spread it out. Instead of saying,"You got 73, 000 results. This is one through 20. Next,"they just give you as many o ' s as there are pages. It ' s really simple and subtle. I bet a lot of you have seen it and never noticed it. That ' s the subconscious mind that sort of notices it — it probably is kind of pleasant and you didn ' t know why. And it ' s just clever. And of course, what ' s especially good is, if you type"design and emotion,"the first response out of those 10 pages is my website. Now, the weird thing is Google lies, because if I type"design and emotion,"it says,"You don ' t need the ' and. ' We do it anyway."So, OK. So I type"design emotion"and my website wasn ' t first again. It was third. Oh well, different story. There was this wonderful review in The New York Times about the MINI Cooper automobile. It said,"You know, this is a car that has lots of faults. Buy it anyway. It ' s so much fun to drive."And if you look at the inside of the car — I mean, I loved it, I wanted to see it, I rented it, this is me taking a picture while my son is driving — and the inside of the car, the whole design is fun. It ' s round, it ' s neat. The controls work wonderfully. So that ' s my new life ; it ' s all about fun. I really have the feeling that pleasant things work better, and that never made any sense to me until I finally figured out — look... I ' m going to put a plank on the ground. So, imagine I have a plank about two feet wide and 30 feet long and I ' m going to walk on it, and you see I can walk on it without looking, I can go back and forth and I can jump up and down. No problem. Now I ' m going to put the plank 300 feet in the air — and I ' m not going to go near it, thank you. Intense fear paralyzes you. It actually affects the way the **brain** works. So, Paul Saffo, before his talk said that he didn ' t really have it down until just a few days or hours before the talk, and that anxiety was really helpful in causing him to focus. That ' s what fear and anxiety does ; it causes you to be — what ' s called depth-first processing — to focus, not be distracted. And I couldn ' t force myself across that. Now some people can — circus workers, steel workers. But it really changes the way you think. And then, a psychologist, Alice Isen, did this wonderful experiment. She brought students in to solve problems. So, she ' d bring people into the room, and there ' d be a string hanging down here and a string hanging down here. It was an empty room, except for a table with a bunch of crap on it — some papers and scissors and stuff. And she ' d bring them in, and she ' d say,"This is an IQ test and it determines how well you do in life. Would you tie those two strings together?"So they ' d take one string and they ' d pull it over here and they couldn ' t reach the other string. Still can ' t reach it. And, basically, none of them could solve it. You bring in a second group of people, and you say,"Oh, before we start, I got this box of candy, and I don ' t eat candy. Would you like the box of candy?"And turns out they liked it, and it made them happy — not very happy, but a little bit of happy. And guess what — they solved the problem. And it turns out that when you ' re anxious you squirt neural transmitters in the **brain**, which focuses you makes you depth-first. And when you ' re happy — what we call positive valence — you squirt dopamine into the prefrontal lobes, which makes you a breadth-first problem solver : you ' re more susceptible to interruption ; you do out-of-the-box thinking. That ' s what brainstorming is about, right? With brainstorming we make you happy, we play games, and we say,"No criticism,"and you get all these weird, neat ideas. But in fact, if that ' s how you always were you ' d never get any work done because you ' d be working along and say,"Oh, I got a new way of doing it."So to get work done, you ' ve got to set a deadline, right? You ' ve got be anxious. The **brain** works differently if you ' re happy. Things work better because you ' re more creative. You get a little problem, you say,”Ah, I ’ ll figure it out.”No big deal. There ’ s something I call the visceral level of processing, and there will be visceral-level design. Biology — we have co-adapted through biology to like bright colors. That ’ s especially good that mammals and primates like fruits and bright plants, because you eat the fruit and you thereby spread the seed. There ’ s an amazing amount of stuff that ’ s built into the **brain**. We dislike bitter tastes, we dislike loud sounds, we dislike hot temperatures, cold temperatures. We dislike scolding voices. We dislike frowning faces ; we like symmetrical faces, etc., etc. So that ’ s the visceral level. In design, you can express visceral in lots of ways, like the choice of type fonts and the red for hot, exciting. Or the 1963 Jaguar : It ’ s actually a crummy car, falls apart all the time, but the owners love it. And it ’ s beautiful — it ’ s in the Museum of Modern Art. A water bottle : You buy it because of the bottle, not because of the water. And when people are finished, they don ’ t throw it away. They keep it for — you know, it ’ s like the old wine bottles, you keep it for decoration or maybe fill it with water again, which proves it ’ s not the water. It ’ s all about the visceral experience. The middle level of processing is the behavioral level and that ’ s actually where most of our stuff gets done. Visceral is subconscious, you ’ re unaware of it. Behavioral is subconscious, you ’ re unaware of it. Almost everything we do is subconscious. I ’ m walking around the stage — I ’ m not attending to the control of my legs. I ’ m doing a lot ; most of my talk is subconscious ; it has been rehearsed and thought about a lot. Most of what we do is subconscious. Automatic behavior — skilled behavior — is subconscious, controlled by the behavioral side. And behavioral design is all about feeling in control, which includes usability, understanding — but also the feel and heft. That ’ s why the Global knives are so neat. They ’ re so nicely balanced, so sharp, that you really feel you ’ re in control of the cutting. Or, just driving a high- performance sports car over a demanding curb — again, feeling that you are in complete control of the environment. Or the sensual feeling. This is a Kohler shower, a waterfall shower, and actually, all those knobs beneath are also showerheads. It will squirt you all around and you can stay in that shower for hours — and not waste water, by the way, because it recirculates the same dirty water. Or this — this is a really neat teapot I found at high tea at The Four Seasons Hotel in Chicago. It ’ s a Ronnefeldt tilting teapot. That ’ s kind of what the teapot looks like but the way you use it is you lay it on its back, and you put tea in, and then you fill it with water. The water then seeps over the tea. And the tea is sitting in this stuff to the right — the tea is to the right of this line. There ’ s a little ledge inside, so the tea is sitting there and the water is filling it up like that. And when the tea is ready, or almost ready, you tilt it. And that means the tea is partially covered while it completes the brewing. And when it ’ s finished, you put it vertically, and now the tea is — you remember — above this line and the water only comes to here — and so it keeps the tea out. On top of that, it communicates, which is what emotion does. Emotion is all about acting ; emotion is really about acting. It ’ s being safe in the world. Cognition is about understanding the world, emotion is about interpreting it — saying good, bad, safe, dangerous, and getting us ready to act, which is why the muscles tense or relax. And that ’ s why we can tell the emotion of somebody else — because their muscles are acting, subconsciously, except that we ’ ve evolved to make the facial muscles really rich with emotion. Well, this has emotions if you like, because it signals the waiter that,”Hey, I ’ m finished. See — upright.”And the waiter can come by and say,”Would you like more water?”It ’ s kind of neat. What a wonderful design. And the third level is reflective, which is, if you like the superego, it ’ s a little part of the **brain** that has no control over what you do, no control over the — doesn ’ t see the senses, doesn ’ t control the muscles. It looks over what ’ s going on.

It ’ s that little voice in your head that ’ s watching and saying,”That ’ s good. That ’ s bad.”Or,”Why are you doing that? I don ’ t understand.”It ’ s that little voice in your head that ’ s the seat of consciousness. Here ’ s a great reflective product. Owners of the Hummer have said,”You know I ’ ve owned many cars in my life — all sorts of exotic cars, but never have I had a car that attracted so much attention.”It ’ s about attention. It ’ s about their image, not about the car. If you want a more positive model — this is the GM car. And the reason you might buy it now is because you care about the environment. And you ’ ll buy it to protect the environment, even though the first few cars are going to be really expensive and not perfected. But that ’ s reflective design as well. Or an expensive watch, so you can impress people —”Oh gee, I didn ’ t know you had that watch.”As opposed to this one, which is a pure behavioral watch, which probably keeps better time than the $13, 000 watch I just showed you. But it ’ s ugly. This is a clear Don Norman watch. And what ’ s neat is sometimes you pit one emotion against the other, the visceral fear of falling against the reflective state saying,”It ’ s OK. It ’ s OK. It ’ s safe. It ’ s safe.”If that amusement park were rusty and falling apart, you ’ d never go on the ride. So, it ’ s pitting one against the other. The other neat thing... So Jake Cress is this furniture maker, and he makes this unbelievable set of furniture. And this is his chair with claw, and the poor little chair has lost its ball and it ’ s trying to get it back before anybody notices. And what ’ s so neat about it is how you accept that story. And that ’ s what ’ s nice about emotion. So that ’ s the new me. I ’ m only saying positive things from now on.

Text Sample 631: NEG Dim 4 – 2021 – Score -1.00 – 2021/t003768.txt
I had a friend, a songwriting mentor and a great songwriter, John Stewart, who told me just before he died,”We are all just radios, hoping to pick up each other ’ s signals.”I found that to be true and profound. And I ’ ve spent my life trying to clear the static. The strongest signals that come to me are musical in the form of songs or stories told in rhythm and rhyme. Sometimes I can tune in to a revolution in the heart. Sometimes I hear a keen from my Celtic ancestors. And some songs have been postcards from my future. In my family, there was a song for every loss, every celebration, every unspoken need, every longing. But there was also so much chaos that often I was the only one who recognized what was being communicated. My grandmother, Carrie Cash, moved with my grandfather and their five children into a New Deal era colony created by FDR for poor families in the sunken lands of the Arkansas Delta in 1935. So they moved into this freshly painted cottage, and she gave birth to two more babies there with the assistance only of a doctor who came by in a horse and buggy and pulled two loose aspirin from his pocket to give to her. The same pocket in which he kept his fishing worms. That ’ s true. I read once that every time an old woman dies, a library disappears. And before her library disappeared, I tuned into my grandmother ’ s signals and gleaned her tenacity which I borrowed, and her long suffering in her life of constant work with seven children, six of whom made it to adulthood. In a house without electricity. In the sweltering cotton fields, and I wrote these words about her. Five cans of paint in the empty fields And the dust reveals And the children cry the work never ends There ’ s not a single friend Who will hold her hand in the sunken lands? And the mud and tears melt the cotton balls It ’ s a heavy toll Oh, oh His words are cruel and they sting like fire Like the devil ’ s choir Oh, oh Who will hold her hand in the sunken lands? The river rises and she sails away She could never stay Oh, oh Now her work is done in the sunken lands There ’ s

five empty cans In 1992, I was writing a song about my divorce, which hadn ’ t happened yet. But which I saw coming like a freight train. So I was stuck in this song like I was stuck in my life. And the same time across the country, my mother was going through a box of my school assignments and childhood drawings, and she sent it to me. So I started going through this box, and I came across this yellowed paper, this school assignment I had done in the seventh grade in Catholic school on metaphors and similes. Now I vividly remember the pleasure I took in that assignment because it was literally the only thing the nuns had ever given me to do that I enjoyed. So this line I had written **popped** out at me.”A lonely road is a bodyguard.”What did it mean? I had even pasted a picture of this empty road next to the line. It was a metaphor. It wasn ’ t”a lonely road is like a bodyguard,”a simile. It was the much more poetic :”A lonely road is a bodyguard.”As painful as that was then, and as it still can be painful now, I knew what she was telling me. That... Solitude can protect the seeds of creativity. And that loneliness contains a priceless gift if we can tolerate the initial discomfort and avoid the seduction of despair. So my 12-year-old waved at me across the decades, saying that who I was was who I would become. And I waved back and I dropped her line right in the song I was writing. I ’ ll send the angels to watch over you tonight And you send them right back to me A lonely road is a bodyguard If we really want it to be We ’ re all just radios hoping to pick up each other ’ s signals. And some of those signals have a backbeat and a melody, and they ’ re universal. And music can unlock a frozen memory that melts into the seeds of our creativity. And the reverse is also true. A memory can unlock a song that ’ s waiting to be written. It can reveal us to ourselves across time and generations, in community, in solitude. Some frequencies are sound, and some frequencies are light. And some take a half a lifetime to reach their destination. Light is particle and wave Our histories written large upon the page The star in middle age The love that fades to black Once revealed, won ’ t be taken back Light nothing can escape The ignorance we once forgave In the future, if we don ’ t decide to change The things we cannot save But it slows to shine upon your face We owe everything Everything Everything To this rainbow of suffering Light is particle and wave Refractions of this place Reflections of our grace It reveals what we hold dear And it ’ s slow so I can hold you near There ’ s one thing I know for certain. That we clear the static by being vulnerable and by telling the truth. And here we are doing just that. Thank you.

Text Sample 632: NEG Dim 4 – 2021 – Score -1.00 – 2021/t003815.txt

Breast cancer is one of the leading causes of cancer deaths globally. About one in eight US women will develop invasive breast cancer over the course of their lifetime. And globally, millions of women suffer from breast cancer every year. But it is quite treatable if detected early. Right now, actually, mammography is the gold standard for breast cancer diagnosis. But mammography has a 10 percent chance of missed detection. Thousands of lives could be lost each year because of this 10 percent. Today, I ’ m going to introduce a new technology : photoacoustic imaging. As you can see, it provides a much clearer image, leading to a more accurate diagnosis. It will be affordable, just like an ultrasound scan. It ’ s painless and fast, taking only 15 seconds to scan the entire breast in 3D. And immediate results will be delivered to the patients. Beyond breast imaging, this technology will broadly transform how we see inside our bodies – and, maybe one day, even allow us to diagnose cancer via a wearable watch-like device that monitors circulating tumor cells. So what is photoacoustic imaging? Based on a photoacoustic effect, it is a conversion of light energy into sound energy. We shot a gentle laser pulse onto the tissue. The light is absorbed, raising its temperature a bit. The rise in temperature leads to a tiny fraction of volume expansion, which, in turn, generates acoustic waves. Sensors process those sound signals, resulting in a high-resolution image whose level of clarity and detail far surpasses what you ’ ve got with traditional CT scans or ultrasound. Now, about me. I started out in industrial optics, but changed direction after my grandparents died of cancer and stroke. I realized that we needed better imaging technology to aid early diagnosis and to provide a better understanding of the diseases. So I decided to devote myself to biomedical optical imaging. I now research and develop next generation medical imaging with applications ranging from diagnosing cancer to mapping **brain** functions and navigating medical micro robots for drug delivery. Here are some examples showing what we can do. Take this mouse. The mouse has been virtually sliced into 600 pieces from head to toe. It took only 12 seconds to complete the whole body scan. It looks a little like a mouse carpaccio. But don ’ t worry, no mice were hurt during the imaging. In this next video, we hold the animal, another mouse, in position to image its liver. The liver has a lot of blood vessels inside. You can see them as a tree-like network. Because our imaging exposure time is too short, only 15 microseconds, there is no blur at all, despite the movement of the animal during the imaging. The mouse is breathing normally, and every frame in our video is clear. With each slice we can clearly see the internal structure and the blood vessel network. This enables us to differentiate a tumor from normal tissue. The light dose we use is well below the safety limit, and we don ’ t need to inject any contrast agents. It is totally non-invasive. Now, for an example, that is a little closer to home. This is a side by side comparison of human **brain** images. On the left, you see an image from an MRI. On the right, from photoacoustic imaging. Photoacoustic imaging can reveal detailed vasculature, but with even faster detection of the **brain** functions and without using the costly high-magnetic field. What you are seeing here is the **brain** ’ s activity, where a patient, now a human this time, taps his finger, puckers his lips, taps his tongue and is listening and thinking of words. Although I don ’ t have a visual for it, I ’ d like to share one more example. In science fiction, micro robots enter our bodies to cure diseases in hard-to-reach areas. However, in reality, locating, guiding and controlling them inside of the body is a big challenge. Just like the satellites in space guiding cars to their destinations, a photoacoustic imaging system outside the body can serve similarly as a GPS for the micro robots. Biomedical optics has come a long way. The microscope used every day in modern medical diagnosis was invented in the 17th century, which revolutionized 19th century medicine by letting us see into a cell. Then, optical coherence tomography developed in 1990s increased optical penetration to 1 millimeter, bringing huge benefits to clinical care for skin and eyes. Now, photoacoustic imaging, first adopted for medical use in the 2000s, allows us to see even more, allowing penetration by another order of magnitude, to several centimeters, allowing organ-level in vivo human imaging. Photoacoustic imaging is a highly-active and a fast-growing research field. Using microwaves instead of light, this imaging method holds promises for whole body penetration in humans in the future. We are hoping that the further advancement of this technology will aid early diagnosis of cancer and **brain** diseases, ultimately benefiting global health. I hope you all can share my excitement over this fast-growing field and hope you ’ ll join us in advancing the technology. Thank you.

Text Sample 633: NEG Dim 4 – 2021 – Score 1.00 – 2021/t003792.txt

Pasture is the single largest type of land on the surface of the Earth today, thanks to our taste for meat and dairy. Just over a quarter of all land is used for livestock. That ' s more than forests or farm fields or anything else. Most of that land is best for ruminants, such as cows, that can digest high-fiber feed such as grass and straw. However, the process by which grass and fiber is broken up in the stomachs of cows and other grazing ruminants has a byproduct, methane, a potent greenhouse gas. Despite what you might have heard about methane and cows, most of the methane is actually burped out, not through the back end. And that represents about two billion tons of carbon dioxide equivalent per year, or more than four percent of our annual global greenhouse gas emissions. We have a methane problem from cows. So how can you reduce these methane burps? My colleagues and I may have found a solution. Seaweed! Let me explain. A couple of years ago, an article was published by Rob Kinley and colleagues that showed almost complete elimination of methane when seaweed was added to chopped grass in the lab. Great. But as an agricultural researcher, I know lots of additives work well in the lab, but not in real animals. But there was something different about seaweed and the way in which it reduced methane. So we thought we should test this in live animals. In collaboration with Joan Salwen, an entrepreneur, and colleagues from James Cook University and CSIRO, we decided to conduct a small experiment to determine the amount of seaweed we might need to use. This was the first ever experiment in dairy cattle, and we had no idea how much to give them. So we started with about 60 grams per day, going up to 250 grams. Mind you, this was mixed in with 25 kilograms of their feed. One of the graduate students I work with, Breanna Roque, trapped their methane burps. In that first experiment, the emissions were reduced by up to 67 percent. And I thought at first, the equipment must have malfunctioned, but it was real. But we are left with more questions than answers. Would the microbes in the gut get used to it and start producing methane over time? Would the seaweed be stable over a long period of time in storage? Would the taste be affected and the cows turn up their noses? Or would the seaweed affect the cows ' s health or milk production? So we teamed up again to conduct another trial. Over a five-month period, we saw the seaweed that was harvested three years prior reduce emissions by over 80 percent. Our colleagues in Australia, they saw up to 98 percent reduction in a similar trial. That kind of reduction is simply staggering. And in the graph, you see methane emissions in three levels of intake. So the first line is for cattle with no seaweed, The second line is for cows that were supplemented with about 30 to 40 grams of seaweed. And the last one is for cows supplemented with about 60 to 80 grams of seaweed. As you can see, as you increase the amount of seaweed, you see a reduction in methane emissions. We have also seen an improvement in bulking up of the beef cattle with no adverse health effects. So it ' s a win for the environment ; it ' s a win for the farmers and consumers. A panel of 112 people got to taste steak made from steers offered seaweed and control. And they did not detect any difference. We also did a nutritional quality of the meat, and we found no difference between animals that were offered seaweed and the control. So how does it work? Some seaweeds contain ingredients that directly inhibit microbes in the cow ' s gut from forming methane without interfering with food digestion. The amount of methane produced is dependent on how much the animal is eating and what ' s in the diet. And as such, previous efforts to reduce methane emissions focused on changing their diets or improving forage quality. And we do have potential solutions other than seaweed to reduce methane emissions. We looked at additives to feed, such as 3-NOPs, reduce emissions by about 30 percent. Even garlic and citrus extract can reduce methane burps by over 20 percent without affecting animal health and productivity. Now you may ask : Why not stop eating beef and drinking milk? Audience member : Yeah! EK : That would be a good question. So adopting a plant-based diet with supplements may help shrink a person ' s carbon footprint in high-income countries like the US. But, you know, a lot of people are not going to do that. And for the rest of the world, these foods are needed to provide key nutrients, such as vitamin B12 and vitamin A, which are critical for **brain** function, for vision and immunity. These are found almost exclusively in beef and milk. In this graph, you see different countries with their annual meat consumption per capita on the bar graph, and then you see the dots representing the stunting rate in children below the age of five years old. And countries that have lower consumption of methane are associated with higher incidence of stunting. I know this firsthand. Growing up in Eritrea, I loved milk and meat when you could get it, which wasn ' t often. Even as a kid, I always wondered how a cow, eating just grass, produces nutritious milk I love to drink. And that wonder pushed me into a career to understand and improve livestock production so that people in low-income countries do not suffer with stunting and other nutrient-deficiency diseases. So what now? We know seaweed can work. But the cultivation of the specific seaweed has been a barrier. It ' s not so easy to farm asparagopsis taxiformis. But there are a number of efforts going on at the moment to scale up production. Blue Ocean Barns is growing seaweed in Hawaii already, and they estimate that there will be enough production to feed all cattle in the US by 2030. All we need now is for governments to step up and facilitate the use of these methane-busting feed additives. Cattle industries in some countries have already committed to climate neutrality by 2050. But if we can get these feed-additive innovations into cow stomachs earlier, we can cut methane burps significantly. Given that methane only lasts in the atmosphere for a decade or so, we could even slow global warming in the short term. Yes, we have a methane problem from cows, but we may have seaweed and other solutions for these methane burps, helping us provide meat and dairy while maintaining a safe climate. Thank you.

I was born and I grew up in Ivory Coast, and like so many other African kids, I used to resent my Blackness, including my hair. I longed for straight hair that could be easily managed and brushed. After years of using hair relaxer, I went back to natural hair at 16 after an incident with my hair that forced me to shave and start over, and it was a very hard new beginning. But at 18, while I was still in the process of learning how to love my natural hair, I came across a photo album showing the hair of African women in pre-colonial society, and I was instantly inspired. Seeing that photo album was so powerful to me. It made me see hair completely differently. Not just as a beauty tool, but as a way to communicate and to tell stories about who we are. And immediately, I started to experiment with my own hair. I wanted to see what I was able to create. And today I ' m an artist and hair sculpting is one of my media. I use my hair to advocate for what I believe in, particularly for issues that affect women and girls. But it didn ' t start that way. At the beginning, I was just doing beautiful shapes for the aesthetic aspects. I started with doing simple geometrical shapes just for the beauty of it, and when I was posting those shapes online, I was receiving so much love that it encouraged me to push my limit to create more complex sculpture. From 2017 when I first started until now, I ' ve made hundreds of sculptures. Some can be playful, others can be very serious. So here are just a few examples of what I can do with my hair. Animals. Random things, like an umbrella or car. Portraits. Audience : Wow! Text, like here where I write"perfect"with my hair because I do believe my hair is perfect. Cartoon. Sunflowers. Fashion accessories. Wings. Even zodiac-inspired hairstyle because my rising sign is Scorpio. I ' m another astrology freak. Medusa and even body parts. Thanks. The process to make the sculpture is actually pretty simple. The idea comes to my head, I do a little sketch and then I just sculpt, using my natural hair, some hair extension and wire. I just wrap the braid around the wire, and then it ' s very easy for me to shape as I want. And in general, you know, to make the sculpture being able to stand on top of my head, the base needs to be extremely tight. So if you ' re wondering, is it hurtful? Yes. Yes it is. But this is why, in general, I quickly undo it after the photo shoot. Most of the time I will take the picture by myself, but when I need help, my little sister, Florencia, who is the most supportive person on the planet, will help me. And depending on what I want to create, a sculpture can take me from five minutes to more than three, four or five hours. When I started to create, I was just doing, as I said before, for the beauty of it, no meanings. But it changed in 2018 when one of my photo series went completely viral. It was this one. I shaped my hair as a second pair of hands, very playful, in various configurations, and I started to receive a lot of messages from Black women around the world telling me that seeing my hair helped them to feel better about their hair, about their Blackness. And I realized, OK, actually, what I ' m doing is pretty powerful. So maybe it can just serve a greater purpose and I can use it to advocate for change. So I decided to use my hair as a platform to advocate for the equity of sexes. Why this specific subject, you may ask? Because I was born and I grew up in an environment that normalized the bad treatment of women. I have my experience, many women have their experience, so it touched me a lot. And when it comes to equality of sexes, I touch a lot of different subjects. Unfortunately, I can ' t share all of them with you. I can just give you today a glimpse of it. Bodily autonomy and self-love is very important for me. I went myself into a long process towards self love. Coming from a place where I used to dislike everything about myself to a place where I just love everything. So I love to inspire myself – So I love to inspire myself from our female body to create sculpture and shapes that are associated with uplifting words to empower those who need it. And with this sculpture, what I want to do is to encourage women to have agency over their body, but also to destigmatize all the classic taboos around our bodies, like, for example, periods. Aging, disabilities and much more. This sculpture, for example, was to – Was to address the big taboo of body hair on women. When I was 15, I posted a photograph of me on social media without realizing that my armpit hair was visible and immediately, the comments were wild."This is disgusting.""Go shave.""Ew, I can buy you a razor if you want."I was traumatized, so I deleted the picture and after that I started to shave way more regularly. Even if, for me, it ' s a very uncomfortable routine. It took me years to be able to love my body the way it is and to embrace everything, including my body hair. Besides all the topics related to bodies, I love to also address topics related to our intellect as women, because this world doesn ' t only encourage women to dislike the body, but also encourages women to dislike what they have inside. And I think just as we ' re supposed to love our bodies, we ' re supposed to also own our hopes, dreams, our ideas or opinion without shame. And for that, I think – And for that I think education is extremely important. This is why I did this sculpture. Unfortunately, in Ivory Coast, many women still can ' t read. When I was a child, many women were working at our home as nannies. They weren ' t educated. They would ask me to read the text messages because they couldn ' t. In rural Ivory Coast, many parents think that it ' s useless to put a girl in school because they are better at home learning how to cook or to take care of of the home for their future husbands. But when it comes to their son, they are allowed to have an education. So most of the time those women will end up marrying older men, and when those men abandon them, they are left with nothing, with very few career options, because they are not educated. And to me, this is revolting. Growing up in an environment where I wasn ’ t always encouraged to love who I was, my journey has been about becoming my own friend and advocate. And when I embraced the capacity I have to share my stories and the ones of others, I found the strength to advocate for what I believe in through my hair. Thank you.

When I was a medical student at UCLA, one of my patients was a young boy suffering from dozens of seizures daily. His family was going bankrupt, paying out of pocket for a cocktail of drugs with little benefit. Between the side effects and his constant seizures, this boy was wasting away. On a return visit, I was in disbelief to find that he was now seizure-free on most days. His mom beamed, telling me he was going to school for the first time, at the age of 10, and attributed this life-changing improvement to a regimen of natural supplements. It sounded incredible, but this was an anecdote. But it gave me a radical idea. What if it was easy to prove the effects of natural products? Maybe anyone could treat their own health affordably, more effectively, and with less side effects. No pharma or insurance needed. You see, for millennia, humans relied on plants as medicine. It was only a century ago that pharma created synthetic drugs, and for the first time ever, medicine could be patented and highly profitable. But to prove the safety and effectiveness of these never-before-seen compounds, slow, expensive clinical trials were invented. The natural medicines can ’ t be patented and can ’ t afford these trials. Ironically, nearly half of all FDA-approved drugs were first discovered in plants, but pharma created a synthetic version and only funded trials into what they could own and monopolize. And that ’ s why you see these natural products, a vast majority of them haven ’ t been able to prove they ’ re better than placebo. But AI, virtualization and the ubiquity of smartphones is changing all of that. What if it was easy to prove the right natural product, the right dose, for the right person and the right condition? You could bypass a broken healthcare system, go to the grocery store and buy the product proven for someone like you. It ’ s personalized and accessible and affordable for all. So to make this proof-generation easy, Pelin Thorogood and I created a B Corp called Radicle Science. We ’ re using AI-driven, crowdsourced trials so these natural products can generate proof at a fraction of the cost and time. Volunteers automatically get mailed product or placebo, and we collect data via smartphones and wearables. And since these are direct-to-consumer, anyone can join, including those historically excluded from trials – women, minorities, rural populations. You see, trials have studied mostly white, urban men. Last time I checked, I don ’ t think that ’ s me, and for my cofounder, that wasn ’ t her either. But direct-to-consumer crowdsourced trials can finally generate diverse data that ’ s relevant to all of us. So what happens when proof is easy? You get medicines that are natural, personalized, proven and democratized. Medicines that are directly available for all future generations. Because it turns out no one can patent nature. Thank you.

The fairytale industrial complex has been lying to you. Through a pervasive web of marketing, advertising, music, movies and more, it ’ s said that while you can ’ t buy love, you can buy your worthiness of being loved. Its comodofication of romantic love as a storybook fantasy can be summed up in three simple words :”Happily ever after.”Happiness, forever. If only you ’ re lucky enough and good enough and good-looking enough to be chosen by a high-status partner, ideally in a romantic comedy-worthy moment. Over the last 10 years, I have spoken to thousands of people about their romantic hopes and dreams, and I can report that for many, their vision of an ideal relationship is straight out of the fairytale fantasy playbook. Which is no wonder, given that”happily ever after”is used to sell us everything, from makeup to cars to chewing gum. We ’ ve incorporated this propaganda into our real-life approach to relationships, which disconnects us from love, which disconnects us from self-worth and causes genuine confusion about compatibility. Instead of making us feel that love is an abundant, infinitely renewable resource inside of us, which it is, it tries to convince us that love is external and scarce. It ’ s time to consider a new possibility for our collective romantic future. One that centers self-love, self-worth and prioritizes making romantic choices in alignment with our authentic values. No purchase required. Despite what you ’ ve been told, each of us holds the keys to true love. A true-love relationship, as I define it, has the foundational values of love, respect, intimacy, safety, commitment, adoration and joy. When you approach romantic love from this foundation, you empower yourself to transcend the shallow fantasy of love you ’ ve been sold for so long. With sincere intention, the courage to open your heart to be vulnerable and the cultivation of dating and love skills, true love can be a reality for all. How could it be any other way? You are a born love genius. You were born knowing how to love. All of the love that you ’ ve ever experienced and ever will experience is inside of you right now. The more that we cultivate the love within, the better it is for everyone. That ’ s because how we each individually approach love contributes to how we all collectively experience it. We have the opportunity to transcend the manipulations of the fairytale industrial complex and embrace a brighter, more intentional, more inclusive romantic future for all. One that sees us all as worthy without exception. Thank you.

About a decade ago, I met someone who had experienced a few episodes of schizophrenia. They had felt that their sense of self, of what it feels like to be them, changing somewhat. The boundaries of their body began to feel a bit nebulous. Even their psychological self felt a bit porous at times. They were experiencing what could be called an altered sense of self. Over the years, I met many such brave and insightful people who shared what it ’ s like to live with their altered selves. And by”altered,”I mean”different,”not”deficient,”while acknowledging that coping with altered selves can be a struggle at times. So speaking with them, and with theologians, philosophers, neuroscientists, I came to understand that this self that each one of us takes oneself to be is not as real as it seems. The self is a slippery subject. We all intuitively know what it means. It ’ s there when we wake up. It disappears when we fall asleep. It reappears in our dreams. It ’ s what makes us who we are. It seems solid, unchanging, permanent. And yet, we can examine aspects of the self that seem real to us, and ask,”Just how real are they?”Take, for instance, the question”Who am I?”The most likely answer you will get or give to such a

question will be in the form of a story. We tell others – and indeed, ourselves – stories about who we are. We take our stories to be sacrosanct. We are our stories. But a condition that most of us, sadly, will be familiar with – Alzheimer ' s disease – tells us something quite different. Alzheimer ' s begins by affecting short-term memory. Think about what that does to someone ' s story. In order for our stories to form, to grow, something that just happens to us has to first enter short-term memory, and then, get incorporated into what ' s called long-term episodic memory. It has to become an episode in our narrative. But what if the experience doesn ' t even enter short-term memory? That ' s exactly what Alzheimer ' s does. In the beginning, Alzheimer ' s impairs the formation of short-term memory. It impairs the growth of the narrative. It ' s as if our stories begin stalling upon the onset of the disease. Eventually, Alzheimer ' s eats away at all the long-term memories. So if you were to meet someone with mid-stage Alzheimer ' s, they will likely be able to tell you stories about who they are. But if you know their real stories, you ' ll be able to tell that they sometimes scramble up their narrative, that they sometimes mix up the sequence of episodes from their lives. It ' s as if they are recalling their own stories in ways that are not quite accurate. It ' s important, at this stage, to realize that there is still a person experiencing that scrambled narrative. Sadly, Alzheimer ' s goes on to destroy one ' s narrative, and so much more. And towards the end, it ' s unclear whether there is still someone experiencing something, because the person cannot communicate verbally anymore. And yet, Alzheimer ' s tells us that these stories that we take ourselves to be, what philosophers call the"narrative self,"these are spun by the **brain** and body. They are constructions. Sometimes, the constructions are disrupted, even destroyed. And while that is horrific for the person experiencing it, and for their caregivers, it is nonetheless a window onto the constructed nature of our narrative self. And when the construction goes wrong, we perceive our own stories in ways that are not quite real. From the narrative self, let ' s talk about our body. Let ' s take a very basic aspect of our bodily self. This feeling we all have, that we are owners of our body and body parts, that our bodies and body parts belong to us. It seems such a strange thing to think that it could even be otherwise. If I were to ask you,"Does your hand belong to you?"you ' re going to say,"Of course it does. What a foolish question."But not everyone would agree. Early on in my research, a neuropsychologist alerted me to a condition called xenomelia, or foreign limb syndrome. You may have heard of something called phantom limb syndrome, in which people who have had an amputation feel the presence of that limb, sometimes. Xenomelia is somewhat of an opposite condition, where people feel like some part of their body – usually the extremities, their hands or legs – don ' t belong to them. So this neuropsychologist talked of phantom limb syndrome as animation without incarnation. So the limb is gone, it ' s not incarnate anymore, but it ' s animated in your mind. And he talked of xenomelia as incarnation without animation. So the limb is present, healthy even, incarnate, and yet, in your own mind, it feels like it doesn ' t belong to you. So in xenomelia, the **brain** and bodily processes that give rise to our sense of ownership of our body parts, they ' re misfiring, so to speak, and the consequences can be serious. People with xenomelia will sometimes take extreme measures to get rid of, to amputate their foreign-seeming body parts. From the perspective of the self, though, xenomelia is telling us something very profound. It ' s telling us that something as basic as the sense of ownership of our own body parts is a construction. And sometimes, the construction goes wrong, and we perceive our own bodies in ways that are not quite real. Let ' s take another aspect of our bodily self. It ' s called the sense of agency. So when I do something like pick up a cup, I have this implicit feeling that I am the agent of that action, that I have willed that action into existence. That feeling is the sense of agency. But someone with schizophrenia may not have that feeling, always. Someone with schizophrenia might do something and not feel like they are the agent of that action. So schizophrenia tells us that it is possible to be someone who does something but doesn ’ t have an accompanying sense of agency. So just like the narrative self and the sense of ownership of body parts, the sense of agency is also a construction, and it, too, can fail. So you can see where this is going. Let me take one more example to drive home this point. Let ’ s talk of what it feels to be a body here and now. Not the feeling of being a story, but the feeling of being a body in the present moment. Psychologists estimate that about five percent of the general population will, at some point in their lives, have an out-of-body experience. Let ’ s assume that all of us right now are having an in-body experience. But what that means is having this feeling of being in a body, being anchored to a body, occupying a certain volume of space and looking at the world from behind our eyes. But if you are having an out-of-body experience, you could possibly be feeling that you ’ re up near the ceiling, looking down at your own body sitting in the chair below. People do report such experiences, and mild versions of this have been replicated in labs. But if you think, like I do, that out-of-body experiences are the outcome of **brain** processes that are misfiring, then it stands to reason that the experience of being in-body, of being embodied, is itself a construction, and that, too, can come apart. So what are these experiences of altered selves telling us? They ’ re telling us that just about everything we take to be real about ourselves –”real”in the sense that we think we are always experiencing undeniable truths about our bodies, our stories – well, that ’ s just not the case. So when theologians and philosophers tell us that the self is an illusion, this is partly what they mean. You may have realized by now that there still remains the question of who or what is doing the experiencing, even in the case of altered selves. This experiencing”I”in the question”Who am I?”is at the heart of the debate about the self. This experiencing”I”doesn ’ t go away if one or a few aspects of the self are disrupted. But what if all of the aspects of the self that comprise us were to be disrupted? Would the experiencing”I”disappear? We don ’ t have a satisfactory answer to that question, yet. It ’ s possible that the experiencing”I”is also an illusion, in the sense of being a construction, a construction without a constructor. That debate, however, is somewhat unresolved. Despite such doubts, I, personally – whatever I am – think that the self has no reality outside of the **brain** and body. I think that the experiencing”I”will not persist after the body is gone. So what does one make of such knowledge? Well, firstly, these ideas will feel liberating to some and might sit heavily upon others. Regardless, I think we can all attend to the stories that we think we are. Our feelings and emotions are modulated by our stories, and in turn, our feelings and emotions become part of our stories. And our stories, our narratives, are not just cognitive – they live in our bodies, and our bodies structure and shape our stories. So knowing all this, recognizing the constructive nature of it all, maybe we can hold on less tightly to our stories. Maybe we can learn to let go. But that ’ s easier said than done, because the thing that is doing the letting go is also the thing that has to be let go of. Maybe we can just marvel at the efforts of people over millennia, from the Buddha sitting under the Bodhi tree to the modern philosopher and neuroscientist who has asked themselves the question”Who am I?”But most of all, I think we owe a debt to those amongst us who bravely bear witness to our altered selves – whether we do so voluntarily, like monks and nuns do when they meditate, or whether it ’ s brought upon us by biology and circumstance. There is something remarkably robust about the processes that give rise to the totality of our sense of self. But there ’ s something frighteningly fragile about them too. They can crack. And any one of us, at any time in our lives, may have to confront such cracks. And that knowledge, I believe, should make us empathetic towards those of us dealing with altered selves. But I also believe that altered selves should not be seen as the outcome of deficits, or as the outcome of a lack of attributes considered normal. They are different ways of being, and it ’ s the willingness of some of us to confront the self ’ s constructed nature that is helping make sense of the self for all of us. Thank you. Thank you.

Text Sample 638: NEG Dim 4 – 2022 – Score -1.00 – 2022/t003583.txt
On a usual Saturday, you wouldn ’ t find me here. And I mean, of course, I don ’ t give TEDx Talks every Saturday. But what I mean is you probably wouldn ’ t find me in a museum. Further, if you were looking for me, you ’ d probably have to go to the mountains. And that is because I absolutely love hiking. And in addition to just being outside and being in the nature, what I really like is this feeling of physical exhaustion, sort of this satisfaction you can feel in every single muscle. And in the evening when it ’ s time to go to bed, I absolutely cherish this amazing sleepiness that fills you from head to toe. Now, you might say,”Well, of course she ’ s tired. She ’ s been hiking all day.”Plus, not to forget about the effects of supposedly fresh air. But there is one factor that most likely outweighs the effects of fresh air and perhaps even physical activity, and that is exposure to natural daylight. And today I hope to convince you that we should all appreciate daylight as sort of of a natural soporific. And hopefully by the end of the talk, you will also recognize that we should all pay more attention to our daily light diet. But let ’ s start with a question, why daylight is so important for our organism, for health and eventually for sleep. Now, throughout your body, in each and every single cell, there is a tiny molecular clock ticking inside it. And to keep these millions of clocks in sync, we have one central body clock that is located in the **brain** in an area which we call the hypothalamus. And like the conductor of an orchestra, it communicates the time of day to each of these molecular clocks. And this way it is able to regulate bodily processes in sync with the time of day. For example, it causes your body temperature to increase in the morning and to decrease in the evening. It choreographs the release of certain hormones at a proper time, and in the evening when it ’ s time to go to bed, it will also make you tired and sleepy. But given this precise synchronization between internal or biological time and external time or environmental time, it seems clear that the body clock cannot be blind or isolated or shut off from the environment, but rather it needs to receive information about the time of day from the environment for it to synchronize with sun time. And this is achieved by close connections between the internal biological clock in the **brain** and our eyes. And now you may know that in the human retina, there are different types of receptors, photoreceptors, so receptors that sense light. And classically, we distinguish two types : the rods and the cones. Now, the rods, they only contribute to a visual impression under very **dim** lighting conditions. And here in the background, you now see a picture that might more or less be brought about by only the involvement of the rods. What you can see is that it ’ s only shades of gray, it ’ s slightly blurred, and around the point of fixation, which is indicated by the gray dot here, you have a little scotoma, so an area where you can ’ t really see anything. Now, who recognizes what that is? Yeah? Yeah, excellent. But it ’ s going to be way easier, and the majority of you will recognize what it is when I now switch to the next slide, which is brought about by the involvement of the cones. Of course, it ’ s the town hall of Basel, but now you can appreciate the colors, fine details,

and if this was animated, you ’ d even see fine details in motion. But this is not the whole story. Because only fairly recently, only in the early 2000s, another type of cell has been discovered, and we call them retinal ganglion cells. Now, you might ask yourselves, well, What picture ’ s she going to show next? But I have to disappoint you. I actually can ’ t show another picture because from all we know, these cells do not contribute to a visual impression. But they ’ re exclusively designed to sense short wavelength proportions in daylight. Sometimes we also call this blue light. So they ’ re designed to extract important information about the time of day from the environment and pass this on to the internal biological clock in the **brain**. And I guess you ’ ve all experienced how well this biological timing system, this connection between our biological clock and the external world or our eyes works, when we, for example, travel across time zones, because with a speed of approximately one hour per day, you can fairly easily adapt to the new time zone. Now, how much light do we actually need? How much light is enough for the positive effects on, for instance, sleep to occur? And I have to admit, this is not so easy to answer. But I think what we have to keep in mind is that the biological timing system has evolved under the open sky and not in offices or museums. So it is also optimally tuned to the conditions we find outside. Office light or light in rooms is in no way comparable to what we find outside. And therefore, from a scientific perspective, I can only recommend you to spend as much time as you can under the open sky, but try to make it at least 30 minutes per day. Now, let ’ s finally talk about sleep. And I ’ ve repeatedly alluded to the fact that daylight is beneficial and important for sleep. And in this context, I ’ d like to share a little story : So last year I had to go to hospital for surgery. And generally the hospital environment is a very challenging one for sleep because you spend way too much time in bed not moving much, you might be in pain, now and then someone comes in to check on you even during the night, and if you ’ re as lucky as I was, you have a snoring roommate, and because you, of course, don ’ t get a lot of daylight. And that ’ s why many people, while they ’ re in hospital, ask for sleep medication. But as I consider myself to be a generally good sleeper, and also because I know how these drugs work, I didn ’ t want this. But I knew there was something I could do to help my body sleep as well as possible, even in this situation, and that was to maximize exposure to daylight. Because as a sleep scientist, of course I know about the research findings. I know that the more daylight that you get, the more tired you will be in the evening, the easier it will be for you to fall asleep and better the experienced sleep quality. And in addition, daylight exposure has also been shown to increase proportions of deep sleep, which again has been linked to processes of tissue repair, something not to be underestimated after surgery. And beyond the effects on sleep, we know that patients in brighter rooms experience less pain and less stress. And also the effects of daylight on mood are well-established. So I thought it might be time for me to put into practice what I often preach. And I have to confess that usually I ’ m much better at giving advice than following it myself. But here ’ s what I did. So first, when it became free, I asked the nurses to move my bed to the window place because that does not only give you power of a fresh air supply, which is highly recommended in the hospital, but it also maximizes daylight exposure even though you ’ re inside. Second, as soon as I could leave my bed again, I went to the park for short walks, and last, every meal I had, I tried to take on the little balcony. Did it work? Well, it ’ s a bit difficult to say because it, of course, was the single case study. But from patients suffering from insomnia, so one of the most common sleep disorders, we know that light therapy is beneficial. And therefore, I would like to encourage all of you, and perhaps especially those who might belong to the 25 percent suffering from sleep problems to start your own single case study. Thank you.

On a usual Saturday, you wouldn ’ t find me here. And I mean, of course, I don ’ t give TEDx Talks every Saturday. But what I mean is, you probably wouldn ’ t find me in a museum. Rather, if you were looking for me, you ’ d probably have to go to the mountains, and that is because I absolutely love hiking. And in addition to just being outside and being in nature, what I really like is this feeling of physical exhaustion, sort of this satisfaction you can feel in every single muscle. And in the evening, when it ’ s time to go to bed, I absolutely cherish this amazing sleepiness that fills you from head to toe. Now you might say,”Well, of course she ’ s tired. She ’ s been hiking all day. Plus, not to forget about the effects of supposedly fresh air.”But there is one factor that most likely outweighs the effects of fresh air and perhaps even physical activity, and that is exposure to natural daylight. And today, I hope to convince you that we should all appreciate daylight as sort of a natural soporific. And hopefully, by the end of the talk, you will also recognize that we should all pay more attention to our daily light diet. But let ’ s start with the question why daylight is so important for our organism, for health and, eventually, for sleep. Now throughout your body, in each and every single cell, there is a tiny molecular clock ticking inside it. And to keep these millions of clocks in sync, we have one central body clock that is located in the **brain**, in an area which we call the hypothalamus. And like the conductor of an orchestra, it communicates the time of day to each of these molecular clocks. And this way, it is able to regulate bodily processes in sync with the time of day. For example, it causes your body temperature to increase in the morning and to decrease in the evening. It choreographs the release of certain hormones at appropriate times. And in the evening, when it ’ s time to go to bed, it will also make you tired and sleepy. But given this precise synchronization between internal or biological time and external time or environmental time, it seems clear that the body clock cannot be blind or isolated or shut off from the environment, but rather, it needs to receive information about the time of day from the environment for it to synchronize with sun time. And this is achieved by close connections between the internal biological clock in the **brain** and our eyes. And now you may know that in the human retina, there are different types of receptors, so photoreceptors, so receptors that sense light. And classically, we distinguish two types, the rods and the cones. Now the rods only contribute to a visual impression under very **dim** lighting conditions. And here, in the background, you now see a picture that might, more or less, be brought about by only the involvement of the rods. Thank you. Ooh, I ’ m like,”Phew, phew, calm down. Get back into my body now.”Usually when I play out, the first thing that happens is people scream out,”What ’ s she doing?!”I ’ ll play at these rock shows, be on stage standing completely still, and they ’ re like,”What ’ s she doing?! What ’ s she doing?!”And then I ’ ll kind of be like — — and then they ’ re like,”Whoa!”I ’ m sure you ’ re trying to figure out,”Well, how does this thing work?”Well, what I ’ m doing is controlling the pitch with my left hand. See, the closer I get to this antenna, the higher the note gets — — and you can get it really low. And with this hand I ’ m controlling the volume, so the further away my right hand gets, the louder it gets. So basically, with both of your hands you ’ re controlling pitch and volume and kind of trying to create the illusion that you ’ re doing separate notes, when really it ’ s continuously going... Sometimes I startle myself : I ’ ll forget that I have it on, and I ’ ll lean over to pick up something, and then it goes like — —”Oh!”And it ’ s like a funny sound effect that follows you around if you don ’ t turn the thing off. Maybe we ’ ll go into the next tune, because I totally lost where this is going. We ’ re going to do a song by David Mash called”Listen : the Words Are Gone,”and maybe I ’ ll have words come back into me afterwards if I can relax. So, I ’ m trying to think of some of the questions that are commonly asked ; there are so many. And... Well, I guess I could tell you a little of the history of the theremin. It was invented around the 1920s, and the inventor, Lon Theremin — he also was a musician besides an inventor — he came up with the idea for making the theremin, I think, when he was working on some shortwave radios. And there ’ d be that sound in the signal — it ’ s like — and he thought,”Oh, what if I could control that sound and turn it into an instrument, because there are pitches in it.”And so somehow through developing that, he eventually came to make the theremin the way it is now. And a lot of times, even kids nowadays, they ’ ll make reference to a theremin by going,”Whoo-hoo-hoo-hoo,”because in the ’ 50s it was used in the sci-fi horror movies, that sound that ’ s like... It ’ s kind of a funny, goofy sound to do. And sometimes if I have too much coffee, then my vibrato gets out of hand. You ’ re really sensitive to your body and its functions when you ’ re behind this thing. You have to stay so still if you want to have the most control. It reminds me of the balancing act earlier on — what Michael was doing — because you ’ re fighting so hard to keep the balance with what you ’ re playing with and stay in tune, and at the same time you don ’ t want to focus so much on being in tune all the time ; you want to be feeling the music. And then also, you ’ re trying to stay very, very, very still because little movements with other parts of your body will affect the pitch, or sometimes if you ’ re holding a low note — — and breathing will make it... If I pass out on the next song... I think of it almost like like a yoga instrument because it makes you so aware of every little crazy thing your body is doing, or just aware of what you don ’ t want it to be doing while you ’ re playing ; you don ’ t want to have any sudden movements. And if I go to a club and play a gig, people are like,”Here, have some drinks on us!”And it ’ s like,”Well, I ’ m about to go on soon ; I don ’ t want to be like — — you know?”It really does reflect the mood that you ’ re in also, if you ’ re... it ’ s similar to being a vocalist, except instead of it coming out of your throat, you ’ re controlling it just in the air and you don ’ t really have a point of reference ; you ’ re always relying on your ears and adjusting constantly. You just have to always adjust to what ’ s happening and realize you ’ ll have bummer notes come here and there and listen to it, adjust it, and just move on, or else you ’ ll get too tied up and go crazy. Like me. I think we will play another tune now. I ’ m going to do”Lush Life.”It ’ s one of my favorite tunes to play.

I ’ m going to read a few strips. These are, most of these are from a monthly page I do in and architecture and design magazine called Metropolis. And the first story is called”The Faulty Switch.”Another beautifully designed new building ruined by the sound of a common wall light switch. It ’ s fine during the day when the main rooms are flooded with sunlight. But at dusk everything changes. The architect spent hundreds of hours designing the burnished brass switchplates for his new office tower. And then left it to a contractor to install these 79-cent switches behind them. We know instinctively where to reach when we enter a dark room. We automatically throw the little nub of plastic upward. But the sound we are greeted with, as the room is bathed in the simulated glow of late-afternoon light, recalls to mind a dirty men ’ s room in the rear of a Greek coffee shop. This sound colors our first impression of any room ; it can ’ t be helped. But where does this sound, commonly described as a click, come from? Is it simply the byproduct of a crude mechanical action? Or is it an imitation of one half the set of sounds we make to express disappointment? The often dental consonant of no Indo-European language. Or is it the amplified sound of a synapse firing in the **brain** of a cockroach? In the 1950s they tried their best to muffle this sound with mercury switches and silent knob controls. But today these improvements seem somehow inauthentic. The click is the modern triumphal clarion proceeding us through life, announcing our entry into every lightless room. The sound made flicking a wall switch off is of a completely different nature. It has a deep melancholy ring. Children don ’ t like it. It ’ s why they leave lights on around the house. Adults find it comforting. But wouldn ’ t it be an easy matter to wire a wall switch so that it triggers the muted horn of a steam ship? Or the recorded crowing of a rooster? Or the distant peel of thunder? Thomas Edison went through thousands of unlikely substances before he came upon the right one for the filament of his electric light bulb. Why have we settled so quickly for the sound of its switch? That ’ s the end of that. The next story is called”In Praise of the Taxpayer.”That so many of the city ’ s most venerable taxpayers have survived yet another commercial building boom, is cause for celebration. These one or two story structures, designed to yield only enough income to cover the taxes on the land on which they stand, were not meant to be permanent buildings. Yet for one reason or another they have confounded the efforts of developers to be combined into lots suitable for high-rise construction. Although they make no claim to architectural beauty, they are, in their perfect temporariness, a delightful alternative to the large-scale structures that might someday take their place. The most perfect examples occupy corner lots. They offer a pleasant respite from the high-density development around them. A break of light and air, an architectural biding of time. So buried in signage are these structures, that it often takes a moment to distinguish the modern specially constructed taxpayer from its neighbor : the small commercial building from an earlier century, whose upper floors have been sealed, and whose groundfloor space now functions as a taxpayer. The few surfaces not covered by signs are often clad in a distinctive, dark green-gray, striated aluminum siding. Take-out sandwich shops, film processing drop-offs, peep-shows and necktie stores. Now these provisional structures have, in some cases, remained standing for the better part of a human lifetime. The temporary building is a triumph of modern industrial organization, a healthy sublimation of the urge to build, and proof that not every architectural idea need be set in stone. That ’ s the end. And the next story is called,”On the Human Lap.”For the ancient Egyptians the lap was a platform upon which to place the earthly possessions of the dead — 30 cubits from foot to knee. It was not until the 14th century that an Italian painter recognized the lap as a Grecian temple, upholstered in flesh and cloth. Over the next 200 years we see the infant Christ go from a sitting to a standing position on the Virgin ’ s lap, and then back again. Every child recapitulates this ascension, straddling one or both legs, sitting sideways, or leaning against the body. From there, to the modern ventriloquist ’ s dummy, is but a brief moment in history. You were late for school again this morning. The ventriloquist must first make us believe that a small boy is sitting on his lap. The illusion of speech follows incidentally. What have you got to say for yourself, Jimmy? As adults we admire the lap from a nostalgic distance. We have fading memories of that provisional temple, erected each time an adult sat down. On a crowded bus there was always a lap to sit on. It is children and teenage girls who are most keenly aware of its architectural beauty. They understand the structural integrity of a deep avuncular lap, as compared to the shaky arrangement of a neurotic niece in high heels. The relationship between the lap and its owner is direct and intimate. I envision a 36-story, 450-unit residential high-rise — a reason to consider the mental health of any architect before granting an important commission. The bathrooms and kitchens will, of course, have no windows. The lap of luxury is an architectural construct of childhood, which we seek, in vain, as adults, to employ. That ’ s the end. The next story is called”The Haverpiece Collection”A nondescript warehouse, visible for a moment from the northbound lanes of the Prykushko Expressway, serves as the temporary resting place for the Haverpiece collection of European dried fruit. The profound convolutions on the surface of a dried cherry. The foreboding sheen of an extra-large date. Do you remember wandering as a child through those dark wooden storefront galleries? Where everything was displayed in poorly labeled roach-proof bins. Pears dried in the form of genital organs. Apricot halves like the ears of cherubim. In 1962 the unsold stock was purchased by Maurice Haverpiece, a wealthy prune juice bottler, and consolidated to form the core collection. As an art form it lies somewhere between still-life painting and plumbing. Upon his death in 1967, a quarter of the items were sold off for compote to a high-class hotel restaurant. Unsuspecting guests were served stewed turn-of-the-century Turkish figs for breakfast. The rest of the collection remains here, stored in plain brown paper bags until funds can be raised to build a permanent museum and study center. A shoe made of apricot leather for the daughter of a czar. That ’ s the end. Thank you.

Text Sample 642: NEG Dim 4 – 2002 – Score 2.00 – 2002/t000397.txt

How many Creationists do we have in the room? Probably none. I think we ’ re all Darwinians. And yet many Darwinians are anxious, a little uneasy â would like to see some limits on just how far the Darwinism goes. It ’ s all right. You know spiderwebs? Sure, they are products of evolution. The World Wide Web? Not so sure. Beaver dams, yes. Hoover Dam, no. What do they think it is that prevents the products of human ingenuity from being themselves, fruits of the tree of life, and hence, in some sense, obeying evolutionary rules? And yet people are interestingly resistant to the idea of applying evolutionary thinking to thinking â to our thinking. And so I ’ m going to talk a little bit about that, keeping in mind that we have a lot on the program here. So you ’ re out in the woods, or you ’ re out in the pasture, and you see this ant **crawling** up this blade of grass. It climbs up to the top, and it falls, and it climbs, and it falls, and it climbs â trying to stay at the very top of the blade of grass. What is this ant doing? What is this in aid of? What goals is this ant trying to achieve by climbing this blade of grass? What ’ s in it for the ant? And the answer is : nothing. There ’ s nothing in it for the ant. Well then, why is it doing this? Is it just a fluke? Yeah, it ’ s just a fluke. It ’ s a lancet fluke. It ’ s a little **brain** worm. It ’ s a parasitic **brain** worm that has to get into the stomach of a sheep or a cow in order to continue its life cycle. Salmon swim upstream to get to their spawning grounds, and lancet flukes commandeer a passing ant, **crawl** into its **brain**, and drive it up a blade of grass like an all-terrain vehicle. So there ’ s nothing in it for the ant. The ant ’ s **brain** has been hijacked by a parasite that infects the **brain**, inducing suicidal behavior. Pretty scary. Well, does anything like that happen with human beings? This is all on behalf of a cause other than one ’ s own genetic fitness, of course. Well, it may already have occurred to you that Islam means”surrender,”or”submission of self-interest to the will of Allah.”Well, it ’ s ideas â not worms â that hijack our **brains**. Now, am I saying that a sizable minority of the world ’ s population has had their **brain** hijacked by parasitic ideas? No, it ’ s worse than that. Most people have. There are a lot of ideas to die for. Freedom, if you ’ re from New Hampshire. Justice. Truth. Communism. Many people have laid down their lives for communism, and many have laid down their lives for capitalism. And many for Catholicism. And many for Islam. These are just a few of the ideas that are to die for. They ’ re infectious. Yesterday, Amory Lovins spoke about”infectious repititis.”It was a term of abuse, in effect. This is unthinking engineering. Well, most of the cultural spread that goes on is not brilliant, new, out-of-the-box thinking. It ’ s”infectious repetitis,”and we might as well try to have a theory of what ’ s going on when that happens so that we can understand the conditions of infection. Hosts work hard to spread these ideas to others. I myself am a philosopher, and one of our occupational hazards is that people ask us what the meaning of life is. And you have to have a bumper sticker, you know. You have to have a statement. So, this is mine. The secret of happiness is : Find something more important than you are and dedicate your life to it. Most of us â now that the”Me Decade”is well in the past â now we actually do this. One set of ideas or another have simply replaced our biological imperatives in our own lives. This is what our summum bonum is. It ’ s not maximizing the number of grandchildren we have. Now, this is a profound biological effect. It ’ s the subordination of genetic interest to other interests. And no other species does anything at all like it. Well, how are we going to think about this? It is, on the one hand, a biological effect, and a very large one. Unmistakable. Now, what theories do we want to use to look at this? Well, many theories. But how could something tie them together? The idea of replicating ideas ; ideas that replicate by passing from **brain** to **brain**. Richard Dawkins, whom you ’ ll be hearing later in the day, invented the term”memes,”and put forward the first really clear and vivid version of this idea in his book”The Selfish Gene.”Now here am I talking about his idea. Well, you see, it ’ s not his. Yes â he started it. But it ’ s everybody ’ s idea now. And he ’ s not responsible for what I say about memes. I ’ m responsible for what I say about memes. Actually, I think we ’ re all responsible for not just the intended effects of our ideas, but for their likely misuses. So it is important, I think, to Richard, and to me, that these ideas not be abused and misused. They ’ re very easy to misuse. That ’ s why they ’ re dangerous. And it ’ s just about a full-time job trying to prevent people who are scared of these ideas from caricaturing them and then running off to one dire purpose or another. So we have to keep plugging away, trying to correct the misapprehensions so that only the benign and useful variants of our ideas continue to spread. But it is a problem. We don ’ t have much time, and I ’ m going to go over just a little bit of this and cut out, because there ’ s a lot of other things that are going to be said. So let me just point out : memes are like viruses. That ’ s what Richard said, back in ’ 93. And you might think,”Well, how can that be? I mean, a virus is â you know, it ' s stuff! What ' s a meme made of?"Yesterday, Negroponte was talking about viral telecommunications but â what ' s a virus? A virus is a string of nucleic acid with attitude. That is, there is something about it that tends to make it replicate better than the competition does. And that ' s what a meme is. It ' s an information packet with attitude. What ' s a meme made of? What are bits made of, Mom? Not silicon. They ' re made of information, and can be carried in any physical medium. What ' s a word made of? Sometimes when people say,"Do memes exist?"I say,"Well, do words exist? Are they in your ontology?"If they are, words are memes that can be pronounced. Then there ' s all the other memes that can ' t be pronounced. There are different species of memes. Remember the Shakers? Gift to be simple? Simple, beautiful furniture? And, of course, they ' re basically extinct now. And one of the reasons is that among the creed of Shaker-dom is that one should be celibate. Not just the priests. Everybody. Well, it ' s not so surprising that they ' ve gone extinct. But in fact that ' s not why they went extinct. They survived as long as they did at a time when the social safety nets weren ' t there. And there were lots of widows and orphans, people like that, who needed a foster home. And so they had a ready supply of converts. And they could keep it going. And, in principle, it could ' ve gone on forever, with perfect celibacy on the part of the hosts. The idea being passed on through proselytizing, instead of through the gene line. So the ideas can live on in spite of the fact that they ' re not being passed on genetically. A meme can flourish in spite of having a negative impact on genetic fitness. After all, the meme for Shaker-dom was essentially a sterilizing parasite. There are other parasites that do this â which render the host sterile. It ' s part of their plan. They don ' t have to have minds to have a plan. I ' m just going to draw your attention to just one of the many implications of the memetic perspective, which I recommend. I ' ve not time to go into more of it. In Jared Diamond ' s wonderful book,"Guns, Germs and Steel,"he talks about how it was germs, more than guns and steel, that conquered the new hemisphere â the Western hemisphere â that conquered the rest of the world. When European explorers and travelers spread out, they brought with them the germs that they had become essentially immune to, that they had learned how to tolerate over hundreds and hundreds of years, thousands of years, of living with domesticated animals who were the sources of those pathogens. And they just wiped out â these pathogens just wiped out the native people, who had no immunity to them at all. And we ' re doing it again. We ' re doing it this time with toxic ideas. Yesterday, a number of people â Nicholas Negroponte and others â spoke about all the wonderful things that are happening when our ideas get spread out, thanks to all the new technology all over the world. And I agree. It is largely wonderful. Largely wonderful. But among all those ideas that inevitably flow out into the whole world thanks to our technology, are a lot of toxic ideas. Now, this has been realized for some time. Sayyid Qutb is one of the founding fathers of fanatical Islam, one of the ideologues that inspired Osama bin Laden."One has only to glance at its press films, fashion shows, beauty contests, ballrooms, wine bars and broadcasting stations."Memes. These memes are spreading around the world and they are wiping out whole cultures. They are wiping out languages. They are wiping out traditions and practices. And it ' s not our fault, anymore than it ' s our fault when our germs lay waste to people that haven ' t developed the immunity. We have an immunity to all of the junk that lies around the edges of our culture. We ' re a free society, so we let pornography and all these things â we shrug them off. They ' re like a mild cold. They ' re not a big deal for us. But we should recognize that for many people in the world, they are a big deal. And we should be very alert to this. As we spread our education and our technology, one of the things that we are doing is we ’ re the vectors of memes that are correctly viewed by the hosts of many other memes as a dire threat to their favorite memes â the memes that they are prepared to die for. Well now, how are we going to tell the good memes from the bad memes? That is not the job of the science of memetics. Memetics is morally neutral. And so it should be. This is not the place for hate and anger. If you ’ ve had a friend who ’ s died of AIDS, then you hate HIV. But the way to deal with that is to do science, and understand how it spreads and why in a morally neutral perspective. Get the facts. Work out the implications. There ’ s plenty of room for moral passion once we ’ ve got the facts and can figure out the best thing to do. And, as with germs, the trick is not to try to annihilate them. You will never annihilate the germs. What you can do, however, is foster public health measures and the like that will encourage the evolution of avirulence. That will encourage the spread of relatively benign mutations of the most toxic varieties. That ’ s all the time I have, so thank you very much for your attention.

Sleep is perhaps the single most effective thing that we can do each and every day to reset the health of our **brain** and our body. And by understanding a little bit more about what sleep is, perhaps we can get the chance to improve both the quantity and the quality of our sleep. [Sleeping with Science] So, exactly what is sleep? Well, sleep, at least in human beings, is subdivided into two main types. On the one hand, we have non-rapid eye movement sleep, or non-REM sleep for short. But on the other hand, we have rapid eye movement sleep, or REM sleep. And non-REM sleep has been further subdivided into four separate stages, unimaginatively called stages one through four, increasing in their depth of sleep. And as we go into those light stages of non-REM sleep, your heart rate starts to decrease, your body temperature starts to drop and your electrical **brain** wave activity starts to slow down. But as we move into deeper non-rapid eye movement sleep, stages three and four, now all of a sudden the **brain** erupts with these huge, big, powerful **brain** waves. The body is actually recharged in terms of its immune system. We also get this beautiful overhaul of our cardiovascular system. And, in fact, upstairs in the **brain**, deep non-REM sleep will help consolidate memories and fixate them into the neural architecture of the **brain**. So that ’ s non-REM sleep. But let ’ s come on to REM sleep, which is the other main type of sleep. And it ’ s during REM sleep when we principally have the most vivid, the most hallucinogenic types of dreams. The **brain** wave activity actually starts to speed up again. It ’ s during REM sleep that we receive almost a form of emotional first aid. And it ’ s also during REM sleep where we get a boost for creativity, that it stitches information together so that we wake up with solutions to previously difficult problems that we were facing. Coming back to these two types of sleep, it turns out that non-REM and REM will play out in a battle for **brain** domination throughout the night, and that cerebral war is going to be won and lost every 90 minutes, and then it ’ s going to be replayed every 90 minutes. And what this produces is a standard cycling architecture of human sleep, a standard 90-minute cycle. But what ’ s different, however, is that the ratio of non-REM to REM within those 90-minute cycles changes as we move across the night, such that in the first half the night, the majority of those 90-minute cycles are comprised of lots of deep non-REM sleep, particularly stages three and four of non-REM sleep. But as we push through to the second half of the night, now that seesaw balance actually shifts over, and instead, most of those 90-minute cycles are comprised of a lot more rapid eye movement sleep, or dream sleep, as well as stage-two non-REM sleep, that lighter form of non-REM sleep. And it turns out that there are implications for understanding how sleep is structured in this way. Let ’ s take someone who typically goes to bed at 10pm, and they wake up at 6am, so they have an eight-hour sleep window. But this morning, they have to wake up early for an early morning meeting, or they want to get a jump start on the day to get to the gym. And as a consequence, they have to wake up at 4am in the morning, rather than 6am in the morning. How much sleep have they actually lost? Two hours out of an eight-hour night of sleep means that they ’ ve lost 25 percent of their sleep. Well, yes and no. They have lost 25 percent of all of their sleep, but because REM sleep comes mostly in the second half of the night and particularly in those last few hours, they may have lost perhaps 50, 60, maybe even 70 percent of all of their REM sleep. So there are real consequences to understanding what sleep is and how sleep is structured. And we ’ ll learn all about the benefits of these different stages of sleep and the detriments that happen when we don ’ t get enough of them in subsequent episodes.

Whether you ’ re cramming for an exam or trying to learn a new musical instrument or even trying to perfect a new sport, sleep may actually be your secret memory weapon. [Sleeping with Science] Studies have actually told us that sleep is critical for memory in at least three different ways. First, we know that you need sleep before learning to actually get your **brain** ready, almost like a dry sponge, ready to initially soak up new information. And without sleep, the memory circuits within the **brain** effectively become waterlogged, as it were, and we can ’ t absorb new information. We can ’ t effectively lay down those new memory traces. But it ’ s not only important that you sleep before learning, because we also know that you need sleep after learning to essentially hit the save button on those new memories so that we don ’ t forget. In fact, sleep will actually future-proof that information within the **brain**, cementing those memories into the architecture of those neural networks. And we ’ ve begun to discover exactly how sleep achieves this memory-consolidation benefit. The first mechanism is a file-transfer process. And here, we can speak about two different structures within the **brain**. The first is called the hippocampus and the hippocampus sits on the left and the right side of your **brain**. And you can think of the hippocampus almost like the informational inbox of your **brain**. It ’ s very good at receiving new memory files and holding onto them. The second structure that we can speak about is called the cortex. This wrinkled massive tissue that sits on top of your **brain**. And during deep sleep, there is this file-transfer mechanism. Think of the hippocampus like a USB stick and your cortex like the hard drive. And during the day, we ’ re going around and we ’ re gathering lots of files, but then during deep sleep at night, because of that limited storage capacity, we have to transfer those files from the hippocampus over to the hard drive of the **brain**, the cortex. And that ’ s exactly one of the mechanisms that deep sleep seems to provide. But there ’ s another mechanism that we ’ ve become aware of that helps cement those memories into the **brain**. And it ’ s called replay. Several years ago, scientists were looking at how rats learned as they would run around a maze. And they were recording the activity in the memory centers of these rats. And as the rat was running around the maze, different **brain** cells would code different parts of the maze. And so if you added a tone to each one of the **brain** cells what you would hear as the rat was starting to learn the maze was the signature of that memory. So it would sound a little bit like... It was this signature of learning that we could hear. But then they did something clever. They kept listening to the **brain** as these rats fell asleep, and what they heard was remarkable. The rat, as it was sleeping, started to replay that same memory signature. But now it started to replay it almost 10 times faster than it was doing when it was awake. So now instead you would start to hear... That seems to be the second way in which sleep can actually strengthen these memories. Sleep is actually replaying and scoring those memories into a new circuit within the **brain**, strengthening that memory representation. The final way in which sleep is beneficial for memory is integration and association. In fact, we ' re now learning that sleep is much more intelligent than we ever imagined. Sleep doesn ' t just simply strengthen individual memories, sleep will actually cleverly interconnect new memories together. And as a consequence, you can wake up the next day with a revised mind-wide web of associations, we can come up with solutions to previously impenetrable problems. And this is probably the reason that you ' ve never been told to stay awake on a problem. Instead, you ' re told to sleep on a problem, and that ' s exactly what the science teaching us.

It is the third of March, 2016, and I ' m anxiously waiting for my wife to deliver our firstborn son. Seconds turn into minutes, then hours, without a sign of a child coming through. Then a midwife emerges with a silent baby in her hands, and she runs past me as though I ' m not even there. Why is he not crying? I ' m gripped with chills in my spine as I run after her in terror. She puts the baby on a bench and begins a resuscitation procedure. Thirty minutes later, she tells me,"Don ' t worry, he will be fine, and thank you for staying calm."He was placed in the ICU, and though I cannot touch him, I repeatedly say,"Shine on, my son. Don ' t give up. I am here with you, and you don ' t have to be scared. Please pull through and let us go home. You do not belong here."Seven months later, he would be diagnosed with cerebral palsy, a nonprogressive **brain** injury which primarily affects body movement and muscle coordination. About two to three children out of 1, 000 in the United States have cerebral palsy. I do not know the statistics for my country and continent, because there ' s not much documentation. Maybe this could be the journey that changes everything. We named him Lubuto, a beautiful Zambian name from my Lunda tribe of the Bemba-speaking people, meaning"light."By the time he was seven months, Lubuto ' s physical impairment was predominant in the left part of his body. Both his left leg and arm were less responsive. He couldn ' t grasp items ; worse off, couldn ' t babble his first words because the cerebral palsy shackle affects the muscle in his lips. Rolling over and other milestones that come naturally in typical babies, couldn ' t be seen in our son. Lubuto was visibly unaware of his own body. And some specialists started preparing us for the worst by telling us that we were going to be very lucky if he ever sat upright and unsupported. Before us was a gigantic, seemingly immovable mountain. What do we do? For the past 15 years, I have worked as a computer programmer, and now I ' m a certified project management professional. After the denial, crying and partial depression was over, I began to wonder if we could put my programming and project management skills together to try and help the situation. Acceptance kicked in, and I searched from deep within for strength and any available knowledge to help with the challenge before us. I ordered two books online and spent countless sleepless nights researching neuroplasticity in a child ' s **brain**. My extensive research indicated that people who have

strokes are able to recover through assiduous rehabilitation programs that activates new parts in the better part of their **brains**. This left me with one big question : If this works for grown people, why should it not work for a baby? I also learned that human beings pick up fundamental patterns mainly between ages zero to five, and after that, consolidation of habits happens. It was scary to realize that we may just have five years to figure out the immobility of Lubuto. On such a tight timeline, we needed to build a support system around him, leveraging the limited resources available to us. This was a clear project before us which needed to be carefully executed, and we needed a capable, self-driven team, an agile team.”Agile”is a methodology that we use to execute projects with changing requirements to achieve progressive results in increments. We needed to deliver quick results, and in pieces, considering our work was largely dependent on Lubuto ’ s responsiveness and capability. The first team member I acquired was my beautiful wife Abigail, who is luckily a project manager, too. You know how rough that can be, right? Two project managers under one roof. We searched around Zambia for a neonatal physiotherapist, an occupational therapist and a speech therapist. It felt like mission impossible. We set road maps of one to three months, just enough planning and just in time. We then identified features like,”We want him to stand and walk independently,”under different themes like gross motor, fine motor, adaptive skills, communication, asymmetric movement and balance. Next, we created sprints to work on the stimulation of different parts of Lubuto ’ s body. When you ’ re working on an agile project, you do a series of lead-to tasks, collectively called”sprints,”which the team reviews after execution. We, for example, set a goal to stimulate his left arm. Say occupational therapists use different textures to rub on his arm. Physiotherapists make deliberate movements in his arm to build the muscles. And self-proclaimed general therapists, who was usually myself, engage in logical stimulations like slowly moving his favorite toy from his right hand across and by in front of him to his left side to prompt movement in his left arm. And at the end of each week, we would review our results as a team : How did OT go? How did physio go? How did stimulation go? Did we meet our goal? Because frequent communication is very important on an agile project, we created a WhatsApp group for quicker updates. Failing early and picking up is a special characteristic of agility, and we leveraged that because our work is largely dependent on his response. Luckily, Lubuto is a fighter, and his determination is out of this world. After we achieved the goal of activating his arm, we then moved to his leg. The activities were totally different, but followed the similar iterative process. I would come to learn in **brain** plasticity that Lubuto was better off learning certain skills when he was ready, even if it meant delaying him, because he had to learn it right. While working and managing Lubuto as an agile project, a new team member **popped** up. Oh! It ’ s Lubuto ’ s sister, Yawila. We had no idea how we were going to manage the process without disturbing him while not making the sister feel neglected because we were giving the brother a lot of attention. Our daily iterations continued, and now Lubuto was able to walk on his stiff legs. With me cheerleading from the front as I walked backwards, because I needed to keep eye contact with him, I sang his favorite songs, as we oscillated between our bedroom and the kitchen. We then traveled to South Africa and introduced a neuromovement therapist to the team, coupled with hyperbaric oxygen therapy. These sprints were much shorter and focused on his **brain**, teaching him about his own body through small body movements. Terry did a miraculous job. Lubuto started opening his knees in unison with his hips. And in our second week, he was able to run with better balance. He started making intentional sounds to communicate with us as a result of the new neuropaths firing. We returned to Zambia with amazing results. And guess who effectively picked up the therapy? The new team member. Lubuto started mimicking the sister, and soon he was learning more things good and bad from the sister than he was learning from his team of therapists. To make sure that he stays on track, we built a unique curriculum that incorporates all the therapies with teacher Goodson. We ' ve been blessed to have the knowledge before us and be able to practically apply it. Not all families with special needs children are as fortunate as we are. We still have backlog stories, which is a fancy agile term for pushing failure to a later date, in Lubuto ' s case, drooling and potty training. But in iterative, little daily activities, we managed to improve the entire left part of Lubuto ' s body – from the arm, to one finger to the other, from the leg to the toes. Lubuto began to roll over. He began to independently sit. He was able to **crawl**, stand, walk, run, and now he plays soccer with me in a more coordinated manner. This has left my wife ' s heart and mine melting, and we ' ve been blown away by the unbelievable results we ' ve witnessed as a result of this experimental methodology. And now, we proudly call ourselves"agile parents."You may be a parent with a special needs child like me, or you could be facing different types of limitation in your life : professionally, financially, academically or even physically. I want to remind you that, in striving for bigger goals, dare to take small sprints. These sprints are usually far from excellent themselves, but they add up to magnificent results. Thank you.

So I thought,"I will talk about death."Seemed to be the passion today. Actually, it ' s not about death. It ' s inevitable, terrible, but really what I want to talk about is, I ' m just fascinated by the legacy people leave when they die. That ' s what I want to talk about. So Art Buchwald left his legacy of humor with a video that appeared soon after he died, saying,"Hi! I ' m Art Buchwald, and I just died."And Mike, who I met at Galapagos, a trip which I won at TED, is leaving notes on cyberspace where he is chronicling his journey through cancer. And my father left me a legacy of his handwriting through letters and a notebook. In the last two years of his life, when he was sick, he filled a notebook with his thoughts about me. He wrote about my strengths, weaknesses, and gentle suggestions for improvement, quoting specific incidents, and held a mirror to my life. After he died, I realized that no one writes to me anymore. Handwriting is a disappearing art. I ' m all for email and thinking while typing, but why give up old habits for new? Why can ' t we have letter writing and email exchange in our lives? There are times when I want to trade all those years that I was too busy to sit with my dad and chat with him, and trade all those years for one hug. But too late. But that ' s when I take out his letters and I read them, and the paper that touched his hand is in mine, and I feel connected to him. So maybe we all need to leave our children with a value legacy, and not a financial one. A value for things with a personal touch — an autographed book, a soul-searching letter. If a fraction of this powerful TED audience could be inspired to buy a beautiful paper — John, it ' ll be a recycled one — and write a beautiful letter to someone they love, we actually may start a revolution where our children may go to penmanship classes. So what do I plan to leave for my son? I collect autographed books, and those of you authors in the audience know I hound you for them — and CDs too, Tracy. I plan to publish my own notebook. As I witnessed my father ' s body being swallowed by fire, I sat by his funeral pyre and wrote. I have no idea how I ' m going to do it, but I am committed to compiling his thoughts and mine into a book, and leave that published book

for my son. I ’ d like to end with a few verses of what I wrote at my father ’ s cremation. And those linguists, please pardon the grammar, because I ’ ve not looked at it in the last 10 years. I took it out for the first time to come here.”Picture in a frame, ashes in a bottle, boundless energy confined in the bottle, forcing me to deal with reality, forcing me to deal with being grown up. I hear you and I know that you would want me to be strong, but right now, I am being sucked down, surrounded and suffocated by these raging emotional waters, craving to cleanse my soul, trying to emerge on a firm footing one more time, to keep on fighting and flourishing just as you taught me. Your encouraging whispers in my whirlpool of despair, holding me and heaving me to shores of sanity, to live again and to love again.”Thank you.

What I want to talk to you about today is virtual worlds, digital globes, the 3-D Web, the Metaverse. What does this all mean for us? What it means is the Web is going to become an exciting place again. It ’ s going to become super exciting as we transform to this highly immersive and interactive world. With graphics, computing power, low latencies, these types of applications and possibilities are going to stream rich data into your lives. So the Virtual Earth initiative, and other types of these initiatives, are all about extending our current search metaphor. When you think about it, we ’ re so constrained by browsing the Web, remembering URLs, saving favorites. As we move to search, we rely on the relevance rankings, the Web matching, the index **crawling**. But we want to use our **brain**! We want to navigate, explore, discover information. In order to do that, we have to put you as a user back in the driver ’ s seat. We need cooperation between you and the computing network and the computer. So what better way to put you back in the driver ’ s seat than to put you in the real world that you interact in every day? Why not leverage the learnings that you ’ ve been learning your entire life? So Virtual Earth is about starting off creating the first digital representation, comprehensive, of the entire world. What we want to do is mix in all types of data. Tag it. Attribute it. Metadata. Get the community to add local depth, global perspective, local knowledge. So when you think about this problem, what an enormous undertaking. Where do you begin? Well, we collect data from satellites, from airplanes, from ground vehicles, from people. This process is an engineering problem, a mechanical problem, a logistical problem, an operational problem. Here is an example of our aerial camera. This is panchromatic. It ’ s actually four color cones. In addition, it ’ s multi-spectral. We collect four gigabits per second of data, if you can imagine that kind of data stream coming down. That ’ s equivalent to a constellation of 12 satellites at highest res capacity. We fly these airplanes at 5, 000 feet in the air. You can see the camera on the front. We collect multiple viewpoints, vantage points, angles, textures. We bring all that data back in. We sit here — you know, think about the ground vehicles, the human scale — what do you see in person? We need to capture that up close to establish that what it ’ s like-type experience. I bet many of you have seen the Apple commercials, kind of poking at the PC for their brilliance and simplicity. So a little unknown secret is — did you see the one with the guy, he ’ s got the Web cam? The poor PC guy. They ’ re duct taping his head. They ’ re just wrapping it on him. Well, a little unknown secret is his brother actually works on the Virtual Earth team.. So they ’ ve got a little bit of a sibling rivalry thing going on here. But let me tell you — it doesn ’ t affect his day job. We think a lot of good can come from this technology. This was after Katrina. We were the first commercial fleet of airplanes to be cleared into the disaster impact zone. We flew the area. We imaged it. We sent in people. We took pictures of interiors, disaster areas. We helped with the first responders, the search and rescue. Often the first time anyone saw what happened to their house was on Virtual Earth. We made it all freely available on the Web, just to — it was obviously our chance of helping out with the cause. When we think about how all this comes together, it ’ s all about software, algorithms and math. You know, we capture this imagery but to build the 3- D models we need to do geo-positioning. We need to do geo-registering of the images. We have to bundle adjust them. Find tie points. Extract geometry from the images. This process is a very calculated process. In fact, it was always done manual. Hollywood would spend millions of dollars to do a small urban corridor for a movie because they ’ d have to do it manually. They ’ d drive the streets with lasers called LIDAR. They ’ d collected information with photos. They ’ d manually build each building. We do this all through software, algorithms and math — a highly automated pipeline creating these cities. We took a decimal point off what it cost to build these cities, and that ’ s how we ’ re going to be able to scale this out and make this reality a dream. We think about the user interface. What does it mean to look at it from multiple perspectives? An ortho-view, a nadir-view. How do you keep the precision of the fidelity of the imagery while maintaining the fluidity of the model? I ’ ll wrap up by showing you the — this is a brand-new peek I haven ’ t really shown into the lab area of Virtual Earth. What we ’ re doing is — people like this a lot, this bird ’ s eye imagery we work with. It ’ s this high resolution data. But what we ’ ve found is they like the fluidity of the 3- D model. A child can navigate with an Xbox controller or a game controller. So here what we ’ re trying to do is we bring the picture and project it into the 3-D model space. You can see all types of resolution. From here, I can slowly pan the image over. I can get the next image. I can blend and transition. By doing this I don ’ t lose the original detail. In fact, I might be recording history. The freshness, the capacity. I can turn this image. I can look at it from multiple viewpoints and angles. What we ’ re trying to do is build a virtual world. We hope that we can make computing a user model you ’ re familiar with, and really derive insights from you, from all different directions. I thank you very much for your time.

You know, what I do is write for children, and I ’ m probably America ’ s most widely read children ’ s author, in fact. And I always tell people that I don ’ t want to show up looking like a scientist. You can have me as a farmer, or in leathers, and no one has ever chose farmer. I ’ m here today to talk to you about circles and epiphanies. And you know, an epiphany is usually something you find that you dropped someplace. You ’ ve just got to go around the block to see it as an epiphany. That ’ s a painting of a circle. A friend of mine did that — Richard Bollingbroke. It ’ s the kind of complicated circle that I ’ m going to tell you about. My circle began back in the ’ 60s in high school in Stow, Ohio where I was the class queer. I was the guy beaten up bloody every week in the boys ’ room, until one teacher saved my life. She saved my life by letting me go to the bathroom in the teachers ’ lounge. She did it in secret. She did it for three years. And I had to get out of town. I had a thumb, I had 85 dollars, and I ended up in San Francisco, California — met a lover — and back in the ’ 80s, found it necessary to begin work on AIDS organizations. About three or four years ago, I got a phone call in the middle of the night from that teacher, Mrs. Posten, who said,”I need to see you. I ’ m disappointed that we never got to know each other as adults. Could you please come to Ohio, and please bring that man that I know you have found by now. And I should mention that I have pancreatic cancer, and I ’ d like you to please be quick about this.”Well, the next day we were in Cleveland. We took a look at her, we laughed, we cried, and we knew that she needed to be in a hospice. We found her one, we got her there, and we took care of her and watched over her family, because it was necessary. It ’ s something we knew how to do. And just as the woman who wanted to know me as an adult got to know me, she turned into a box of ashes and was placed in my hands. And what had happened was the circle had closed, it had become a circle — and that epiphany I talked about presented itself. The epiphany is that death is a part of life. She saved my life ; I and my partner saved hers. And you know, that part of life needs everything that the rest of life does. It needs truth and beauty, and I ’ m so happy it ’ s been mentioned so much here today. It also needs — it needs dignity, love and pleasure, and it ’ s our job to hand those things out. Thank you.

Text Sample 649: NEG Dim 4 – 2005 – Score 1.00 – 2005/t002624.txt

I ’ m used to thinking of the TED audience as a wonderful collection of some of the most effective, intelligent, intellectual, savvy, worldly and innovative people in the world. And I think that ’ s true. However, I also have reason to believe that many, if not most, of you are actually tying your shoes incorrectly. Now I know that seems ludicrous. I know that seems ludicrous. And believe me, I lived the same sad life until about three years ago. And what happened to me was I bought, what was for me, a very expensive pair of shoes. But those shoes came with round nylon laces, and I couldn ’ t keep them tied. So I went back to the store and said to the owner,”I love the shoes, but I hate the laces.”He took a look and said,”Oh, you ’ re tying them wrong.”Now up until that moment, I would have thought that, by age 50, one of the life skills that I had really nailed was tying my shoes. But not so — let me demonstrate. This is the way that most of us were taught to tie our shoes. Now as it turns out — thank you. Wait, there ’ s more. As it turns out — there ’ s a strong form and a weak form of this knot, and we were taught the weak form. And here ’ s how to tell. If you pull the strands at the base of the knot, you will see that the bow will orient itself down the long axis of the shoe. That ’ s the weak form of the knot. But not to worry. If we start over and simply go the other direction around the bow, we get this, the strong form of the knot. And if you pull the cords under the knot, you will see that the bow orients itself along the transverse axis of the shoe. This is a stronger knot. It will come untied less often. It will let you down less, and not only that, it looks better. We ’ re going to do this one more time. Start as usual — go the other way around the loop. This is a little hard for children, but I think you can handle it. Pull the knot. There it is : the strong form of the shoe knot. Now, in keeping with today ’ s theme, I ’ d like to point out — something you already know — that sometimes a small advantage someplace in life can yield tremendous results someplace else. Live long and prosper.

Text Sample 650: NEG Dim 4 – 2005 – Score 4.00 – 2005/t000467.txt

I want to start with a story, a la Seth Godin, from when I was 12 years old. My uncle Ed gave me a beautiful blue sweater â at least I thought it was beautiful. And it had fuzzy zebras walking across the stomach, and Mount Kilimanjaro and Mount Meru were kind of right across the chest, that were also fuzzy. And I wore it whenever I could, thinking it was the most fabulous thing I owned.

Until one day in ninth grade, when I was standing with a number of the football players. And my body had clearly changed, and Matt, who was undeniably my nemesis in high school, said in a booming voice that we no longer had to go far away to go on ski trips, but we could all ski on Mount Novogratz. And I was so humiliated and mortified that I immediately ran home to my mother and chastised her for ever letting me wear the hideous sweater. We drove to the Goodwill and we threw the sweater away somewhat ceremoniously, my idea being that I would never have to think about the sweater nor see it ever again. Fast forward â 11 years later, I ’ m a 25-year-old kid. I ’ m working in Kigali, Rwanda, jogging through the steep slopes, when I see, 10 feet in front of me, a little boy â 11 years old â running toward me, wearing my sweater. And I ’ m thinking, no, this is not possible. But so, curious, I run up to the child â of course scaring the living bejesus out of him â grab him by the collar, turn it over, and there is my name written on the collar of this sweater. I tell that story, because it has served and continues to serve as a metaphor to me about the level of connectedness that we all have on this Earth. We so often don ’ t realize what our action and our inaction does to people we think we will never see and never know. I also tell it because it tells a larger contextual story of what aid is and can be. That this traveled into the Goodwill in Virginia, and moved its way into the larger industry, which at that point was giving millions of tons of secondhand clothing to Africa and Asia. Which was a very good thing, providing low cost clothing. And at the same time, certainly in Rwanda, it destroyed the local retailing industry. Not to say that it shouldn ’ t have, but that we have to get better at answering the questions that need to be considered when we think about consequences and responses. So, I ’ m going to stick in Rwanda, circa 1985, 1986, where I was doing two things. I had started a bakery with 20 unwed mothers. We were called the”Bad News Bears,”and our notion was we were going to corner the snack food business in Kigali, which was not hard because there were no snacks before us. And because we had a good business model, we actually did it, and I watched these women transform on a micro-level. But at the same time, I started a micro- finance bank, and tomorrow Iqbal Quadir is going to talk about Grameen, which is the grandfather of all micro-finance banks, which now is a worldwide movement â you talk about a meme â but then it was quite new, especially in an economy that was moving from barter into trade. We got a lot of things right. We focused on a business model ; we insisted on skin in the game. The women made their own decisions at the end of the day as to how they would use this access to credit to build their little businesses, earn more income so they could take care of their families better. What we didn ’ t understand, what was happening all around us, with the confluence of fear, ethnic strife and certainly an aid game, if you will, that was playing into this invisible but certainly palpable movement inside Rwanda, that at that time, 30 percent of the budget was all foreign aid. The genocide happened in 1994, seven years after these women all worked together to build this dream. And the good news was that the institution, the banking institution, lasted. In fact, it became the largest rehabilitation lender in the country. The bakery was completely wiped out, but the lessons for me were that accountability counts â got to build things with people on the ground, using business models where, as Steven Levitt would say, the incentives matter. Understand, however complex we may be, incentives matter. So when Chris raised to me how wonderful everything that was happening in the world, that we were seeing a shift in zeitgeist, on the one hand I absolutely agree with him, and I was so thrilled to see what happened with the G8 â that the world, because of people like Tony Blair and Bono and Bob Geldof â the world is talking about global poverty ; the world is talking about Africa in ways I have never seen in my life. It ' s thrilling. And at the same time, what keeps me up at night is a fear that we ' ll look at the victories of the G8 â 50 billion dollars in increased aid to Africa, 40 billion in reduced debt â as the victory, as more than chapter one, as our moral absolution. And in fact, what we need to do is see that as chapter one, celebrate it, close it, and recognize that we need a chapter two that is all about execution, all about the how-to. And if you remember one thing from what I want to talk about today, it ' s that the only way to end poverty, to make it history, is to build viable systems on the ground that deliver critical and affordable goods and services to the poor, in ways that are financially sustainable and scaleable. If we do that, we really can make poverty history. And it was that â that whole philosophy â that encouraged me to start my current endeavor called"Acumen Fund,"which is trying to build some mini- blueprints for how we might do that in water, health and housing in Pakistan, India, Kenya, Tanzania and Egypt. And I want to talk a little bit about that, and some of the examples, so you can see what it is that we ' re doing. But before I do this â and this is another one of my pet peeves â I want to talk a little bit about who the poor are. Because we too often talk about them as these strong, huge masses of people yearning to be free, when in fact, it ' s quite an amazing story. On a macro level, four billion people on Earth make less than four dollars a day. That ' s who we talk about when we think about"the poor."If you aggregate it, it ' s the third largest economy on Earth, and yet most of these people go invisible. Where we typically work, there ' s people making between one and three dollars a day. Who are these people? They are farmers and factory workers. They work in government offices. They ' re drivers. They are domestics. They typically pay for critical goods and services like water, like healthcare, like housing, and they pay 30 to 40 times what their middleclass counterparts pay â certainly where we work in Karachi and Nairobi. The poor also are willing to make, and do make, smart decisions, if you give them that opportunity. So, two examples. One is in India, where there are 240 million farmers, most of whom make less than two dollars a day. Where we work in Aurangabad, the land is extraordinarily parched. You see people on average making 60 cents to a dollar. This guy in pink is a social entrepreneur named Ami Tabar. What he did was see what was happening in Israel, larger approaches, and figure out how to do a drip irrigation, which is a way of bringing water directly to the plant stock. But previously it ' s only been created for large-scale farms, so Ami Tabar took this and modularized it down to an eighth of an acre. A couple of principles : build small. Make it infinitely expandable and affordable to the poor. This family, Sarita and her husband, bought a 15-dollar unit when they were living in a â literally a three-walled lean-to with a corrugated iron roof. After one harvest, they had increased their income enough to buy a second system to do their full quarter-acre. A couple of years later, I meet them. They now make four dollars a day, which is pretty much middle class for India, and they showed me the concrete foundation they had just laid to build their house. And I swear, you could see the future in that woman ' s eyes. Something I truly believe. You can ' t talk about poverty today without talking about malaria bed nets, and I again give Jeffrey Sachs of Harvard huge kudos for bringing to the world this notion of his rage â for five dollars you can save a life. Malaria is a disease that kills one to three million people a year. 300 to 500 million cases are reported. It ' s estimated that Africa loses about 13 billion dollars a year to the disease. Five dollars can save a life. We can send people to the moon ; we can see if there ' s life on Mars â why can ' t we get five-dollar nets to 500 million people? The question, though, is not"Why can ' t we?"The question is how can we help Africans do this for themselves? A lot of hurdles. One : production is too low. Two : price is too high. Three : this is a good road in â right near where our factory is located. Distribution is a nightmare, but not impossible. We started by making a 350, 000-dollar loan to the largest traditional bed net manufacturer in Africa so that they could transfer technology from Japan and build these long-lasting, five-year nets. Here are just some pictures of the factory. Today, three years later, the company has employed another thousand women. It contributes about 600, 000 dollars in wages to the economy of Tanzania. It ’ s the largest company in Tanzania. The throughput rate right now is 1. 5 million nets, three million by the end of the year. We hope to have seven million at the end of next year. So the production side is working. On the distribution side, though, as a world, we have a lot of work to do. Right now, 95 percent of these nets are being bought by the U. N., and then given primarily to people around Africa. We ’ re looking at building on some of the most precious resources of Africa : people. Their women. And so I want you to meet Jacqueline, my namesake, 21 years old. If she were born anywhere else but Tanzania, I ’ m telling you, she could run Wall Street. She runs two of the lines, and has already saved enough money to put a down payment on her house. She makes about two dollars a day, is creating an education fund, and told me she is not marrying nor having children until these things are completed. And so, when I told her about our idea â that maybe we could take a Tupperware model from the United States, and find a way for the women themselves to go out and sell these nets to others â she quickly started calculating what she herself could make and signed up. We took a lesson from IDEO, one of our favorite companies, and quickly did a prototyping on this, and took Jacqueline into the area where she lives. She brought 10 of the women with whom she interacts together to see if she could sell these nets, five dollars apiece, despite the fact that people say nobody will buy one, and we learned a lot about how you sell things. Not coming in with our own notions, because she didn ’ t even talk about malaria until the very end. First, she talked about comfort, status, beauty. These nets, she said, you put them on the floor, bugs leave your house. Children can sleep through the night ; the house looks beautiful ; you hang them in the window. And we ’ ve started making curtains, and not only is it beautiful, but people can see status â that you care about your children. Only then did she talk about saving your children ’ s lives. A lot of lessons to be learned in terms of how we sell goods and services to the poor. I want to end just by saying that there ’ s enormous opportunity to make poverty history. To do it right, we have to build business models that matter, that are scaleable and that work with Africans, Indians, people all over the developing world who fit in this category, to do it themselves. Because at the end of the day, it ’ s about engagement. It ’ s about understanding that people really don ’ t want handouts, that they want to make their own decisions ; they want to solve their own problems ; and that by engaging with them, not only do we create much more dignity for them, but for us as well. And so I urge all of you to think next time as to how to engage with this notion and this opportunity that we all have â to make poverty history â by really becoming part of the process and moving away from an us-and-them world, and realizing that it ’ s about all of us, and the kind of world that we, together, want to live in and share. Thank you.

This is really a two-hour presentation I give to high school students, cut down to three minutes. And it all started one day on a plane, on my way to TED, seven years ago. And in the seat next to me was a high school student, a teenager, and she came from a really poor family. And she wanted to make something of her life, and she asked me a simple little question. She said,”What leads to success?”And I felt really badly, because I couldn ’ t give her a good answer. So I get off the plane, and I come to TED. And I think, jeez, I ’ m in the middle of a room of successful people! So why don ’ t I ask them what helped them succeed, and pass it on to kids? So here we are, seven years, 500 interviews later, and I ’ m going to tell you what really leads to success and makes TEDsters tick. And the first thing is passion. Freeman Thomas says,”I ’ m driven by my passion.”TEDsters do it for love ; they don ’ t do it for money. Carol Coletta says,”I would pay someone to do what I do.”And the interesting thing is : if you do it for love, the money comes anyway. Work! Rupert Murdoch said to me,”It ’ s all hard work. Nothing comes easily. But I have a lot of fun.”Did he say fun? Rupert? Yes! TEDsters do have fun working. And they work hard. I figured, they ’ re not workaholics. They ’ re workafrolics. Good! Alex Garden says,”To be successful, put your nose down in something and get damn good at it.”There ’ s no magic ; it ’ s practice, practice, practice. And it ’ s focus. Norman Jewison said to me,”I think it all has to do with focusing yourself on one thing.”And push! David Gallo says,”Push yourself. Physically, mentally, you ’ ve got to push, push, push.”You ’ ve got to push through shyness and self-doubt. Goldie Hawn says,”I always had self-doubts. I wasn ’ t good enough ; I wasn ’ t smart enough. I didn ’ t think I ’ d make it.”Now it ’ s not always easy to push yourself, and that ’ s why they invented mothers. Frank Gehry said to me,”My mother pushed me.”Serve! Sherwin Nuland says,”It was a privilege to serve as a doctor.”A lot of kids want to be millionaires. The first thing I say is :”OK, well you can ’ t serve yourself ; you ’ ve got to serve others something of value. Because that ’ s the way people really get rich.”Ideas! TEDster Bill Gates says,”I had an idea : founding the first micro- computer software company.”I ’ d say it was a pretty good idea. And there ’ s no magic to creativity in coming up with ideas — it ’ s just doing some very simple things. And I give lots of evidence. Persist! Joe Kraus says,”Persistence is the number one reason for our success.”You ’ ve got to persist through failure. You ’ ve got to persist through crap! Which of course means”Criticism, Rejection, Assholes and Pressure.”So, the answer to this question is simple : Pay 4, 000 bucks and come to TED. Or failing that, do the eight things — and trust me, these are the big eight things that lead to success. Thank you TEDsters for all your interviews!

’ Theme and variations ’ is one of those forms that require a certain kind of intellectual activity, because you are always comparing the variation with the theme that you hold in your mind. You might say that the theme is nature and everything that follows is a variation on the subject. I was asked, I guess about six years ago, to do a series of paintings that in some way would celebrate the birth of Piero della Francesca. And it was very difficult for me to imagine how to paint pictures that were based on Piero until I realized that I could look at Piero as nature — that I would have the same attitude towards looking at Piero della Francesca as I would if I were looking out a window at a tree. And that was enormously liberating to me. Perhaps it ’ s not a very insightful observation, but that really started me on a path to be able to do a kind of theme and variations based on a work by Piero, in this case that remarkable painting that ’ s in the Uffizi,”The Duke of Montefeltro,”who faces his consort, Battista. Once I realized that I could take some liberties with the subject, I did the following series of drawings. That ’ s the real Piero della Francesca —

one of the greatest portraits in human history. And these, I ’ ll just show these without comment. It ’ s just a series of variations on the head of the Duke of Montefeltro, who ’ s a great, great figure in the Renaissance, and probably the basis for Machiavelli ’ s”The Prince.”He apparently lost an eye in battle, which is why he is always shown in profile. And this is Battista. And then I decided I could move them around a little bit — so that for the first time in history, they ’ re facing the same direction. Whoops! Passed each other. And then a visitor from another painting by Piero, this is from”The Resurrection of Christ”— as though the cast had just gotten of the set to have a chat. And now, four large panels : this is upper left ; upper right ; lower left ; lower right. Incidentally, I ’ ve never understood the conflict between abstraction and naturalism. Since all paintings are inherently abstract to begin with there doesn ’ t seem to be an argument there. On another subject — — I was driving in the country one day with my wife, and I saw this sign, and I said,”That is a fabulous piece of design.”And she said,”What are you talking about?”I said,”Well, it ’ s so persuasive, because the purpose of that sign is to get you into the garage, and since most people are so suspicious of garages, and know that they ’ re going to be ripped off, they use the word ’ reliable. ’ But everybody says they ’ re reliable. But, reliable Dutchman”— —”Fantastic!”Because as soon as you hear the word Dutchman — which is an archaic word, nobody calls Dutch people”Dutchmen”anymore — but as soon as you hear Dutchman, you get this picture of the kid with his finger in the dike, preventing the thing from falling and flooding Holland, and so on. And so the entire issue is detoxified by the use of”Dutchman.”Now, if you think I ’ m exaggerating at all in this, all you have to do is substitute something else, like”Indonesian.”Or even”French.”Now,”Swiss”works, but you know it ’ s going to cost a lot of money. I ’ m going to take you quickly through the actual process of doing a poster. I do a lot of work for the School of Visual Arts, where I teach, and the director of this school — a remarkable man named Silas Rhodes — often gives you a piece of text and he says,”Do something with this.”And so he did. And this was the text —”In words as fashion the same rule will hold / Alike fantastic if too new or old / Be not the first by whom the new are tried / Nor yet the last to lay the old aside.”I could make nothing of that. And I really struggled with this one. And the first thing I did, which was sort of in the absence of another idea, was say I ’ ll sort of write it out and make some words big, and I ’ ll have some kind of design on the back somehow, and I was hoping — as one often does — to stumble into something. So I took another crack at it — you ’ ve got to keep it moving — and I Xeroxed some words on pieces of colored paper and I pasted them down on an ugly board. I thought that something would come out of it, like”Words rule fantastic new old first last Pope”because it ’ s by Alexander Pope, but I sort of made a mess out of it, and then I thought I ’ d repeat it in some way so it was legible. So, it was going nowhere. Sometimes, in the middle of a resistant problem, I write down things that I know about it. But you can see the beginning of an idea there, because you can see the word”new”emerging from the”old.”That ’ s what happens. There ’ s a relationship between the old and the new ; the new emerges from the context of the old. And then I did some variations of it, but it still wasn ’ t coalescing graphically at all. I had this other version which had something interesting about it in terms of being able to put it together in your mind from clues. The W was clearly a W, the N was clearly an N, even though they were very fragmentary and there wasn ’ t a lot of information in it. Then I got the words”new”and”old”and now I had regressed back to a point where there seemed to be no return. I was really desperate at this point. And so, I do something I ’ m truthfully ashamed of, which is that I took two drawings I had made for another purpose and I put them together. It says”dreams”at the top. And I was going to do a thing, I say,"Well, change the copy. Let it say something about dreams, and come to SVA and you ' ll sort of fulfill your dreams."But, to my credit, I was so embarrassed about doing that that I never submitted this sketch. And, finally, I arrived at the following solution. Now, it doesn ' t look terribly interesting, but it does have something that distinguishes it from a lot of other posters. For one thing, it transgresses the idea of what a poster ' s supposed to be, which is to be understood and seen immediately, and not explained. I remember hearing all of you in the graphic arts —"If you have to explain it, it ain ' t working."And one day I woke up and I said,"Well, suppose that ' s not true?"So here ' s what it says in my explanation at the bottom left. It says,"Thoughts : This poem is impossible. Silas usually has a better touch with his choice of quotations. This one generates no imagery at all."I am now exposing myself to my audience, right? Which is something you never want to do professionally."Maybe the words can make the image without anything else happening. What ' s the heart of this poem? Don ' t be trendy if you want to be serious. Is doing the poster this way trendy in itself? I guess one could reduce the idea further by suggesting that the new emerges behind and through the old, like this."And then I show you a little drawing — you see, you remember that old thing I discarded? Well, I found a way to use it. So, there ' s that little alternative over there, and I say,"Not bad,"— criticizing myself —"but more didactic than visual. Maybe what wants to be said is that old and the new are locked in a dialectical embrace, a kind of dance where each defines the other."And then more self-questioning —"Am I being simple-minded? Is this the kind of simple that looks obvious, or the kind that looks profound? There ' s a significant difference. This could be embarrassing. Actually, I realize fear of embarrassment drives me as much as any ambition. Do you think this sort of thing could really attract a student to the school?"Well, I think there are two fresh things here — two fresh things. One is the sort of willingness to expose myself to a critical audience, and not to suggest that I am confident about what I ' m doing. And as you know, you have to have a front. I mean — you ' ve got to be confident ; if you don ' t believe in your work, who else is going to believe in it? So that ' s one thing, to introduce the idea of doubt into graphics. That can be a big contribution. The other thing is to actually give you two solutions for the price of one ; you get the big one and if you don ' t like that, how about the little one? And that too is a relatively new idea. And here ' s just a series of experiments where I ask the question of — does a poster have to be square? Now, this is a little illusion. That poster is not folded. It ' s not folded, that ' s a photograph and it ' s cut on the diagonal. Same cheap trick in the upper left- hand corner. And here, a very peculiar poster because, simply because of using the isometric perspective in the computer, it won ' t sit still in the space. At times, it seems to be wider at the back than the front, and then it shifts. And if you sit here long enough, it ' ll float off the page into the audience. But, we don ' t have time. And then an experiment — a little bit about the nature of perspective, where the outside shape is determined by the peculiarity of perspective, but the shape of the bottle — which is identical to the outside shape — is seen frontally. And another piece for the art directors ' club is"Anna Rees"casting long shadows. This is another poster from the School of Visual Arts. There were 10 artists invited to participate in it, and it was one of those things where it was extremely competitive and I didn ' t want to be embarrassed, so I worked very hard on this. The idea was — and it was a brilliant idea — was to have 10 posters distributed throughout the city ' s subway system so every time you got on the subway you ' d be passing a different poster, all of which had a different idea of what art is. But I was absolutely stuck on the idea of"art is"and trying to determine what art was.

But then I gave up and I said,”Well, art is whatever.”And as soon as I said that, I discovered that the word”hat”was hidden in the word”whatever,”and that led me to the inevitable conclusion. But then again, it ’ s on my list of didactic posters. My intent is to have a literary accompaniment that explains the poster, in case you don ’ t get it. Now this says,”Note to the viewer : I thought I might use a visual cliche of our time — Magritte ’ s everyman — to express the idea that art is mystery, continuity and history. I ’ m also convinced that, in an age of computer manipulation, surrealism has become banal, a shadow of its former self. The phrase ’ Art is whatever ’ expresses the current inclusiveness that surrounds art-making — a sort of ’ it ain ’ t what you do, it ’ s the way that you do it ’ notion. The shadow of Magritte falls across the central part of the poster a poetic event that occurs as the shadow man isolates the word ’ hat, ’ hidden in the word ’ whatever. ’ The four hats shown in the poster suggests how art might be defined : as a thing itself, the worth of the thing, the shadow of the thing, and the shape of the thing. Whatever.”OK. And the one that I did not submit, which I still like, I wanted to use the same phrase. There were wonderful experiments by Bruno Munari on letterforms some years ago — sort of, see how far you could go and still be able to read them. And that idea stuck in my head. But then I took the pieces that I had taken off and put them at the bottom. And, of course those are the remains, and they ’ re so labeled. But what really happens is that you read it as :”Art is whatever remains.”Thank you.

David Gallo : This is Bill Lange. I ’ m Dave Gallo. And we ’ re going to tell you some stories from the sea here in video. We ’ ve got some of the most incredible video of Titanic that ’ s ever been seen, and we ’ re not going to show you any of it. The truth of the matter is that the Titanic — even though it ’ s breaking all sorts of box office records — it ’ s not the most exciting story from the sea. And the problem, I think, is that we take the ocean for granted. When you think about it, the oceans are 75 percent of the planet. Most of the planet is ocean water. The average depth is about two miles. Part of the problem, I think, is we stand at the beach, or we see images like this of the ocean, and you look out at this great big blue expanse, and it ’ s shimmering and it ’ s moving and there ’ s waves and there ’ s surf and there ’ s tides, but you have no idea for what lies in there. And in the oceans, there are the longest mountain ranges on the planet. Most of the animals are in the oceans. Most of the earthquakes and volcanoes are in the sea, at the bottom of the sea. The biodiversity and the biodensity in the ocean is higher, in places, than it is in the rainforests. It ’ s mostly unexplored, and yet there are beautiful sights like this that captivate us and make us become familiar with it. But when you ’ re standing at the beach, I want you to think that you ’ re standing at the edge of a very unfamiliar world. We have to have a very special technology to get into that unfamiliar world. We use the submarine Alvin and we use cameras, and the cameras are something that Bill Lange has developed with the help of Sony. Marcel Proust said,”The true voyage of discovery is not so much in seeking new landscapes as in having new eyes.”People that have partnered with us have given us new eyes, not only on what exists — the new landscapes at the bottom of the sea — but also how we think about life on the planet itself. Here ’ s a jelly. It ’ s one of my favorites, because it ’ s got all sorts of working parts. This turns out to be the longest creature in the oceans. It gets up to about 150 feet long. But see all those different working things? I love that kind of stuff. It ’ s got

these fishing lures on the bottom. They ’ re going up and down. It ’ s got tentacles dangling, swirling around like that. It ’ s a colonial animal. These are all individual animals banding together to make this one creature. And it ’ s got these jet thrusters up in front that it ’ ll use in a moment, and a little light. If you take all the big fish and schooling fish and all that, put them on one side of the scale, put all the jelly-type of animals on the other side, those guys win hands down. Most of the biomass in the ocean is made out of creatures like this. Here ’ s the X-wing death jelly. The bioluminescence — they use the lights for attracting mates and attracting prey and communicating. We couldn ’ t begin to show you our archival stuff from the jellies. They come in all different sizes and shapes. Bill Lange : We tend to forget about the fact that the ocean is miles deep on average, and that we ’ re real familiar with the animals that are in the first 200 or 300 feet, but we ’ re not familiar with what exists from there all the way down to the bottom. And these are the types of animals that live in that three- dimensional space, that micro-gravity environment that we really haven ’ t explored. You hear about giant squid and things like that, but some of these animals get up to be approximately 140, 160 feet long. They ’ re very little understood. DG : This is one of them, another one of our favorites, because it ’ s a little octopod. You can actually see through his head. And here he is, flapping with his ears and very gracefully going up. We see those at all depths and even at the greatest depths. They go from a couple of inches to a couple of feet. They come right up to the submarine — they ’ ll put their eyes right up to the window and peek inside the sub. This is really a world within a world, and we ’ re going to show you two. In this case, we ’ re passing down through the mid-ocean and we see creatures like this. This is kind of like an undersea rooster. This guy, that looks incredibly formal, in a way. And then one of my favorites. What a face! This is basically scientific data that you ’ re looking at. It ’ s footage that we ’ ve collected for scientific purposes. And that ’ s one of the things that Bill ’ s been doing, is providing scientists with this first view of animals like this, in the world where they belong. They don ’ t catch them in a net. They ’ re actually looking at them down in that world. We ’ re going to take a joystick, sit in front of our computer, on the Earth, and press the joystick forward, and fly around the planet. We ’ re going to look at the mid-ocean ridge, a 40, 000-mile long mountain range. The average depth at the top of it is about a mile and a half. And we ’ re over the Atlantic — that ’ s the ridge right there — but we ’ re going to go across the Caribbean, Central America, and end up against the Pacific, nine degrees north. We make maps of these mountain ranges with sound, with sonar, and this is one of those mountain ranges. We ’ re coming around a cliff here on the right. The height of these mountains on either side of this valley is greater than the Alps in most cases. And there ’ s tens of thousands of those mountains out there that haven ’ t been mapped yet. This is a volcanic ridge. We ’ re getting down further and further in scale. And eventually, we can come up with something like this. This is an icon of our robot, Jason, it ’ s called. And you can sit in a room like this, with a joystick and a headset, and drive a robot like that around the bottom of the ocean in real time. One of the things we ’ re trying to do at Woods Hole with our partners is to bring this virtual world — this world, this unexplored region — back to the laboratory. Because we see it in bits and pieces right now. We see it either as sound, or we see it as video, or we see it as photographs, or we see it as chemical sensors, but we never have yet put it all together into one interesting picture. Here ’ s where Bill ’ s cameras really do shine. This is what ’ s called a hydrothermal vent. And what you ’ re seeing here is a cloud of densely packed, hydrogen-sulfide-rich water coming out of a volcanic axis on the sea floor. Gets up to 600, 700 degrees F, somewhere in that range. So that ’ s all water under the sea — a mile and a half, two miles, three miles down. And we knew it was volcanic back in the ’ 60s, ’ 70s. And then we had some hint that these things existed all along the axis of it, because if you ’ ve got volcanism, water ’ s going to get down from the sea into cracks in the sea floor, come in contact with magma, and come shooting out hot. We weren ’ t really aware that it would be so rich with sulfides, hydrogen sulfides. We didn ’ t have any idea about these things, which we call chimneys. This is one of these hydrothermal vents. Six hundred degree F water coming out of the Earth. On either side of us are mountain ranges that are higher than the Alps, so the setting here is very dramatic. BL : The white material is a type of bacteria that thrives at 180 degrees C. DG : I think that ’ s one of the greatest stories right now that we ’ re seeing from the bottom of the sea, is that the first thing we see coming out of the sea floor after a volcanic eruption is bacteria. And we started to wonder for a long time, how did it all get down there? What we find out now is that it ’ s probably coming from inside the Earth. Not only is it coming out of the Earth — so, biogenesis made from volcanic activity — but that bacteria supports these colonies of life. The pressure here is 4, 000 pounds per square inch. A mile and a half from the surface to two miles to three miles — no sun has ever gotten down here. All the energy to support these life forms is coming from inside the Earth — so, chemosynthesis. And you can see how dense the population is. These are called tube worms. BL : These worms have no digestive system. They have no mouth. But they have two types of gill structures. One for extracting oxygen out of the deep-sea water, another one which houses this chemosynthetic bacteria, which takes the hydrothermal fluid — that hot water that you saw coming out of the bottom — and converts that into simple sugars that the tube worm can digest. DG : You can see, here ’ s a crab that lives down there. He ’ s managed to grab a tip of these worms. Now, they normally retract as soon as a crab touches them. Oh! Good going. So, as soon as a crab touches them, they retract down into their shells, just like your fingernails. There ’ s a whole story being played out here that we ’ re just now beginning to have some idea of because of this new camera technology. BL : These worms live in a real temperature extreme. Their foot is at about 200 degrees C and their head is out at three degrees C, so it ’ s like having your hand in boiling water and your foot in freezing water. That ’ s how they like to live. DG : This is a female of this kind of worm. And here ’ s a male. You watch. It doesn ’ t take long before two guys here — this one and one that will show up over here — start to fight. Everything you see is played out in the pitch black of the deep sea. There are never any lights there, except the lights that we bring. Here they go. On one of the last dive series, we counted 200 species in these areas — 198 were new, new species. BL : One of the big problems is that for the biologists working at these sites, it ’ s rather difficult to collect these animals. And they disintegrate on the way up, so the imagery is critical for the science. DG : Two octopods at about two miles depth. This pressure thing really amazes me — that these animals can exist there at a depth with pressure enough to crush the Titanic like an empty Pepsi can. What we saw up till now was from the Pacific. This is from the Atlantic. Even greater depth. You can see this shrimp is harassing this poor little guy here, and he ’ ll bat it away with his claw. Whack! And the same thing ’ s going on over here. What they ’ re getting at is that — on the back of this crab — the foodstuff here is this very strange bacteria that lives on the backs of all these animals. And what these shrimp are trying to do is actually harvest the bacteria from the backs of these animals. And the crabs don ’ t like it at all. These long filaments that you see on the back of the crab are actually created by the product of that bacteria. So, the bacteria grows hair on the crab. On the back, you see this again. The red dot is the laser light of the submarine Alvin to give us an idea about how far away we are from the vents. Those are all shrimp. You see the hot water over here, here and here, coming out. They ’ re clinging to a rock face and actually scraping bacteria off that rock face. Here ’ s a tiny, little vent that ’ s come out of the side of that pillar. Those pillars get up to several stories. So here, you ’ ve got this valley with this incredible alien landscape of pillars and hot springs and volcanic eruptions and earthquakes, inhabited by these very strange animals that live only on chemical energy coming out of the ground. They don ’ t need the sun at all. BL : You see this white V-shaped mark on the back of the shrimp? It ’ s actually a light-sensing organ. It ’ s how they find the hydrothermal vents. The vents are emitting a black body radiation — an IR signature — and so they ’ re able to find these vents at considerable distances. DG : All this stuff is happening along that 40, 000-mile long mountain range that we ’ re calling the ribbon of life, because just even today, as we speak, there ’ s life being generated there from volcanic activity. This is the first time we ’ ve ever tried this any place. We ’ re going to try to show you high definition from the Pacific. We ’ re moving up one of these pillars. This one ’ s several stories tall. In it, you ’ ll see that it ’ s a habitat for a lot of different animals. There ’ s a funny kind of hot plate here, with vent water coming out of it. So all of these are individual homes for worms. Now here ’ s a closer view of that community. Here ’ s crabs here, worms here. There are smaller animals **crawling** around. Here ’ s pagoda structures. I think this is the neatest-looking thing. I just can ’ t get over this — that you ’ ve got these little chimneys sitting here smoking away. This stuff is toxic as hell, by the way. You could never get a permit to dump this in the ocean, and it ’ s coming out all from it. It ’ s unbelievable. It ’ s basically sulfuric acid, and it ’ s being just dumped out, at incredible rates. And animals are thriving — and we probably came from here. That ’ s probably where we evolved from. BL : This bacteria that we ’ ve been talking about turns out to be the most simplest form of life found. There are a number of groups that are proposing that life evolved at these vent sites. Although the vent sites are short-lived — an individual site may last only 10 years or so — as an ecosystem they ’ ve been stable for millions — well, billions — of years. DG : It works too well. You see there ’ re some fish inside here as well. There ’ s a fish sitting here. Here ’ s a crab with his claw right at the end of that tube worm, waiting for that worm to stick his head out. BL : The biologists right now cannot explain why these animals are so active. The worms are growing inches per week! DG : I already said that this site, from a human perspective, is toxic as hell. Not only that, but on top — the lifeblood — that plumbing system turns off every year or so. Their plumbing system turns off, so the sites have to move. And then there ’ s earthquakes, and then volcanic eruptions, on the order of one every five years, that completely wipes the area out. Despite that, these animals grow back in about a year ’ s time. You ’ re talking about biodensities and biodiversity, again, higher than the rainforest that just springs back to life. Is it sensitive? Yes. Is it fragile? No, it ’ s not really very fragile. I ’ ll end up with saying one thing. There ’ s a story in the sea, in the waters of the sea, in the sediments and the rocks of the sea floor. It ’ s an incredible story. What we see when we look back in time, in those sediments and rocks, is a record of Earth history. Everything on this planet — everything — works by cycles and rhythms. The continents move apart. They come back together. Oceans come and go. Mountains come and go. Glaciers come and go. El Nino comes and goes. It ’ s not a disaster, it ’ s rhythmic. What we ’ re learning now, it ’ s almost like a symphony. It ’ s just like music — it really is just like music. And what we ’ re learning now is that you can ’ t listen to a five-billion-year long symphony, get to today and say,”Stop! We want tomorrow ’ s note to be the same as it was today.”It ’ s absurd. It ’ s just absurd. So, what we ’ ve got to learn now is to find out where this planet ’ s going at all these different scales and work with it. Learn to manage it. The concept of preservation is futile. Conservation ’ s tougher, but we can probably get there. Thank you very much. Thank you.

Text Sample 654: NEG Dim 4 – 1998 – Score 8.00 – 1998/t000113.txt
Sheryl Shade : Hi, Aimee. Aimee Mullins : Hi. SS : Aimee and I thought we ’ d just talk a little bit, and I wanted her to tell all of you what makes her a distinctive athlete. AM : Well, for those of you who have seen the picture in the little bio â it might have given it away â I ’ m a double amputee, and I was born without fibulas in both legs. I was amputated at age one, and I ’ ve been running like hell ever since, all over the place. SS : Well, why don ’ t you tell them how you got to Georgetown â why don ’ t we start there? Why don ’ t we start there? AM : I ’ m a senior in Georgetown in the Foreign Service program. I won a full academic scholarship out of high school. They pick three students out of the nation every year to get involved in international affairs, and so I won a full ride to Georgetown and I ’ ve been there for four years. Love it. SS : When Aimee got there, she decided that she ’ s, kind of, curious about track and field, so she decided to call someone and start asking about it. So, why don ’ t you tell that story? AM : Yeah. Well, I guess I ’ ve always been involved in sports. I played softball for five years growing up. I skied competitively throughout high school, and I got a little restless in college because I wasn ’ t doing anything for about a year or two sports-wise. And I ’ d never competed on a disabled level, you know â I ’ d always competed against other able-bodied athletes. That ’ s all I ’ d ever known. In fact, I ’ d never even met another amputee until I was 17. And I heard that they do these track meets with all disabled runners, and I figured,”Oh, I don ’ t know about this, but before I judge it, let me go see what it ’ s all about.”So, I booked myself a flight to Boston in ’ 95, 19 years old and definitely the dark horse candidate at this race. I ’ d never done it before. I went out on a gravel track a couple of weeks before this meet to see how far I could run, and about 50 meters was enough for me, panting and heaving. And I had these legs that were made of a wood and plastic compound, attached with Velcro straps â big, thick, five-ply wool socks on â you know, not the most comfortable things, but all I ’ d ever known. And I ’ m up there in Boston against people wearing legs made of all things â carbon graphite and, you know, shock absorbers in them and all sorts of things â and they ’ re all looking at me like, OK, we know who ’ s not going to win this race. And, I mean, I went up there expecting â I don ’ t know what I was expecting â but, you know, when I saw a man who was missing an entire leg go up to the high jump, hop on one leg to the high jump and clear it at six feet, two inches... Dan O ’ Brien jumped 5 ’ 11”in ’ 96 in Atlanta, I mean, if it just gives you a comparison of â these are truly accomplished athletes, without qualifying that word”athlete.”And so I decided to give this a shot : heart pounding, I ran my first race and I beat the national record-holder by three hundredths of a second, and became the new national record-holder on my first try out. And, you know, people said,”Aimee, you know, you ’ ve got speed â you ’ ve got natural speed â but you don ’ t have any skill or finesse going down that track. You were all over the place. We all saw how hard you were working.”And so I decided to call the track coach at Georgetown. And I thank god I didn ’ t know just how huge this man is in the track and field world. He ’ s coached five Olympians, and the man ’ s office is lined from floor to ceiling with All America certificates of all these athletes he ’ s coached. He ’ s just a rather intimidating figure. And I called him up and said,”Listen, I ran

one race and I won...""I want to see if I can, you know â I need to just see if I can sit in on some of your practices, see what drills you do and whatever."That ' s all I wanted â just two practices."Can I just sit in and see what you do?"And he said,"Well, we should meet first, before we decide anything."You know, he ' s thinking,"What am I getting myself into?"So, I met the man, walked in his office, and saw these posters and magazine covers of people he has coached. And we got to talking, and it turned out to be a great partnership because he ' d never coached a disabled athlete, so therefore he had no preconceived notions of what I was or wasn ' t capable of, and I ' d never been coached before. So this was like,"Here we go â let ' s start on this trip."So he started giving me four days a week of his lunch break, his free time, and I would come up to the track and train with him. So that ' s how I met Frank. That was fall of ' 95. But then, by the time that winter was rolling around, he said,"You know, you ' re good enough. You can run on our women ' s track team here."And I said,"No, come on."And he said,"No, no, really. You can. You can run with our women ' s track team."In the spring of 1996, with my goal of making the U. S. Paralympic team that May coming up full speed, I joined the women ' s track team. And no disabled person had ever done that â run at a collegiate level. So I don ' t know, it started to become an interesting mix. SS : Well, on your way to the Olympics, a couple of memorable events happened at Georgetown. Why don ' t you just tell them? AM : Yes, well, you know, I ' d won everything as far as the disabled meets â everything I competed in â and, you know, training in Georgetown and knowing that I was going to have to get used to seeing the backs of all these women ' s shirts â you know, I ' m running against the next Flo-Jo â and they ' re all looking at me like,"Hmm, what ' s, you know, what ' s going on here?"And putting on my Georgetown uniform and going out there and knowing that, you know, in order to become better â and I ' m already the best in the country â you know, you have to train with people who are inherently better than you. And I went out there and made it to the Big East, which was sort of the championship race at the end of the season. It was really, really hot. And it ' s the first â I had just gotten these new sprinting legs that you see in that bio, and I didn ' t realize at that time that the amount of sweating I would be doing in the sock â it actually acted like a lubricant and I ' d be, kind of, pistoning in the socket. And at about 85 meters of my 100 meters sprint, in all my glory, I came out of my leg. Like, I almost came out of it, in front of, like, 5, 000 people. And I, I mean, was just mortified â because I was signed up for the 200, you know, which went off in a half hour. I went to my coach :"Please, don ' t make me do this."I can ' t do this in front of all those people. My legs will come off. And if it came off at 85 there ' s no way I ' m going 200 meters. And he just sat there like this. My pleas fell on deaf ears, thank god. Because you know, the man is from Brooklyn ; he ' s a big man. He says,"Aimee, so what if your leg falls off? You pick it up, you put the damn thing back on, and finish the goddamn race!"And I did. So, he kept me in line. He kept me on the right track. SS : So, then Aimee makes it to the 1996 Paralympics, and she ' s all excited. Her family ' s coming down â it ' s a big deal. It ' s now two years that you ' ve been running? AM : No, a year. SS : A year. And why don ' t you tell them what happened right before you go run your race? AM : Okay, well, Atlanta. The Paralympics, just for a little bit of clarification, are the Olympics for people with physical disabilities â amputees, persons with cerebral palsy, and wheelchair athletes â as opposed to the Special Olympics, which deals with people with mental disabilities. So, here we are, a week after the Olympics and down at Atlanta, and I ' m just blown away by the fact that just a year ago, I got out on a gravel track and couldn ' t run 50 meters. And so, here I am â never lost. I set new records at the U. S. Nationals â the

Olympic trials â that May, and was sure that I was coming home with the gold. I was also the only, what they call”bilateral BK”â below the knee. I was the only woman who would be doing the long jump. I had just done the long jump, and a guy who was missing two legs came up to me and says,”How do you do that? You know, we ’ re supposed to have a planar foot, so we can ’ t get off on the springboard.”I said,”Well, I just did it. No one told me that.”So, it ’ s funny â I ’ m three inches within the world record â and kept on from that point, you know, so I ’ m signed up in the long jump â signed up? No, I made it for the long jump and the 100-meter. And I ’ m sure of it, you know? I made the front page of my hometown paper that I delivered for six years, you know? It was, like, this is my time for shine. And we ’ re at the trainee warm-up track, which is a few blocks away from the Olympic stadium. These legs that I was on, which I ’ ll take out right now â I was the first person in the world on these legs. I was the guinea pig., I ’ m telling you, this was, like â talk about a tourist attraction. Everyone was taking pictures â”What is this girl running on?”And I ’ m always looking around, like, where is my competition? It ’ s my first international meet. I tried to get it out of anybody I could, you know,”Who am I running against here?””Oh, Aimee, we ’ ll have to get back to you on that one.”I wanted to find out times.”Don ’ t worry, you ’ re doing great.”This is 20 minutes before my race in the Olympic stadium, and they post the heat sheets. And I go over and look. And my fastest time, which was the world record, was 15. 77. Then I ’ m looking : the next lane, lane two, is 12. 8. Lane three is 12. 5. Lane four is 12. 2. I said,”What ’ s going on?”And they shove us all into the shuttle bus, and all the women there are missing a hand. So, I ’ m just, like â they ’ re all looking at me like ’ which one of these is not like the other, ’ you know? I ’ m sitting there, like,”Oh, my god. Oh, my god.”You know, I ’ d never lost anything, like, whether it would be the scholarship or, you know, I ’ d won five golds when I skied. In everything, I came in first. And Georgetown â that was great. I was losing, but it was the best training because this was Atlanta. Here we are, like, crĂ¨me de la crĂ¨me, and there is no doubt about it, that I ’ m going to lose big. And, you know, I ’ m just thinking,”Oh, my god, my whole family got in a van and drove down here from Pennsylvania.”And, you know, I was the only female U. S. sprinter. So they call us out and, you know â”Ladies, you have one minute.”And I remember putting my blocks in and just feeling horrified because there was just this murmur coming over the crowd, like, the ones who are close enough to the starting line to see. And I ’ m like,”I know! Look! This isn ’ t right.”And I ’ m thinking that ’ s my last card to play here ; if I ’ m not going to beat these girls, I ’ m going to mess their heads a little, you know? I mean, it was definitely the”Rocky IV”sensation of me versus Germany, and everyone else â Estonia and Poland â was in this heat. And the gun went off, and all I remember was finishing last and fighting back tears of frustration and incredible â incredible â this feeling of just being overwhelmed. And I had to think,”Why did I do this?”If I had won everything â but it was like, what was the point? All this training â I had transformed my life. I became a collegiate athlete, you know. I became an Olympic athlete. And it made me really think about how the achievement was getting there. I mean, the fact that I set my sights, just a year and three months before, on becoming an Olympic athlete and saying,”Here ’ s my life going in this direction â and I want to take it here for a while, and just seeing how far I could push it.”And the fact that I asked for help â how many people jumped on board? How many people gave of their time and their expertise, and their patience, to deal with me? And that was this collective glory â that there was, you know, 50 people behind me that had joined in this incredible experience of going to Atlanta. So, I apply this sort of philosophy now to everything I do : sitting back and realizing the progression, how far you ’ ve come at this day to this goal, you know. It ’ s important to focus on a goal, I think, but also recognize the progression on the way there and how you ’ ve grown as a person. That ’ s the achievement, I think. That ’ s the real achievement. SS : Why don ’ t you show them your legs? AM : Oh, sure. SS : You know, show us more than one set of legs. AM : Well, these are my pretty legs. No, these are my cosmetic legs, actually, and they ’ re absolutely beautiful. You ’ ve got to come up and see them. There are hair follicles on them, and I can paint my toenails. And, seriously, like, I can wear heels. Like, you guys don ’ t understand what that ’ s like to be able to just go into a shoe store and buy whatever you want. SS : You got to pick your height? AM : I got to pick my height, exactly. Patrick Ewing, who played for Georgetown in the ’ 80s, comes back every summer. And I had incessant fun making fun of him in the training room because he ’ d come in with foot injuries. I ’ m like,”Get it off! Don ’ t worry about it, you know. You can be eight feet tall. Just take them off.”He didn ’ t find it as humorous as I did, anyway. OK, now, these are my sprinting legs, made of carbon graphite, like I said, and I ’ ve got to make sure I ’ ve got the right socket. No, I ’ ve got so many legs in here. These are â do you want to hold that actually? That ’ s another leg I have for, like, tennis and softball. It has a shock absorber in it so it, like,”Shhhh,”makes this neat sound when you jump around on it. All right. And then this is the silicon sheath I roll over, to keep it on. Which, when I sweat, you know, I ’ m pistoning out of it. SS : Are you a different height? AM : In these? SS : In these. AM : I don ’ t know. I don ’ t think so. I may be a little taller. I actually can put both of them on. SS : She can ’ t really stand on these legs. She has to be moving, so... AM : Yeah, I definitely have to be moving, and balance is a little bit of an art in them. But without having the silicon sock, I ’ m just going to try slip in it. And so, I run on these, and have shocked half the world on these. These are supposed to simulate the actual form of a sprinter when they run. If you ever watch a sprinter, the ball of their foot is the only thing that ever hits the track. So when I stand in these legs, my hamstring and my glutes are contracted, as they would be had I had feet and were standing on the ball of my feet. AM : It ’ s a company in San Diego called Flex-Foot. And I was a guinea pig, as I hope to continue to be in every new form of prosthetic limbs that come out. But actually these, like I said, are still the actual prototype. I need to get some new ones because the last meet I was at, they were everywhere. You know, it ’ s like a big â it ’ s come full circle. Moderator : Aimee and the designer of them will be at TEDMED 2, and we ’ ll talk about the design of them. AM : Yes, we ’ ll do that. SS : Yes, there you go. AM : So, these are the sprint legs, and I can put my other... SS : Can you tell about who designed your other legs? AM : Yes. These I got in a place called Bournemouth, England, about two hours south of London, and I ’ m the only person in the United States with these, which is a crime because they are so beautiful. And I don ’ t even mean, like, because of the toes and everything. For me, while I ’ m such a serious athlete on the track, I want to be feminine off the track, and I think it ’ s so important not to be limited in any capacity, whether it ’ s, you know, your mobility or even fashion. I mean, I love the fact that I can go in anywhere and pick out what I want â the shoes I want, the skirts I want â and I ’ m hoping to try to bring these over here and make them accessible to a lot of people. They ’ re also silicon. This is a really basic, basic prosthetic limb under here. It ’ s like a Barbie foot under this. It is. It ’ s just stuck in this position, so I have to wear a two-inch heel. And, I mean, it ’ s really â let me take this off so you can see it. I don ’ t know how good you can see it, but, like, it really is. There ’ re veins on the feet, and then my heel is pink, and my Achilles ’ tendon â that moves a little bit. And it ’ s really an amazing store. I got them a year and two weeks ago. And this is just a silicon piece of skin. I mean, what happened was, two years ago this man in Belgium was saying,”God, if I can go to Madame Tussauds ’ wax museum and see Jerry Hall replicated down to the color of her eyes, looking so real as if she breathed, why can ’ t they build a limb for someone that looks like a leg, or an arm, or a hand?”I mean, they make ears for burn victims. They do amazing stuff with silicon. SS : Two weeks ago, Aimee was up for the Arthur Ashe award at the ESPYs. And she came into town and she rushed around and she said,”I have to buy some new shoes!”We ’ re an hour before the ESPYs, and she thought she ’ d gotten a two-inch heel but she ’ d actually bought a three-inch heel. AM : And this poses a problem for me, because it means I ’ m walking like that all night long. SS : For 45 minutes. Luckily, the hotel was terrific. They got someone to come in and saw off the shoes. AM : I said to the receptionist â I mean, I am just harried, and Sheryl ’ s at my side â I said,”Look, do you have anybody here who could help me? Because I have this problem...”You know, at first they were just going to write me off, like,”If you don ’ t like your shoes, sorry. It ’ s too late.””No, no, no, no. I ’ ve got these special feet that need a two-inch heel. I have a three-inch heel. I need a little bit off.”They didn ’ t even want to go there. They didn ’ t even want to touch that one. They just did it. No, these legs are great. I ’ m actually going back in a couple of weeks to get some improvements. I want to get legs like these made for flat feet so I can wear sneakers, because I can ’ t with these ones. So... Moderator : That ’ s it. SS : That ’ s Aimee Mullins.

Text Sample 655: NEG Dim 4 – 2024 – Score -1.00 – 2024/t003036.txt

I am a cognitive neuroscientist, and I ’ m trying to understand how we perceive time and how our perception of time arises from the workings of our **brain**. Why? Why do I want to understand that? Well, time is the ultimate master of our lives. We are all constantly faced with its fleeting nature. Yet how we feel the passing of time can be highly malleable. When we are bored, in pain, but also when we encounter something novel or extraordinary, time feels to be passing much slower than when we are busy or simply having fun. But what does it mean to feel time? And why does the feeling of time distort depending on the situation, our level of focus, our emotional state? Do these distortions serve some function, and can we gain some level of control over how we feel time? These are very big questions, and we do not have the answer to any of them. Not just yet. But I will tell you about a surprising discovery I believe will take us a step closer to unlocking the neural basis of time. And I will show you that time is not something that is created solely by the **brain**, but it is also intimately shaped by what is happening inside the rest of the body. I work in the Lab of Action and Body at Royal Holloway, University of London, and in our lab we look at the **brain** from an embodied point of view. What this means is that we believe we cannot fully understand the workings of the **brain** if we take it out of the body, because after all, the main reason for us to have a **brain** is to keep the body alive, so that we can act in the world. And for that, it is not enough for the **brain** to perceive what is happening in the world around us, but it also needs to perceive what is happening inside of our own body. It needs to understand what our body needs at any moment in time. That additional internal sense, the perception of the body from within is called interoception. And one example of interoception is the perception of our own heart. Yes, the heart. I think all of us know that the main function of the heart is to transport oxygen-rich blood all through the body, and like other bodily functions, it is controlled by the **brain**. So when I ’ m on the move, the heart should start beating faster to provide more oxygen. When I need to slow down and focus, it will also slow down to preserve the oxygen. But what many of you may not know is that the activity of the heart itself shapes the activity of the **brain**. But before I get into that, let me give you some very basic neuroscience. So the **brain** receives information from the outside world through our eyes, through our ears. But to make sense of that information, to perceive, it has specialized sensory areas, like the visual sensory area that allows us to see the redness of the TEDx sign, or the auditory-sensory areas that allow us to hear the sound of my voice. The information can be the same, but our perception can differ very much. But in order to act in response to what we perceive, the **brain** has separate movement control centers that are responsible for initiating and controlling movement. That ’ s what makes me move my hands constantly as I ’ m speaking. So how does the heart shape the **brain** then? Well, it turns out that there are sensory neurons in our heart that fire signals to our **brain** to inform it about the state of the body. But they fire only at a time when the heart contracts, and they remain silent when the heart is relaxed. So the **brain** and the heart are in a constant rhythmic dance. Every beat makes the **brain** step into an active mode, priming us for action. And between the beats, the **brain** steps back into perceptual mode, priming us to take in information. Now imagine what happens when the heart starts beating faster. There are more beats, so the **brain** is more likely to be in the active mode, whereas when the heart slows down, there are more periods of time between the beats, so the **brain** is more likely to be in the perceptual mode. This got me thinking. If the heart shapes perception in such a way, will it also shape the perception of time? Is there a causal relationship between our heart and how we experience time? Of course, we tested that in our lab. We invited 67 volunteers to participate in a study where we asked them to judge very brief durations of different stimuli. These could be sounds, images of simple shapes, images of people showing different emotions. We wanted to systematically determine whether what participants felt and sensed influenced how they perceived durations. But the key part of that study was that we hooked the volunteers to an ECG machine so we could see their heart beating in real time while they were doing this study. And this allowed us to flash the stimuli precisely at the moment when the heart squeezed tight or when it relaxed. And what we found was that stimuli that occurred during heart ’ s contraction were perceived to last shorter than stimuli that occurred between the beats, when the heart was relaxed. What this means is that the momentary state of the heart caused time to contract and expand within each heartbeat. Why am I so excited about this finding? Well because it shows that perception of time is an embodied experience. It might be constructed in the **brain**, but it is molded by the body. And I ’ m sure it seems intuitive, you know, that something rhythmic, like the heartbeat, would influence something rhythmic like time perception. But now we have a scientific evidence for that intuition. What ’ s more, I can use these heart-driven time distortions to look at what is happening in the **brain** just before duration is distorted by each beat. Could it be that distortions in time are connected to how each heartbeat affects the sensory and the movement centers of the **brain**? Remember how I told you that each beat momentarily suppressed perception, but between the beats, suppression was momentarily increased? So could it be... And we showed that time is contracted during the beat, but expanded in between the beats. So could it be that our experience of time arises from the way in which our **brain** takes in sensory information that is shaped by the heart? And if that is true, could the function of our highly distorted sense of time be to shift us between an active and perceptual mode? Time could contract when we need to move, but it may expand when we want to perceive. So maybe that slowing of time you feel when you ’ re bored is there to actually expand your perception and allow your mind to wander to something new. I hope I ’ ve shown you that one way to shape how we experience time is to work on the internal state of our body. So the next time time becomes a little bit too fleeting, like right now for me – Let ’ s maybe try to take a deep breath. Yeah? Feel the heart slow down, and let the **brain** expand the moment. And maybe that momentary expansion of time will also broaden our perception. Thank you very much for listening. Thank you.

When I was younger, I just did not heal the same way. I would see these scabs, and, like, I ’ d pick at them, they ’ d take forever to close, and my brother ’ s skin would just close right up. And then, you know, my sisters could have cramps, and they would just take ibuprofen, and it would be like nothing. And I would take ibuprofen, I would take a lot of ibuprofen, and I would get no response for my whole body. And so I just was like,”Why? Please help me.”At first, I felt like I got the short end of the biological stick, right? Why does my body not work the same way? There was a lot of frustration, because no one knows how they respond to something until they try it. But it was just I was different from them, that ’ s all. I ’ m Dr. Erika Moore and I ’ m an equity bioengineer. So every single time you get a paper cut or even a bruise, your immune system is there. Macrophage immune cells are present. They ’ re like the watchdog of the body. I think of them as, like, squishy balls, and they just kind of are always surveilling around the body. Sometimes, they ’ re eating, but other times, they ’ re just saying,”Hey, man, don ’ t be mad. This is cool. We can heal now, right?”Just imagine, like, a squishy ball that ’ s sometimes angry, sometimes happy. They ’ re super cute, I love them. I really study what function or state they adopt based on what environment they ’ re in and based on whose body they come from. There are a lot of other material scientists, bioengineers who ’ ve asked and developed really cool applications, but oftentimes, we don ’ t really consider who is studied. My work really focuses on the who of the disease, so I really want to study the diseases that particularly are health disparities, that only certain swaths of the population are affected by, because I think that by shining a light on those diseases, we can ensure better health equity for everyone in the world. I think I ’ m the first person or lab to really spearhead or cheerlead some of these endeavors, because there are lived experiences that a lot of other people in academia and in traditional PhD training don ’ t really have to consider, right? So there aren ’ t that many women of color who are assistant professors, who run research programs and do these other things. I knew so many women, growing up, who died from lupus. It was very common. When I went to try to study lupus, there were a lot of people who were like,”We ’ re agnostic. Like, we don ’ t care about the background of the patients.”But I was like,”We know that, like, 90 percent of lupus patients are women, and of that, about 70 percent are women of color.”So we really have to consider that, right? It should be a variable. Some women develop lupus, they don ’ t ever have flares. They ’ re fine. Other women develop lupus and have flares back to back, and pretty much develop major cardiovascular disease very early on. And so we want to take their patient cells and look at their interactions with blood vessels and see how they confer or propagate different inflammation in the system. And we do that all in this little jello construct. So it ’ s almost like a mini-tissue outside of the body. And we put the cells in it, and then we can study how they would respond in a tissue-like environment. What we found was really cool. The patient ' s background really directly affected the blood vessels in the system. We saw an increased number of blood vessel interactions between macrophages that were isolated from African-American women compared to those macrophages that were isolated from European women. These tissue models help us answer some really important questions. What if we could pinpoint why inflammation happens in certain bodies more violently than others? What if we could cure autoimmune illnesses by accounting for disease differences based on your background? What if we could prevent excessive fibrosis by tailoring your macrophages to respond differently to injury? I think my lived experiences made me more likely to ask these questions. And then I was just willing to try, you know, and I ' m still willing to try. I think by continuing to try, we innovate on what ' s the norm and set new standards for the future. If we pay a little bit more attention to the details, I think we can easily build a more equitable health care system for everyone. That ' s my goal.

Welcome, ladies and gentlemen, to the Alchemy of Pop. What else in the world can change your mind, can change your mood, can change your entire energetic frequency in 3. 5 minutes? For me, that ' s **pop** music. And for me, that ' s alchemy. I ' m Kesha, and I am a **pop** star. I ' m a singer, I ' m a songwriter, I ' m an activist, and I ' m a surprisingly good scuba diver, amongst many other things. But the thing that drives me the most in this life is to write **pop** songs. And let me tell you why. For me, songwriting and scuba diving are actually very similar. When I go diving, I like to go deep. I just jump right in that bitch. And I am a cave diver, so I go in and I see this looming darkness, and I swim right into it, and I look behind every corner, I leave no stone unturned. That ' s where the exciting shit happens. When I ' m writing a song, I also like to go deep. I like to explore my deepest, darkest thoughts. This is also where the exciting shit happens. This is where I find my truth. Songwriting is a direct line of communication with the truth. In song you can say things you can ' t say out loud to anybody else. Not your friends, not your therapist, not your mom. When I ' m feeling anything intensely, I know it ' s time for me to write a song. I don ' t hide from my emotions. I dive into them. You can write a song and you can not tell the truth, but your song will suck. So if you would like to write a good song, you have to be honest. You have to sit with yourself and let your truth come, whatever it is. This sounds simple, but where it can lead is profound. Songwriting teaches you that all emotions are valid, deserving of curiosity and deserving of a voice. The song called"Tik Tok,"I wrote that when I was 21. Yeah. It was way before the app. Don ' t blame me. I was feeling very playful. I was a young nihilist. I didn ' t have too many problems at the time. That was so fucking nice. And the dumber the lyrics got, the better the song got. And I thought these feelings, they were kind of frivolous. They were just a guilty pleasure. But those exact emotions, that youthful, playful, pure stupidity, made"Tik Tok"connect globally in ways I could have never imagined. Now, let me take you to a very different point in my life. It was 2017, and I had to make a boundary that affected every corner of my life. I found myself in a very ugly litigation with the same person who I had signed the rights to my recorded voice to. I had lost the rights to my voice, and in that I felt as if I had lost the rights to myself. It was very public. It was very painful. I was very angry. So I did what I do with all my emotions, and I wrote my way through it. And that led me to a song called"Praying."Someday, maybe you ' ll see the light

Oh, some say, in life, you ’ re gonna get what you give But some things only God can forgive I hope you ’ re somewhere prayin ’, prayin ’ I hope your soul is changin ’, changin ’ I hope you find your peace Falling on your knees prayin ’ Thank you, thank you. So after”Tik Tok,”I wondered if anybody would connect to these uglier emotions coming from me, like, I ’ m the girl who”brushes her teeth with a bottle of Jack,”you know? And also, who wants to listen to an angry woman? Turns out a lot of fucking people do. Hehehe That was the first time I was nominated for a Grammy ; it ’ s the first time I performed at the Grammys. And I ’ ve heard from many people going through their own struggles that this song helped them in some way. I dove deep into the pain. I didn ’ t hide from it. I alchemized it into something healing not only for me but, inadvertently, for other people. I ’ m now – probably going to cry – I ’ m now in a drastically different point in my life. On March 6, 2024, I ’ ve gained back legal rights over my own voice. And with it, a newly found freedom for the first time in nearly 20 years. It ’ s funny how you can lose the rights to your own voice, but you can never lose the rights to your truth. Throughout this journey, songwriting has been my therapist, my best friend, my lover, my drinking buddy, and my higher power. It ’ s where I can be truly honest. And I don ’ t claim to be an expert on much, but I ’ ve experienced over and over and over how you can create art out of emotion and through that process, not only heal yourself but help to heal others. And I believe there ’ s an artist in every single one of us. Creation is just exploring. It ’ s becoming childlike. It ’ s not judging yourself. So I encourage all of you to not be afraid of the intensity inside of you. The stupidity, the rage, the anger, the darkness. All of it. Dive into it. Explore it. And I want to remind you that whether or not you are free, you are entitled to your truth. Find your medium, whatever speaks to you, and let your truth come. You never know who else will need to hear it. You never know who else can heal from it. Please don ’ t take this for granted. I ’ d like to share a song I wrote recently. No one has heard this. This is the first time I have shared a new song since I have owned my voice as an adult woman. So this song is called”Cathedral.”Baby, I ’ ve been baptized Been bathing in the moonlight I surrender, so take your time I ’ m summoning my divine Tried it all to numb the pain But nobody ever stayed It could be too much to even take Look what you find when there ’ s nothing left to lose I kept on running, just gasping for breath Nothing to trust in ’ cause nothing was left I pray when I ’ m desperate I ’ m down on my knees Oh, my God, I ’ m the cathedral Finally coming home Life was so lethal I ’ m the savior, I ’ m the altar, I ’ m the Holy Ghost Pain was my ritual, fear my religion I was the one who needed forgiving, oh I ’ m the cathedral Let it in, sunlight It feels good, that ’ s alright Touch my skin, love my pain away And, God, forgive all my mistakes Maybe redemption lies in the dark My happy ending ’ s through my broken heart Hope is a madman that hides in my mind Oh, my God I ’ m the cathedral Finally coming home Life was so lethal I ’ m the savior, I ’ m the altar, I ’ m the Holy Ghost Pain was my ritual, fear my religion I was the one who needed forgiving, oh I ’ m the cathedral Who I once was, she seems so far I ’ ve had to sacrifice her from the start I ’ m born again with every scar I can ’ t control what ’ s written in the stars Been on my knees, begging for God She ’ s there inside of me, she was just lost Oh, my mind, look what it caused Darkness leads into light all along I ’ m the cathedral Finally coming home Oh, God, it feels good I ’ m the savior, I ’ m the altar, I ’ m the Holy Ghost Every minute is a new beginning I died in hell, and I ’ m finally living again In the cathedral I ’ m the cathedral Thank you so much.

Hi, everyone. I ’ m Sirena. I ’ m 11 years old and from Connecticut. Well, I ’ m not really sure why I ’ m here. I mean, what does this have to do with technology, entertainment and design? Well, I count my iPod, cellphone and computer as technology, but this has nothing to do with that. So I did a little research on it. Well, this is what I found. Of course, I hope I can memorize it. The violin is made of a wood box and four metal strings. By pulling a string, it vibrates and produces a sound wave, which passes through a piece of wood called a bridge, and goes down to the wood box and gets amplified, but... let me think. Placing your finger at different places on the fingerboard changes the string length, and that changes the frequency of the sound wave. Oh, my gosh! OK, this is sort of technology, but I can call it a 16th-century technology. But actually, the most fascinating thing that I found was that even the audio system or wave transmission nowadays are still based on the same principle of producing and projecting sound. Isn ’ t that cool? Design — I love its design. I remember when I was little, my mom asked me,”Would you like to play the violin or the piano?”I looked at that giant monster and said to myself —”I am not going to lock myself on that bench the whole day!”This is small and lightweight. I can play from standing, sitting or walking. And, you know what? The best of all is that if I don ’ t want to practice, I can hide it. The violin is very beautiful. Some people relate it as the shape of a lady. But whether you like it or not, it ’ s been so for more than 400 years, unlike modern stuff [that] easily looks dated. But I think it ’ s very personal and unique that, although each violin looks pretty similar, no two violins sound the same — even from the same maker or based on the same model. Entertainment — I love the entertainment. But actually, the instrument itself isn ’ t very entertaining. I mean, when I first got my violin and tried to play around on it, it was actually really bad, because it didn ’ t sound the way I ’ d heard from other kids — it was so horrible and so scratchy. So, it wasn ’ t entertaining at all. But besides, my brother found this very funny : Yuk! Yuk! Yuk! A few years later, I heard a joke about the greatest violinist, Jascha Heifetz. After Mr. Heifetz ’ s concert, a lady came over and complimented him :”Oh, Mr. Heifetz, your violin sounded so great tonight!”And Mr. Heifetz was a very cool person, so he picked up his violin and said,”Funny — I don ’ t hear anything.”Now I realize that as the musician, we human beings, with our great mind, artistic heart and skill, can change this 16th-century technology and a legendary design to a wonderful entertainment. Now I know why I ’ m here. At first, I thought I was just going to be here to perform, but unexpectedly, I learned and enjoyed much more. But... although some of the talks were quite up there for me. Like the multi-dimension stuff. I mean, honestly, I ’ d be happy enough if I could actually get my two dimensions correct in school. But actually, the most impressive thing to me is that — well, actually, I would also like to say this for all children is to say thank you to all adults, for actually caring for us a lot, and to make our future world much better. Thank you.

With all the legitimate concerns about AIDS and avian flu — and we ’ ll hear about that from the brilliant Dr. Brilliant later today — I want to talk about the other pandemic, which is cardiovascular disease, diabetes, hypertension — all of which are completely preventable for at least 95 percent of people just by changing diet and lifestyle. And what ’ s happening is that there ’ s a globalization of illness occurring, that people are starting to eat like us, and live like us, and die like us. And in one generation, for example, Asia ’ s gone from having one of the lowest rates of heart disease and obesity and diabetes to one of the highest. And in Africa, cardiovascular disease equals the HIV and AIDS deaths in most countries. So there ' s a critical window of opportunity we have to make an important difference that can affect the lives of literally millions of people, and practice preventive medicine on a global scale. Heart and blood vessel diseases still kill more people — not only in this country, but also worldwide — than everything else combined, and yet it ' s completely preventable for almost everybody. It ' s not only preventable ; it ' s actually reversible. And for the last almost 29 years, we ' ve been able to show that by simply changing diet and lifestyle, using these very high-tech, expensive, state-of-the-art measures to prove how powerful these very simple and low-tech and low-cost interventions can be like — quantitative arteriography, before and after a year, and cardiac PET scans. We showed a few months ago — we published the first study showing you can actually stop or reverse the progression of prostate cancer by making changes in diet and lifestyle, and 70 percent regression in the tumor growth, or inhibition of the tumor growth, compared to only nine percent in the control group. And in the MRI and MR spectroscopy here, the prostate tumor activity is shown in red — you can see it diminishing after a year. Now there is an epidemic of obesity : two-thirds of adults and 15 percent of kids. What ' s really concerning to me is that diabetes has increased 70 percent in the past 10 years, and this may be the first generation in which our kids live a shorter life span than we do. That ' s pitiful, and it ' s preventable. Now these are not election returns, these are the people — the number of the people who are obese by state, beginning in ' 85, ' 86, ' 87 — these are from the CDC website — ' 88, ' 89, ' 90, ' 91 — you get a new category — ' 92, ' 93, ' 94, ' 95, ' 96, ' 97, ' 98, ' 99, 2000, 2001 — it gets worse. We ' re kind of devolving. Now what can we do about this? Well, you know, the diet that we ' ve found that can reverse heart disease and cancer is an Asian diet. But the people in Asia are starting to eat like we are, which is why they ' re starting to get sick like we are. So I ' ve been working with a lot of the big food companies. They can make it fun and sexy and hip and crunchy and convenient to eat healthier foods, like — I chair the advisory boards to McDonald ' s, and PepsiCo, and ConAgra, and Safeway, and soon Del Monte, and they ' re finding that it ' s good business. The salads that you see at McDonald ' s came from the work — they ' re going to have an Asian salad. At Pepsi, two-thirds of their revenue growth came from their better foods. And so if we can do that, then we can free up resources for buying drugs that you really do need for treating AIDS and HIV and malaria and for preventing avian flu. Thank you.

I wrote this poem after hearing a pretty well known actress tell a very well known interviewer on television,"I ' m really getting into the Internet lately. I just wish it were more organized."So... If I controlled the Internet, you could auction your broken heart on eBay. Take the money ; go to Amazon ; buy a phonebook for a country you ' ve never been to — call folks at random until you find someone who flirts really well in a foreign language. If I were in charge of the Internet, you could Mapquest your lover ' s mood swings. Hang left at cranky, right at preoccupied, U-turn on silent treatment, all the way back to tongue kissing and good lovin '. You could navigate and understand every emotional intersection. Some days, I ' m as shallow as a baking pan, but I still stretch miles in all directions. If I owned the Internet, Napster, Monster and Friendster. com would be one big website. That way you could listen to cool music while you pretend to look for a job and you ’ re really just chattin ’ with your pals. Heck, if I ran the Web, you could email dead people. They would not email you back — but you ’ d get an automated reply. Their name in your inbox — it ’ s all you wanted anyway. And a message saying,”Hey, it ’ s me. I miss you. Listen, you ’ ll see being dead is dandy. Now you go back to raising kids and waging peace and craving candy.”If I designed the Internet, childhood. com would be a loop of a boy in an orchard, with a ski pole for a sword, trashcan lid for a shield, shouting,”I am the emperor of oranges. I am the emperor of oranges. I am the emperor of oranges.”Now follow me, OK? Grandma. com would be a recipe for biscuits and spit-bath instructions. One, two, three. That links with hotdiggitydog. com. That is my grandfather. They take you to gruff-ex-cop-on-his-fourth-marriage. dad. He forms an attachment to kind-of-ditzy-but-still-sends-ginger-snaps-for-Christmas. mom, who downloads the boy in the orchard, the emperor of oranges, who grows up to be me — the guy who usually goes too far. So if I were emperor of the Internet, I guess I ’ d still be mortal, huh? But at that point, I would probably already have the lowest possible mortgage and the most enlarged possible penis — so I would outlaw spam on my first day in office. I wouldn ’ t need it. I ’ d be like some kind of Internet genius, and me, I ’ d like to upgrade to deity and maybe just like that — **pop**! — I ’ d go wireless. Huh? Maybe Google would hire this. I could zip through your servers and firewalls like a virus until the World Wide Web is as wise, as wild and as organized as I think a modern-day miracle / oracle can get, but, ooh-eee, you want to bet just how whack and un-PC your Mac or PC is going to be when I ’ m rocking hot-shit-hot-shot-god. net? I guess it ’ s just like life. It is not a question of if you can — it ’ s : do ya? We can interfere with the interface. We can make”You ’ ve got Hallelujah”the national anthem of cyberspace every lucky time we log on. You don ’ t say a prayer. You don ’ t write a psalm. You don ’ t chant an”om.”You send one blessed email to whomever you ’ re thinking of at dah-da-la-dat-da-dah-da-la-dat. com. Thank you, TED.

I ’ m going to go right into the slides. And all I ’ m going to try and prove to you with these slides is that I do just very straight stuff. And my ideas are â in my head, anyway â they ’ re very logical and relate to what ’ s going on and problem solving for clients. I either convince clients at the end that I solve their problems, or I really do solve their problems, because usually they seem to like it. Let me go right into the slides. Can you turn off the light? Down. I like to be in the dark. I don ’ t want you to see what I ’ m doing up here. Anyway, I did this house in Santa Monica, and it got a lot of notoriety. In fact, it appeared in a porno comic book, which is the slide on the right. This is in Venice. I just show it because I want you to know I ’ m concerned about context. On the left-hand side, I had the context of those little houses, and I tried to build a building that fit into that context. When people take pictures of these buildings out of that context they look really weird, and my premise is that they make a lot more sense when they ’ re photographed or seen in that space. And then, once I deal with the context, I then try to make a place that ’ s comfortable and private and fairly serene, as I hope you ’ ll find that slide on the right. And then I did a law school for Loyola in downtown L. A. I was concerned about making a place for the study of law. And we continue to work with this client. The building on the right at the top is now under construction. The garage on the right â the gray structure â will be torn down, finally, and several small classrooms will be placed along this avenue that we ’ ve created, this campus. And it all related to the clients and the students from the very first meeting saying they felt denied a place. They wanted a sense of place. And so the whole idea here was to create that kind of space in downtown, in a neighborhood that was difficult to fit into. And it was my theory, or my point of view, that one didn ’ t upstage the neighborhood â one made accommodations. I tried to be inclusive, to include the buildings in the neighborhood, whether they were buildings I liked or not. In the ’ 60s I started working with paper furniture and made a bunch of stuff that was very successful in Bloomingdale ’ s. We even made flooring, walls and everything, out of cardboard. And the success of it threw me for a loop. I couldn ’ t deal with the success of furniture â I wasn ’ t secure enough as an architect â and so I closed it all up and made furniture that nobody would like. So, nobody would like this. And it was in this, preliminary to these pieces of furniture, that Ricky and I worked on furniture by the slice. And after we failed, I just kept failing. The piece on the left â and that ultimately led to the piece on the right â happened when the kid that was working on this took one of those long strings of stuff and folded it up to put it in the wastebasket. And I put a piece of tape around it, as you see there, and realized you could sit on it, and it had a lot of resilience and strength and so on. So, it was an accidental discovery. I got into fish. I mean, the story I tell is that I got mad at postmodernism â at po-mo â and said that fish were 500 million years earlier than man, and if you ’ re going to go back, we might as well go back to the beginning. And so I started making these funny things. And they started to have a life of their own and got bigger â as the one glass at the Walker. And then, I sliced off the head and the tail and everything and tried to translate what I was learning about the form of the fish and the movement. And a lot of my architectural ideas that came from it â accidental, again â it was an intuitive kind of thing, and I just kept going with it, and made this proposal for a building, which was only a proposal. I did this building in Japan. I was taken out to dinner after the contract for this little restaurant was signed. And I love sake and Kobe and all that stuff. And after I got â I was really drunk â I was asked to do some sketches on napkins. And I made some sketches on napkins â little boxes and Morandi-like things that I used to do. And the client said,”Why no fish?”And so I made a drawing with a fish, and I left Japan. Three weeks later, I received a complete set of drawings saying we ’ d won the competition. Now, it ’ s hard to do. It ’ s hard to translate a fish form, because they ’ re so beautiful â perfect â into a building or object like this. And Oldenburg, who I work with a little once in a while, told me I couldn ’ t do it, and so that made it even more exciting. But he was right â I couldn ’ t do the tail. I started to get the head OK, but the tail I couldn ’ t do. It was pretty hard. The thing on the right is a snake form, a ziggurat. And I put them together, and you walk between them. It was a dialog with the context again. Now, if you saw a picture of this as it was published in Architectural Record â they didn ’ t show the context, so you would think,”God, what a pushy guy this is.”But a friend of mine spent four hours wandering around here looking for this restaurant. Couldn ’ t find it. So... As for craft and technology and all those things that you ’ ve all been talking about, I was thrown for a complete loop. This was built in six months. The way we sent drawings to Japan : we used the magic computer in Michigan that does carved models, and we used to make foam models, which that thing scanned. We made the drawings of the fish and the scales. And when I got there, everything was perfect â except the tail. So, I decided to cut off the head and the tail. And I made the object on the left for my show at the Walker. And it ’ s one of the nicest pieces I ’ ve ever made, I think. And then Jay Chiat, a friend and client, asked me to do his headquarters building in L. A. For reasons we don ’ t want to talk about, it got delayed. Toxic waste, I guess, is the key clue to that one. And so we built a temporary building â I ' m getting good at temporary â and we put a conference room in that ' s a fish. And, finally, Jay dragged me to my hometown, Toronto, Canada. And there is a story â it ' s a real story â about my grandmother buying a carp on Thursday, bringing it home, putting it in the bathtub when I was a kid. I played with it in the evening. When I went to sleep, the next day it wasn ' t there. And the next night, we had gefilte fish. And so I set up this interior for Jay ' s offices and I made a pedestal for a sculpture. And he didn ' t buy a sculpture, so I made one. I went around Toronto and found a bathtub like my grandmother ' s, and I put the fish in. It was a joke. I play with funny people like [Claes] Oldenburg. We ' ve been friends for a long time. And we ' ve started to work on things. A few years ago, we did a performance piece in Venice, Italy, called"Il Corso del Coltello"â the Swiss Army knife. And most of the imagery is â Claes ', but those two little boys are my sons, and they were Claes ' assistants in the play. He was the Swiss Army knife. He was a souvenir salesman who always wanted to be a painter, and I was Frankie P. Toronto. P for Palladio. Dressed up like the AT&T building by Claes â with a fish hat. The highlight of the performance was at the end. This beautiful object, the Swiss Army knife, which I get credit for participating in. And I can tell you â it ' s totally an Oldenburg. I had nothing to do with it. The only thing I did was, I made it possible for them to turn those blades so you could sail this thing in the canal, because I love sailing. We made it into a sailing craft. I ' ve been known to mess with things like chain link fencing. I do it because it ' s a curious thing in the culture, when things are made in such great quantities, absorbed in such great quantities, and there ' s so much denial about them. People hate it. And I ' m fascinated with that, which, like the paper furniture â it ' s one of those materials. And I ' m always drawn to that. And so I did a lot of dirty things with chain link, which nobody will forgive me for. But Claes made homage to it in the Loyola Law School. And that chain link is really expensive. It ' s in perspective and everything. And then we did a camp together for children with cancer. And you can see, we started making a building together. Of course, the milk can is his. But we were trying to collide our ideas, to put objects next to each other. Like a Morandi â like the little bottles â composing them like a still life. And it seemed to work as a way to put he and I together. Then Jay Chiat asked me to do this building on this funny lot in Venice, and I started with this three-piece thing, and you entered in the middle. And Jay asked me what I was going to do with the piece in the middle. And he pushed that. And one day I had a â oh, well, the other way. I had the binoculars from Claes, and I put them there, and I could never get rid of them after that. Oldenburg made the binoculars incredible when he sent me the first model of the real proposal. It made my building look sick. And it was this interaction between that kind of, up-the-ante stuff that became pretty interesting. It led to the building on the left. And I still think the Time magazine picture will be of the binoculars, you know, leaving out the â what the hell. I use a lot of metal in my work, and I have a hard time connecting with the craft. The whole thing about my house, the whole use of rough carpentry and everything, was the frustration with the crafts available. I said,"If I can ' t get the craft that I want, I ' ll use the craft I can get."There were plenty of models for that, in Rauschenberg and Jasper Johns, and many artists who were making beautiful art and sculpture with junk materials. I went into the metal because it was a way of building a building that was a sculpture. And it was all of one material, and the metal could go on the roof as well as the walls. The metalworkers, for the most part, do ducts behind the ceilings and stuff. I was given an opportunity to design an exhibit for the metalworkers ' unions of America and Canada in Washington, and I did it on the condition that they become my partners in the future and help me with all future metal buildings, etc. etc. And it ’ s working very well to have these people, these craftsmen, interested in it. I just tell the stories. It ’ s a way of connecting, at least, with some of those people that are so important to the realization of architecture. The metal continued into a building â Herman Miller, in Sacramento. And it ’ s just a complex of factory buildings. And Herman Miller has this philosophy of having a place â a people place. I mean, it ’ s kind of a trite thing to say, but it is real that they wanted to have a central place where the cafeteria would be, where the people would come and where the people working would interact. So it ’ s out in the middle of nowhere, and you approach it. It ’ s copper and galvanize. I used the galvanize and copper in a very light gauge, so it would buckle. I spent a lot of time undoing Richard Meier ’ s aesthetic. Everybody ’ s trying to get the panels perfect, and I always try to get them sloppy and fuzzy. And they end up looking like stone. This is the central area. There ’ s a ramp. And that little dome in there is a building by Stanley Tigerman. Stanley was instrumental in my getting this job. And when I was awarded the contract I, at the very beginning, asked the client if they would let Stanley do a cameo piece with me. Because these were ideas that we were talking about, building things next to each other, making â it ’ s all about [a] metaphor for a city, maybe. And so Stanley did the little dome thing. And we did it over the phone and by fax. He would send me a fax and show me something. He ’ d made a building with a dome and he had a little tower. I told him,”No, no, that ’ s too ongepotchket. I don ’ t want the tower.”So he came back with a simpler building, but he put some funny details on it, and he moved it closer to my building. And so I decided to put him in a depression. I put him in a hole and made a kind of a hole that he sits in. And so then he put two bridges â this all happened on the fax, going back and forth over a couple of weeks ’ period. And he put these two bridges with pink guardrails on it. And so then I put this big billboard behind it. And I call it,”David and Goliath.”And that ’ s my cafeteria. In Boston, we had that old building on the left. It was a very prominent building off the freeway, and we added a floor and cleaned it up and fixed it up and used the kind of â I thought â the language of the neighborhood, which had these cornices, projecting cornices. Mine got a little exuberant, but I used lead copper, which is a beautiful material, and it turns green in 100 years. Instead of, like, copper in 10 or 15. We redid the side of the building and re-proportioned the windows so it sort of fit into the space. And it surprised both Boston and myself that we got it approved, because they have very strict kind of design guideline, and they wouldn ’ t normally think I would fit them. The detailing was very careful with the lead copper and making panels and fitting it tightly into the fabric of the existing building. In Barcelona, on Las Ramblas for some film festival, I did the Hollywood sign going and coming, made a building out of it, and they built it. I flew in one night and took this picture. But they made it a third smaller than my model without telling me. And then more metal and some chain link in Santa Monica â a little shopping center. And this is a laser laboratory at the University of Iowa, in which the fish comes back as an abstraction in the back. It ’ s the support labs, which, by some coincidence, required no windows. And the shape fit perfectly. I just joined the points. In the curved part there ’ s all the mechanical equipment. That solid wall behind it is a pipe chase â a pipe canyon â and so it was an opportunity that I seized, because I didn ’ t have to have any protruding ducts or vents or things in this form. It gave me an opportunity to make a sculpture out of it. This is a small house somewhere. They ’ ve been building it so long I don ’ t remember where it is. It ’ s in the West Valley. And we started with the stream and built the house along the stream â dammed it up to make a lake.

These are the models. The reality, with the lake â the workmanship is pretty bad. And it reminded me why I play defensively in things like my house. When you have to do something really cheaply, it ’ s hard to get perfect corners and stuff. That big metal thing is a passage, and in it is â you go downstairs into the living room and then down into the bedroom, which is on the right. It ’ s kind of like a whole built town. I was asked to do a hospital for schizophrenic adolescents at Yale. I thought it was fitting for me to be doing that. This is a house next to a Philip Johnson house in Minnesota. The owners had a dilemma â they asked Philip to do it. He was too busy. He didn ’ t recommend me, by the way. We ended up having to make it a sculpture, because the dilemma was, how do you build a building that doesn ’ t look like the language? Is it going to look like this beautiful estate is sub-divided? Etc. etc. You ’ ve got the idea. And so we finally ended up making it. These people are art collectors. And we finally made it so it appears very sculptural from the main house and all the windows are on the other side. And the building is very sculptural as you walk around it. It ’ s made of metal and the brown stuff is Fin-Ply â it ’ s that formed lumber from Finland. We used it at Loyola on the chapel, and it didn ’ t work. I keep trying to make it work. In this case we learned how to detail it. In Cleveland, there ’ s Burnham Mall, on the left. It ’ s never been finished. Going out to the lake, you can see all those new buildings we built. And we had the opportunity to build a building on this site. There ’ s a railroad track. This is the city hall over here somewhere, and the courthouse. And the centerline of the mall goes out. Burnham had designed a railroad station that was never built, and so we followed. Sohio is on the axis here, and we followed the axis, and they ’ re two kind of goalposts. And this is our building, which is a corporate headquarters for an insurance company. We collaborated with Oldenburg and put the newspaper on top, folded. The health club is fastened to the garage with a C-clamp, for Cleveland. You drive down. So it ’ s about a 10-story C-clamp. And all this stuff at the bottom is a museum, and an idea for a very fancy automobile entry. This owner has a pet peeve about bad automobile entries. And this would be a hotel. So, the centerline of this thing â we ’ d preserve it, and it would start to work with the scale of the new buildings by Pelli and Kohn Pederson Fox, etc., that are underway. It ’ s hard to do high-rise. I feel much more comfortable down here. This is a piece of property in Brentwood. And a long time ago, about ’ 82 or something, after my house â I designed a house for myself that would be a village of several pavilions around a courtyard â and the owner of this lot worked for me and built that actual model on the left. And she came back, I guess wealthier or something â something happened â and asked me to design a house for her on this site. And following that basic idea of the village, we changed it as we got into it. I locked the house into the site by cutting the back end â here you see on the photographs of the site â slicing into it and putting all the bathrooms and dressing rooms like a retaining wall, creating a lower level zone for the master bedroom, which I designed like a kind of a barge, looking like a boat. And that ’ s it, built. The dome was a request from the client. She wanted a dome somewhere in the house. She didn ’ t care where. When you sleep in this bedroom, I hope â I mean, I haven ’ t slept in it yet. I ’ ve offered to marry her so I could sleep there, but she said I didn ’ t have to do that. But when you ’ re in that room, you feel like you ’ re on a kind of barge on some kind of lake. And it ’ s very private. The landscape is being built around to create a private garden. And then up above there ’ s a garden on this side of the living room, and one on the other side. These aren ’ t focused very well. I don ’ t know how to do it from here. Focus the one on the right. It ’ s up there. Left â it ’ s my right. Anyway, you enter into a garden with a beautiful grove of trees.

That ’ s the living room. Servants ’ quarters. A guest bedroom, which has this dome with marble on it. And then you enter into the living room and then so on. This is the bedroom. You come down from this level along the stairway, and you enter the bedroom here, going into the lake. And the bed is back in this space, with windows looking out onto the lake. These Stonehenge things were designed to give foreground and to create a greater depth in this shallow lot. The material is lead copper, like in the building in Boston. And so it was an intent to make this small piece of land â it ’ s 100 by 250 â into a kind of an estate by separating these areas and making the living room and dining room into this pavilion with a high space in it. And this happened by accident that I got this right on axis with the dining room table. It looks like I got a Baldessari painting for free. But the idea is, the windows are all placed so you see pieces of the house outside. Eventually this will be screened â these trees will come up â and it will be very private. And you feel like you ’ re in your own kind of village. This is for Michael Eisner â Disney. We ’ re doing some work for him. And this is in Anaheim, California, and it ’ s a freeway building. You go under this bridge at about 65 miles an hour, and there ’ s another bridge here. And you ’ re through this room in a split second, and the building will sort of reflect that. On the backside, it ’ s much more humane â entrance, dining hall, etc. And then this thing here â I ’ m hoping as you drive by you ’ ll hear the picket fence effect of the sound hitting it. Kind of a fun thing to do. I ’ m doing a building in Switzerland, Basel, which is an office building for a furniture company. And we struggled with the image. These are the early studies, but they have to sell furniture to normal people, so if I did the building and it was too fancy, then people might say,”Well, the furniture looks OK in his thing, but no, it ain ’ t going to look good in my normal building.”So we ’ ve made a kind of pragmatic slab in the second phase here, and we ’ ve taken the conference facilities and made a villa out of them so that the communal space is very sculptural and separate. And you ’ re looking at it from the offices and you create a kind of interaction between these pieces. This is in Paris, along the Seine. Palais des Sports, the Gare de Lyon over here. The Minister of Finance â the guy that moved from the Louvre â goes in here. There ’ s a new library across the river. And back in here, in this already treed park, we ’ re doing a very dense building called the American Center, which has a theater, apartments, dance school, an art museum, restaurants and all kinds of â it ’ s a very dense program â bookstores, etc. In a very tight, small â this is the ground level. And the French have this extraordinary way of screwing things up by taking a beautiful site and cutting the corner off. They call it the plan coupe. And I struggled with that thing â how to get around the corner. These are the models for it. I showed you the other model, the one â this is the way I organized myself so I could make the drawing â so I understood the problem. I was trying to get around this plan coupe â how do you do it? Apartments, etc. And these are the kind of study models we did. And the one on the left is pretty awful. You can see why I was ready to commit suicide when this one was built. But out of it came finally this resolution, where the elevator piece worked frontally to this, parallel to this street, and also parallel to here. And then this kind of twist, with this balcony and the skirt, kind of like a ballerina lifting her skirt to let you into the foyer. The restaurants here â the apartments and the theater, etc. So it would all be built in stone, in French limestone, except for this metal piece. And it faces into a park. And the idea was to make this express the energy of this. On the side facing the street it ’ s much more normal, except I slipped a few mansards down, so that coming on the point, these housing units made a gesture to the corner. And this will be some kind of high-tech billboard. If any of you guys have any ideas for it, please contact me. I don ’ t know what to do. Jay Chiat is a glutton for punishment, and he hired me to do a house for him in the Hamptons. And it ’ s got a fish. And I keep thinking,”This is going to be the last fish.”It ’ s like a drug addict. I say,”I ’ m not going to do it anymore â I don ’ t want to do it anymore â I ’ m not going to do it.”And then I do it. There it is. But it ’ s the living room. And this piece here is â I don ’ t know what it is. I just added it so that we ’ d have enough money in the budget so we could take something out. This is Euro Disney, and I ’ ve worked with all of the guys that presented to you earlier. We ’ ve had a lot of fun working together. I think I ’ m from Mars for them, and they are for me, but somehow we all manage to work together, and I think, productively. So far. This is a shopping thing. You come into the Magic Kingdom and the hotel that Tony Baxter ’ s group is doing out here. And then this is a kind of a shopping mall, with a rodeo and restaurants. And another restaurant. What I did â because of the Paris skies being quite dull, I made a light grid that ’ s perpendicular to the train station, to the route of the train. It looks like it ’ s kind of been there, and then crashed all these simpler forms into it. The light grid will have a light, be lit up at night and give a kind of light ceiling. In Switzerland â Germany, actually â on the Rhine across from Basel, we did a furniture factory and a furniture museum. And I tried to â there ’ s a Nick Grimshaw building over here, there ’ s an Oldenburg sculpture over here â I tried to make a relationship urbanistically. And I don ’ t gave good slides to show â it ’ s just been completed â but this piece here is this building, and these pieces here and here. And as you pass by it ’ s always part â you see it as all of these pieces accrue and become part of an overall neighborhood. It ’ s plaster and just zinc. And you wonder, if this is a museum, what it ’ s going to be like inside? If it ’ s going to be so busy and crazy that you wouldn ’ t show anything, and just wait. I ’ m so cunning and clever â I made it quiet and wonderful. But on the outside it does scream out at you a bit. It ’ s actually basically three square rooms with a couple of skylights and stuff. And from the building in the back, you see it as an iceberg floating by in the hills. I know I ’ m over time. See, that skylight goes down and becomes that one. So it ’ s pretty quiet inside. This is the Disney Hall â the concert hall. It ’ s a complicated project. It has a chamber hall. It ’ s related to an existing Chandler Pavilion that was built with a lot of love and tears and caring. And it ’ s not a great building, but I approached it optimistically, that we would make a compositional relationship between us that would strengthen both of us. And the plan of this â it ’ s a concert hall. This is the foyer, which is kind of a garden structure. There ’ s commercial at the ground floor. These are offices, which, really, in the competition, we didn ’ t have to design. But finally, there ’ s a hotel there. These were the kind of relationships made to the Chandler, composing these elevations together and relating them to the buildings that existed â to MOCA, etc. The acoustician in the competition gave us criteria, which led to this compartmentalized scheme, which we found out after the competition would not work at all. But everybody liked these forms and liked the space, and so that ’ s one of the problems of a competition. You have to then try and get that back in some way. And we studied many models. This was our original model. These were the three buildings that were the ideal â the Concertgebouw, Boston and Berlin. Everybody liked the surround. Actually, this is the smallest hall in size, and it has more seats than any of these because it has double balconies. Our client doesn ’ t want balconies, so â and when we met our new acoustician, he told us this was the right shape or this was the right shape. And we tried many shapes, trying to get the energy of the original design within an acoustical, acceptable format. We finally settled on a shape that was the proportion of the Concertgebouw with the sloping outside walls, which the acoustician said were crucial to this and later decided they weren ’ t, but now we have them. And our idea is to make the seating carriage very sculptural and out of wood and like a big boat sitting in this plaster room. That ’ s the idea. And the corners would have skylights and these columns would be structural. And the nice thing about introducing columns is they give you a kind of sense of proscenium from wherever you sit, and create intimacy. Now, this is not a final design â these are just on the way to being â and so I wouldn ’ t take it literally, except the feeling of the space. We studied the acoustics with laser stuff, and they bounce them off this and see where it all works. But you get the sense of the hall in section. Most halls come straight down into a proscenium. In this case we ’ re opening it back up and getting skylights in the four corners. And so it will be quite a different shape. The original building, because it was frog-like, fit nicely on the site and cranked itself well. When you get into a box, it ’ s harder to do it â and here we are, struggling with how to put the hotel in. And this is a teapot I designed for Alessi. I just stuck it on there. But this is how I do work. I do take pieces and bits and look at it and struggle with it and cut it away. And of course it ’ s not going to look like that, but it is the crazy way I tend to work. And then finally, in L. A. I was asked to do a sculpture at the foot of Interstate Bank Tower, the highest building in L. A. Larry Halprin is doing the stairs. And I was asked to do a fish, and so I did a snake. It ’ s a public space, and I made it kind of a garden structure, and you can go in it. It ’ s a kiva, and Larry ’ s putting some water in there, and it works much better than a fish. In Barcelona I was asked to do a fish, and we ’ re working on that, at the foot of a Ritz-Carlton Tower being done by Skidmore, Owings and Merrill. And the Ritz-Carlton Tower is being designed with exposed steel, non-fire proof, much like those old gas tanks. And so we took the language of this exposed steel and used it, perverted it, into the form of the fish, and created a kind of a 19th- century contraption that looks like, that will sit â this is the beach and the harbor out in front, and this is really a shopping center with department stores. And we split these bridges. Originally, this was all solid with a hole in it. We cut them loose and made several bridges and created a kind of a foreground for this hotel. We showed this to the hotel people the other day, and they were terrified and said that nobody would come to the Ritz-Carlton anymore, because of this fish. And finally, I just threw these in â Lou Danziger. I didn ’ t expect Lou Danziger to be here, but this is a building I did for him in 1964, I think. A little studio â and it ’ s sadly for sale. Time goes on. And this is my son working with me on a small fast-food thing. He designed the robot as the cashier, and the head moves, and I did the rest of it. And the food wasn ’ t as good as the stuff, and so it failed. It should have been the other way around â the food should have been good first. It didn ’ t work. Thank you very much.

A Love Letter to my Garden by Debbie Millman In the beginning of time, there was no time. The universe began with every bit of energy contained in a very tiny, incredibly dense point. It was even smaller than this point. The point exploded with an unimaginable force and created everything we know and are made of. Seeds are a bit like that too. They ’ re tiny and densely packed with their entire existence. Time feels different now, while we shelter at home. Time is scary and uncertain. So we decided to plant some mint. We actually started a little garden a while ago, but now we have more time. We thought that these flowers had died, but they miraculously came back to life. A hopeful sign about the future, perhaps? We planted foxglove and it thrived. And then we went a little crazy. We planted tomatoes, carrots, beans, corn, lettuce and cucumbers, strawberries, blueberries and limes. It ’ s such a strange time in the world. There is so much beauty amidst so much fear. It ’ s so hard to know what to do. In the meantime, we watch and wait and remain grateful we ’ re able to make things with our hands. A love letter to New York City by Debbie Millman I ’ m a native New Yorker. I ’ ve lived here my entire life, yet the city never ceases to surprise me. Everywhere you look, there ’ s something to see. There is Tom Otterness underground and Lawrence Weiner underfoot. There are so many of us. Everyone wants to be someone. Everyone seeks to be heard. Everyone has an opinion, A point of view. And seemingly something to sell. But life is different now as we shelter at home. Under the same sky, at the same moment, at the same time. I ’ m thinking about how tough New York can be, how rough and unrelenting. But maybe that intensity is what fuels our tenacity. As we navigate through this crisis, I am hopeful we will find some solace together. A Love Letter to Travel by Debbie Millman My work has taken me all over the world. There have been many early departures, and many evenings in the air. In all my travels, I ’ ve been struck by so many things. I ’ ve observed how people lived in some of the most ancient places on the planet. This is Machu Picchu. This is Easter Island. This is Samoa. This is Angkor Wat. This is Petra in Jordan. The ancient city contained a church, a theater and tombs for the dead. Families lived in two and three-bedroom apartments. We ’ ve come a long way. Some of the structures that remain are rather mysterious, some are otherworldly, some are glorious odes to love, some house the souls of the dead. Some have forced us to choose sides. Some have succumbed to the power of nature. And some have not. The view from the sky is so abstract. It reveals our connections, our continuity and our scale. Nevertheless, it ’ s hard to see the big picture right now. It ’ s such a difficult time in the world as we pause and dismantle and rebuild our culture. I think back to my travels. I ’ ve seen how different we are, how diverse and distinct. But I ’ ve also seen our commonalities. How much worship means in Tibet, in Pakistan, in Italy, in China, in Cambodia and in Peru. How much peace means to our future. How much we regret the mistakes of our past. And now, insisting on what matters no matter what. There is still so much beauty in the world. So much love. I ’ m hopeful for the next generation. For every creature, large and small. And for the planet we call home. A Love Letter to Storytelling by Debbie Millman”A need to tell and hear stories is essential to the species Homo Sapiens. The sound of story is the dominant sound of our lives.”- Joseph Campbell I ’ ve loved telling stories all of my life. I ’ ve loved writing them and drawing them, and I love teaching my students how to make them. Now I conduct visual storytelling workshops all over the world. Over the years, the students have invented many new ways of expressing their stories. They tell their truths. They reveal secrets. They bare their souls. They share stories of pain, of feeling seen, of not being smart enough. Stories of being scared, feeling pretty or not. No matter where I teach, I ’ ve come to realize how many of their stories are universal. They convey so many shared experiences : rejection, judgment, insecurity, prejudice, forgetting and remembering. But there are also stories of hope, strength, awareness, courage and realizations. Their stories reflect who they really are, how deeply they want to feel connected. And now, as they share their visions for a more optimistic future, their stories are becoming the stories of our times.

Text Sample 663: NEG Dim 4 – 2025 – Score 7.00 – 2025/t003001.txt

- I don ’ t remember exactly, but... I use the most expensive hair color in the world. It ’ s not that I care about the money, it ’ s that I care about my hair. It ’ s not just the color. I expect great color. What ’ s worth more to me is the way my hair feels. Feels good around my neck. I can ’ t remember it. I can ’ t finish it all. If only we had more time. - Why don ’ t we have more time? - I ’ m dying. I ’ m croaking! - It ’ s tough, coming home. But this is what you do for a parent that you love. But, you know? She ’ s not my mother. Technically. In my own family, there ’ s a lot of dysfunction, a lot of mental illness, a lot of substance abuse. Every generation. My parents divorced when I was about five. My mother moved us out of state, so we had to fly to New York to see my father ’ cause he was already working in advertising, and New York was the only place to be. - Many of the commercials you see on television begin life here. - Advertising is one of the main sources of messaging about who you should be. - Nowadays, most of you women lead two lives, combining homemaking with the role of glamorous hostess. - And in the ’ 60s, the ads were often made from a male point of view. - In the pre-production meeting, everybody who has anything to do with the commercial is there. - It was mostly men. These superstar art directors and writers. Like my father, Gene Case.”Mad Men”was like home movies, and he was Don Draper. He was very witty, but I don ’ t think my father realized how powerful his words were. He knew it professionally. But with his kids, he could be incredibly cutting. Flay you just with a phrase. But it ’ s the time with my mother that was the nightmare. She had a horrible childhood, but she sure as hell didn ’ t make any effort to overcome that in her relations with us. You know, it was really horrifying to my mother that I was not popular. But I was also really awkward because she had been undermining my confidence for all my life. She would pick apart your personality in detail. I was lazy, I looked bad, I acted bad, I was awkward. Emotionally, just out for blood. At a certain point in the night, I would know,”OK, the situation is dangerous. I need to get outta here.”I had this fantasy when I was in fourth grade that I vividly remember that some kind of outside agency was gonna come in and determine from all the salt on my pillow that I was crying myself to sleep every night and do something about it. No, it was awful. It was awful. And that was the point where Ilon came into my life. - Ilon, do you need anything to eat? - I don ’ t think so, but look up this wallpaper, Waverly Fabrics, and see if they have a rose pattern. - OK. Oh, what about this one here? - That ’ s not it. - No? - No, first of all, I was an art dir... I was a creative director at an advertising agency. The first thing I know is what I ’ m looking at. Ilon the girl. I don ’ t remember particularly being into advertising, but somehow I found myself in it. And I seemed to be very good at it. First of all, I ’ d always listened to everybody. And I noticed that I saw things differently than other people. - Women could get somewhere in advertising, but they were marginalized. - Women were given a lesser role. All the men were always arguing with you and always taking credit. - And one of the things that was coming through loud and clear is that women are for men. - Glory, glory, hallelujah Glory, glory, hallelujah Glory, glory, hallelujah His truth is marching on - Men were always the ones who everyone was pleasing. - What will your eyes say to him tonight? Wait till the fellas take a look at this plunging backline. - You look at ads from that period, and it ’ s jaw-dropping. - This is one of our nation ’ s most beautiful sights, the kind of girl who keeps her figure. - But that ’ s what feminism was pushing back against. - I was a feminist. I knew women were equal if not superior to men from the time I was a little girl. - And in advertising, she wanted to be a trailblazer that way. At one point, she worked in the same agency with my father, and that ’ s how they met. - He was a good writer, and I was a good writer. I liked the fact that he was good at what he did and cared about it. We got engaged, and then we got married. - I ’ m sitting there in the background. I ’ m grinning. I ’ m so thrilled because I adored her instantly. I thought she was super cool. And she treated me like I mattered. - She was a sweet little girl, and she deserved some caretaking. My mother was kinda terrible, so I knew that she needed support, and I gave her support. And that was what we did. - She was interested in me. She listened to me. Treated me like I was lovable. - She didn ’ t have anyone to recognize her being, to support her, to see who she could be, who she was. - She was very interested in what I would do with my life, and the assumption was that it would be something worthwhile. She just went way, way beyond the call of duty to make me feel like I was worth it. And she did that for a lot of other women, too. - I was working at McCann Erickson. We were given an assignment. L ’ Oréal, they wanted a campaign for Preference, it ’ s a hair color. - She ’ s in this room full of men brainstorming for this ad. - The men were busy flirting with the women, telling us we all looked like models and we didn ’ t look like advertising people, you know? - They ’ re like,”Oh, this woman is gonna be standing by an open window, and the wind will be blowing the curtains.”And she ’ s thinking, you know, this is just making the woman totally an object. - I was feeling angry. I ’ m not interested in writing anything about looking good for men. Fuck ’ em. Fuck you too. - Why fuck me? - Well, you ’ re a man. - Yeah, but I ’ m here trying to help you tell your story. - Yeah, that ’ s good. I like that part. I was pissed. We weren ’ t there to just dance for the men. - It is what she said. She just thought,”Fuck you.”And wrote this. - I just opened my eyes and knew. Because I ’ m worth it. The campaign got approved, but all the men were always telling you that you were doing something wrong or they knew how to do it better. - The agency insisted on a male voiceover. - She uses the most expensive hair color in the world, Preference by L ’ Oréal. - You know, it was just totally different. - Smooth and silky, but with body. It feels good against her neck. Actually, she doesn ’ t mind spending more for L ’ Oréal. Because she ’ s worth it. - It was wrong. This was not for men but for women and for other human beings. - I use the most expensive hair color in the world, Preference by L ’ Oréal. It ’ s not that I care about the money, it ’ s that I care about my hair. It ’ s not just the color, I expect great color. What ’ s worth more to me is the way my hair feels. Smooth and silky, but with body. It feels good against my neck. Actually, I don ’ t mind spending more for L ’ Oréal. Because I ’ m worth it. - I wrote that. - It was everywhere. It was a national campaign. - Yes, it ’ s expensive, but I ’ m worth it. - What they realized after they started running it was that that was only the tip of the iceberg. - It was supporting women, finally. - And I ’ m worth it. And I ’ m worth it. I ’ m worth it. - It ’ s a four-word feminist manifesto, defying this social pressure to think about yourself in relation to men. - You ’ re worth it. I ’ m worth it. I ’ m worth it. - It was a very big success. - At a certain point, L ’ Oréal adopted it as the tagline for their entire business. - Parce que je le vaux bien. - Even today, that ’ s their motto. - Because I ’ m worth it. - ’ Cause you ’ re worth it. - You ’ re worth it. - We ’ re worth it. - And I ’ m worth it. - She wrote the most influential tagline in women ’ s beauty advertising. - I ’ m worth it. - It ’ s magic, that phrase. - Those words just get better with age, don ’ t they? - I ’ m worth it. Because you are and always will be. - She came up with that line because she believed it. She believed it about herself, and she believed that women should believe it. She did that for me. You know, even after they split up, she was still a big part of my life. I ’ ve always kind of felt like I dodged a bullet that I have watched take down other members of my family. She saved me. And today, I am a professor of English at Williams College. I teach Victorian literature, and I also teach women ’ s, gender and sexuality studies. She was my mother. She also taught me how to be a mother. I had been very uncertain about motherhood for myself because my role model for that was so nightmarish. But Ilon really taught me, I can do this. I can be a good mother. She made me believe that I was worth it. And I was not either the first or the last. - I have to go away now. Go to my room. - It ’ s been lovely. - It ’ s been lovely. Oh... I ’ m not interested in advertising. I don ’ t give a shit. It wasn ’ t like it was my whole life. It was just a portion. It ’ s about humans ; it ’ s not about advertising. It ’ s about caring for people because... we ’ re all worth it, or no one is worth it.

Can you paint with all the colors of the wind? I love this song from the first time I heard it. I was 14, growing up in public housing in western Sydney. So maybe a little too old for this Disney classic from”Pocahontas.”But it spoke to me. I saw something of myself in it. At this stage, I think I knew I was queer. I mean, come on, I was rocking out to Disney. And look at those glasses. Seriously, what a queer kid. But I was also from a Pacific Indigenous heritage with conservative views and values. I didn ’ t feel like I could fit into any of the boxes that were being presented to me. Straight, gay, Fijian, Australian. I couldn ’ t pick just one color to paint with. Prior to colonization, sexuality amongst many of our Pacific islands across the region was fluid. Men would have sex with men without the stigma or shame afforded it today. Sexual intimacy was a way of being able to connect socially and relationally. Sex wasn ’ t just for procreation. Or in marriage. It wasn ’ t exclusively monogamous. Just because you had sex with a man didn ’ t define your sexuality. It didn ’ t make you an outcast. But as Europeans started to colonize the Pacific region, they brought Christian missionaries with them. They told us to cover up our beautiful bodies. We were taught shame. We were told to stop practicing Pacifica cultures and values that were seen as provocative. To a Western and white perspective, our non-binary sexuality was judged as tribal, outdated, sinful and impossible to practice alongside a Christian faith. Still today, those who are Indigenous to the Pacific are negatively impacted by whiteness. That”white is right, West is best.”I was brought up to espouse strong Christian beliefs, views and values which would shape my burgeoning identity as an adult. From these staunch conservative views, I was taught to fear the queer. Those people that were seen as unusual and fruity. And in essence, I grew to despise a part of myself. I sought to separate my queerness from my identity. I could never see myself as part of that world. Growing up, biracial and bisexual constantly challenged the way I saw the world around me. I was unsure about my thinking, feelings and behaviors around liking males and females. I was unsure about my thinking, feelings and behaviors when it came to whether I needed to be a white Australian or a Fijian person. And whether this needed to be framed within a binary to choose one over the other. In this way, I don ’ t think that my story is unique. There ’ s plenty of people in the queer world that have escaped conservative upbringings, religions and cultures. But this is only part of my story. Another common story in the queer community is the coming-out story. When did you tell your parents? How did they react? How it liberated you or ultimately separated you from your family. But this didn ’ t feel like an option for me either. I believe that embedded in these particular stories, these tropes, is a part of dominant queer culture that made it very hard for me to access the queer world. For example, when I started to go to gay clubs, I would be lining up at the front of the club and often I would get door staff come up to me and go,”Sorry, you do know this is a gay club, right?”From these lived experiences, I feel that there is a whiteness that pervades queer culture. And I didn ’ t want to give up my identity and my appearance as a Pacific indigenous person to be queer. Pacifica cultures really, really value and esteem the collective above the individual. For Pacifica people, our families are inextricably connected to our own sense of self-agency, self-determination, self-esteem, self-love and self-worth. Our own individual identities are meshed and intertwined with our family ’ s reputation and standing in the community. Our mind, body and souls are inextricably connected to the broader community, to our families, to ourselves and to others. I didn ’ t want to come out to potentially ostracize myself, to make a point to separate myself from my Pacific and faith communities. I couldn ’ t then see my authentic self in any of these spaces. And a quick shout out to my son on the left-hand side. Round of applause for my son. He said to me this morning,”Daddy, make sure you mention me.”So I was like,”OK, son. Alright.”So there you go for the recording, son. And the rest are my other family, that ’ s up there as well. Across queer cultures and the broader community, we have learned to embrace our gender and sexual differences. We encourage individuals to be allies for each other and to support safe spaces for those that are seen to not fit in. We empower and really encourage individuals to really develop and express their self-agency, their self-determination, their self love, their self-worth. We boldly go into spaces striving to bring others with us to ensure that we can create inclusive societies for everyone. However, the dominant Western view in queer cultures is still based on the individual. Me, myself and I. And my individual pursuits towards happiness. As a queer Indigenous Pacific person, I feel that there are parts of queer culture that is white, feels very white. We may fail to see the importance of bringing our families and our cultural communities along our journey as queer people. It ’ s either the queer way or the highway. It ’ s one or the other. Young or old. Rich or poor. Smart or stupid. Masculine or feminine. Fit or fat. These binaries create a sense of us and them, those people. A binary approach and position that we generally in Western white societies use to determine the norm. We create, conflate, perpetuate binaries that create divisions in our society. Saints or sinner, straight or gay. I see it like this. Binaries are a very white and Western way of thinking, feeling and behaving. As individuals today, we live within these binaries and create identities that then create these labels. We use these labels to then define and confine people and places. We are one or the other. But what we fail to see is that our identities are more than a set of binaries. Our own identities are comprised of intersecting identifiers that contributes to who you are, including our age, class, color, education, gender, size, spirituality, sexuality, and so, so much more. We need to decolonize queerness, to live beyond”white is right, West is best.”Because if we don ’ t, we ’ re going to continue to create silos and divisions in our societies that don ’ t create inclusive and safe spaces for everyone. For Indigenous queer people, they shape our connection to community and culture, our families. If we don ’ t include that within our understanding of who we are, even as queer people, then we ’ re not able to be, again, our true and authentic selves. We ’ re not able to then be our fabulous selves as part of the queer community. And it ’ s really, really interesting because I believe that we can learn so much from pre-colonial cultures like those that were practiced in the Pacific, that provide a different way of looking at a society. A queer way that pre-dates all the privileges that go into binary ways of thinking, feeling and behaving. Across many of our Pacifica languages we have a lot of key concepts that help solidify and support a shared understanding of the collective. For example, in Fijian,”solesolevaki”is all about reciprocal living, where my wellbeing is your wellbeing. I will actively seek to ensure that your well-being and every part of your life is catered for, knowing that you will do the same for me. We strive to enact”veiqaravi,”as tatted here on my hand, to serve others. We strive to also embed and embold and empower people to practice”veirokovi,”respect for self and others where we are relationally driven, where that is so important to our spaces and places. My sense of ability to actually put this into practice, my ability to actually understand these Indigenous perspectives has greatly helped shape and reconcile my queer identity today. But what ’ s really interesting is that it ’ s not just queer communities that need to decolonize itself. It ’ s all of us as a broader society that needs to be part of a shared conversation to decolonize, deconstruct and disrupt binary ways of thinking, feeling and behaving. So how can we practically do that? Practice cultural humility, where you are constantly learning and embracing differences, where you get over yourselves and strive to learn about other people ’ s differences and how that can be meaningfully included in the way in which you create safe spaces for everyone. I also believe it ’ s possible to bring Indigenous perspectives into Western and white workplaces. For example, I ’ ve introduced the concept of”talanoa”in all of my work meetings. Talanoa is all about being able to create a safe space where everyone is able to contribute to a collective, collegial and collaborative conversation. Where people are able to bring their authentic selves into these spaces. Literally, I will chair meetings where I have no firm set agenda items and I literally would just hold space for participants just to bring themselves. So you can tell I ’ m a social worker, right? Safe space, safe space, safe space. It ’ s OK, it ’ s OK. But it ’ s through these safe spaces that people can bring their multiple, intersecting identifiers, including their age, their class, color, education, gender, size, spirituality, sexuality and so, so much more. I invite queer communities to come talanoa with Pacific Indigenous Communities to create robust and resilient queer cultures. I have been able to greatly reconcile my queer and Pacifica identities, which has now really been embraced to help shape how I see the world around me today. And it ’ s through these shared perspectives and approaches that we can truly embrace cultural diversity and its differences. And to know that people can live beyond those binaries and those labels we continue to perpetuate and perpetrate against others. It is a commitment from queer communities to decolonize queerness. It ’ s a commitment from me, from you and all of us to decolonize Western and white societies and to live beyond the binary way of thinking, feeling and behaving. I genuinely believe that it ’ s through this common goal that we can truly learn how to paint with all the colors of the wind.”Vinaka vakalevu”and thank you.

I ’ m going to go right into the slides. And all I ’ m going to try and prove to you with these slides is that I do just very straight stuff. And my ideas are â in my head, anyway â they ’ re very logical and relate to what ’ s going on and problem solving for clients. I either convince clients at the end that I solve their problems, or I really do solve their problems, because usually they seem to like it. Let me go right into the slides. Can you turn off the light? Down. I like to be in the dark. I don ’ t want you to see what I ’ m doing up here. Anyway, I did this house in Santa Monica, and it got a lot of notoriety. In fact, it appeared in a **porno** comic book, which is the slide on the right. This is in Venice. I just show it because I want you to know I ’ m concerned about context. On the **left-hand** side, I had the context of those little houses, and I tried to build a building that fit into that context. When people take **pictures** of these buildings out of that context they look really weird, and my premise is that they make a lot more sense when they ’ re photographed or seen in that space. And then, once I deal with the context, I then try to make a place that ’ s comfortable and private and fairly serene, as I hope you ’ ll find that slide on the right. And then I did a law school for Loyola in downtown L. A. I was concerned about making a place for the study of law. And we continue to work with this client. The building on the right at the top is now under construction. The garage on the right â the gray structure â will be torn down, finally, and several small classrooms will be placed along this **avenue** that we ’ ve created, this campus. And it all related to the clients and the students from the very first meeting saying they felt denied a place. They wanted a sense of place. And so the whole idea here was to create that kind of space in downtown, in a neighborhood that was difficult to fit into. And it was my theory, or my point of view, that one didn ’ t **upstage** the neighborhood â one made accommodations. I tried to be inclusive, to include the buildings in the neighborhood, whether they were buildings I liked or not. In the ’ 60s I started working with paper furniture and made a bunch of stuff that was very successful in Bloomingdale ’ s. We even made **flooring**, walls and everything, out of cardboard. And the success of it threw me for a loop. I couldn ’ t deal with the success of furniture â I wasn ’ t secure enough as an **architect** â and so I closed it all up and made furniture that nobody would like. So, nobody would like this. And it was in this, preliminary to these pieces of furniture, that Ricky and I worked on furniture by the slice. And after we failed, I just kept failing. The piece on the left â and that ultimately led to the piece on the right â happened when the kid that was working on this took one of those long strings of stuff and folded it up to put it in the **wastebasket**. And I put a piece of **tape** around it, as you see there, and realized you could sit on it, and it had a lot of **resilience** and strength and so on. So, it was an accidental discovery. I got into fish. I mean, the story I tell is that I got mad at **postmodernism** â at po-mo â and said that fish were 500 million years earlier than man, and if you ’ re going to go back, we might as well go back to the beginning. And so I started making these funny things. And they started to have a life of their own and got bigger â as the one glass at the Walker. And then, I sliced off the head and the tail and everything and tried to translate what I was learning about the form of the fish and the movement. And a lot of my architectural ideas that came from it â accidental, again â it was an intuitive kind of thing, and I just kept going with it, and made this proposal for a building, which was only a proposal. I did this building in Japan. I was taken out to dinner after the contract for this little restaurant was signed. And I love sake and Kobe and all that stuff. And after I got â I was really drunk â I was asked to do some sketches on **napkins**. And I made some sketches on **napkins** â little boxes and Morandi-like things that I used to do. And the client said,”Why no fish?”And so I made a **drawing** with a fish, and I left Japan. Three weeks later, I received a complete set of **drawings** saying we ’ d won the competition. Now, it ’ s hard to do. It ’ s hard to translate a fish form, because they ’ re so beautiful â perfect â into a building or object like this. And Oldenburg, who I work with a little once in a while, told me I couldn ’ t do it, and so that made it even more exciting. But he was right â I couldn ’ t do the tail. I started to get the head OK, but the tail I couldn ’ t do. It was pretty hard. The thing on the right is a snake form, a **ziggurat**. And I put them together, and you walk between them. It was a dialog with the context again. Now, if you saw a **picture** of this as it was published in Architectural Record â they didn ’ t show the context, so you would think,”God, what a pushy guy this is.”But a friend of mine spent four hours wandering around here looking for this restaurant. Couldn ’ t find it. So... As for craft and technology and all those things that you ’ ve all been talking about, I was thrown for a complete loop. This was built in six months. The way we sent **drawings** to Japan : we used the magic computer in Michigan that does carved models, and we used to make foam models, which that thing **scanned**. We made the **drawings** of the fish and the scales. And when I got there, everything was perfect â except the tail. So, I decided to cut off the head and the tail. And I made the object on the left for my show at the Walker. And it ’ s one of the nicest pieces I ’ ve ever made, I think. And then Jay Chiat, a friend and client, asked me to do his headquarters building in L. A. For reasons we don ’ t want to talk about, it got delayed. Toxic waste, I guess, is the key clue to that one. And so we built a temporary building â I ’ m getting good at temporary â and we put a conference room in that ’ s a fish. And, finally, Jay dragged me to my hometown, Toronto, Canada. And there is a story â it ’ s a real story â about my grandmother buying a **carp** on Thursday, bringing it home, putting it in the bathtub when I was a kid. I played with it in the evening. When I went to sleep, the next day it wasn ’ t there. And the next night, we had gefilte fish. And so I set up this interior for Jay ’ s offices and I made a pedestal for a sculpture. And he didn ’ t buy a sculpture, so I made one. I went around Toronto and found a bathtub like my grandmother ’ s, and I put the fish in. It was a joke. I play with funny people like [Claes] Oldenburg. We ’ ve been friends for a long time. And we ’ ve started to work on things. A few years ago, we did a performance piece in Venice, Italy, called”Il Corso del Coltello”â the Swiss Army knife. And most of the imagery is â Claes ’, but those two little boys are my sons, and they were Claes ’ assistants in the play. He was the Swiss Army knife. He was a souvenir salesman who always wanted to be a painter, and I was Frankie P. Toronto. P for Palladio. Dressed up like the AT&T building by Claes â with a fish hat. The highlight of the performance was at the end. This beautiful object, the Swiss Army knife, which I get credit for participating in. And I can tell you â it ’ s totally an Oldenburg. I had nothing to do with it. The only thing I did was, I made it possible for them to turn those blades so you could sail this thing in the canal, because I love sailing. We made it into a sailing craft. I ’ ve been known to mess with things like chain link **fencing**. I do it because it ’ s a curious thing in the culture, when things are made in such great quantities, absorbed in such great quantities, and there ’ s so much denial about them. People hate it. And I ’ m **fascinated** with that, which, like the paper furniture â it ’ s one of those materials. And I ’ m always drawn to that. And so I did a lot of dirty things with chain link, which nobody will forgive me for. But Claes made homage to it in the Loyola Law School. And that chain link is really expensive. It ’ s in perspective and everything. And then we did a camp together for children with cancer. And you can see, we started making a building together. Of course, the milk can is his. But we were trying to collide our ideas, to put objects next to each other. Like a Morandi â like the little bottles â composing them like a still life. And it seemed to work as a way to put he and I together. Then Jay Chiat asked me to do this building on this funny lot in Venice, and I started with this **three-piece** thing, and you entered in the middle. And Jay asked me what I was going to do with the piece in the middle. And he pushed that. And one day I had a â oh, well, the other way. I had the binoculars from Claes, and I put them there, and I could never get rid of them after that. Oldenburg made the binoculars incredible when he sent me the first model of the real proposal. It made my building look sick. And it was this interaction between that kind of, up-the-ante stuff that became pretty interesting. It led to the building on the left. And I still think the Time magazine **picture** will be of the binoculars, you know, leaving out the â what the **hell**. I use a lot of **metal** in my work, and I have a hard time connecting with the craft. The whole thing about my house, the whole use of rough carpentry and everything, was the frustration with the crafts available. I said,”If I can ’ t get the craft that I want, I ’ ll use the craft I can get.”There were plenty of models for that, in Rauschenberg and Jasper Johns, and many artists who were making beautiful art and sculpture with junk materials. I went into the **metal** because it was a way of building a building that was a sculpture. And it was all of one material, and the **metal** could go on the **roof** as well as the walls. The metalworkers, for the most part, do ducts behind the ceilings and stuff. I was given an opportunity to design an exhibit for the metalworkers ’ unions of America and Canada in Washington, and I did it on the condition that they become my partners in the future and help me with all future **metal** buildings, etc. etc. And it ’ s working very well to have these people, these craftsmen, interested in it. I just tell the stories. It ’ s a way of connecting, at least, with some of those people that are so important to the realization of architecture. The **metal** continued into a building â Herman Miller, in Sacramento. And it ’ s just a complex of factory buildings. And Herman Miller has this philosophy of having a place â a people place. I mean, it ’ s kind of a trite thing to say, but it is real that they wanted to have a central place where the cafeteria would be, where the people would come and where the people working would interact. So it ’ s out in the middle of nowhere, and you approach it. It ’ s copper and galvanize. I used the galvanize and copper in a very light gauge, so it would buckle. I spent a lot of time undoing Richard Meier ’ s aesthetic. Everybody ’ s trying to get the **panels** perfect, and I always try to get them sloppy and fuzzy. And they end up looking like stone. This is the central area. There ’ s a ramp. And that little dome in there is a building by Stanley Tigerman. Stanley was instrumental in my getting this job. And when I was awarded the contract I, at the very beginning, asked the client if they would let Stanley do a cameo piece with me. Because these were ideas that we were talking about, building things next to each other, making â it ’ s all about [a] **metaphor** for a city, maybe. And so Stanley did the little dome thing. And we did it over the phone and by fax. He would send me a fax and show me something. He ’ d made a building with a dome and he had a little tower. I told him,”No, no, that ’ s too ongepotchket. I don ’ t want the tower.”So he came back with a simpler building, but he put some funny details on it, and he moved it closer to my building. And so I decided to put him in a depression. I put him in a hole and made a kind of a hole that he sits in. And so then he put two bridges â this all happened on the fax, going back and forth over a couple of weeks ’ period. And he put these two bridges with pink guardrails on it. And so then I put this big billboard behind it. And I call it,”David and Goliath.”And that ’ s my cafeteria. In Boston, we had that old building on the left. It was a very prominent building off the freeway, and we added a floor and **cleaned** it up and fixed it up and used the kind of â I thought â the language of the neighborhood, which had these **cornices**, projecting **cornices**. Mine got a little exuberant, but I used lead copper, which is a beautiful material, and it turns green in 100 years. Instead of, like, copper in 10 or 15. We redid the side of the building and re-proportioned the windows so it sort of fit into the space. And it surprised both Boston and myself that we got it approved, because they have very strict kind of design guideline, and they wouldn ’ t normally think I would fit them. The detailing was very careful with the lead copper and making **panels** and fitting it tightly into the fabric of the existing building. In Barcelona, on Las Ramblas for some **film** festival, I did the Hollywood sign going and coming, made a building out of it, and they built it. I flew in one night and took this **picture**. But they made it a third smaller than my model without telling me.

And then more **metal** and some chain link in Santa Monica â a little shopping center. And this is a **laser** laboratory at the University of Iowa, in which the fish comes back as an **abstraction** in the back. It ' s the support labs, which, by some coincidence, required no windows. And the shape fit perfectly. I just joined the points. In the **curved** part there ' s all the **mechanical** equipment. That solid wall behind it is a pipe chase â a pipe canyon â and so it was an opportunity that I seized, because I didn ' t have to have any **protruding** ducts or vents or things in this form. It gave me an opportunity to make a sculpture out of it. This is a small house somewhere. They ' ve been building it so long I don ' t remember where it is. It ' s in the West Valley. And we started with the stream and built the house along the stream â dammed it up to make a lake. These are the models. The reality, with the lake â the **workmanship** is pretty bad. And it reminded me why I play defensively in things like my house. When you have to do something really cheaply, it ' s hard to get perfect corners and stuff. That big **metal** thing is a passage, and in it is â you go downstairs into the living room and then down into the bedroom, which is on the right. It ' s kind of like a whole built town. I was asked to do a hospital for schizophrenic adolescents at Yale. I thought it was fitting for me to be doing that. This is a house next to a Philip Johnson house in Minnesota. The owners had a dilemma â they asked Philip to do it. He was too busy. He didn ' t recommend me, by the way. We ended up having to make it a sculpture, because the dilemma was, how do you build a building that doesn ' t look like the language? Is it going to look like this beautiful estate is sub-divided? Etc. etc. You ' ve got the idea. And so we finally ended up making it. These people are art collectors. And we finally made it so it appears very sculptural from the main house and all the windows are on the other side. And the building is very sculptural as you walk around it. It ' s made of **metal** and the brown stuff is Fin-Ply â it ' s that formed lumber from Finland. We used it at Loyola on the chapel, and it didn ' t work. I keep trying to make it work. In this case we learned how to detail it. In Cleveland, there ' s Burnham Mall, on the left. It ' s never been finished. Going out to the lake, you can see all those new buildings we built. And we had the opportunity to build a building on this site. There ' s a **railroad** track. This is the city hall over here somewhere, and the courthouse. And the **centerline** of the mall goes out. Burnham had designed a **railroad** station that was never built, and so we followed. Sohio is on the axis here, and we followed the axis, and they ' re two kind of **goalposts**. And this is our building, which is a corporate headquarters for an insurance company. We collaborated with Oldenburg and put the newspaper on top, folded. The health club is fastened to the garage with a C-clamp, for Cleveland. You drive down. So it ' s about a 10-story C-clamp. And all this stuff at the **bottom** is a **museum**, and an idea for a very fancy automobile entry. This owner has a pet peeve about bad automobile entries. And this would be a hotel. So, the **centerline** of this thing â we ' d preserve it, and it would start to work with the scale of the new buildings by Pelli and Kohn Pederson Fox, etc., that are underway. It ' s hard to do high-rise. I feel much more comfortable down here. This is a piece of property in Brentwood. And a long time ago, about ' 82 or something, after my house â I designed a house for myself that would be a village of several pavilions around a courtyard â and the owner of this lot worked for me and built that actual model on the left. And she came back, I guess wealthier or something â something happened â and asked me to design a house for her on this site. And following that basic idea of the village, we changed it as we got into it. I locked the house into the site by cutting the back end â here you see on the photographs of the site â slicing into it and putting all the bathrooms and dressing rooms like a retaining wall, creating a lower level zone for the master bedroom, which I designed like a kind of a barge, looking like a boat. And that ’ s it, built. The dome was a request from the client. She wanted a dome somewhere in the house. She didn ’ t care where. When you sleep in this bedroom, I hope â I mean, I haven ’ t slept in it yet. I ’ ve offered to marry her so I could sleep there, but she said I didn ’ t have to do that. But when you ’ re in that room, you feel like you ’ re on a kind of barge on some kind of lake. And it ’ s very private. The landscape is being built around to create a private garden. And then up above there ’ s a garden on this side of the living room, and one on the other side. These aren ’ t focused very well. I don ’ t know how to do it from here. Focus the one on the right. It ’ s up there. Left â it ’ s my right. Anyway, you enter into a garden with a beautiful grove of trees. That ’ s the living room. Servants ’ quarters. A **guest** bedroom, which has this dome with marble on it. And then you enter into the living room and then so on. This is the bedroom. You come down from this level along the stairway, and you enter the bedroom here, going into the lake. And the bed is back in this space, with windows looking out onto the lake. These Stonehenge things were designed to give foreground and to create a greater depth in this shallow lot. The material is lead copper, like in the building in Boston. And so it was an intent to make this small piece of land â it ’ s 100 by 250 â into a kind of an estate by separating these areas and making the living room and dining room into this pavilion with a high space in it. And this happened by accident that I got this right on axis with the dining room table. It looks like I got a Baldessari painting for free. But the idea is, the windows are all placed so you see pieces of the house outside. Eventually this will be screened â these trees will come up â and it will be very private. And you feel like you ’ re in your own kind of village. This is for Michael Eisner â Disney. We ’ re doing some work for him. And this is in Anaheim, California, and it ’ s a freeway building. You go under this bridge at about 65 miles an hour, and there ’ s another bridge here. And you ’ re through this room in a split second, and the building will sort of reflect that. On the backside, it ’ s much more humane â entrance, dining hall, etc. And then this thing here â I ’ m hoping as you drive by you ’ ll hear the picket fence effect of the sound hitting it. Kind of a **fun** thing to do. I ’ m doing a building in Switzerland, Basel, which is an office building for a furniture company. And we struggled with the image. These are the early studies, but they have to sell furniture to normal people, so if I did the building and it was too fancy, then people might say,”Well, the furniture looks OK in his thing, but no, it **ain** ’ t going to look good in my normal building.”So we ’ ve made a kind of pragmatic slab in the second phase here, and we ’ ve taken the conference facilities and made a villa out of them so that the communal space is very sculptural and separate. And you ’ re looking at it from the offices and you create a kind of interaction between these pieces. This is in Paris, along the Seine. Palais **des** Sports, the Gare de Lyon over here. The Minister of Finance â the guy that moved from the Louvre â goes in here. There ’ s a new library across the river. And back in here, in this already treed **park**, we ’ re doing a very dense building called the American Center, which has a theater, apartments, dance school, an art **museum**, restaurants and all kinds of â it ’ s a very dense program â bookstores, etc. In a very tight, small â this is the ground level. And the French have this extraordinary way of screwing things up by taking a beautiful site and cutting the corner off. They call it the plan **coupe**. And I struggled with that thing â how to get around the corner. These are the models for it. I showed you the other model, the one â this is the way I organized myself so I could make the drawing â so I understood the problem. I was trying to get around this plan **coupe** â how do you do it? Apartments, etc. And these are the kind of study models we did. And the one on the left is pretty awful. You can see why I was ready to commit suicide when this one was built. But out of it came finally this resolution, where the elevator piece worked frontally to this, parallel to this street, and also parallel to here. And then this kind of twist, with this balcony and the skirt, kind of like a ballerina lifting her skirt to let you into the foyer. The restaurants here â the apartments and the theater, etc. So it would all be built in stone, in French limestone, except for this **metal** piece. And it faces into a **park**. And the idea was to make this express the energy of this. On the side facing the street it ’ s much more normal, except I slipped a few mansards down, so that coming on the point, these housing units made a gesture to the corner. And this will be some kind of high-tech billboard. If any of you guys have any ideas for it, please contact me. I don ’ t know what to do. Jay Chiat is a **glutton** for punishment, and he hired me to do a house for him in the Hamptons. And it ’ s got a fish. And I keep thinking,”This is going to be the last fish.”It ’ s like a drug addict. I say,”I ’ m not going to do it anymore â I don ’ t want to do it anymore â I ’ m not going to do it.”And then I do it. There it is. But it ’ s the living room. And this piece here is â I don ’ t know what it is. I just added it so that we ’ d have enough money in the budget so we could take something out. This is Euro Disney, and I ’ ve worked with all of the guys that presented to you earlier. We ’ ve had a lot of **fun** working together. I think I ’ m from Mars for them, and they are for me, but somehow we all manage to work together, and I think, productively. So far. This is a shopping thing. You come into the Magic Kingdom and the hotel that Tony Baxter ’ s group is doing out here. And then this is a kind of a shopping mall, with a rodeo and restaurants. And another restaurant. What I did â because of the Paris skies being quite dull, I made a light grid that ’ s perpendicular to the train station, to the route of the train. It looks like it ’ s kind of been there, and then crashed all these simpler forms into it. The light grid will have a light, be lit up at night and give a kind of light ceiling. In Switzerland â Germany, actually â on the Rhine across from Basel, we did a furniture factory and a furniture **museum**. And I tried to â there ’ s a Nick Grimshaw building over here, there ’ s an Oldenburg sculpture over here â I tried to make a relationship urbanistically. And I don ’ t gave good slides to show â it ’ s just been completed â but this piece here is this building, and these pieces here and here. And as you pass by it ’ s always part â you see it as all of these pieces accrue and become part of an overall neighborhood. It ’ s plaster and just zinc. And you wonder, if this is a **museum**, what it ’ s going to be like inside? If it ’ s going to be so busy and crazy that you wouldn ’ t show anything, and just wait. I ’ m so cunning and clever â I made it quiet and wonderful. But on the outside it does scream out at you a bit. It ’ s actually basically three square rooms with a couple of skylights and stuff. And from the building in the back, you see it as an iceberg floating by in the hills. I know I ’ m over time. See, that skylight goes down and becomes that one. So it ’ s pretty quiet inside. This is the Disney Hall â the concert hall. It ’ s a complicated project. It has a chamber hall. It ’ s related to an existing Chandler Pavilion that was built with a lot of love and tears and caring. And it ’ s not a great building, but I approached it optimistically, that we would make a **compositional** relationship between us that would strengthen both of us. And the plan of this â it ’ s a concert hall. This is the foyer, which is kind of a garden structure. There ’ s commercial at the ground floor. These are offices, which, really, in the competition, we didn ’ t have to design. But finally, there ’ s a hotel there. These were the kind of relationships made to the Chandler, composing these elevations together and relating them to the buildings that existed â to MOCA, etc. The **acoustician** in the competition gave us criteria, which led to this compartmentalized scheme, which we found out after the competition would not work at all. But everybody liked these forms and liked the space, and so that ’ s one of the problems of a competition. You have to then try and get that back in some way. And we studied many models. This was our original model. These were the three buildings that were the **ideal** â the Concertgebouw, Boston and Berlin. Everybody liked the surround. Actually, this is the smallest hall in size, and it has more seats than any of these because it has double balconies. Our client doesn ’ t want balconies, so â and when we met our new **acoustician**, he told us this was the right shape or this was the right shape. And we tried many shapes, trying to get the energy of the original design within an **acoustical**, acceptable format. We finally settled on a shape that was the proportion of the Concertgebouw with the **sloping** outside walls, which the **acoustician** said were **crucial** to this and later decided they weren ’ t, but now we have them. And our idea is to make the seating carriage very sculptural and out of wood and like a big boat sitting in this plaster room. That ’ s the idea. And the corners would have skylights and these columns would be structural. And the nice thing about introducing columns is they give you a kind of sense of proscenium from wherever you sit, and create intimacy. Now, this is not a final design â these are just on the way to being â and so I wouldn ’ t take it literally, except the feeling of the space. We studied the acoustics with **laser** stuff, and they bounce them off this and see where it all works. But you get the sense of the hall in section. Most halls come straight down into a proscenium. In this case we ’ re opening it back up and getting skylights in the four corners. And so it will be quite a different shape. The original building, because it was frog-like, fit nicely on the site and cranked itself well. When you get into a box, it ’ s harder to do it â and here we are, struggling with how to put the hotel in. And this is a teapot I designed for Alessi. I just stuck it on there. But this is how I do work. I do take pieces and bits and look at it and struggle with it and cut it away. And of course it ’ s not going to look like that, but it is the crazy way I tend to work. And then finally, in L. A. I was asked to do a sculpture at the **foot** of Interstate Bank Tower, the highest building in L. A. Larry Halprin is doing the stairs. And I was asked to do a fish, and so I did a snake. It ’ s a public space, and I made it kind of a garden structure, and you can go in it. It ’ s a kiva, and Larry ’ s putting some water in there, and it works much better than a fish. In Barcelona I was asked to do a fish, and we ’ re working on that, at the **foot** of a Ritz-Carlton Tower being done by Skidmore, Owings and Merrill. And the Ritz-Carlton Tower is being designed with exposed steel, non-fire proof, much like those old **gas** tanks. And so we took the language of this exposed steel and used it, perverted it, into the form of the fish, and created a kind of a 19th-century contraption that looks like, that will sit â this is the beach and the harbor out in front, and this is really a shopping center with department stores. And we split these bridges. Originally, this was all solid with a hole in it. We cut them loose and made several bridges and created a kind of a foreground for this hotel. We showed this to the hotel people the other day, and they were terrified and said that nobody would come to the Ritz-Carlton anymore, because of this fish. And finally, I just threw these in â Lou Danziger. I didn ’ t expect Lou Danziger to be here, but this is a building I did for him in 1964, I think. A little studio â and it ’ s sadly for sale. Time goes on. And this is my son working with me on a small fast-food thing. He designed the robot as the cashier, and the head moves, and I did the rest of it. And the food wasn ’ t as good as the stuff, and so it failed. It should have been the other way around â the food should have been good first. It didn ’ t work. Thank you very much.

Frank Gehry : I listened to this scientist this morning. Dr. Mullis was talking about his experiments, and I realized that I almost became a scientist. When I was 14 my parents bought me a chemistry set and I decided to make water. So, I made a hydrogen generator and I made an oxygen generator, and I had the two pipes leading into a beaker and I threw a match in. And the glass — luckily I turned around — I had it all in my back and I was about 15 **feet** away. The wall was covered with... I had an explosion. Richard Saul Wurman : Really? FG : People on the street came and knocked on the door to see if I was okay. RSW :... huh. I ’ d like to start this session again. The gentleman to my left is the very famous, perhaps overly famous, Frank Gehry. And Frank, you ’ ve come to a place in your life, which is astonishing. I mean it is astonishing for an artist, for an **architect**, to become actually an icon and a legend in their own time. I mean you have become, whether you can giggle at it because it ’ s a funny... you know, it ’ s a strange thought, but your building is an icon — you can draw a little **picture** of that building, it can be used in ads — and you ’ ve had not rock star status, but celebrity status in doing what you wanted to do for most of your life. And I know the road was extremely difficult. And it didn ’ t seem, at least, that your sell outs, whatever they were, were very big. You kept moving ahead in a life where you ’ re dependent on working for somebody. But that ’ s an interesting thing for a creative person. A lot of us work for people ; we ’ re in the hands of other people. And that ’ s one of the great dilemmas — we ’ re in a creativity session — it ’ s one of the great dilemmas in creativity : how to do work that ’ s big enough and not sell out. And you ’ ve achieved that and that makes your win doubly big, triply big. It ’ s not quite a question but you can comment on it. It ’ s a big issue. FG : Well, I ’ ve always just... I ’ ve never really gone out looking for work. I always waited for it to sort of hit me on the head. And when I started out, I thought that architecture was a service business and that you had to please the clients and stuff. And I realized when I ’ d come into the meetings with these corrugated **metal** and chain link stuff, and people would just look at me like I ’ d just landed from Mars. But I couldn ’ t do anything else. That was my response to the people in the time. And actually, it was responding to clients that I had who didn ’ t have very much money, so they couldn ’ t afford very much. I think it was circumstantial. Until I got to my house, where the client was my wife. We bought this tiny little bungalow in Santa Monica and for like 50 grand I built a house around it. And a few people got excited about it. I was visiting with an artist, Michael Heizer, out in the desert near Las Vegas somewhere. He ’ s building this huge concrete place. And it was late in the evening. We ’ d had a lot to drink. We were standing out in the desert all alone and, thinking about my house, he said,”Did it ever occur to you if you built stuff more permanent, somewhere in 2000 years somebody ’ s going to like it?”So, I thought,”Yeah, that ’ s probably a good idea.”Luckily I started to get some clients that had a little more money, so the stuff was a little more permanent. But I just found out the world **ain** ’ t going to last that long, this guy was telling us the other day. So where do we go now? Back to — everything ’ s so temporary. I don ’ t see it the way you characterized it. For me, every day is a new thing. I approach each project with a new insecurity, almost like the first project I ever did, and I get the sweats, I go in and start working, I ’ m not sure where I ’ m going — if I knew where I was going, I wouldn ’ t do it. When I can predict or plan it, I don ’ t do it. I discard it. So I approach it with the same trepidation. Obviously, over time I have a lot more confidence that it ’ s going to be OK. I do run a kind of a business — I ’ ve got 120 people and you ’ ve got to pay them, so there ’ s a lot of responsibility involved — but the actual work on the project is with, I think, a healthy insecurity. And like the playwright said the other day — I could relate to him : you ’ re not sure. When Bilbao was finished and I looked at it, I saw all the mistakes, I saw... They weren ’ t mistakes ; I saw everything that I would have changed and I was embarrassed by it. I felt an embarrassment —”How could I have done that? How could I have made shapes like that or done stuff like that?”It ’ s taken several years to now look at it detached and say — as you walk around the corner and a piece of it works with the road and the street, and it appears to have a relationship — that I started to like it. RSW : What ’ s the status of the New York project? FG : I don ’ t really know. Tom Krens came to me with Bilbao and explained it all to me, and I thought he was nuts. I didn ’ t think he knew what he was doing, and he pulled it off. So, I think he ’ s Icarus and Phoenix all in one guy. He gets up there and then he... comes back up. They ’ re still talking about it. September 11 generated some interest in moving it over to Ground Zero, and I ’ m totally against that. I just feel uncomfortable talking about or building anything on Ground Zero I think for a long time. RSW : The **picture** on the screen, is that Disney? FG : Yeah. RSW : How much further along is it than that, and when will that be finished? FG : That will be finished in 2003 — September, October — and I ’ m hoping Kyu, and Herbie, and Yo-Yo and all those guys come play with us at that place. Luckily, today most of the people I ’ m working with are people I really like. Richard Koshalek is probably one of the main reasons that Disney Hall came to me. He ’ s been a cheerleader for quite a long time. There aren ’ t many people around that are really involved with architecture as clients. If you think about the world, and even just in this audience, most of us are involved with buildings. Nothing that you would call architecture, right? And so to find one, a guy like that, you hang on to him. He ’ s become the head of Art Center, and there ’ s a building by Craig Ellwood there. I knew Craig and respected him. They want to add to it and it ’ s hard to add to a building like that — it ’ s a beautiful, minimalist, black steel building — and Richard wants to add a library and more student stuff and it ’ s a lot of acreage. I convinced him to let me bring in another **architect** from Portugal : Alvaro Siza. RSW : Why did you want that? FG : I knew you ’ d ask that question. It was intuitive. Alvaro Siza grew up and lived in Portugal and is probably considered the Portuguese main guy in architecture. I visited with him a few years ago and he showed me his early work, and his early work had a resemblance to my early work. When I came out of college, I started to try to do things contextually in Southern California, and you got into the logic of Spanish colonial tile **roofs** and things like that. I tried to understand that language as a beginning, as a place to jump off, and there was so much of it being done by spec builders and it was trivialized so much that it wasn ’ t... I just stopped. I mean, Charlie Moore did a bunch of it, but it didn ’ t feel good to me. Siza, on the other hand, continued in Portugal where the real stuff was and evolved a modern language that relates to that historic language. And I always felt that he should come to Southern California and do a building. I tried to get him a couple of jobs and they didn ’ t pan out. I like the idea of collaboration with people like that because it pushes you. I ’ ve done it with Claes Oldenburg and with Richard Serra, who doesn ’ t think architecture is art. Did you see that thing? RSW : No. What did he say? FG : He calls architecture”plumbing.”FG : Anyway, the Siza thing. It ’ s a richer experience. It must be like that for Kyu doing things with musicians — it ’ s similar to that I would imagine — where you... huh? Audience : Liquid architecture. FG : Liquid architecture. Where you... It ’ s like jazz : you improvise, you work together, you play off each other, you make something, they make something. And I think for me, it ’ s a way of trying to understand the city and what might happen in the city. RSW : Is it going to be near the current campus? Or is it going to be down near... FG :

No, it ’ s near the current campus. Anyway, he ’ s that kind of patron. It ’ s not his money, of course. RSW : What ’ s his schedule on that? FG : I don ’ t know. What ’ s the schedule, Richard? Richard Koshalek : [Unclear] starts from 2004. FG : 2004. You can come to the opening. I ’ ll invite you. No, but the issue of city building in democracy is interesting because it creates chaos, right? Everybody doing their thing makes a very chaotic environment, and if you can figure out how to work off each other — if you can get a bunch of people who respect each other ’ s work and play off each other, you might be able to create models for how to build sections of the city without resorting to the one **architect**. Like the Rockefeller Center model, which is kind of from another era. RSW : I found the most remarkable thing. My preconception of Bilbao was this wonderful building, you go inside and there ’ d be extraordinary spaces. I ’ d seen **drawings** you had presented here at TED. The surprise of Bilbao was in its context to the city. That was the surprise of going across the river, of going on the highway around it, of walking down the street and finding it. That was the real surprise of Bilbao. FG : But you know, Richard, most **architects** when they present their work — most of the people we know, you get up and you talk about your work, and it ’ s almost like you tell everybody you ’ re a good guy by saying,”Look, I ’ m worried about the context, I ’ m worried about the city, I ’ m worried about my client, I worry about budget, that I ’ m on time.”Blah, blah, blah and all that stuff. And it ’ s like cleansing yourself so that you can... by saying all that, it means your work is good somehow. And I think everybody — I mean that should be a matter of fact, like gravity. You ’ re not going to defy gravity. You ’ ve got to work with the building department. If you don ’ t meet the budgets, you ’ re not going to get much work. If it leaks — Bilbao did not leak. I was so proud. The MIT project — they were interviewing me for MIT and they sent their facilities people to Bilbao. I met them in Bilbao. They came for three days. RSW : This is the computer building? FG : Yeah, the computer building. They were there three days and it rained every day and they kept walking around — I noticed they were looking under things and looking for things, and they wanted to know where the buckets were hidden, you know? People put buckets out... I was **clean**. There wasn ’ t a bloody leak in the place, it was just fantastic. But you ’ ve got to — yeah, well up until then every building leaked, so this... RSW : Frank had a sort of... FG : Ask Miriam! RW :... sort of had a fame. His fame was built on that in L. A. for a while. FG : You ’ ve all heard the Frank Lloyd Wright story, when the woman called and said,”Mr. Wright, I ’ m sitting on the couch and the water ’ s pouring in on my head.”And he said,”Madam, move your chair.”So, some years later I was doing a building, a little house on the beach for Norton Simon, and his secretary, who was kind of a **hell** on wheels type lady, called me and said,”Mr. Simon ’ s sitting at his desk and the water ’ s coming in on his head.”And I told her the Frank Lloyd Wright story. RSW : Didn ’ t get a laugh. FG : No. Not now either. But my point is that... and I call it the”then what?”OK, you solved all the problems, you did all the stuff, you made nice, you loved your clients, you loved the city, you ’ re a good guy, you ’ re a good person... and then what? What do you bring to it? And I think that ’ s what I ’ ve always been interested in, is that — which is a personal kind of expression. Bilbao, I think, shows that you can have that kind of personal expression and still touch all the bases that are necessary of fitting into the city. That ’ s what reminded me of it. And I think that ’ s the issue, you know ; it ’ s the”then what”that most clients who hire **architects** — most clients aren ’ t hiring **architects** for that. They ’ re hiring them to get it done, get it on budget, be polite, and they ’ re missing out on the real value of an **architect**. RSW : At a certain point a number of years ago, people — when Michael Graves was a fashion, before teapots... FG : I did a teapot and nobody bought it. RSW : Did it leak? FG : No. RSW :... people wanted a Michael Graves building. Is that a curse, that people want a Bilbao building? FG : Yeah. Since Bilbao opened, which is now four, five years, both Krens and I have been called with at least 100 opportunities — China, Brazil, other parts of Spain — to come in and do the Bilbao effect. And I ' ve met with some of these people. Usually I say no right away, but some of them come with pedigree and they sound well-intentioned and they get you for at least one or two meetings. In one case, I flew all the way to Malaga with a team because the thing was signed with seals and various very official seals from the city, and that they wanted me to come and do a building in their port. I asked them what kind of building it was."When you get here we ' ll explain it."Blah, blah, blah. So four of us went. And they took us — they put us up in a great hotel and we were looking over the bay, and then they took us in a boat out in the water and showed us all these sights in the harbor. Each one was more beautiful than the other. And then we were going to have lunch with the mayor and we were going to have dinner with the most important people in Malaga. Just before going to lunch with the mayor, we went to the harbor commissioner. It was a table as long as this carpet and the harbor commissioner was here, and I was here, and my guys. We sat down, and we had a drink of water and everybody was quiet. And the guy looked at me and said,"Now what can I do for you, Mr. Gehry?"RSW : Oh, my God. FG : So, I got up. I said to my team,"Let ' s get out of here."We stood up, we walked out. They followed — the guy that dragged us there followed us and he said,"You mean you ' re not going to have lunch with the mayor?"I said,"Nope.""You ' re not going to have dinner at all?"They just brought us there to hustle this group, you know, to create a project. And we get a lot of that. Luckily, I ' m old enough that I can complain I can ' t travel. I don ' t have my own plane yet. RSW : Well, I ' m going to wind this up and wind up the meeting because it ' s been very long. But let me just say a couple words. FG : Can I say something? Are you going to talk about me or you? RSW : Once a shit, always a shit! FG : Because I want to get a standing ovation like everybody, so... RSW : You ' re going to get one! You ' re going to get one! I ' m going to make it for you! FG : No, no. Wait a minute!

Text Sample 667: POS Dim 5 – 2002 – Score 11.00 – 2002/t000317.txt

I draw to better understand things. Sometimes I make a lot of **drawings** and I still don ' t understand what it is I ' m **drawing**. Those of you who are comfortable with digital stuff and even smug about that relationship might be amused to know that the guy who is best known for"The Way Things Work,"while preparing for part of a **panel** for called Understanding, spent two days trying to get his laptop to communicate with his new CD burner. Who knew about extension managers? I ' ve always managed my own extensions so it never even occurred to me to read the instructions, but I did finally figure it out. I had to figure it out, because along with the invitation came the frightening reminder that there would be no projector, so bringing those carousels would no longer be necessary but some alternate form of communication would. Now, I could talk about something that I ' m known for, something that would be particularly appropriate for many of the more technically minded people here, or I could talk about something I really care about. I decided to go with the latter. I ' m going to talk about Rome. Now, why would I care about Rome, particularly? Well, I went to Rhode Island School of Design in the second half of the ' 60s to study architecture. I was lucky enough to spend my last year, my fifth year, in Rome as a student. It changed my life. Not the least reason was the fact that I had spent those first four years living at home, driving into RISD everyday, driving back. I missed the ' 60s. I read about them ; I understand they were pretty interesting. I missed them, but I did spend that extraordinary year in Rome, and it ' s a place that is never far from my mind. So, whenever given an opportunity, I try to do something in it or with it or for it. I also make **drawings** to help people understand things. Things that I want them to believe I understand. And that ' s what I do as an illustrator, that ' s my job. So, I ' m going to show you some **pictures** of Rome. I ' ve made a lot of **drawings** of Rome over the years. These are just **drawings** of Rome. I get back as often as possible — I need to. All different materials, all different styles, all different times, **drawings** from sketchbooks looking at the details of Rome. Part of the reason I ' m showing you these is that it sort of helps illustrate this process I go through of trying to figure out what it is I feel about Rome and why I feel it. These are sketches of some of the little details. Rome is a city full of surprises. I mean, we ' re talking about unusual perspectives, we ' re talking about narrow little winding streets that suddenly open into vast, sun-drenched piazzas — never, though, piazzas that are not humanly scaled. Part of the reason for that is the fact that they grew up organically. That amazing juxtaposition of old and new, the bits of light that come down between the buildings that sort of create a map that ' s traveling above your head of usually blue — especially in the summer — compared to the map that you would normally expect to see of conventional streets. And I began to think about how I could communicate this in book form. How could I share my sense of Rome, my understanding of Rome? And I ' m going to show you a bunch of dead ends, basically. The primary reason for all these dead ends is when if you ' re not quite sure where you ' re going, you ' re certainly not going to get there with any kind of efficiency. Here ' s a little map. And I thought of maps at the beginning ; maybe I should just try and do a little atlas of my favorite streets and connections in Rome. And here ' s a line of text that actually evolves from the exhaust of a scooter zipping across the page. Here that same line of text wraps around a fountain in an illustration that can be turned upside down and read both ways. Maybe that line of text could be a story to help give some human aspect to this. Maybe I should get away from this map completely, and really be honest about wanting to show you my favorite bits and pieces of Rome and simply kick a soccer ball in the air — which happens in so many of the squares in the city — and let it bounce off of things. And I ' ll simply explain what each of those things is that the soccer ball hits. That seemed like a sort of a cheap shot. But even though I just started this presentation, this is not the first thing that I tried to do and I was getting sort of desperate. Eventually, I realized that I had really no content that I could count on, so I decided to move towards packaging. I mean, it seems to work for a lot of things. So I thought a little box set of four small books might do the trick. But one of the ideas that emerged from some of those sketches was the notion of traveling through Rome in different vehicles at different speeds in order to show the different aspects of Rome. Sort of an overview of Rome and the plan that you might see from a dirigible. Quick snapshots of things you might see from a speeding motor scooter, and very slow walking through Rome, you might be able to study in more detail some of the wonderful surfaces and whatnot that you come across. Anyways, I went back to the dirigible notion. Went to Alberto Santos-Dumont. Found one of his dirigibles that had enough dimensions so I could actually use it as a scale that I would then juxtapose with some of the things in Rome. This thing would be flying over or past or be **parked** in front of, but it would be like having a ruler — sort of travel through the pages without being a ruler. Not that you know how long number 11 actually is, but you would be able to compare number 11 against the Pantheon with number 11 against the Baths of Caracalla, and so on and so forth. If you were interested. This is Beatrix. She has a dog named Ajax, she has purchased a dirigible — a small dirigible — she ’ s assembling the structure, Ajax is sniffing for holes in the balloon before they set off. She launches this thing above the Spanish Steps and sets off for an aerial tour of the city. Over the Spanish Steps we go. A nice way to show that river, that stream sort of pouring down the hill. Unfortunately, just across the road from it or quite close by is the Column of Marcus Aurelius, and the diameter of the dirigible makes an impression, as you can see, as she starts trying to read the story that spirals around the Column of Marcus Aurelius — gets a little too close, nudges it. This gives me a chance to suggest to you the structure of the Column of Marcus Aurelius, which is really no more than a pile of quarters high — thick quarters. Over the Piazza of Saint Ignacio, completely ruining the symmetry, but that aside a spectacular place to visit. A spectacular framework, inside of which you see, usually, extraordinary blue sky. Over the Pantheon and the 26-foot diameter Oculus. She **parks** her dirigible, lowers the anchor rope and climbs down for a closer look inside. The text here is right side and upside down so that you are forced to turn the book around, and you can see it from ground point of view and from her point of view — looking in the hole, getting a different kind of perspective, moving you around the space. Particularly appropriate in a building that can contain perfectly a sphere dimensions of the diameter being the same as the distance from the center of the floor to the center of the Oculus. Unfortunately for her, the anchor line gets tangled around the **feet** of some Boy Scouts who are visiting the Pantheon, and they are immediately yanked out and given an extraordinary but terrifying tour of some of the domes of Rome, which would, from their point of view, naturally be hanging upside down. They bail out as soon as they get to the top of Saint Ivo, that little spiral structure you see there. She continues on her way over Piazza Navona. Notices a lot of activity at the Tre Scalini restaurant, is reminded that it is lunchtime and she ’ s hungry. They keep on motoring towards the Campo de ’ Fiori, which they soon reach. Ajax the dog is put in a basket and lowered with a list of food into the marketplace, which flourishes there until about one in the afternoon, and then is completely removed and doesn ’ t appear again until six or seven the following morning. Anyway, the pooch gets back to the dirigible with the stuff. Unfortunately, when she goes to unwrap the prosciutto, Ajax makes a lunge for it. She ’ s managed to save the prosciutto, but in the process she loses the tablecloth, which you can see flying away in the upper **left-hand** corner. They continue without their tablecloth, looking for a place to land this thing so that they can actually have lunch. They eventually discover a huge wall that ’ s filled with small holes, **ideal** for docking a dirigible because you ’ ve got a place to tie up. Turns out to be the exterior wall — that part of it that remains — of the Coliseum, so they **park** themselves there and have a terrific lunch and have a spectacular view. At the end of lunch, they untie the anchor, they set off through the Baths of Caracalla and over the walls of the city and then an abandoned gatehouse and decide to take one more look at the Pyramid of Cestius, which has this lightning rod on top. Unfortunately, that ’ s a problem : they get a little too close, and when you ’ re in a dirigible you have to be very careful about spikes. So that sort of brings her little story to a conclusion. Marcello, on the other hand, is sort of a lazy guy, but he ’ s not due at work until about noon. So, the alarm goes off and it ’ s five to 12 or so. He gets up, leaps onto his scooter, races through the city past the church of Santa Maria della Pace, down the alleys, through the streets that tourists may be wandering through, disturbing the quiet backstreet life of Rome at every turn. That speed with which he is moving, I hope I have suggested in this little image, which, again, can be turned around and read from both sides because there ’ s text on the **bottom** and text on the top, one of which is upside down in this image. So, he keeps on moving, approaching an unsuspecting waiter who is trying to deliver two plates of linguine in a delicate white wine clam sauce to diners who are sitting at a table just outside of a restaurant in the street. Waiter catches on, but it ’ s too late. And Marcello keeps moving in his scooter. Everything he sees from this point on is slightly affected by the linguine, but keeps on moving because this guy ’ s got a job to do. Removes some scaffolding. One of the reasons Rome remains the extraordinary place it is that because of scaffolding and the determination to maintain the fabric, it is a city that continues to grow and adapt to the needs of the particular time in which it finds itself, or we find it. Right through the Piazza della Rotonda, in front of the Pantheon — again wreaking havoc — and finally getting to work. Marcello, as it turns out, is the driver of the number 64 bus, and if you ’ ve been on the number 64 bus, you know that it ’ s driven with the same kind of exuberance as Marcello demonstrated on his scooter. And finally Carletto. You see his apartment in the upper **left-hand** corner. He ’ s looking at his table ; he ’ s planning to propose this evening to his girlfriend of 40 years, and he wants it to be perfect. He ’ s got candles out, he ’ s got flowers in the middle and he ’ s trying to figure out where to put the plates and the glasses. But he ’ s not happy ; something ’ s wrong. The phone rings anyway, he ’ s called to the palazzo. He saunters — he saunters at a good clip, but as compared to all the traveling we ’ ve just seen, he ’ s sauntering. Everybody knows Carletto, because he ’ s in entertainment, actually ; he ’ s in television. He ’ s actually in television repair, which is why people know him. So they all have his number. He arrives at the palazzo, arrives at the big front door. Enters the courtyard and talks to the custodian, who tells him that there ’ s been a disaster in the palazzo ; nobody ’ s TVs are working and there ’ s a big soccer game coming up, and the crowd is getting a little restless and a little nervous. He goes down to the basement and starts to check the wiring, and then gradually works his way up to the top of the building, apartment by apartment, checking every television, checking every connection, hoping to find out what this problem is. He works his way up, finally, the grand staircase and then a smaller staircase until he reaches the attic. He opens the window of the attic, of course, and there ’ s a tablecloth wrapped around the building ’ s television antenna. He removes it, the problems are solved, everybody in the palazzo is happy. And of course, he also solves his own problem. All he has to do now, with a perfect table, is wait for her to arrive. That was the first attempt, but it didn ’ t seem substantial enough to convey whatever it was I wanted to convey about Rome. So I thought, well, I ’ ll just do piazzas, and I ’ ll get inside and underneath and I ’ ll show these things growing and show why they ’ re shaped the way they are and so on. And then I thought, that ’ s too complicated. No, I ’ ll just take my favorite bits and pieces and I ’ ll put them inside the Pantheon but keep the scale, so you can see the top of Sant ’ Ivo and the Pyramid of Cestius and the Tempietto of Bramante all side by side in this amazing space. Now that ’ s one **drawing**, so I thought maybe it ’ s time for Piranesi to meet Escher. You see that I ’ m beginning to really lose control here and also hope. There ’ s a very thin blue line of exhaust that sort of runs through this thing that would be kind of the trail that holds it all together. Then I thought,”Wait a minute, what am I doing?”A book is not only a neat way of collecting and storing information, it ’ s a series of layers. I mean, you always peel one layer off another ; we think of them as pages, doing it a certain way. But think of them as layers. I mean, Rome is a place of layers — horizontal layers, vertical layers — and I thought, well just peeling off a page would allow me to — if I got you thinking about it the right way — would allow me to sort of show you the depth of layers. The stucco on the walls of most of the buildings in Rome covers the scars ; the scars of centuries of change as these structures have been adapted rather than being torn down. If I do a foldout page on the **left-hand** side and let you just unfold it, you see behind it what I mean by scar tissue. You can see that in 1635, it became essential to make smaller windows because the bad guys were coming or whatever. Adaptations all get buried under the stucco. I could peel out a page of this palazzo to show you what ' s going on inside of it. But more importantly, I could also show you what it looks like at the corner of one of those magnificent buildings with all the massive stone blocks, or the fake stone blocks done with brick and stucco, which is more often the case. So it becomes slightly three-dimensional. I could take you down one of those narrow little streets into one of those surprising piazzas by using a double gate fold — double foldout page — which, if you were like me reading a pop- up book as a child, you hopefully stick your head into. You wrap the pages around your head and are in that piazza for that brief period of time. And I ' ve really not done anything much more complicated than make foldout pages. But then I thought, maybe I could be simpler here. Let ' s look at the Pantheon and the Piazza della Rotonda in front of it. Here ' s a book completely wide open. OK, if I don ' t open the book the whole way, if I just open it 90 degrees, we ' re looking down the front of the Pantheon, and we ' re looking sort of at the top, more or less down on the square. And if I turn the book the other way, we ' re looking across the square at the front of the Pantheon. No foldouts, no tricks — just a book that isn ' t open the whole way. That seemed promising. I thought, maybe I ' ll do it inside and I can even combine the foldouts with the only partially opened book. So we get inside the Pantheon and it grows and so on and so forth. And I thought, maybe I ' m on the right track, but it sort of lost its human quality. So I went back to the notion of story, which is always a good thing to have if you ' re trying to get people to pay attention to a book and pick up information along the way."Pigeon ' s Progress"struck me as a catchy title. If it was a homing pigeon, it would be called"Homer ' s Odyssey."But it was the journey of the... I mean, if a title works, use it. But it would be a journey that went through Rome and showed all the things that I like about Rome. It ' s a pigeon sitting on top of a church. Goes off during the day and does normal pigeon stuff. Comes back, the whole place is covered with scaffolding and green netting and there ' s no way this pigeon can get home. So it ' s a homeless pigeon now and it ' s going to have to find another place to live, and that allows me to go through my catalog of favorite things, and we start with the tall ones and so on. Maybe it has to go back and live with family members ; that ' s not always a good thing, but it does sort of bring pigeons together again. And I thought, that ' s sort of interesting, but maybe there ' s a person who should be involved in this in some way. So I kind of came up with this old guy who spends his life looking after sick pigeons. He ' ll go anywhere to get them — dangerous places and whatnot — and they become really friends with this guy, and learn to do tricks for him and entertain him at lunchtime and stuff like that. There ' s a real bond that develops between this old man and these pigeons. But unfortunately he gets sick. He gets really sick at the end of the story. He ' s taught them to spell his name, which is Aldo. They show up one day after three or four days of not seeing him — he lives in this little garret — and they spell his name and fly around. And he finally gets enough strength together to climb up the ladder onto the **roof**, and all the pigeons, a la Red Balloon, are there waiting for him and they carry him off over the walls of the city. And I forgot to mention this : whenever he lost a pigeon, he would take that pigeon out beyond the walls of the city. In the old Roman custom, the dead were never buried within the walls. And I thought that ' s a really cheery story.. That ' s really going to go a long way. So anyway, I went through... And again, if packaging doesn ’ t work and if the stories aren ’ t going anywhere, I just come up with titles and hope that a title will sort of kick me off in the right direction. And sometimes it does focus me enough and I ’ ll even do a title page. So, these are all title pages that eventually led me to the solution I settled on, which is the story of a young woman who sends a message on a homing pigeon — she lives outside the walls of the city of Rome — to someone in the city. And the pigeon is flying down above the Appian Way here. You can see the tombs and pines and so on and so forth along the way. If you see the red line, you are seeing the trail of the pigeon ; if you don ’ t see the red line, you are the pigeon. And it becomes necessary and possible, at this point, to try to convey what that sense would be like of flying over the city without actually moving. Past the Pyramid of Cestius — these will seem very familiar to you, even if you haven ’ t been to Rome recently — past the gatehouse. This is something that ’ s a little bit unusual. This pigeon does something that most homing pigeons do not do : it takes the scenic route, which was a device that I felt was necessary to actually extend this book beyond about four pages. So, we circle around the Coliseum, past the Church of Santa Maria in Cosmedin and the Temple of Hercules towards the river. We almost collide with the **cornice** of the Palazzo Farnese — designed by Michelangelo, built of stone taken from the Coliseum — narrow escape. We swoop down over the Campo de ’ Fiori. This is one of those things I show to my students because it ’ s a complete bastardization — a denial of any rules of perspective. The only rule of perspective that I think matters is if it looks believable, you ’ ve succeeded. But you try and figure out where the vanishing points meet here ; a couple are on Mars and a couple of others in Cremona. But into the piazza in front of Santa Maria della Pace, where invariably a soccer game is going on, and we ’ re hit by a soccer ball. Now this is a terrible illustration of being hit by a soccer ball. I have all the pieces : there ’ s Santa Maria della Pace, there ’ s a soccer ball, there ’ s a little bit of a bird ’ s wing — nothing ’ s happening, so I had to rethink it. And if you do want to see Santa Maria della Pace, these books are really flexible, incredibly interactive — just turn it around and look at it the other way. Through the alley, we can see the impact is captured in the red line. And then bird manages to pull itself together past this medieval tower — one of the few remaining medieval towers — towards the church of Sant ’ Agnese and around the dome looking down into Piazza Navona — which we ’ ve already mentioned and seen and flown over a couple of times ; there ’ s the Bernini statue of the Four Rivers — and then past the wonderful Borromini Sant ’ Ivo, stopping just long enough on the 26-foot diameter Oculus of the Pantheon to catch our breath. And then we can swoop inside and around ; and because we ’ re flying, we don ’ t really have to worry about gravity at this particular moment in time, so this **drawing** can be oriented in any way on the page. We get a little exuberant as we pass Gesu ; it ’ s not surprising to sort of mimic the architecture in this way. Past the wonderful wall filled with the juxtaposition that I was talking about ; beautiful carvings set into the walls above the neon”Ristorante”sign, and so on. And eventually, we arrive at the courtyard of the palazzo, which is our destination. Straight up through the courtyard into a little window into the attic, where somebody is working at the **drawing** board. He removes the message from the leg of the bird ; this is what it says. As we look at the **drawing** board, we see what he ’ s working on is, in fact, a map of the journey that the pigeon has just taken, and the red line extends through all the sights. And if you want the information, so that we complete this cycle of understanding, all you have to do is read these paragraphs. Thank you very much.

Text Sample 668: POS Dim 5 – 2002 – Score 9.00 – 2002/t000312.txt

It ’ s a great honor to be here with you. The good news is I ’ m very aware of my responsibilities to get you out of here because I ’ m the only thing standing between you and the bar. And the good news is I don ’ t have a prepared speech, but I have a box of slides. I have some **pictures** that represent my life and what I do for a living. I ’ ve learned through experience that people remember **pictures** long after they ’ ve forgotten words, and so I hope you ’ ll remember some of the **pictures** I ’ m going to share with you for just a few minutes. The whole story really starts with me as a high school kid in Pittsburgh, Pennsylvania, in a tough neighborhood that everybody gave up on for dead. And on a Wednesday afternoon, I was walking down the corridor of my high school kind of minding my own business. And there was this artist teaching, who made a great big old ceramic vessel, and I happened to be looking in the door of the art room — and if you ’ ve ever seen clay done, it ’ s magic — and I ’ d never seen anything like that before in my life. So, I walked in the art room and I said,”What is that?”And he said,”Ceramics. And who are you?”And I said,”I ’ m Bill Strickland. I want you to teach me that.”And he said,”Well, get your homeroom teacher to sign a piece of paper that says you can come here, and I ’ ll teach it to you.”And so for the remaining two years of my high school, I cut all my classes. But I had the presence of mind to give the teachers ’ classes that I cut the pottery that I made, and they gave me passing grades. And that ’ s how I got out of high school. And Mr. Ross said,”You ’ re too smart to die and I don ’ t want it on my conscience, so I ’ m leaving this school and I ’ m taking you with me.”And he drove me out to the University of Pittsburgh where I filled out a college application and got in on probation. Well, I ’ m now a trustee of the university, and at my installation ceremony I said,”I ’ m the guy who came from the neighborhood who got into the place on probation. Don ’ t give up on the poor kids, because you never know what ’ s going to happen to those children in life.”What I ’ m going to show you for a couple of minutes is a facility that I built in the toughest neighborhood in Pittsburgh with the highest crime rate. One is called Bidwell Training Center ; it is a vocational school for ex-steel workers and single parents and welfare mothers. You remember we used to make steel in Pittsburgh? Well, we don ’ t make any steel anymore, and the people who used to make the steel are having a very tough time of it. And I rebuild them and give them new life. Manchester Craftsmen ’ s Guild is named after my neighborhood. I was adopted by the Bishop of the Episcopal Diocese during the riots, and he donated a row house. And in that row house I started Manchester Craftsmen ’ s Guild, and I learned very quickly that wherever there are Episcopalians, there ’ s money in very close proximity. And the Bishop adopted me as his kid. And last year I spoke at his memorial service and wished him well in this life. I went out and hired a student of Frank Lloyd Wright, the **architect**, and I asked him to build me a world class center in the worst neighborhood in Pittsburgh. And my building was a scale model for the Pittsburgh airport. And when you come to Pittsburgh — and you ’ re all invited — you ’ ll be flying into the blown-up version of my building. That ’ s the building. Built in a tough neighborhood where people have been given up for dead. My view is that if you want to involve yourself in the life of people who have been given up on, you have to look like the solution and not the problem. As you can see, it has a fountain in the courtyard. And the reason it has a fountain in the courtyard is I wanted one and I had the checkbook, so I bought one and put it there. And now that I ’ m giving speeches at conferences like TED, I got put on the board of the Carnegie Museum. At a reception in their courtyard, I noticed that they had a fountain because they think that the people who go to the **museum** deserve a fountain. Well, I think that welfare mothers and at-risk kids and ex-steel workers deserve a fountain in their life. And so the first thing that you see in my center in the springtime is water that greets you — water is life and water of human possibility — and it sets an attitude and expectation about how you feel about people before you ever give them a speech. So, from that fountain I built this building. As you can see, it has world class art, and it ' s all my taste because I raised all the money. I said to my boy,"When you raise the money, we ' ll put your taste on the wall."That we have quilts and clay and calligraphy and everywhere your eye turns, there ' s something beautiful looking back at you, that ' s deliberate. That ' s intentional. In my view, it is this kind of world that can redeem the soul of poor people. We also created a boardroom, and I hired a Japanese cabinetmaker from Kyoto, Japan, and commissioned him to do 60 pieces of furniture for our building. We have since spun him off into his own business. He ' s making a ton of money doing custom furniture for rich people. And I got 60 pieces out of it for my school because I felt that welfare moms and ex-steel workers and single parents deserved to come to a school where there was handcrafted furniture that greeted them every day. Because it sets a tone and an attitude about how you feel about people long before you give them the speech. We even have flowers in the hallway, and they ' re not plastic. Those are real and they ' re in my building every day. And now that I ' ve given lots of speeches, we had a bunch of high school principals come and see me, and they said,"Mr. Strickland, what an extraordinary story and what a great school. And we were particularly touched by the flowers and we were curious as to how the flowers got there."I said,"Well, I got in my car and I went out to the greenhouse and I bought them and I brought them back and I put them there."You don ' t need a task force or a study group to buy flowers for your kids. What you need to know is that the children and the adults deserve flowers in their life. The cost is incidental but the gesture is huge. And so in my building, which is full of sunlight and full of flowers, we believe in hope and human possibilities. That happens to be at Christmas time. And so the next thing you ' ll see is a million dollar kitchen that was built by the Heinz company — you ' ve heard of them? They did all right in the ketchup business. And I happen to know that company pretty well because John Heinz, who was our U. S. senator — who was tragically killed in a plane accident — he had heard about my desire to build a new building, because I had a cardboard box and I put it in a garbage bag and I walking all over Pittsburgh trying to raise money for this site. And he called me into his office — which is the equivalent of going to see the Wizard of Oz — and John Heinz had 600 million dollars, and at the time I had about 60 cents. And he said,"But we ' ve heard about you. We ' ve heard about your work with the kids and the ex- steel workers, and we ' re inclined to want to support your desire to build a new building. And you could do us a great service if you would add a culinary program to your program."Because back then, we were building a trades program. He said,"That way we could fulfill our affirmative action goals for the Heinz company."I said,"Senator, I ' m reluctant to go into a field that I don ' t know much about, but I promise you that if you ' ll support my school, I ' ll get it built and in a couple of years, I ' ll come back and weigh out that program that you desire."And Senator Heinz sat very quietly and he said,"Well, what would your reaction be if I said I ' d give you a million dollars?"I said,"Senator, it appears that we ' re going into the food training business."And John Heinz did give me a million bucks. And most importantly, he loaned me the head of research for the Heinz company. And we kind of borrowed the curriculum from the Culinary Institute of America, which in their mind is kind of the Harvard of cooking schools, and we created a gourmet cooks program for welfare mothers in this million dollar kitchen in the middle of the inner city. And we ' ve never looked back. I would like to show you now some of the food that these welfare mothers do in this million dollar kitchen. That happens to be our cafeteria line. That ' s puff pastry day. Why? Because the students made puff pastry and that ' s what the school ate every day. But the concept was that I wanted to take the stigma out of food. That good food ' s not for rich people — good food ' s for everybody on the planet, and there ' s no excuse why we all can ' t be eating it. So at my school, we subsidize a gourmet lunch program for welfare mothers in the middle of the inner city because we ' ve discovered that it ' s good for their stomachs, but it ' s better for their heads. Because I wanted to let them know every day of their life that they have value at this place I call my center. We have students who sit together, black kids and white kids, and what we ' ve discovered is you can solve the race problem by creating a world class environment, because people will have a tendency to show you world class behavior if you treat them in that way. These are examples of the food that welfare mothers are doing after six months in the training program. No sophistication, no class, no dignity, no history. What we ' ve discovered is the only thing wrong with poor people is they don ' t have any money, which happens to be a curable condition. It ' s all in the way that you think about people that often determines their behavior. That was done by a student after seven months in the program, done by a very brilliant young woman who was taught by our pastry chef. I ' ve actually eaten seven of those baskets and they ' re very good. They have no calories. That ' s our dining room. It looks like your average high school cafeteria in your average town in America. But this is my view of how students ought to be treated, particularly once they have been pushed aside. We train pharmaceutical technicians for the pharmacy industry, we train medical technicians for the medical industry, and we train chemical technicians for companies like Bayer and Calgon Carbon and Fisher Scientific and Exxon. And I will guarantee you that if you come to my center in Pittsburgh — and you ' re all invited — you ' ll see welfare mothers doing analytical chemistry with logarithmic calculators 10 months from enrolling in the program. There is absolutely no reason why poor people can ' t learn world class technology. What we ' ve discovered is you have to give them flowers and sunlight and food and expectations and Herbie ' s music, and you can cure a spiritual cancer every time. We train corporate travel agents for the travel industry. We even teach people how to read. The kid with the red stripe was in the program two years ago — he ' s now an instructor. And I have children with high school diplomas that they can ' t read. And so you must ask yourself the question : how is it possible in the 21st century that we graduate children from schools who can ' t read the diplomas that they have in their hands? The reason is that the system gets reimbursed for the kids they spit out the other end, not the children who read. I can take these children and in 20 weeks, demonstrated aptitude ; I can get them high school equivalent. No big deal. That ' s our library with more handcrafted furniture. And this is the arts program I started in 1968. Remember I ' m the black kid from the ' 60s who got his life saved with ceramics. Well, I went out and decided to reproduce my experience with other kids in the neighborhood, the theory being if you get kids flowers and you give them food and you give them sunshine and enthusiasm, you can bring them right back to life. I have 400 kids from the Pittsburgh public school system that come to me every day of the week for arts education. And these are children who are flunking out of public school. And last year I put 88 percent of those kids in college and I ' ve averaged over 80 percent for 15 years. We ' ve made a fascinating discovery : there ' s nothing wrong with the kids that affection and sunshine and food and enthusiasm and Herbie ' s music can ' t cure. For that I won a big old plaque — Man of the Year in Education. I beat out all the Ph. D. ' s because I figured that if you treat children like human beings, it increases the likelihood they ’ re going to behave that way. And why we can ’ t institute that policy in every school and in every city and every town remains a mystery to me. Let me show you what these people do. We have ceramics and photography and computer imaging. And these are all kids with no artistic ability, no talent, no imagination. And we bring in the world ’ s greatest artists — Gordon Parks has been there, Chester Higgins has been there — and what we ’ ve learned is that the children will become like the people who teach them. In fact, I brought in a mosaic artist from the Vatican, an African-American woman who had studied the old Vatican mosaic techniques, and let me show you what they did with the work. These were children who the whole world had given up on, who were flunking out of public school, and that ’ s what they ’ re capable of doing with affection and sunlight and food and good music and confidence. We teach photography. And these are examples of some of the kids ’ work. That boy won a four-year scholarship on the strength of that photograph. This is our gallery. We have a world class gallery because we believe that poor kids need a world class gallery, so I designed this thing. We have smoked salmon at the art openings, we have a formal printed invitation, and I even have figured out a way to get their parents to come. I couldn ’ t buy a parent 15 years ago so I hired a guy who got off on the Jesus big time. He was dragging guys out of bars and saving those lives for the Lord. And I said,”Bill, I want to hire you, man. You have to tone down the Jesus stuff a little bit, but keep the enthusiasm. I can ’ t get these parents to come to the school.”He said,”I ’ ll get them to come to the school.”So, he jumped in the van, he went to Miss Jones ’ house and said,”Miss Jones, I knew you wanted to come to your kid ’ s art opening but you probably didn ’ t have a ride. So, I came to give you a ride.”And he got 10 parents and then 20 parents. At the last show that we did, 200 parents showed up and we didn ’ t pick up one parent. Because now it ’ s become socially not acceptable not to show up to support your children at the Manchester Craftsmen ’ s Guild because people think you ’ re bad parents. And there is no statistical difference between the white parents and the black parents. Mothers will go where their children are being celebrated, every time, every town, every city. I wanted you to see this gallery because it ’ s as good as it gets. And by the time I cut these kids loose from high school, they ’ ve got four shows on their resume before they apply to college because it ’ s all up here. You have to change the way that people see themselves before you can change their behavior. And it ’ s worked out pretty good up to this day. I even stuck another room on the building, which I ’ d like to show you. This is brand new. We just got this slide done in time for the TED Conference. I gave this little slide show at a place called the Silicon Valley and I did all right. And the woman came out of the audience, she said,”That was a great story and I was very impressed with your presentation. My only criticism is your computers are getting a little bit old.”And I said,”Well, what do you do for a living?”She said,”Well, I work for a company called Hewlett-Packard.”And I said,”You ’ re in the computer business, is that right?”She said,”Yes, sir.”And I said,”Well, there ’ s an easy solution to that problem.”Well, I ’ m very pleased to announce to you that HP and a furniture company called Steelcase have adopted us as a demonstration model for all of their technology and all their furniture for the United States of America. And that ’ s the room that ’ s initiating the relationship. We got it just done in time to show you, so it ’ s kind of the world debut of our digital imaging center. I only have a couple more slides, and this is where the story gets kind of interesting. So, I just want you to listen up for a couple more minutes and you ’ ll understand why he ’ s there and I ’ m here. In 1986, I had the presence of mind to stick a music hall on the north end of the building while I was building it. And a guy named Dizzy Gillespie showed up to play there because he knew this man over here, Marty Ashby. And I stood on that stage with Dizzy Gillespie on sound check on a Wednesday afternoon, and I said,”Dizzy, why would you come to a black-run center in the middle of an industrial **park** with a high crime rate that doesn ’ t even have a reputation in music?”He said,”Because I heard you built the center and I didn ’ t believe that you did it, and I wanted to see for myself. And now that I have, I want to give you a gift.”I said,”You ’ re the gift.”He said,”No, sir. You ’ re the gift. And I ’ m going to allow you to record the concert and I ’ m going to give you the music, and if you ever choose to sell it, you must sign an agreement that says the money will come back and support the school.”And I recorded Dizzy. And he died a year later, but not before telling a fellow named McCoy Tyner what we were doing. And he showed up and said,”Dizzy talking about you all over the country, man, and I want to help you.”And then a guy named Wynton Marsalis showed up. Then a bass player named Ray Brown, and a fellow named Stanley Turrentine, and a piano player named Herbie Hancock, and a band called the Count Basie Orchestra, and a fellow named Tito Puente, and a guy named Gary Burton, and Shirley Horn, and Betty Carter, and Dakota Staton and Nancy Wilson all have come to this center in the middle of an industrial **park** to sold out audiences in the middle of the inner city. And I ’ m very pleased to tell you that, with their permission, I have now accumulated 600 recordings of the greatest artists in the world, including Joe Williams, who died, but not before his last recording was done at my school. And Joe Williams came up to me and he put his hand on my shoulder and he said,”God ’ s picked you, man, to do this work. And I want my music to be with you.”And that worked out all right. When the Basie band came, the band got so excited about the school they voted to give me the rights to the music. And I recorded it and we won something called a Grammy. And like a fool, I didn ’ t go to the ceremony because I didn ’ t think we were going to win. Well, we did win, and our name was literally in lights over Madison Square Garden. Then the U. N. Jazz Orchestra dropped by and we recorded them and got nominated for a second Grammy back to back. So, we ’ ve become one of the hot, young jazz recording studios in the United States of America in the middle of the inner city with a high crime rate. That ’ s the place all filled up with Republicans. If you ’ d have dropped a bomb on that room, you ’ d have wiped out all the money in Pennsylvania because it was all sitting there. Including my mother and father, who lived long enough to see their kid build that building. And there ’ s Dizzy, just like I told you. He was there. And he was there, Tito Puente. And Pat Metheny and Jim Hall were there and they recorded with us. And that was our first recording studio, which was the broom closet. We put the mops in the hallway and re-engineered the thing and that ’ s where we recorded the first Grammy. And this is our new facility, which is all video technology. And that is a room that was built for a woman named Nancy Wilson, who recorded that album at our school last Christmas. And any of you who happened to have been watching Oprah Winfrey on Christmas Day, he was there and Nancy was there singing excerpts from this album, the rights to which she donated to our school. And I can now tell you with absolute certainty that an appearance on Oprah Winfrey will sell 10, 000 CDs. We are currently number four on the Billboard Charts, right behind Tony Bennett. And I think we ’ re going to be fine. This was burned out during the riots — this is next to my building — and so I had another cardboard box built and I walked back out in the streets again. And that ’ s the building, and that ’ s the model, and on the right ’ s a high-tech greenhouse and in the middle ’ s the medical technology building. And I ’ m very pleased to tell you that the building ’ s done. It ’ s also full of anchor tenants at 20 dollars a **foot** — triple that in the middle of the inner city. And there ’ s the fountain. Every building has a fountain. And the University of Pittsburgh Medical Center are anchor tenants and they took half the building, and we now train medical technicians through all their system. And Mellon Bank ’ s a tenant. And I love them because they pay the rent on time. And as a result of the association, I ’ m now a director of the Mellon Financial Corporation that bought Dreyfus. And this is in the process of being built as we speak. Multiply that **picture** times four and you will see the greenhouse that ’ s going to open in October this year because we ’ re going to grow those flowers in the middle of the inner city. And we ’ re going to have high school kids growing Phalaenopsis orchids in the middle of the inner city. And we have a handshake with one of the large retail grocers to sell our orchids in all 240 stores in six states. And our partners are Zuma Canyon Orchids of Malibu, California, who are Hispanic. So, the Hispanics and the black folks have formed a partnership to grow high technology orchids in the middle of the inner city. And I told my United States senator that there was a very high probability that if he could find some funding for this, we would become a **left-hand** column in the Wall Street Journal, to which he readily agreed. And we got the funding and we open in the fall. And you ought to come and see it — it ’ s going to be a **hell** of a story. And this is what I want to do when I grow up. The brown building is the one you guys have been looking at and I ’ ll tell you where I made my big mistake. I had a chance to buy this whole industrial **park** — which is less than 1, 000 **feet** from the riverfront — for four million dollars and I didn ’ t do it. And I built the first building, and guess what happened? I appreciated the real estate values beyond everybody ’ s expectations and the owners of the **park** turned me down for eight million dollars last year, and said,”Mr. Strickland, you ought to get the Civic Leader of the Year Award because you ’ ve appreciated our property values beyond our wildest expectations. Thank you very much for that.”The moral of the story is you must be prepared to act on your dreams, just in case they do come true. And finally, there ’ s this **picture**. This is in a place called San Francisco. And the reason this **picture** ’ s in here is I did this slide show a couple years ago at a big economics summit, and there was a fellow in the audience who came up to me. He said,”Man, that ’ s a great story. I want one of those.”I said,”Well, I ’ m very flattered. What do you do for a living?”He says,”I run the city of San Francisco. My name ’ s Willie Brown.”And so I kind of accepted the flattery and the praise and put it out of my mind. And that weekend, I was going back home and Herbie Hancock was playing our center that night — first time I ’ d met him. And he walked in and he says,”What is this?”And I said,”Herbie, this is my concept of a training center for poor people.”And he said,”As God as my witness, I ’ ve had a center like this in my mind for 25 years and you ’ ve built it. And now I really want to build one.”I said,”Well, where would you build this thing?”He said,”San Francisco.”I said,”Any chance you know Willie Brown?”As a matter of fact he did know Willie Brown, and Willie Brown and Herbie and I had dinner four years ago, and we started drawing out that center on the tablecloth. And Willie Brown said,”As sure as I ’ m the mayor of San Francisco, I ’ m going to build this thing as a legacy to the poor people of this city.”And he got me five acres of land on San Francisco Bay and we got an **architect** and we got a general contractor and we got Herbie on the board, and our friends from HP, and our friends from Steelcase, and our friends from Cisco, and our friends from Wells Fargo and Genentech. And along the way, I met this real short guy at my slide show in the Silicon Valley. He came up to me afterwards, he said,”Man, that ’ s a fabulous story. I want to help you.”And I said,”Well, thank you very much for that. What do you do for a living?”He said,”Well, I built a company called eBay.”I said,”Well, that ’ s very nice. Thanks very much, and give me your card and sometime we ’ ll talk.”I didn ’ t know eBay from that jar of water sitting on that piano, but I had the presence of mind to go back and talk to one of the techie kids at my center. I said,"Hey man, what is eBay?"He said,"Well, that ' s the electronic commerce network."I said,"Well, I met the guy who built the thing and he left me his card."So, I called him up on the phone and I said,"Mr. Skoll, I ' ve come to have a much deeper appreciation of who you are and I ' d like to become your friend."And Jeff and I did become friends, and he ' s organized a team of people and we ' re going to build this center. And I went down into the neighborhood called Bayview-Hunters Point, and I said,"The mayor sent me down here to work with you and I want to build a center with you, but I ' m not going to build you anything if you don ' t want it. And all I ' ve got is a box of slides."And so I stood up in front of 200 very angry, very disappointed people on a summer night, and the air conditioner had broken and it was 100 degrees outside, and I started showing these **pictures**. And after about 10 **pictures** they all settled down. And I ran the story and I said,"What do you think?"And in the back of the room, a woman stood up and she said,"In 35 years of living in this God forsaken place, you ' re the only person that ' s come down here and treated us with dignity. I ' m going with you, man."And she turned that audience around on a pin. And I promised these people that I was going to build this thing, and we ' re going to build it all right. And I think we can get in the ground this year as the first replication of the center in Pittsburgh. But I met a guy named Quincy Jones along the way and I showed him the box of slides. And Quincy said,"I want to help you, man. Let ' s do one in L. A."And so he ' s assembled a group of people. And I ' ve fallen in love with him, as I have with Herbie and with his music. And Quincy said,"Where did the idea for centers like this come from?"And I said,"It came from your music, man. Because Mr. Ross used to bring in your albums when I was 16 years old in the pottery class, when the world was all dark, and your music got me to the sunlight."And I said,"If I can follow that music, I ' ll get out into the sunlight and I ' ll be OK. And if that ' s not true, how did I get here?"I want you all to know that I think the world is a place that ' s worth living. I believe in you. I believe in your hopes and your dreams, I believe in your intelligence and I believe in your enthusiasm. And I ' m tired of living like this, going into town after town with people standing around on corners with holes where eyes used to be, their spirits damaged. We won ' t make it as a country unless we can turn this thing around. In Pennsylvania it costs 60, 000 dollars to keep people in jail, most of whom look like me. It ' s 40, 000 dollars to build the University of Pittsburgh Medical School. It ' s 20, 000 dollars cheaper to build a medical school than to keep people in jail. Do the math — it will never work. I am banking on you and I ' m banking on guys like Herbie and Quincy and Hackett and Richard and very decent people who still believe in something. And I want to do this in my lifetime, in every city and in every town. And I don ' t think I ' m crazy. I think we can get home on this thing and I think we can build these all over the country for less money than we ' re spending on prisons. And I believe we can turn this whole story around to one of celebration and one of hope. In my business it ' s very difficult work. You ' re always fighting upstream like a salmon — never enough money, too much need — and so there is a tendency to have an occupational depression that accompanies my work. And so I ' ve figured out, over time, the solution to the depression : you make a friend in every town and you ' ll never be lonely. And my hope is that I ' ve made a few here tonight. And thanks for listening to what I had to say.

Text Sample 669: POS Dim 5 – 1984 – Score 5.00 – 1984/t000297.txt

In this rather long sort of marathon presentation, I ' ve tried to break it up into three parts : the first being a whole lot of examples on how it can be a little bit more pleasurable to deal with a computer and really address the qualities of the human interface. And these will be some simple design qualities and they will also be some qualities of, if you will, the intelligence of interaction. Then the second part will really just be examples of new technologies — new media falling very much into that mold. Again, I will go through them as fast as possible. And then the last one will be some examples I ' ve been able to collect, which I think illustrate this at least as best I can, in the world of entertainment. People have this belief — and I share most of it — that we will be using the TV screens or their equivalents for electronic books of the future. But then you think,"My God! What a terrible image you get when you look at still **pictures** on TV."Well, it doesn ' t have to be terrible. And that is a slide taken from a TV set and it was pre- processed to be very sympathetic to the TV medium, and it absolutely looks beautiful. Well, what ' s happened? How did people get into this mess? Where you are now, all of a sudden, sitting in front of personal computers and video text — teletext systems, and somewhat horrified by what you see on the screen? Well, you have to remember that TV was designed to be looked at eight times the distance of the diagonal. So you get a 13-inch, 19-inch, whatever, TV, and then you should multiply that by eight and that ' s the distance you should sit away from the TV set. Now we ' ve put people 18 inches in front of a TV, and all the artifacts that none of the original designers expected to be seen, all of a sudden, are staring you in the face : the shadow mask, the **scan** lines, all of that. And they can be treated very easily ; there are actually ways of getting rid of them, there are actually ways of just making absolutely beautiful **pictures**. I ' m talking here a little bit about display technologies. Let me talk about how you might input information. And my favorite example is always fingers. I ' m very interested in touch-sensitive displays. High-tech, high-touch. Isn ' t that what some of you said? It ' s certainly a very important medium for input, and a lot of people think that fingers are a very low- resolution sort of stylus for inputting to a display. In fact, they ' re not : it ' s really a very, very high-resolution input medium — you have to just do it twice, you have to touch the screen and then rotate your finger slightly — and you can move a cursor with great accuracy. And so when you see on the market these systems that have just a few light emitting diodes on the side and are very low resolution, it ' s nice that they exist because it still is better than nothing. But it, in some sense, misses the point : namely, that fingers are a very, very high-resolution input medium. Now, what are some of the other advantages? Well, the one advantage is that you don ' t have to pick them up, and people don ' t realize how important that is — not having to pick up your fingers to use them. When you think for a second of the mouse on Macintosh — and I will not criticize the mouse too much — when you ' re typing — what you have — you want to now put something — first of all, you ' ve got to find the mouse. You have to probably stop. Maybe not come to a grinding halt, but you ' ve got to sort of find that mouse. Then you find the mouse, and you ' re going to have to wiggle it a little bit to see where the cursor is on the screen. And then when you finally see where it is, then you ' ve got to move it to get the cursor over there, and then —"Bang"— you ' ve got to hit a button or do whatever. That ' s four separate steps versus typing and then touching and typing and just doing it all in one motion — or one-and-a-half, depending on how you want to count. Again, what I ' m trying to do is just illustrate the kinds of problems that I think face the designers of new computer systems and entertainment systems and educational systems from the perspective of the quality of that interface. And another advantage, of course, of using fingers is you have 10 of them. And we have never known how to do this technically, so this slide is a fake slide. We never succeeded in using ten fingers, but there are certain things you can do, obviously, with more than one-finger input, which is rather fascinating. What we did stumble across was something... Again, which is typical of the computer field, is when you have a bug that you can ' t get rid of you turn it into a feature. And maybe... maybe a mouse is a new kind of bug. But the bug in our case was in touch-sensitive displays : we wanted to be able to draw — you know, rub your finger across the screen to input continuous points — and there was just too much friction created between your finger and the glass — if glass was the substrate, which it usually is. So we found that that actually was a feature in the sense you could build a pressure-sensitive display. And when you touch it with your finger, you can actually, then, introduce all the forces on the face of that screen, and that actually has a certain amount of value. Let me see if I can load another disc and show you, quickly, an example. Now, imagine a screen, which is not only touch-sensitive now, it ' s pressure-sensitive. And it ' s pressure-sensitive to the forces both in the plane of the screen — X, Y, and Z at least in one direction ; we couldn ' t figure out how to come in the other direction. But let me get rid of the slide, and let ' s see if this comes on. OK. So there is the pressure-sensitive display in operation. The person ' s just, if you will, pushing on the screen to make a **curve**. But this is the interesting part. I want to stop it for a second because the movie is very badly made. And the particular display was built about six years ago, and when we moved from one room to another room, a rather large person sat on it and it got destroyed. So all we have is this record. But imagine that screen having lots of objects on it and the person has touched an object — one of N — like he did there, and then pushed on it. Now, imagine a program where some of those objects are physically heavy and some are light : one is an anvil on a fuzzy rug and the other one is a ping-pong ball on a sheet of glass. And when you touch it, you have to really push very hard to move that anvil across the screen, and yet you touch the ping-pong ball very lightly and it just scoots across the screen. And what you can do — oops, I didn ' t mean to do that — what you can do is actually feed back to the user the feeling of the physical properties. So again, they don ' t have to be weight ; they could be a general trying to move troops, and he ' s got to move an aircraft carrier versus a little boat. In fact, they funded it for that very reason. The whole notion, then, is one that at the interface there are physical properties in that transducer — in this case it ' s pressure and touches — that allow you to present things to the user that you could never present before. So it ' s not simply looking at the quality or, if you will, the luxury of that interface, but it ' s actually looking at the idea of presenting things that previously couldn ' t be presented before. I want to move on to another example, which is one of a different sort, where we ' re trying to use computer and video disc technology now to come up with a new kind of book. Here, the idea is that you ' re going to take this book, if you will, and it ' s going to come alive. You ' re going to sort of breathe life into it. We are so used to doing monologues. Filmmakers, for example, are the experts in monologue making : you make a **film** and it has a well-formed beginning, middle and end, and in some sense the art of it is that. And you then say,”There ' s an opportunity for making conversational movies.”Well, what does that mean? And it sort of nibbles at the core of the whole profession and all the assumptions of that medium. So, book writing is the same thing. What I ' ll show you very quickly is a new kind of book where it is mixed now with... all sorts of things live in there, but you have to keep a few things in mind. One is that this book knows about itself. Each frame of the movie has information about itself. So it knows, or at least there is computer-readable information in the medium itself.

It ’ s just not a static movie frame. That ’ s one thing. The other is that you have to realize that it is a random access medium, and you can, in fact, branch and expand and elaborate and shrink. And here — again, my favorite example — is the cookbook, the”Larousse Gastronomique.”And I think I use the example all too often, but it ’ s a great one because there is a classic ending in that little encyclopedia-style cookbook that tells you how to do something like penguin, and you get to the end of the recipe and it says,”Cook until done.”Now, that would be, if you will, the top green track, which doesn ’ t mean too much. But you might have to elaborate for me or for somebody who isn ’ t an expert, and say,”Cook at 380 degrees for 45 minutes.”And then for a real beginner, you would go down even further and elaborate more — say,”Open the oven, preheat, wait for the light to go out, open the door, don ’ t leave it open too long, put the penguin in and shut the door...”whatever. And that ’ s a much more elaborate one than you dribble back. That ’ s one kind of use of random access. And the other is where you want to explain the same thing in different ways. If you ’ re in a classroom situation and somebody asks a question, the last thing you do is repeat what you just said. You try and think of a different way of saying the same thing, or if you know the particular student and that student ’ s cognitive style, then you might say it in a way that you think would have a good impedance match with that student. There are all sorts of techniques you will use — and again, this is a different kind of branching. So, what I will show you is... it ’ s a rather boring book, but I ’ m afraid sometimes you have to do boring books because your sponsors aren ’ t necessarily interested in fiction and entertainment. And this is a book on how to repair a transmission. Now, I don ’ t even know what vintage the transmission is, but let me just show you very quickly some of it, and we ’ ll move on. Narrator : And continue to get descriptions for each of these chapters. Nicholas Negroponte : Now, this is his table of contents. Just a **picture** of the transmission, and as you rub your finger across the transmission it highlights the various parts. Narrator : When I find a chapter that I want to see, I just touch the text and the system will format pages for me to read. The words or phrases that are lit up in red are glossary words, so I can get a different definition by just touching the word, and the definition appears, superimposed over the illustration. NN : This is about the oil pan, or the oil filter and all that. This is relatively important because it sets the page... Narrator : This is another example of a page with glossary words highlighted in red. I can get a definition of these words just by touching them, and the definition will appear in the illustration corner. I can get back to the illustration, but in this case it ’ s not a single frame, but it ’ s actually a movie of someone coming into the frame and doing the repair that ’ s described in the text. The two-headed slider is a speed control that allows me to watch the movie at various speeds, in forward or reverse. And the movie is displayed as a full frame movie. I can go back to the beginning... and play the movie at full speed. Here ’ s another step-by-step procedure, only in this case — NN : Okay, this movie is... Everybody ’ s heard of sound-sync movies — this is text-sync movies, so as the movie plays, the text gets highlighted. We highlight the text as we go through the movie. Repairman :... Not too far out. Front poles, preferably. Don ’ t loosen them too far. If you loosen them too far, you ’ ll have a big mess. NN : I suspect that some of you might not even understand that language. OK. I ’ m at the third and last part of this, which I said I would make an attempt to at least give you some examples that may be more directly related to the world of entertainment. And of course, good education has got to be good entertainment, so my first example will be drawn from a very recent experiment that we ’ ve been doing — in this case, in Senegal — where we have tried to use personal computers as a pedagogical medium. But not as teaching machines at all ; the whole notion is to use this as an instrument where there is a complete reversal of roles — the child is, if you will, the teacher and the machine is the student — and the art of computer programming is a vehicle that sort of approximates thinking about thinking. But teaching kids programming per se is utterly irrelevant. And there are just a few slides I want to go through, but there ' s a story I ' d like to tell. And that was when, before we did this in any developing countries — we ' re doing it, in fact, in three developing countries right now : Pakistan, Colombia and Senegal — we did it in some pretty rough areas of New York City. And one child, whose name I ' ve forgotten, was about seven or eight years old, absolutely considered mentally handicapped — couldn ' t read, didn ' t even make it in the lowest section of the school ' s classes — and was pretty much not in school, though physically there. But did hang around the, quote,"computer room,"where there were quite a few computers, and learned this particular language called Logo — and learned it with great ease and found it a lot of **fun**, it was very interesting. And one day, by chance, some visitors from the NIE came by in their double-breasted suits looking at this setup, and none of the children who were normally there, except for this one child, were there. He was, and he said,"Let me show you how this works,"and they got an absolutely ingenuous, wonderful description of Logo. And the child was just zipping right through it, showing them all sorts of things until they asked him how to do something which he couldn ' t explain and so he flipped through the manual, found the explanation and typed the command and got it to do what they asked. They were delighted, and by the time it was time to go see the principal, whom they ' d actually come to see — not the computer room — they went upstairs and they said,"This is absolutely remarkable! That child was very articulate and showed us and even dealt with the things he couldn ' t do automatically with that manual. It was just absolutely fantastic."The principal said,"There ' s a dreadful mistake, because that child can ' t read. And you obviously have been hoodwinked or you ' ve talked about somebody else."And they all got up and they all went downstairs and the child was still there. And they did something very intelligent : they asked the child,"Can you read?"And the child said,"No, I can ' t."And then they said,"But wait a minute. You just looked through that manual and you found..."and he said,"Oh, but that ' s not reading."And so they said,"Well, what ' s reading then?"He says,"Well, reading is this junk they give me in little books to read. It ' s absolutely irrelevant, and I get nothing for it. But here, with a little bit of effort I get a lot of return."And it really meant something to the child. The child read beautifully, it turned out, and was really very competent. So it actually meant something. And that story has many other anecdotes that are similar, but wow. The key to the future of computers in education is right there, and it is : when does it mean something to a child? There is a myth, and it truly is a myth : we believe — and I ' m sure a lot of you believe in this room — that it is harder to read and write than it is to learn how to speak. And it ' s not, but we think speech —"My God, little children pick it up somehow, and by the age of two they ' re doing a mediocre job, and by three and four they ' re speaking reasonably well. And yet you ' ve got to go to school to learn how to read, and you have to sit in a classroom and somebody has to teach you. Hence, it must be harder."Well, it ' s not harder. What the truth is is that speaking has great value to a child ; the child can get a great deal by talking to you. Reading and writing is utterly useless. There is no reason for a child to read and write except blind faith, and that it ' s going to help you. So what happens is you go to school and people say,"Just believe me, you ' re going to like it. You ' re going to like reading,"and just read and read. On the other hand, you give a kid — a three-year-old kid — a computer and they type a little command and — Poof! — something happens. And all of a sudden... You may not call that reading and writing, but a certain bit of typing and reading stuff on the screen has a huge payoff, and it ' s a lot of **fun**. And in fact, it ' s a powerful educational instrument. Well, in Senegal we found that this was the traditional classroom : 120 kids — three per desk — one teacher, a little bit of chalk. This student was one of our first students, and it ' s the girl on the left leaning with her chalkboard, and she came... within two days — I want to show you the program she wrote, and remember her hairstyle. And that is the program she made. That ' s what meant something to her, is doing the hair pattern, and actually did it within two days — an hour each day — and found it was, to her, absolutely the most meaningful piece... But rooted in that, little did she know how much knowledge she was acquiring about geometry and just math and logic and all the rest. And again, I could talk for three hours about this subject. I will come to my last example and then quit. And my last example — as some of my former colleagues, whom I see in the room, can imagine what it will be. Yes, it is. It ' s our work — that was a while ago, and it still is my favorite project — of teleconferencing. And the reason it remains a favorite project is that we were asked to do a teleconferencing system where you had the following situation : you had five people at five different sites — they were known people — and you had to have these people in teleconference, such that each one was utterly convinced that the other four were physically present. Now, that is sufficiently zany that we would, obviously, jump to the bait, and we did. And the fact that we knew the people — we had to take a page out of the history of Walt Disney — we actually went so far as to build CRTs in the shapes of the people ' s faces. So if I wanted to call my friend Peter Sprague on the phone, my secretary would get his head out and bring it and set it on the desk, and that would be the TV used for the occasion. And it ' s uncanny : there ' s no way I can explain to you the amount of eye contact you get with that physical face projected on a 3D CRT of that sort. The next thing that we had to do is to persuade them that there needed to be spatial correspondence, which is straightforward, but again, it ' s something that didn ' t fall naturally out of a telecommunications or computing style of thinking ; it was a very, if you will, architectural or spatial concept. And that was to recognize that when you sit around the table, the actual location of the people becomes rather important. And when somebody gets up, in fact, to go answer a phone or use a bathroom or something, the empty seat becomes, if you will, that person. And you point frequently to the empty seat and you say,"He or she wouldn ' t agree,"and the empty chair is that person and the spatiality is **crucial**. So we said,"Well, these will be on round tables and the order around the table had to be the same, so that at my site, I would be, if you will, real and then at each other ' s site you ' d have these plastic heads. And the plastic heads, sometimes you want to project them. And there are a number of schemes, which I don ' t want to dwell on, but this is the one that we finally used where we projected onto rear screen material that was molded in the face — literally in the face of the person. And I ' ll show you one more slide, where this is actually made from something called a solid photograph and is the screen. Now, we track, on the person ' s head, the head motions — so we transmit with a video the head positions — and so this head moves in about two axes. So if I, all of a sudden, turn to the person to my left and start talking to that person, then at the person to my right ' s site, he ' ll see these two plastic heads talking to each other. And then if that person interrupts, then those two heads may turn. And it really is reconstructing, quite accurately, teleconferencing.

Text Sample 670: POS Dim 5 – 1994 – Score 4.00 – 1994/t002458.txt

Because I usually take the role of trying to explain to people how wonderful the new technologies that are coming along are going to be, and I thought that, since I was among friends here, I would tell you what I really think and try to look back and try to understand what is really going on here with these amazing jumps in technology that seem so fast that we can barely keep on top of it. So I ’ m going to start out by showing just one very boring technology slide. And then, so if you can just turn on the slide that ’ s on. This is just a random slide that I picked out of my file. What I want to show you is not so much the details of the slide, but the general form of it. This happens to be a slide of some analysis that we were doing about the power of RISC microprocessors versus the power of local area networks. And the interesting thing about it is that this slide, like so many technology slides that we ’ re used to, is a sort of a straight line on a semi-log **curve**. In other words, every step here represents an order of magnitude in performance scale. And this is a new thing that we talk about technology on semi-log **curves**. Something really weird is going on here. And that ’ s basically what I ’ m going to be talking about. So, if you could bring up the lights. If you could bring up the lights higher, because I ’ m just going to use a piece of paper here. Now why do we draw technology **curves** in semi-log **curves**? Well the answer is, if I drew it on a normal **curve** where, let ’ s say, this is years, this is time of some sort, and this is whatever measure of the technology that I ’ m trying to graph, the graphs look sort of silly. They sort of go like this. And they don ’ t tell us much. Now if I graph, for instance, some other technology, say transportation technology, on a semi-log **curve**, it would look very stupid, it would look like a flat line. But when something like this happens, things are qualitatively changing. So if transportation technology was moving along as fast as microprocessor technology, then the day after tomorrow, I would be able to get in a taxi cab and be in Tokyo in 30 seconds. It ’ s not moving like that. And there ’ s nothing precedented in the history of technology development of this kind of self- feeding growth where you go by orders of magnitude every few years. Now the question that I ’ d like to ask is, if you look at these exponential **curves**, they don ’ t go on forever. Things just can ’ t possibly keep changing as fast as they are. One of two things is going to happen. Either it ’ s going to turn into a sort of classical S-curve like this, until something totally different comes along, or maybe it ’ s going to do this. That ’ s about all it can do. Now I ’ m an optimist, so I sort of think it ’ s probably going to do something like that. If so, that means that what we ’ re in the middle of right now is a transition. We ’ re sort of on this line in a transition from the way the world used to be to some new way that the world is. And so what I ’ m trying to ask, what I ’ ve been asking myself, is what ’ s this new way that the world is? What ’ s that new state that the world is heading toward? Because the transition seems very, very confusing when we ’ re right in the middle of it. Now when I was a kid growing up, the future was kind of the year 2000, and people used to talk about what would happen in the year 2000. Now here ’ s a conference in which people talk about the future, and you notice that the future is still at about the year 2000. It ’ s about as far as we go out. So in other words, the future has kind of been shrinking one year per year for my whole lifetime. Now I think that the reason is because we all feel that something ’ s happening there. That transition is happening. We can all sense it. And we know that it just doesn ’ t make too much sense to think out 30, 50 years because everything ’ s going to be so different that a simple extrapolation of what we ’ re doing just doesn ’ t make any sense at all. So what I would like to talk about is what that could be, what that transition could be that we ’ re going through. Now in order to do that I ’ m going to have to talk about a bunch of stuff that really has nothing to do with technology and computers. Because I think the only way to understand this is to really step back and take a long time scale look at things. So the time scale that I would like to look at this on is the time scale of life on Earth. So I think this **picture** makes sense if you look at it a few billion years at a time. So if you go back about two and a half billion years, the Earth was this big, sterile hunk of rock with a lot of chemicals floating around on it. And if you look at the way that the chemicals got organized, we begin to get a pretty good idea of how they do it. And I think that there ' s theories that are beginning to understand about how it started with RNA, but I ' m going to tell a sort of simple story of it, which is that, at that time, there were little drops of oil floating around with all kinds of different recipes of chemicals in them. And some of those drops of oil had a particular combination of chemicals in them which caused them to incorporate chemicals from the outside and grow the drops of oil. And those that were like that started to split and divide. And those were the most primitive forms of cells in a sense, those little drops of oil. But now those drops of oil weren ' t really alive, as we say it now, because every one of them was a little random recipe of chemicals. And every time it divided, they got sort of unequal division of the chemicals within them. And so every drop was a little bit different. In fact, the drops that were different in a way that caused them to be better at incorporating chemicals around them, grew more and incorporated more chemicals and divided more. So those tended to live longer, get expressed more. Now that ' s sort of just a very simple chemical form of life, but when things got interesting was when these drops learned a trick about **abstraction**. Somehow by ways that we don ' t quite understand, these little drops learned to write down information. They learned to record the information that was the recipe of the cell onto a particular kind of chemical called DNA. So in other words, they worked out, in this mindless sort of evolutionary way, a form of writing that let them write down what they were, so that that way of writing it down could get copied. The amazing thing is that that way of writing seems to have stayed steady since it evolved two and a half billion years ago. In fact the recipe for us, our genes, is exactly that same code and that same way of writing. In fact, every living creature is written in exactly the same set of letters and the same code. In fact, one of the things that I did just for amusement purposes is we can now write things in this code. And I ' ve got here a little 100 micrograms of white powder, which I try not to let the security people see at airports. But this has in it — what I did is I took this code — the code has standard letters that we use for symbolizing it — and I wrote my business card onto a piece of DNA and amplified it 10 to the 22 times. So if anyone would like a hundred million copies of my business card, I have plenty for everyone in the room, and, in fact, everyone in the world, and it ' s right here. If I had really been a egotist, I would have put it into a virus and released it in the room. So what was the next step? Writing down the DNA was an interesting step. And that caused these cells — that kept them happy for another billion years. But then there was another really interesting step where things became completely different, which is these cells started exchanging and communicating information, so that they began to get communities of cells. I don ' t know if you know this, but bacteria can actually exchange DNA. Now that ' s why, for instance, antibiotic resistance has evolved. Some bacteria figured out how to stay away from penicillin, and it went around sort of creating its little DNA information with other bacteria, and now we have a lot of bacteria that are resistant to penicillin, because bacteria communicate. Now what this communication allowed was communities to form that, in some sense, were in the same boat together ; they were synergistic. So they survived or they failed together, which means that if a community was very successful, all the individuals in that community were repeated more and they were favored by evolution. Now the transition point happened when these communities got so close that, in fact, they got together and decided to write down the whole recipe for the community together on one string of DNA. And so the next stage that ’ s interesting in life took about another billion years. And at that stage, we have multi-cellular communities, communities of lots of different types of cells, working together as a single organism. And in fact, we ’ re such a multi- cellular community. We have lots of cells that are not out for themselves anymore. Your skin cell is really useless without a heart cell, muscle cell, a brain cell and so on. So these communities began to evolve so that the interesting level on which evolution was taking place was no longer a cell, but a community which we call an organism. Now the next step that happened is within these communities. These communities of cells, again, began to abstract information. And they began building very special structures that did nothing but process information within the community. And those are the neural structures. So neurons are the information processing apparatus that those communities of cells built up. And in fact, they began to get specialists in the community and special structures that were responsible for recording, understanding, learning information. And that was the brains and the nervous system of those communities. And that gave them an evolutionary advantage. Because at that point, an individual — learning could happen within the time span of a single organism, instead of over this evolutionary time span. So an organism could, for instance, learn not to eat a certain kind of fruit because it tasted bad and it got sick last time it ate it. That could happen within the lifetime of a single organism, whereas before they ’ d built these special information processing structures, that would have had to be learned evolutionarily over hundreds of thousands of years by the individuals dying off that ate that kind of fruit. So that nervous system, the fact that they built these special information structures, tremendously sped up the whole process of evolution. Because evolution could now happen within an individual. It could happen in learning time scales. But then what happened was the individuals worked out, of course, tricks of communicating. And for example, the most sophisticated version that we ’ re aware of is human language. It ’ s really a pretty amazing invention if you think about it. Here I have a very complicated, messy, confused idea in my head. I ’ m sitting here making grunting sounds basically, and hopefully constructing a similar messy, confused idea in your head that bears some analogy to it. But we ’ re taking something very complicated, turning it into sound, sequences of sounds, and producing something very complicated in your brain. So this allows us now to begin to start functioning as a single organism. And so, in fact, what we ’ ve done is we, humanity, have started abstracting out. We ’ re going through the same levels that multi-cellular organisms have gone through — abstracting out our methods of recording, presenting, processing information. So for example, the invention of language was a tiny step in that direction. Telephony, computers, videotapes, CD-ROMs and so on are all our specialized mechanisms that we ’ ve now built within our society for handling that information. And it all connects us together into something that is much bigger and much faster and able to evolve than what we were before. So now, evolution can take place on a scale of microseconds. And you saw Ty ’ s little evolutionary example where he sort of did a little bit of evolution on the Convolution program right before your eyes. So now we ’ ve speeded up the time scales once again. So the first steps of the story that I told you about took a billion years a piece. And the next steps, like nervous systems and brains, took a few hundred million years. Then the next steps, like language and so on, took less than a million years. And these next steps, like electronics, seem to be taking only a few decades. The process is feeding on itself and becoming, I guess, autocatalytic is the word for it — when something reinforces its rate of change. The more it changes, the faster it changes. And I think that that ' s what we ' re seeing here in this explosion of **curve**. We ' re seeing this process feeding back on itself. Now I design computers for a living, and I know that the mechanisms that I use to design computers would be impossible without recent advances in computers. So right now, what I do is I design objects at such complexity that it ' s really impossible for me to design them in the traditional sense. I don ' t know what every transistor in the connection machine does. There are billions of them. Instead, what I do and what the designers at Thinking Machines do is we think at some level of **abstraction** and then we hand it to the machine and the machine takes it beyond what we could ever do, much farther and faster than we could ever do. And in fact, sometimes it takes it by methods that we don ' t quite even understand. One method that ' s particularly interesting that I ' ve been using a lot lately is evolution itself. So what we do is we put inside the machine a process of evolution that takes place on the microsecond time scale. So for example, in the most extreme cases, we can actually evolve a program by starting out with random sequences of instructions. Say,"Computer, would you please make a hundred million random sequences of instructions. Now would you please run all of those random sequences of instructions, run all of those programs, and pick out the ones that came closest to doing what I wanted."So in other words, I define what I wanted. Let ' s say I want to sort numbers, as a simple example I ' ve done it with. So find the programs that come closest to sorting numbers. So of course, random sequences of instructions are very unlikely to sort numbers, so none of them will really do it. But one of them, by luck, may put two numbers in the right order. And I say,"Computer, would you please now take the 10 percent of those random sequences that did the best job. Save those. Kill off the rest. And now let ' s reproduce the ones that sorted numbers the best. And let ' s reproduce them by a process of recombination analogous to sex."Take two programs and they produce children by exchanging their subroutines, and the children inherit the traits of the subroutines of the two programs. So I ' ve got now a new generation of programs that are produced by combinations of the programs that did a little bit better job. Say,"Please repeat that process."Score them again. Introduce some mutations perhaps. And try that again and do that for another generation. Well every one of those generations just takes a few milliseconds. So I can do the equivalent of millions of years of evolution on that within the computer in a few minutes, or in the complicated cases, in a few hours. At the end of that, I end up with programs that are absolutely perfect at sorting numbers. In fact, they are programs that are much more efficient than programs I could have ever written by hand. Now if I look at those programs, I can ' t tell you how they work. I ' ve tried looking at them and telling you how they work. They ' re obscure, weird programs. But they do the job. And in fact, I know, I ' m very confident that they do the job because they come from a line of hundreds of thousands of programs that did the job. In fact, their life depended on doing the job. I was riding in a 747 with Marvin Minsky once, and he pulls out this card and says,"Oh look. Look at this. It says, ' This plane has hundreds of thousands of tiny parts working together to make you a safe flight. ' Doesn ' t that make you feel confident?"In fact, we know that the engineering process doesn ' t work very well when it gets complicated. So we ' re beginning to depend on computers to do a process that ' s very different than engineering. And it lets us produce things of much more complexity than normal engineering lets us produce. And yet, we don ' t quite understand the options of it. So in a sense, it ' s getting ahead of us. We ' re now using those programs to make much faster computers so that we ' ll be able to run this process much faster.

So it ’ s feeding back on itself. The thing is becoming faster and that ’ s why I think it seems so confusing. Because all of these technologies are feeding back on themselves. We ’ re taking off. And what we are is we ’ re at a point in time which is analogous to when single- celled organisms were turning into multi-celled organisms. So we ’ re the amoebas and we can ’ t quite figure out what the **hell** this thing is we ’ re creating. We ’ re right at that point of transition. But I think that there really is something coming along after us. I think it ’ s very haughty of us to think that we ’ re the end product of evolution. And I think all of us here are a part of producing whatever that next thing is. So lunch is coming along, and I think I will stop at that point, before I get selected out.

Text Sample 671: POS Dim 5 – 2005 – Score 10.00 – 2005/t000435.txt

It is a thrill to be here at a conference that ’ s devoted to”Inspired by Nature”â you can imagine. And I ’ m also thrilled to be in the foreplay section. Did you notice this section is foreplay? Because I get to talk about one of my favorite critters, which is the Western Grebe. You haven ’ t lived until you ’ ve seen these guys do their courtship dance. I was on Bowman Lake in Glacier National Park, which is a long, skinny lake with sort of mountains upside down in it, and my partner and I have a rowing shell. And so we were rowing, and one of these Western Grebes came along. And what they do for their courtship dance is, they go together, the two of them, the two mates, and they begin to run underwater. They paddle faster, and faster, and faster, until they ’ re going so fast that they literally lift up out of the water, and they ’ re standing upright, sort of paddling the top of the water. And one of these Grebes came along while we were rowing. And so we ’ re in a skull, and we ’ re moving really, really quickly. And this Grebe, I think, sort of, mistaked us for a prospect, and started to run along the water next to us, in a courtship dance â for miles. It would stop, and then start, and then stop, and then start. Now that is foreplay. I came this close to changing species at that moment. Obviously, life can teach us something in the entertainment section. Life has a lot to teach us. But what I ’ d like to talk about today is what life might teach us in technology and in design. What ’ s happened since the book came out â the book was mainly about research in biomimicry â and what ’ s happened since then is **architects**, designers, engineers â people who make our world â have started to call and say, we want a biologist to sit at the design table to help us, in real time, become inspired. Or â and this is the **fun** part for me â we want you to take us out into the natural world. We ’ ll come with a design challenge and we find the champion adapters in the natural world, who might inspire us. So this is a **picture** from a Galapagos trip that we took with some wastewater treatment engineers ; they purify wastewater. And some of them were very resistant, actually, to being there. What they said to us at first was, you know, we already do biomimicry. We use bacteria to **clean** our water. And we said, well, that ’ s not exactly being inspired by nature. That ’ s bioprocessing, you know ; that ’ s bio-assisted technology : using an organism to do your wastewater treatment is an old, old technology called”domestication.”This is learning something, learning an idea, from an organism and then applying it. And so they still weren ’ t getting it. So we went for a walk on the beach and I said, well, give me one of your big problems. Give me a design challenge, sustainability speed bump, that ’ s keeping you from being sustainable. And they said scaling, which is the build-up of minerals inside of pipes. And they said, you know what happens is, mineral â just like at your house â mineral builds up. And then the aperture closes, and we have to flush the pipes with toxins, or we have to dig them up. So if we had some way to stop this scaling â and so I picked up some shells on the beach. And I asked them, what is scaling? What ’ s inside your pipes? And they said, calcium carbonate. And I said, that ’ s what this is ; this is calcium carbonate. And they didn ’ t know that. They didn ’ t know that what a seashell is, it ’ s templated by proteins, and then ions from the seawater crystallize in place to create a shell. So the same sort of a process, without the proteins, is happening on the inside of their pipes. They didn ’ t know. This is not for lack of information ; it ’ s a lack of integration. You know, it ’ s a silo, people in silos. They didn ’ t know that the same thing was happening. So one of them thought about it and said, OK, well, if this is just crystallization that happens automatically out of seawater â self-assembly â then why aren ’ t shells infinite in size? What stops the scaling? Why don ’ t they just keep on going? And I said, well, in the same way that they exude a protein and it starts the crystallization â and then they all sort of leaned in â they let go of a protein that stops the crystallization. It literally adheres to the growing face of the crystal. And, in fact, there is a product called TPA that ’ s mimicked that protein â that stop-protein â and it ’ s an environmentally friendly way to stop scaling in pipes. That changed everything. From then on, you could not get these engineers back in the boat. The first day they would take a hike, and it was, click, click, click, click. Five minutes later they were back in the boat. We ’ re done. You know, I ’ ve seen that island. After this, they were crawling all over. They would snorkel for as long as we would let them snorkel. What had happened was that they realized that there were organisms out there that had already solved the problems that they had spent their careers trying to solve. Learning about the natural world is one thing ; learning from the natural world â that ’ s the switch. That ’ s the profound switch. What they realized was that the answers to their questions are everywhere ; they just needed to change the lenses with which they saw the world. 3. 8 billion years of field-testing. 10 to 30 â Craig Venter will probably tell you ; I think there ’ s a lot more than 30 million â well-adapted solutions. The important thing for me is that these are solutions solved in context. And the context is the Earth â the same context that we ’ re trying to solve our problems in. So it ’ s the conscious emulation of life ’ s genius. It ’ s not slavishly mimicking â although Al is trying to get the hairdo going â it ’ s not a slavish mimicry ; it ’ s taking the design principles, the genius of the natural world, and learning something from it. Now, in a group with so many IT people, I do have to mention what I ’ m not going to talk about, and that is that your field is one that has learned an enormous amount from living things, on the software side. So there ’ s computers that protect themselves, like an immune system, and we ’ re learning from gene regulation and biological development. And we ’ re learning from neural nets, genetic algorithms, evolutionary computing. That ’ s on the software side. But what ’ s interesting to me is that we haven ’ t looked at this, as much. I mean, these machines are really not very high tech in my estimation in the sense that there ’ s dozens and dozens of carcinogens in the water in Silicon Valley. So the hardware is not at all up to snuff in terms of what life would call a success. So what can we learn about making â not just computers, but everything? The plane you came in, cars, the seats that you ’ re sitting on. How do we redesign the world that we make, the human-made world? More importantly, what should we ask in the next 10 years? And there ’ s a lot of cool technologies out there that life has. What ’ s the syllabus? Three questions, for me, are key. How does life make things? This is the opposite ; this is how we make things. It ’ s called heat, beat and treat â that ’ s what material scientists call it. And it ’ s carving things down from the top, with 96 percent waste left over and only 4 percent product. You heat it up ; you beat it with high pressures ; you use chemicals. OK. Heat, beat and treat. Life can ’ t afford to do that. How does life make things? How does life make the most of things? That ’ s a geranium pollen. And its shape is what gives it the function of being able to tumble through air so easily. Look at that shape. Life adds information to matter. In other words : structure. It gives it information. By adding information to matter, it gives it a function that ’ s different than without that structure. And thirdly, how does life make things disappear into systems? Because life doesn ’ t really deal in things ; there are no things in the natural world divorced from their systems. Really quick syllabus. As I ’ m reading more and more now, and following the story, there are some amazing things coming up in the biological sciences. And at the same time, I ’ m listening to a lot of businesses and finding what their sort of grand challenges are. The two groups are not talking to each other. At all. What in the world of biology might be helpful at this juncture, to get us through this sort of evolutionary knothole that we ’ re in? I ’ m going to try to go through 12, really quickly. One that ’ s exciting to me is self-assembly. Now, you ’ ve heard about this in terms of nanotechnology. Back to that shell : the shell is a self-assembling material. On the lower left there is a **picture** of mother of pearl forming out of seawater. It ’ s a layered structure that ’ s mineral and then polymer, and it makes it very, very tough. It ’ s twice as tough as our high-tech ceramics. But what ’ s really interesting : unlike our ceramics that are in kilns, it happens in seawater. It happens near, in and near, the organism ’ s body. This is Sandia National Labs. A guy named Jeff Brinker has found a way to have a self- assembling coding process. Imagine being able to make ceramics at room temperature by simply dipping something into a liquid, lifting it out of the liquid, and having evaporation force the molecules in the liquid together, so that they jigsaw together in the same way as this crystallization works. Imagine making all of our hard materials that way. Imagine spraying the precursors to a PV cell, to a solar cell, onto a **roof**, and having it self- assemble into a layered structure that harvests light. Here ’ s an interesting one for the IT world : bio-silicon. This is a diatom, which is made of silicates. And so silicon, which we make right now â it ’ s part of our carcinogenic problem in the manufacture of our chips â this is a bio-mineralization process that ’ s now being mimicked. This is at UC Santa Barbara. Look at these diatoms. This is from Ernst Haeckel ’ s work. Imagine being able to â and, again, it ’ s a templated process, and it solidifies out of a liquid process â imagine being able to have that sort of structure coming out at room temperature. Imagine being able to make perfect lenses. On the left, this is a brittle star ; it ’ s covered with lenses that the people at Lucent Technologies have found have no distortion whatsoever. It ’ s one of the most distortion-free lenses we know of. And there ’ s many of them, all over its entire body. What ’ s interesting, again, is that it self-assembles. A woman named Joanna Aizenberg, at Lucent, is now learning to do this in a low- temperature process to create these sort of lenses. She ’ s also looking at fiber optics. That ’ s a sea sponge that has a fiber optic. Down at the very base of it, there ’ s fiber optics that work better than ours, actually, to move light, but you can tie them in a knot ; they ’ re incredibly flexible. Here ’ s another big idea : CO2 as a feedstock. A guy named Geoff Coates, at Cornell, said to himself, you know, plants do not see CO2 as the biggest poison of our time. We see it that way. Plants are busy making long chains of starches and glucose, right, out of CO2. He ’ s found a way â he ’ s found a catalyst â and he ’ s found a way to take CO2 and make it into polycarbonates. Biodegradable plastics out of CO2 â how plant-like. Solar transformations : the most exciting one. There are people who are mimicking the energy-harvesting device inside of purple bacterium, the people at ASU. Even more interesting, lately, in the last couple of weeks, people have seen that there ' s an enzyme called hydrogenase that ' s able to evolve hydrogen from proton and electrons, and is able to take hydrogen up â basically what ' s happening in a fuel cell, in the anode of a fuel cell and in a reversible fuel cell. In our fuel cells, we do it with platinum ; life does it with a very, very common iron. And a team has now just been able to mimic that hydrogen-juggling hydrogenase. That ' s very exciting for fuel cells â to be able to do that without platinum. Power of shape : here ' s a whale. We ' ve seen that the fins of this whale have tubercles on them. And those little bumps actually increase efficiency in, for instance, the edge of an airplane â increase efficiency by about 32 percent. Which is an amazing fossil fuel savings, if we were to just put that on the edge of a wing. Color without pigments : this peacock is creating color with shape. Light comes through, it bounces back off the layers ; it ' s called thin- **film** interference. Imagine being able to self-assemble products with the last few layers playing with light to create color. Imagine being able to create a shape on the outside of a surface, so that it ' s self-cleaning with just water. That ' s what a leaf does. See that up-close **picture**? That ' s a ball of water, and those are dirt particles. And that ' s an up-close **picture** of a lotus leaf. There ' s a company making a product called Lotusan, which mimics â when the building facade paint dries, it mimics the bumps in a self-cleaning leaf, and rainwater **cleans** the building. Water is going to be our big, grand challenge : quenching thirst. Here are two organisms that pull water. The one on the left is the Namibian beetle pulling water out of fog. The one on the right is a pill bug â pulls water out of air, does not drink fresh water. Pulling water out of Monterey fog and out of the sweaty air in Atlanta, before it gets into a building, are key technologies. Separation technologies are going to be extremely important. What if we were to say, no more hard rock mining? What if we were to separate out **metals** from waste streams, small amounts of **metals** in water? That ' s what microbes do ; they chelate **metals** out of water. There ' s a company here in San Francisco called MR3 that is embedding mimics of the microbes ' molecules on filters to mine waste streams. Green chemistry is chemistry in water. We do chemistry in organic solvents. This is a **picture** of the spinnerets coming out of a spider and the silk being formed from a spider. Isn ' t that beautiful? Green chemistry is replacing our industrial chemistry with nature ' s recipe book. It ' s not easy, because life uses only a subset of the elements in the periodic table. And we use all of them, even the toxic ones. To figure out the elegant recipes that would take the small subset of the periodic table, and create miracle materials like that cell, is the task of green chemistry. Timed degradation : packaging that is good until you don ' t want it to be good anymore, and dissolves on cue. That ' s a mussel you can find in the waters out here, and the threads holding it to a rock are timed ; at exactly two years, they begin to dissolve. Healing : this is a good one. That little guy over there is a tardigrade. There is a problem with vaccines around the world not getting to patients. And the reason is that the refrigeration somehow gets broken ; what ' s called the"cold chain"gets broken. A guy named Bruce Rosner looked at the tardigrade â which dries out completely, and yet stays alive for months and months and months, and is able to regenerate itself. And he found a way to dry out vaccines â encase them in the same sort of sugar capsules as the tardigrade has within its cells â meaning that vaccines no longer need to be refrigerated. They can be put in a glove compartment, OK. Learning from organisms. This is a session about water â learning about organisms that can do without water, in order to create a vaccine that lasts and lasts and lasts without refrigeration. I ' m not going to get to 12. But what I am going to do is tell you that the most important thing, besides all of these adaptations, is the fact that these organisms have figured out a way to do the amazing things they do while taking care of the place that ' s going to take care of their offspring. When they ' re involved in foreplay, they ' re thinking about something very, very important â and that ' s having their genetic material remain, 10, 000 generations from now. And that means finding a way to do what they do without destroying the place that ' ll take care of their offspring. That ' s the biggest design challenge. Luckily, there are millions and millions of geniuses willing to gift us with their best ideas. Good luck having a conversation with them. Thank you. Chris Anderson : Talk about foreplay, I â we need to get to 12, but really quickly. Janine Benyus : Oh really? CA : Yeah. Just like, you know, like the 10-second version of 10, 11 and 12. Because we just â your slides are so gorgeous, and the ideas are so big, I can ' t stand to let you go down without seeing 10, 11 and 12. JB : OK, put this â OK, I ' ll just hold this thing. OK, great. OK, so that ' s the healing one. Sensing and responding : feedback is a huge thing. This is a locust. There can be 80 million of them in a square kilometer, and yet they don ' t collide with one another. And yet we have 3. 6 million car collisions a year. Right. There ' s a person at Newcastle who has figured out that it ' s a very large neuron. And she ' s actually figuring out how to make a collision-avoidance circuitry based on this very large neuron in the locust. This is a huge and important one, number 11. And that ' s the growing fertility. That means, you know, net fertility farming. We should be growing fertility. And, oh yes â we get food, too. Because we have to grow the capacity of this planet to create more and more opportunities for life. And really, that ' s what other organisms do as well. In ensemble, that ' s what whole ecosystems do : they create more and more opportunities for life. Our farming has done the opposite. So, farming based on how a prairie builds soil, ranching based on how a native ungulate herd actually increases the health of the range, even wastewater treatment based on how a marsh not only **cleans** the water, but creates incredibly sparkling productivity. This is the simple design brief. I mean, it looks simple because the system, over 3. 8 billion years, has worked this out. That is, those organisms that have not been able to figure out how to enhance or sweeten their places, are not around to tell us about it. That ' s the twelfth one. Life â and this is the secret trick ; this is the magic trick â life creates conditions conducive to life. It builds soil ; it **cleans** air ; it **cleans** water ; it mixes the cocktail of **gases** that you and I need to live. And it does that in the middle of having great foreplay and meeting their needs. So it ' s not mutually exclusive. We have to find a way to meet our needs, while making of this place an Eden. CA : Janine, thank you so much.

Text Sample 672: POS Dim 5 – 2005 – Score 10.00 – 2005/t000418.txt

In 1962, with Rachel Carson ' s"Silent Spring,"I think for people like me in the world of the making of things, the canary in the mine wasn ' t singing. And so the question that we might not have birds became kind of fundamental to those of us wandering around looking for the meadowlarks that seemed to have all disappeared. And the question was, were the birds singing? Now, I ' m not a scientist, that ' ll be really clear. But, you know, we ' ve just come from this discussion of what a bird might be. What is a bird? Well, in my world, this is a rubber duck. It comes in California with a warning —"This product contains chemicals known by the State of California to cause cancer and birth defects or other reproductive harm."This is a bird. What kind of culture would produce a product of this kind and then label it and sell it to children? I think we have a design problem. Someone heard the six hours of talk that I gave called"The Monticello Dialogues"on NPR, and sent me this as a thank you note —"We realize that design is a signal of intention, but it also has to occur within a world, and we have to understand that world in order to imbue our designs with inherent intelligence, and so as we look back at the basic state of affairs in which we design, we, in a way, need to go to the primordial condition to understand the operating system and the frame conditions of a planet, and I think the exciting part of that is the good news that ' s there, because the news is the news of abundance, and not the news of limits, and I think as our culture tortures itself now with tyrannies and concerns over limits and fear, we can add this other dimension of abundance that is coherent, driven by the sun, and start to imagine what that would be like to share."That was a nice thing to get. That was one sentence. Henry James would be proud. This is — I put it down at the **bottom**, but that was extemporaneous, obviously. The fundamental issue is that, for me, design is the first signal of human intentions. So what are our intentions, and what would our intentions be — if we wake up in the morning, we have designs on the world — well, what would our intention be as a species now that we ' re the dominant species? And it ' s not just stewardship and dominion debate, because really, dominion is implicit in stewardship — because how could you dominate something you had killed? And stewardship ' s implicit in dominion, because you can ' t be steward of something if you can ' t dominate it. So the question is, what is the first question for designers? Now, as guardians — let ' s say the state, for example, which reserves the right to kill, the right to be duplicitous and so on — the question we ' re asking the guardian at this point is are we meant, how are we meant, to secure local societies, create world peace and save the environment? But I don ' t know that that ' s the common debate. Commerce, on the other hand, is relatively quick, essentially creative, highly effective and efficient, and fundamentally honest, because we can ' t exchange value for very long if we don ' t trust each other. So we use the tools of commerce primarily for our work, but the question we bring to it is, how do we love all the children of all species for all time? And so we start our designs with that question. Because what we realize today is that modern culture appears to have adopted a strategy of tragedy. If we come here and say,"Well, I didn ' t intend to cause global warming on the way here,"and we say,"That ' s not part of my plan,"then we realize it ' s part of our de facto plan. Because it ' s the thing that ' s happening because we have no other plan. And I was at the White House for President Bush, meeting with every federal department and agency, and I pointed out that they appear to have no plan. If the end game is global warming, they ' re doing great. If the end game is mercury toxification of our children downwind of coal fire plants as they scuttled the Clean Air Act, then I see that our education programs should be explicitly defined as,"Brain death for all children. No child left behind."So, the question is, how many federal officials are ready to move to Ohio and Pennsylvania with their families? So if you don ' t have an endgame of something delightful, then you ' re just moving chess pieces around, if you don ' t know you ' re taking the king. So perhaps we could develop a strategy of change, which requires humility. And in my business as an **architect**, it ' s unfortunate the word"humility"and the word"**architect**"have not appeared in the same paragraph since"The Fountainhead."So if anybody here has trouble with the concept of design humility, reflect on this — it took us 5, 000 years to put wheels on our luggage. So, as Kevin Kelly pointed out, there is no endgame. There is an infinite game, and we ' re playing in that infinite game. And so we call it"cradle to cradle,"and our goal is very simple. This is what I presented to the White House. Our goal is a delightfully diverse, safe, healthy and just world, with **clean** air, **clean** water, soil and power — economically, equitably, ecologically and elegantly enjoyed, period. What don ’ t you like about this? Which part of this don ’ t you like? So we realized we want full diversity, even though it can be difficult to remember what De Gaulle said when asked what it was like to be President of France. He said,”What do you think it ’ s like trying to run a country with 400 kinds of cheese?”But at the same time, we realize that our products are not safe and healthy. So we ’ ve designed products and we analyzed chemicals down to the parts per million. This is a baby blanket by Pendleton that will give your child nutrition instead of Alzheimer ’ s later in life. We can ask ourselves, what is justice, and is justice blind, or is justice blindness? And at what point did that uniform turn from white to black? Water has been declared a human right by the United Nations. Air quality is an obvious thing to anyone who breathes. Is there anybody here who doesn ’ t breathe? **Clean** soil is a critical problem — the nitrification, the dead zones in the Gulf of Mexico. A fundamental issue that ’ s not being addressed. We ’ ve seen the first form of solar energy that ’ s beat the hegemony of fossil fuels in the form of wind here in the Great Plains, and so that hegemony is leaving. And if we remember Sheikh Yamani when he formed OPEC, they asked him,”When will we see the end of the age of oil?”I don ’ t know if you remember his answer, but it was,”The Stone Age didn ’ t end because we ran out of stones.”We see that companies acting ethically in this world are outperforming those that don ’ t. We see the flows of materials in a rather terrifying prospect. This is a hospital monitor from Los Angeles, sent to China. This woman will expose herself to toxic phosphorous, release four pounds of toxic lead into her childrens ’ environment, which is from copper. On the other hand, we see great signs of hope. Here ’ s Dr. Venkataswamy in India, who ’ s figured out how to do mass-produced health. He has given eyesight to two million people for free. We see in our material flows that car steels don ’ t become car steel again because of the contaminants of the coatings — bismuth, antimony, copper and so on. They become building steel. On the other hand, we ’ re working with Berkshire Hathaway, Warren Buffett and Shaw Carpet, the largest carpet company in the world. We ’ ve developed a carpet that is continuously recyclable, down to the parts per million. The upper is Nylon 6 that can go back to caprolactam, the **bottom**, a polyolephine — infinitely recyclable thermoplastic. Now if I was a bird, the building on my left is a liability. The building on my right, which is our corporate campus for The Gap with an ancient meadow, is an asset — its nesting grounds. Here ’ s where I come from. I grew up in Hong Kong, with six million people in 40 square miles. During the dry season, we had four hours of water every fourth day. And the relationship to landscape was that of farmers who have been farming the same piece of ground for 40 centuries. You can ’ t farm the same piece of ground for 40 centuries without understanding nutrient flow. My childhood summers were in the Puget Sound of Washington, among the first growth and big growth. My grandfather had been a lumberjack in the Olympics, so I have a lot of tree karma I am working off. I went to Yale for graduate school, studied in a building of this style by Le Corbusier, affectionately known in our business as Brutalism. If we look at the world of architecture, we see with Mies ’ 1928 tower for Berlin, the question might be,”Well, where ’ s the sun?”And this might have worked in Berlin, but we built it in Houston, and the windows are all closed. And with most products appearing not to have been designed for indoor use, this is actually a vertical **gas** chamber. When I went to Yale, we had the first energy crisis, and I was designing the first solar-heated house in Ireland as a student, which I then built — which would give you a sense of my ambition. And Richard Meier, who was one of my teachers, kept coming over to my desk to give me criticism, and he would say,”Bill, you ’ ve got to understand- — solar energy has nothing to do with architecture.”I guess he didn ’ t read Vitruvius. In 1984, we did the first so- called”green office”in America for Environmental Defense. We started asking manufacturers what were in their materials. They said,”They ’ re proprietary, they ’ re legal, go away.”The only indoor quality work done in this country at that time was sponsored by R. J. Reynolds Tobacco Company, and it was to prove there was no danger from secondhand smoke in the workplace. So, all of a sudden, here I am, graduating from high school in 1969, and this happens, and we realize that”away”went away. Remember we used to throw things away, and we ’ d point to away? And yet, NOAA has now shown us, for example — you see that little blue thing above Hawaii? That ’ s the Pacific Gyre. It was recently dragged for plankton by scientists, and they found six times as much plastic as plankton. When asked, they said,”It ’ s kind of like a giant toilet that doesn ’ t flush.”Perhaps that ’ s away. So we ’ re looking for the design rules of this — this is the highest biodiversity of trees in the world, Irian Jaya, 259 species of tree, and we described this in the book,”Cradle to Cradle.”The book itself is a polymer. It is not a tree. That ’ s the name of the first chapter —”This Book is Not a Tree.”Because in poetics, as Margaret Atwood pointed out,”we write our history on the skin of fish with the blood of bears.”And with so much polymer, what we really need is technical nutrition, and to use something as elegant as a tree — imagine this design assignment : Design something that makes oxygen, sequesters carbon, fixes nitrogen, distills water, accrues solar energy as fuel, makes complex sugars and food, creates microclimates, changes colors with the seasons and self-replicates. Well, why don ’ t we knock that down and write on it? So, we ’ re looking at the same criteria as most people — you know, can I afford it? Does it work? Do I like it? We ’ re adding the Jeffersonian agenda, and I come from Charlottesville, where I ’ ve had the privilege of living in a house designed by Thomas Jefferson. We ’ re adding life, liberty and the pursuit of happiness. Now if we look at the word”competition,”I ’ m sure most of you ’ ve used it. You know, most people don ’ t realize it comes from the Latin competere, which means strive together. It means the way Olympic athletes train with each other. They get fit together, and then they compete. The Williams sisters compete — one wins Wimbledon. So we ’ ve been looking at the idea of competition as a way of cooperating in order to get fit together. And the Chinese government has now — I work with the Chinese government now — has taken this up. We ’ re also looking at survival of the fittest, not in just competition terms in our modern context of destroy the other or beat them to the ground, but really to fit together and build niches and have growth that is good. Now most environmentalists don ’ t say growth is good, because, in our lexicon, asphalt is two words : assigning blame. But if we look at asphalt as our growth, then we realize that all we ’ re doing is destroying the planetary ’ s fundamental underlying operating system. So when we see E equals mc squared come along, from a poet ’ s perspective, we see energy as physics, chemistry as mass, and all of a sudden, you get this biology. And we have plenty of energy, so we ’ ll solve that problem, but the biology problem ’ s tricky, because as we put through all these toxic materials that we disgorge, we will never be able to recover that. And as Francis Crick pointed out, nine years after discovering DNA with Mr. Watson, that life itself has to have growth as a precondition — it has to have free energy, sunlight and it needs to be an open system of chemicals. So we ’ re asking for human artifice to become a living thing, and we want growth, we want free energy from sunlight and we want an open metabolism for chemicals. Then, the question becomes not growth or no growth, but what do you want to grow? So instead of just growing destruction, we want to grow the things that we might enjoy, and someday the FDA will allow us to make French cheese. So therefore, we have these two metabolisms, and I worked with a German chemist, Michael Braungart, and we ' ve identified the two fundamental metabolisms. The biological one I ' m sure you understand, but also the technical one, where we take materials and put them into closed cycles. We call them biological nutrition and technical nutrition. Technical nutrition will be in an order of magnitude of biological nutrition. Biological nutrition can supply about 500 million humans, which means that if we all wore Birkenstocks and cotton, the world would run out of cork and dry up. So we need materials in closed cycles, but we need to analyze them down to the parts per million for cancer, birth defects, mutagenic effects, disruption of our immune systems, biodegradation, persistence, heavy **metal** content, knowledge of how we ' re making them and their production and so on. Our first product was a textile where we analyzed 8, 000 chemicals in the textile industry. Using those intellectual filters, we eliminated [7, 962.] We were left with 38 chemicals. We have since databased the 4000 most commonly used chemicals in human manufacturing, and we ' re releasing this database into the public in six weeks. So designers all over the world can analyze their products down to the parts per million for human and ecological health. We ' ve developed a protocol so that companies can send these same messages all the way through their supply chains, because when we asked most companies we work with — about a trillion dollars — and say,"Where does your stuff come from?"They say,"Suppliers.""And where does it go?""Customers."So we need some help there. So the biological nutrients, the first fabrics — the water coming out was **clean** enough to drink. Technical nutrients — this is for Shaw Carpet, infinitely reusable carpet. Here ' s nylon going back to caprolactam back to carpet. Biotechnical nutrients — the Model U for Ford Motor, a cradle to cradle car — concept car. Shoes for Nike, where the uppers are polyesters, infinitely recyclable, the **bottoms** are biodegradable soles. Wear your old shoes in, your new shoes out. There is no finish line. The idea here of the car is that some of the materials go back to the industry forever, some of the materials go back to soil — it ' s all solar-powered. Here ' s a building at Oberlin College we designed that makes more energy than it needs to operate and purifies its own water. Here ' s a building for The Gap, where the ancient grasses of San Bruno, California, are on the **roof**. And this is our project for Ford Motor Company. It ' s the revitalization of the River Rouge in Dearborn. This is obviously a color photograph. These are our tools. These are how we sold it to Ford. We saved Ford 35 million dollars doing it this way, day one, which is the equivalent of the Ford Taurus at a four percent margin of an order for 900 million dollars worth of cars. Here it is. It ' s the world ' s largest green **roof**, 10 and a half acres. This is the **roof**, saving money, and this is the first species to arrive here. These are killdeer. They showed up in five days. And we now have 350-pound auto workers learning bird songs on the Internet. We ' re developing now protocols for cities — that ' s the home of technical nutrients. The country — the home of biological. And putting them together. And so I will finish by showing you a new city we ' re designing for the Chinese government. We ' re doing 12 cities for China right now, based on cradle to cradle as templates. Our assignment is to develop protocols for the housing for 400 million people in 12 years. We did a mass energy balance — if they use brick, they will lose all their soil and burn all their coal. They ' ll have cities with no energy and no food. We signed a Memorandum of Understanding — here ' s Madam Deng Nan, Deng Xiaoping ' s daughter — for China to adopt cradle to cradle. Because if they toxify themselves, being the lowest-cost producer, send it to the lowest-cost distribution — Wal-Mart — and then we send them all our money, what we ' ll discover is that we have what, effectively, when I was a student, was called mutually assured destruction. Now we do it by molecule.

These are our cities. We ’ re building a new city next to this city ; look at that landscape. This is the site. We don ’ t normally do green fields, but this one is about to be built, so they brought us in to intercede. This is their plan. It ’ s a rubber stamp grid that they laid right on that landscape. And they brought us in and said,”What would you do?”This is what they would end up with, which is another color photograph. So this is the existing site, so this is what it looks like now, and here ’ s our proposal. So the way we approached this is we studied the hydrology very carefully. We studied the biota, the ancient biota, the current farming and the protocols. We studied the winds and the sun to make sure everybody in the city will have fresh air, fresh water and direct sunlight in every single apartment at some point during the day. We then take the **parks** and lay them out as ecological infrastructure. We lay out the building areas. We start to integrate commercial and mixed use so the people all have centers and places to be. The transportation is all very simple, everybody ’ s within a five-minute walk of mobility. We have a 24-hour street, so that there ’ s always a place that ’ s alive. The waste systems all connect. If you flush a toilet, your feces will go to the sewage treatment plants, which are sold as assets, not liabilities. Because who wants the fertilizer factory that makes natural **gas**? The waters are all taken in to construct the wetlands for habitat restorations. And then it makes natural **gas**, which then goes back into the city to power the fuel for the cooking for the city. So this is — these are fertilizer **gas** plants. And then the compost is all taken back to the **roofs** of the city, where we ’ ve got farming, because what we ’ ve done is lifted up the city, the landscape, into the air to — to restore the native landscape on the **roofs** of the buildings. The solar power of all the factory centers and all the industrial zones with their light **roofs** powers the city. And this is the concept for the top of the city. We ’ ve lifted the earth up onto the **roofs**. The farmers have little bridges to get from one **roof** to the next. We inhabit the city with work / live space on all the ground floors. And so this is the existing city, and this is the new city.

Text Sample 673: POS Dim 5 – 2005 – Score 10.00 – 2005/t000237.txt

My mission in life since I was a kid was, and is, to take the rest of you into space. It ’ s during our lifetime that we ’ re going to take the Earth, take the people of Earth and transition off, permanently. And that ’ s exciting. In fact, I think it is a moral imperative that we open the space frontier. You know, it ’ s the first time that we ’ re going to have a chance to have planetary redundancy, a chance to, if you would, back up the biosphere. And if you think about space, everything we hold of value on this planet — **metals** and minerals and real estate and energy — is in infinite quantities in space. In fact, the Earth is a crumb in a supermarket filled with resources. The analogy for me is Alaska. You know, we bought Alaska. We Americans bought Alaska in the 1850s. It ’ s called Seward ’ s folly. We valued it as the number of seal pelts we could kill. And then we discovered these things — gold and oil and fishing and timber — and it became, you know, a trillion-dollar economy, and now we take our honeymoons there. The same thing will happen in space. We are on the verge of the greatest exploration that the human race has ever known. We explore for three reasons, the weakest of which is curiosity. You know, it ’ s funded NASA ’ s budget up until now. Some images from Mars, 1997. In fact, I think in the next decade, without any question, we will discover life on Mars and find that it is literally ubiquitous under the soils and different parts of that planet. The stronger motivator, the much stronger motivator, is fear. It drove us to the moon. We — literally in fear — with the Soviet Union raced to the moon. And we have these huge rocks, you know, killer-sized rocks in the hundreds of thousands or millions out there, and while the probability is very small, the impact, figured in literally, of one of these hitting the Earth is so huge that to spend a small fraction looking, searching, preparing to defend, is not unreasonable. And of course, the third motivator, one near and dear to my heart as an entrepreneur, is wealth. In fact, the greatest wealth. If you think about these other asteroids, there ' s a class of the nickel iron, which in platinum-group **metal** markets alone are worth something like 20 trillion dollars, if you can go out and grab one of these rocks. My plan is to actually buy puts on the precious **metal** market, and then actually claim that I ' m going to go out and get one. And that will fund the actual mission to go and get one. But fear, curiosity and greed have driven us. And for me, this is — I ' m the short kid on the right. This was — my motivation was actually during Apollo. And Apollo was one of the greatest motivators ever. If you think about what happened at the turn of — early 1960s, on May 25, JFK said,"We ' re going to go to the moon."And people left their jobs and they went to obscure locations to go and be part of this amazing mission. And we knew nothing about going to space. We went from having literally put Alan Shepard in suborbital flight to going to the moon in eight years, and the average age of the people that got us there was 26 years old. They didn ' t know what couldn ' t be done. They had to make up everything. And that, my friend, is amazing motivation. This is Gene Cernan, a good friend of mine, saying,"If I can go to the moon"— this is the last human on the moon so far —"nothing, nothing is impossible."But of course, we ' ve thought about the government always as the person taking us there. But I put forward here, the government is not going to get us there. The government is unable to take the risks required to open up this precious frontier. The shuttle is costing a billion dollars a launch. That ' s a pathetic number. It ' s unreasonable. We shouldn ' t be happy in standing for that. One of the things that we did with the Ansari X PRIZE was take the challenge on that risk is OK, you know. As we are going out there and taking on a new frontier, we should be allowed to risk. In fact, anyone who says we shouldn ' t, you know, just needs to be put aside, because, as we go forward, in fact, the greatest discoveries we will ever know is ahead of us. The entrepreneurs in the space business are the furry mammals, and clearly the industrial-military complex — with Boeing and Lockheed and NASA — are the dinosaurs. The ability for us to access these resources to gain planetary redundancy — we can now gather all the information, the genetic codes, you know, everything stored on our databases, and back them up off the planet, in case there would be one of those disastrous situations. The difficulty is getting there, and clearly, the cost to orbit is key. Once you ' re in orbit, you are two thirds of the way, energetically, to anywhere — the moon, to Mars. And today, there ' s only three vehicles — the U. S. shuttle, the Russian Soyuz and the Chinese vehicle — that gets you there. Arguably, it ' s about 100 million dollars a person on the space shuttle. One of the companies I started, Space Adventures, will sell you a ticket. We ' ve done two so far. We ' ll be announcing two more on the Soyuz to go up to the space station for 20 million dollars. But that ' s expensive and to understand what the potential is — — it is expensive. But people are willing to pay that! You know, one — we have a very unique period in time today. For the first time ever, we have enough wealth concentrated in the hands of few individuals and the technology accessible that will allow us to really drive space exploration. But how cheap could it get? I want to give you the end point. We know — 20 million dollars today, you can go and buy a ticket, but how cheap could it get? Let ' s go back to high school physics here. If you calculate the amount of potential energy, mgh, to take you and your spacesuit up to a couple hundred miles, and then you accelerate yourself to 17, 500 miles per hour — remember, that one half MV squared — and you figure it out. It ’ s about 5. 7 gigajoules of energy. If you expended that over an hour, it ’ s about 1. 6 megawatts. If you go to one of Vijay ’ s micro-power sources, and they sell it to you for seven cents a kilowatt hour — anybody here fast in math? How much will it cost you and your spacesuit to go to orbit? 100 bucks. That ’ s the price-improvement **curve** that — we need some breakthroughs in physics along the way, I ’ ll grant you that. But guys, if history has taught us anything, it ’ s that if you can imagine it, you will get there eventually. I have no question that the physics, the engineering to get us down to the point where all of us can afford orbital space flight is around the corner. The difficulty is that there needs to be a real marketplace to drive the investment. Today, the Boeings and the Lockheeds don ’ t spend a dollar of their own money in R&D. It ’ s all government research dollars, and very few of those. And in fact, the large corporations, the governments, can ’ t take the risk. So we need what I call an exothermic economic reaction in space. Today ’ s commercial markets worldwide, global commercial launch market? 12 to 15 launches per year. Number of commercial companies out there? 12 to 15 companies. One per company. That ’ s not it. There ’ s only one marketplace, and I call them self-loading carbon payloads. They come with their own money. They ’ re easy to make. It ’ s people. The Ansari X PRIZE was my solution, reading about Lindbergh for creating the vehicles to get us there. We offered 10 million dollars in cash for the first reusable ship, carry three people up to 100 kilometers, come back down, and within two weeks, make the trip again. Twenty-six teams from seven countries entered the competition, spending between one to 25 million dollars each. And of course, we had beautiful SpaceShipOne, which made those two flights and won the competition. And I ’ d like to take you there, to that morning, for just a quick video. Pilot : Release our fire. Richard Searfoss : Good luck. RS : We ’ ve got an altitude call of 368, 000 **feet**. RS : So in my official capacity as the chief judge of the Ansari X PRIZE competition, I declare that Mojave Aerospace Ventures has indeed earned the Ansari X PRIZE. Peter Diamandis : Probably the most difficult thing that I had to do was raise the capital for this. It was literally impossible. We went — I went to 100, 200 CEOs, CMOs. No one believed it was done. Everyone said,”Oh, what does NASA think? Well, people are going to die, how can you possibly going to put this forward?”I found a visionary family, the Ansari family, and Champ Car, and raised part of the money, but not the full 10 million. And what I ended up doing was going out to the insurance industry and buying a hole-in-one insurance policy. See, the insurance companies went to Boeing and Lockheed, and said,”Are you going to compete?”No.”Are you going to compete?”No.”No one ’ s going to win this thing.”So, they took a bet that no one would win by January of ’ 05, and I took a bet that someone would win. So — and the best thing is they paid off and the check didn ’ t bounce. We ’ ve had a lot of accomplishments and it ’ s been a tremendous success. One of the things I ’ m most happy about is that the SpaceShipOne is going to hang in Air and Space Museum, next to the Spirit of St. Louis and the Wright Flyer. Isn ’ t that great? So a little bit about the future, steps to space, what ’ s available for you. Today, you can go and experience weightless flights. By ’ 08, suborbital flights, the price tag for that, you know, on Virgin, is going to be about 200, 000. There are three or four other serious efforts that will bring the price down very rapidly, I think, to about 25, 000 dollars for a suborbital flight. Orbital flights — we can take you to the space station. And then I truly believe, once a group is in orbit around the Earth — I know if they don ’ t do it, I am — we ’ re going to stockpile some fuel, make a beeline for the moon and grab some real estate. Quick moment for the designers in the audience. We spent 11 years getting FAA approval to do zero gravity flights. Here are some **fun** images. Here ’ s Burt Rutan and my good friend Greg Meronek inside a zero gravity — people think a zero gravity room, there ' s a switch on there that turns it off — but it ' s actually parabolic flight of an airplane. And turns out 7-Up has just done a little commercial that ' s airing this month. If we can get the audio up? Narrator : For a chance to win the first free ticket to space, look for specially marked packages of Diet 7-Up. When you want the taste that won ' t weigh you down, the only way to go is up. PD : That was **filmed** inside our airplane, and so, you can now do this. We ' re based down in Florida. Let me talk about the other thing I ' m excited about. The future of prizes. You know, prizes are a very old idea. I had the pleasure of borrowing from the Longitude Prize and the Orteig Prize that put Lindbergh forward. And we have made a decision in the X PRIZE Foundation to actually carry that concept forward into other technology areas, and we just took on a new mission statement :"to bring about radical breakthroughs in space and other technologies for the benefit of humanity."And this is something that we ' re very excited about. I showed this slide to Larry Page, who just joined our board. And you know, when you give to a nonprofit, you might have 50 cents on the dollar. If you have a matching grant, it ' s typically two or three to one. If you put up a prize, you can get literally a 50 to one leverage on your dollars. And that ' s huge. And then he turned around and said,"Well, if you back a prize institute that runs a 10 prize, you get 500 to one."I said,"Well, that ' s great."So, we have actually — are looking to turn the X PRIZE into a world- class prize institute. This is what happens when you put up a prize, when you announce it and teams start to begin doing trials. You get publicity increase, and when it ' s won, publicity shoots through the **roof** — if it ' s properly managed — and that ' s part of the benefits to a sponsor. Then, when the prize is actually won, after it ' s moving, you get societal benefits, you know, new technology, new capability. And the benefit to the sponsors is the sum of the publicity and societal benefits over the long term. That ' s our value proposition in a prize. If you were going to go and try to create SpaceShipOne, or any kind of a new technology, you have to fund that from the beginning and maintain that funding with an uncertain outcome. It may or may not happen. But if you put up a prize, the beautiful thing is, you know, it ' s a very small maintenance fee, and you pay on success. Orteig didn ' t pay a dime out to the nine teams that went across — tried to go across the Atlantic, and we didn ' t pay a dime until someone won the Ansari X PRIZE. So, prizes work great. You know, innovators, the entrepreneurs out there, you know that when you ' re going for a goal, the first thing you have to do is believe that you can do it yourself. Then, you ' ve got to, you know, face potential public ridicule of — that ' s a crazy idea, it ' ll never work. And then you have to convince others, so that they can, in fact, help you raise the funds, and then you ' ve got to deal with the fact that you ' ve got government bureaucracies and institutions that don ' t want you to move those things forward, and you have to deal with failures. What a prize does, what we ' ve experienced a prize doing, is literally help to short-circuit or support all of these things, because a prize credentials the idea that this is a good idea. Well, it must be a good idea. Someone ' s offering 10 million dollars to go and do this thing. And each of these areas was something that we found the Ansari X PRIZE helped short-circuit these for innovation. So, as an organization, we put together a prize discovery process of how to come up with prizes and write the rules, and we ' re actually looking at creating prizes in a number of different categories. We ' re looking at attacking energy, environment, nanotechnology — and I ' ll talk about those more in a moment. And the way we ' re doing that is we ' re creating prize teams within the X PRIZE. We have a space prize team. We ' re going after an orbital prize. We are looking at a number of energy prizes. Craig Venter has just joined our board and we ' re doing a rapid genome sequencing prize with him, we ’ ll be announcing later this fall, about — imagine being able to sequence anybody ’ s DNA for under 1, 000 dollars, revolutionize medicine. And **clean** water, education, medicine and even looking at social entrepreneurship. So my final slide here is, the most critical tool for solving humanity ’ s grand challenges — it isn ’ t technology, it isn ’ t money, it ’ s only one thing — it ’ s the committed, passionate human mind.

Text Sample 674: POS Dim 5 – 1998 – Score 6.00 – 1998/t000216.txt

David Gallo : This is Bill Lange. I ’ m Dave Gallo. And we ’ re going to tell you some stories from the sea here in video. We ’ ve got some of the most incredible video of Titanic that ’ s ever been seen, and we ’ re not going to show you any of it. The truth of the matter is that the Titanic — even though it ’ s breaking all sorts of box office records — it ’ s not the most exciting story from the sea. And the problem, I think, is that we take the ocean for granted. When you think about it, the oceans are 75 percent of the planet. Most of the planet is ocean water. The average depth is about two miles. Part of the problem, I think, is we stand at the beach, or we see images like this of the ocean, and you look out at this great big blue expanse, and it ’ s shimmering and it ’ s moving and there ’ s waves and there ’ s surf and there ’ s tides, but you have no idea for what lies in there. And in the oceans, there are the longest mountain ranges on the planet. Most of the animals are in the oceans. Most of the earthquakes and volcanoes are in the sea, at the **bottom** of the sea. The biodiversity and the biodensity in the ocean is higher, in places, than it is in the rainforests. It ’ s mostly unexplored, and yet there are beautiful sights like this that captivate us and make us become familiar with it. But when you ’ re standing at the beach, I want you to think that you ’ re standing at the edge of a very unfamiliar world. We have to have a very special technology to get into that unfamiliar world. We use the submarine Alvin and we use cameras, and the cameras are something that Bill Lange has developed with the help of Sony. Marcel Proust said,”The true voyage of discovery is not so much in seeking new landscapes as in having new eyes.”People that have partnered with us have given us new eyes, not only on what exists — the new landscapes at the **bottom** of the sea — but also how we think about life on the planet itself. Here ’ s a jelly. It ’ s one of my favorites, because it ’ s got all sorts of working parts. This turns out to be the longest creature in the oceans. It gets up to about 150 **feet** long. But see all those different working things? I love that kind of stuff. It ’ s got these fishing lures on the **bottom**. They ’ re going up and down. It ’ s got tentacles dangling, swirling around like that. It ’ s a colonial animal. These are all individual animals banding together to make this one creature. And it ’ s got these jet thrusters up in front that it ’ ll use in a moment, and a little light. If you take all the big fish and schooling fish and all that, put them on one side of the scale, put all the jelly-type of animals on the other side, those guys win hands down. Most of the biomass in the ocean is made out of creatures like this. Here ’ s the X-wing death jelly. The bioluminescence — they use the lights for attracting mates and attracting prey and communicating. We couldn ’ t begin to show you our archival stuff from the jellies. They come in all different sizes and shapes. Bill Lange : We tend to forget about the fact that the ocean is miles deep on average, and that we ’ re real familiar with the animals that are in the first 200 or 300 **feet**, but we ’ re not familiar with what exists from there all the way down to the **bottom**. And these are the types of animals that live in that three- dimensional space, that micro-gravity environment that we really haven ’ t explored. You hear about giant squid and things like that, but some of these animals get up to be approximately 140, 160 **feet** long. They ’ re very little understood. DG : This is one of them, another one of our favorites, because it ’ s a little octopod. You can actually see through his head. And here he is, flapping with his ears and very gracefully going up. We see those at all depths and even at the greatest depths. They go from a couple of inches to a couple of **feet**. They come right up to the submarine — they ’ ll put their eyes right up to the window and peek inside the sub. This is really a world within a world, and we ’ re going to show you two. In this case, we ’ re passing down through the mid-ocean and we see creatures like this. This is kind of like an undersea rooster. This guy, that looks incredibly formal, in a way. And then one of my favorites. What a face! This is basically scientific data that you ’ re looking at. It ’ s footage that we ’ ve collected for scientific purposes. And that ’ s one of the things that Bill ’ s been doing, is providing scientists with this first view of animals like this, in the world where they belong. They don ’ t catch them in a net. They ’ re actually looking at them down in that world. We ’ re going to take a joystick, sit in front of our computer, on the Earth, and press the joystick forward, and fly around the planet. We ’ re going to look at the mid-ocean ridge, a 40, 000-mile long mountain range. The average depth at the top of it is about a mile and a half. And we ’ re over the Atlantic — that ’ s the ridge right there — but we ’ re going to go across the Caribbean, Central America, and end up against the Pacific, nine degrees north. We make maps of these mountain ranges with sound, with sonar, and this is one of those mountain ranges. We ’ re coming around a cliff here on the right. The height of these mountains on either side of this **valley** is greater than the Alps in most cases. And there ’ s tens of thousands of those mountains out there that haven ’ t been mapped yet. This is a volcanic ridge. We ’ re getting down further and further in scale. And eventually, we can come up with something like this. This is an icon of our robot, Jason, it ’ s called. And you can sit in a room like this, with a joystick and a headset, and drive a robot like that around the **bottom** of the ocean in real time. One of the things we ’ re trying to do at Woods Hole with our partners is to bring this virtual world — this world, this unexplored region — back to the laboratory. Because we see it in bits and pieces right now. We see it either as sound, or we see it as video, or we see it as photographs, or we see it as chemical sensors, but we never have yet put it all together into one interesting **picture**. Here ’ s where Bill ’ s cameras really do shine. This is what ’ s called a hydrothermal vent. And what you ’ re seeing here is a cloud of densely packed, hydrogen-sulfide-rich water coming out of a volcanic axis on the sea floor. Gets up to 600, 700 degrees F, somewhere in that range. So that ’ s all water under the sea — a mile and a half, two miles, three miles down. And we knew it was volcanic back in the ’ 60s, ’ 70s. And then we had some hint that these things existed all along the axis of it, because if you ’ ve got volcanism, water ’ s going to get down from the sea into cracks in the sea floor, come in contact with magma, and come shooting out hot. We weren ’ t really aware that it would be so rich with sulfides, hydrogen sulfides. We didn ’ t have any idea about these things, which we call chimneys. This is one of these hydrothermal vents. Six hundred degree F water coming out of the Earth. On either side of us are mountain ranges that are higher than the Alps, so the setting here is very dramatic. BL : The white material is a type of bacteria that thrives at 180 degrees C. DG : I think that ’ s one of the greatest stories right now that we ’ re seeing from the **bottom** of the sea, is that the first thing we see coming out of the sea floor after a volcanic eruption is bacteria. And we started to wonder for a long time, how did it all get down there? What we find out now is that it ’ s probably coming from inside the Earth. Not only is it coming out of the Earth — so, biogenesis made from volcanic activity — but that bacteria supports these colonies of life. The pressure here is 4, 000 pounds per square inch. A mile and a half from the surface to two miles to three miles — no sun has ever gotten down here. All the energy to support these life forms is coming from inside the Earth — so, chemosynthesis. And you can see how dense the population is. These are called tube worms. BL : These worms have no digestive system. They have no mouth. But they have two types of gill structures. One for extracting oxygen out of the deep-sea water, another one which houses this chemosynthetic bacteria, which takes the hydrothermal fluid — that hot water that you saw coming out of the **bottom** — and converts that into simple sugars that the tube worm can digest. DG : You can see, here ' s a crab that lives down there. He ' s managed to grab a tip of these worms. Now, they normally retract as soon as a crab touches them. Oh! Good going. So, as soon as a crab touches them, they retract down into their shells, just like your fingernails. There ' s a whole story being played out here that we ' re just now beginning to have some idea of because of this new camera technology. BL : These worms live in a real temperature extreme. Their **foot** is at about 200 degrees C and their head is out at three degrees C, so it ' s like having your hand in boiling water and your **foot** in freezing water. That ' s how they like to live. DG : This is a female of this kind of worm. And here ' s a male. You watch. It doesn ' t take long before two guys here — this one and one that will show up over here — start to fight. Everything you see is played out in the pitch black of the deep sea. There are never any lights there, except the lights that we bring. Here they go. On one of the last dive series, we counted 200 species in these areas — 198 were new, new species. BL : One of the big problems is that for the biologists working at these sites, it ' s rather difficult to collect these animals. And they disintegrate on the way up, so the imagery is critical for the science. DG : Two octopods at about two miles depth. This pressure thing really amazes me — that these animals can exist there at a depth with pressure enough to crush the Titanic like an empty Pepsi can. What we saw up till now was from the Pacific. This is from the Atlantic. Even greater depth. You can see this shrimp is harassing this poor little guy here, and he ' ll bat it away with his claw. Whack! And the same thing ' s going on over here. What they ' re getting at is that — on the back of this crab — the foodstuff here is this very strange bacteria that lives on the backs of all these animals. And what these shrimp are trying to do is actually harvest the bacteria from the backs of these animals. And the crabs don ' t like it at all. These long filaments that you see on the back of the crab are actually created by the product of that bacteria. So, the bacteria grows hair on the crab. On the back, you see this again. The red dot is the **laser** light of the submarine Alvin to give us an idea about how far away we are from the vents. Those are all shrimp. You see the hot water over here, here and here, coming out. They ' re clinging to a rock face and actually scraping bacteria off that rock face. Here ' s a tiny, little vent that ' s come out of the side of that pillar. Those pillars get up to several stories. So here, you ' ve got this **valley** with this incredible alien landscape of pillars and hot springs and volcanic eruptions and earthquakes, inhabited by these very strange animals that live only on chemical energy coming out of the ground. They don ' t need the sun at all. BL : You see this white V-shaped mark on the back of the shrimp? It ' s actually a light-sensing organ. It ' s how they find the hydrothermal vents. The vents are emitting a black body radiation — an IR signature — and so they ' re able to find these vents at considerable distances. DG : All this stuff is happening along that 40, 000-mile long mountain range that we ' re calling the ribbon of life, because just even today, as we speak, there ' s life being generated there from volcanic activity. This is the first time we ' ve ever tried this any place. We ’ re going to try to show you high definition from the Pacific. We ’ re moving up one of these pillars. This one ’ s several stories tall. In it, you ’ ll see that it ’ s a habitat for a lot of different animals. There ’ s a funny kind of hot plate here, with vent water coming out of it. So all of these are individual homes for worms. Now here ’ s a closer view of that community. Here ’ s crabs here, worms here. There are smaller animals crawling around. Here ’ s pagoda structures. I think this is the neatest-looking thing. I just can ’ t get over this — that you ’ ve got these little chimneys sitting here smoking away. This stuff is toxic as **hell**, by the way. You could never get a permit to dump this in the ocean, and it ’ s coming out all from it. It ’ s unbelievable. It ’ s basically sulfuric acid, and it ’ s being just dumped out, at incredible rates. And animals are thriving — and we probably came from here. That ’ s probably where we evolved from. BL : This bacteria that we ’ ve been talking about turns out to be the most simplest form of life found. There are a number of groups that are proposing that life evolved at these vent sites. Although the vent sites are short-lived — an individual site may last only 10 years or so — as an ecosystem they ’ ve been stable for millions — well, billions — of years. DG : It works too well. You see there ’ re some fish inside here as well. There ’ s a fish sitting here. Here ’ s a crab with his claw right at the end of that tube worm, waiting for that worm to stick his head out. BL : The biologists right now cannot explain why these animals are so active. The worms are growing inches per week! DG : I already said that this site, from a human perspective, is toxic as **hell**. Not only that, but on top — the lifeblood — that plumbing system turns off every year or so. Their plumbing system turns off, so the sites have to move. And then there ’ s earthquakes, and then volcanic eruptions, on the order of one every five years, that completely wipes the area out. Despite that, these animals grow back in about a year ’ s time. You ’ re talking about biodensities and biodiversity, again, higher than the rainforest that just springs back to life. Is it sensitive? Yes. Is it fragile? No, it ’ s not really very fragile. I ’ ll end up with saying one thing. There ’ s a story in the sea, in the waters of the sea, in the sediments and the rocks of the sea floor. It ’ s an incredible story. What we see when we look back in time, in those sediments and rocks, is a record of Earth history. Everything on this planet — everything — works by cycles and rhythms. The continents move apart. They come back together. Oceans come and go. Mountains come and go. Glaciers come and go. El Nino comes and goes. It ’ s not a disaster, it ’ s rhythmic. What we ’ re learning now, it ’ s almost like a symphony. It ’ s just like music — it really is just like music. And what we ’ re learning now is that you can ’ t listen to a five-billion-year long symphony, get to today and say,”Stop! We want tomorrow ’ s note to be the same as it was today.”It ’ s absurd. It ’ s just absurd. So, what we ’ ve got to learn now is to find out where this planet ’ s going at all these different scales and work with it. Learn to manage it. The concept of preservation is futile. Conservation ’ s tougher, but we can probably get there. Thank you very much. Thank you.

Text Sample 675: POS Dim 5 – 1998 – Score 5.00 – 1998/t000134.txt

’ Theme and variations ’ is one of those forms that require a certain kind of intellectual activity, because you are always comparing the variation with the theme that you hold in your mind. You might say that the theme is nature and everything that follows is a variation on the subject. I was asked, I guess about six years ago, to do a series of paintings that in some way would celebrate the birth of Piero della Francesca. And it was very difficult for me to imagine how to paint **pictures** that were based on Piero until I realized that I could look at

Piero as nature — that I would have the same attitude towards looking at Piero della Francesca as I would if I were looking out a window at a tree. And that was enormously liberating to me. Perhaps it ' s not a very insightful observation, but that really started me on a path to be able to do a kind of theme and variations based on a work by Piero, in this case that remarkable painting that ' s in the Uffizi,"The Duke of Montefeltro,"who faces his consort, Battista. Once I realized that I could take some liberties with the subject, I did the following series of **drawings**. That ' s the real Piero della Francesca — one of the greatest portraits in human history. And these, I ' ll just show these without comment. It ' s just a series of variations on the head of the Duke of Montefeltro, who ' s a great, great figure in the Renaissance, and probably the basis for Machiavelli ' s"The Prince."He apparently lost an eye in battle, which is why he is always shown in profile. And this is Battista. And then I decided I could move them around a little bit — so that for the first time in history, they ' re facing the same direction. Whoops! Passed each other. And then a visitor from another painting by Piero, this is from"The Resurrection of Christ"— as though the cast had just gotten of the set to have a chat. And now, four large **panels** : this is upper left ; upper right ; lower left ; lower right. Incidentally, I ' ve never understood the conflict between **abstraction** and naturalism. Since all paintings are inherently abstract to begin with there doesn ' t seem to be an argument there. On another subject — — I was driving in the country one day with my wife, and I saw this sign, and I said,"That is a fabulous piece of design."And she said,"What are you talking about?"I said,"Well, it ' s so persuasive, because the purpose of that sign is to get you into the garage, and since most people are so suspicious of garages, and know that they ' re going to be ripped off, they use the word ' reliable. ' But everybody says they ' re reliable. But, reliable Dutchman"— —"Fantastic!"Because as soon as you hear the word Dutchman — which is an archaic word, nobody calls Dutch people"Dutchmen"anymore — but as soon as you hear Dutchman, you get this **picture** of the kid with his finger in the dike, preventing the thing from falling and flooding Holland, and so on. And so the entire issue is detoxified by the use of"Dutchman."Now, if you think I ' m exaggerating at all in this, all you have to do is substitute something else, like"Indonesian."Or even"French."Now,"Swiss"works, but you know it ' s going to cost a lot of money. I ' m going to take you quickly through the actual process of doing a poster. I do a lot of work for the School of Visual Arts, where I teach, and the director of this school — a remarkable man named Silas Rhodes — often gives you a piece of text and he says,"Do something with this."And so he did. And this was the text —"In words as fashion the same rule will hold / Alike fantastic if too new or old / Be not the first by whom the new are tried / Nor yet the last to lay the old aside."I could make nothing of that. And I really struggled with this one. And the first thing I did, which was sort of in the absence of another idea, was say I ' ll sort of write it out and make some words big, and I ' ll have some kind of design on the back somehow, and I was hoping — as one often does — to stumble into something. So I took another crack at it — you ' ve got to keep it moving — and I Xeroxed some words on pieces of colored paper and I pasted them down on an ugly board. I thought that something would come out of it, like"Words rule fantastic new old first last Pope"because it ' s by Alexander Pope, but I sort of made a mess out of it, and then I thought I ' d repeat it in some way so it was legible. So, it was going nowhere. Sometimes, in the middle of a resistant problem, I write down things that I know about it. But you can see the beginning of an idea there, because you can see the word"new"emerging from the"old."That ' s what happens. There ' s a relationship between the old and the new ; the new emerges from the context of the old. And then I did some variations of it, but it still wasn ’ t coalescing graphically at all. I had this other version which had something interesting about it in terms of being able to put it together in your mind from clues. The W was clearly a W, the N was clearly an N, even though they were very fragmentary and there wasn ’ t a lot of information in it. Then I got the words”new”and”old”and now I had regressed back to a point where there seemed to be no return. I was really desperate at this point. And so, I do something I ’ m truthfully ashamed of, which is that I took two **drawings** I had made for another purpose and I put them together. It says”dreams”at the top. And I was going to do a thing, I say,”Well, change the copy. Let it say something about dreams, and come to SVA and you ’ ll sort of fulfill your dreams.”But, to my credit, I was so embarrassed about doing that that I never submitted this sketch. And, finally, I arrived at the following solution. Now, it doesn ’ t look terribly interesting, but it does have something that distinguishes it from a lot of other posters. For one thing, it transgresses the idea of what a poster ’ s supposed to be, which is to be understood and seen immediately, and not explained. I remember hearing all of you in the graphic arts —”If you have to explain it, it **ain** ’ t working.”And one day I woke up and I said,”Well, suppose that ’ s not true?”So here ’ s what it says in my explanation at the **bottom** left. It says,”Thoughts : This poem is impossible. Silas usually has a better touch with his choice of quotations. This one generates no imagery at all.”I am now exposing myself to my audience, right? Which is something you never want to do professionally.”Maybe the words can make the image without anything else happening. What ’ s the heart of this poem? Don ’ t be trendy if you want to be serious. Is doing the poster this way trendy in itself? I guess one could reduce the idea further by suggesting that the new emerges behind and through the old, like this.”And then I show you a little **drawing** — you see, you remember that old thing I discarded? Well, I found a way to use it. So, there ’ s that little alternative over there, and I say,”Not bad,”— criticizing myself —”but more didactic than visual. Maybe what wants to be said is that old and the new are locked in a dialectical embrace, a kind of dance where each defines the other.”And then more self-questioning —”Am I being simple-minded? Is this the kind of simple that looks obvious, or the kind that looks profound? There ’ s a significant difference. This could be embarrassing. Actually, I realize fear of embarrassment drives me as much as any ambition. Do you think this sort of thing could really attract a student to the school?”Well, I think there are two fresh things here — two fresh things. One is the sort of willingness to expose myself to a critical audience, and not to suggest that I am confident about what I ’ m doing. And as you know, you have to have a front. I mean — you ’ ve got to be confident ; if you don ’ t believe in your work, who else is going to believe in it? So that ’ s one thing, to introduce the idea of doubt into graphics. That can be a big contribution. The other thing is to actually give you two solutions for the price of one ; you get the big one and if you don ’ t like that, how about the little one? And that too is a relatively new idea. And here ’ s just a series of experiments where I ask the question of — does a poster have to be square? Now, this is a little illusion. That poster is not folded. It ’ s not folded, that ’ s a photograph and it ’ s cut on the diagonal. Same cheap trick in the upper left-hand corner. And here, a very peculiar poster because, simply because of using the isometric perspective in the computer, it won ’ t sit still in the space. At times, it seems to be wider at the back than the front, and then it shifts. And if you sit here long enough, it ’ ll float off the page into the audience. But, we don ’ t have time. And then an experiment — a little bit about the nature of perspective, where the outside shape is determined by the peculiarity of perspective, but the shape of the bottle — which is identical to the outside shape — is seen frontally. And another piece for the art directors ’ club is”Anna Rees”casting long shadows. This is another poster from the School of Visual Arts. There were 10 artists invited to participate in it, and it was one of those things where it was extremely competitive and I didn ' t want to be embarrassed, so I worked very hard on this. The idea was — and it was a brilliant idea — was to have 10 posters distributed throughout the city ' s subway system so every time you got on the subway you ' d be passing a different poster, all of which had a different idea of what art is. But I was absolutely stuck on the idea of"art is"and trying to determine what art was. But then I gave up and I said,"Well, art is whatever."And as soon as I said that, I discovered that the word"hat"was hidden in the word"whatever,"and that led me to the inevitable conclusion. But then again, it ' s on my list of didactic posters. My intent is to have a literary accompaniment that explains the poster, in case you don ' t get it. Now this says,"Note to the viewer : I thought I might use a visual cliche of our time — Magritte ' s everyman — to express the idea that art is mystery, continuity and history. I ' m also convinced that, in an age of computer manipulation, surrealism has become banal, a shadow of its former self. The phrase ' Art is whatever ' expresses the current inclusiveness that surrounds art-making — a sort of ' it **ain** ' t what you do, it ' s the way that you do it ' notion. The shadow of Magritte falls across the central part of the poster a poetic event that occurs as the shadow man isolates the word ' hat, ' hidden in the word ' whatever. ' The four hats shown in the poster suggests how art might be defined : as a thing itself, the worth of the thing, the shadow of the thing, and the shape of the thing. Whatever."OK. And the one that I did not submit, which I still like, I wanted to use the same phrase. There were wonderful experiments by Bruno Munari on letterforms some years ago — sort of, see how far you could go and still be able to read them. And that idea stuck in my head. But then I took the pieces that I had taken off and put them at the **bottom**. And, of course those are the remains, and they ' re so labeled. But what really happens is that you read it as :"Art is whatever remains."Thank you.

Text Sample 676: POS Dim 5 – 1998 – Score 4.00 – 1998/t000200.txt

You hear that this is the era of environment â or biology, or information technology... Well, it ' s the era of a lot of different things that we ' re in right now. But one thing for sure : it ' s the era of change. There ' s more change going on than ever has occurred in the history of human life on earth. And you all sort of know it, but it ' s hard to get it so that you really understand it. And I ' ve tried to put together something that ' s a good start for this. I ' ve tried to show in this â though the color doesn ' t come out â that what I ' m concerned with is the little 50-year time bubble that you are in. You tend to be interested in a generation past, a generation future â your parents, your kids, things you can change over the next few decades â and this 50-year time bubble you kind of move along in. And in that 50 years, if you look at the population **curve**, you find the population of humans on the earth more than doubles and we ' re up three-and-a-half times since I was born. When you have a new baby, by the time that kid gets out of high school more people will be added than existed on earth when I was born. This is unprecedented, and it ' s big. Where it goes in the future is questioned. So that ' s the human part. Now, the human part related to animals : look at the left side of that. What I call the human portion â humans and their livestock and pets â versus the natural portion â all the other wild animals and just â these are vertebrates and all the birds, etc., in the land and air, not in the water. How does it balance? Certainly, 10, 000 years ago, the civilization ' s beginning, the human portion was less than one tenth of one percent. Let ’ s look at it now. You follow this **curve** and you see the whiter spot in the middle â that ’ s your 50- year time bubble. Humans, livestock and pets are now 97 percent of that integrated total mass on earth and all wild nature is three percent. We have won. The next generation doesn ’ t even have to worry about this game â it is over. And the biggest problem came in the last 25 years : it went from 25 percent up to that 97 percent. And this really is a sobering **picture** upon realizing that we, humans, are in charge of life on earth ; we ’ re like the capricious Gods of old Greek myths, kind of playing with life â and not a great deal of wisdom injected into it. Now, the third **curve** is information technology. This is Moore ’ s Law plotted here, which relates to density of information, but it has been pretty good for showing a lot of other things about information technology â computers, their use, Internet, etc. And what ’ s important is it just goes straight up through the top of the **curve**, and has no real limits to it. Now try and contrast these. This is the size of the earth going through that same â â frame. And to make it really clear, I ’ ve put all four on one graph. There ’ s no need to see the little detailed words on it. That first one is humans-versus-nature ; we ’ ve won, there ’ s no more gain. Human population. And so if you ’ re looking for growth industries to get into, that ’ s not a good one â protecting natural creatures. Human population is going up ; it ’ s going to continue for quite a while. Good business in obstetricians, morticians, and farming, housing, etc. â they all deal with human bodies, which require being fed, transported, housed and so on. And the information technology, which connects to our brains, has no limit â now, that is a wonderful field to be in. You ’ re looking for growth opportunity? It ’ s just going up through the **roof**. And then, the size of the Earth. Somehow making these all compatible with the Earth looks like a pretty bad industry to be involved with. So, that ’ s the stage out of all this. I find, for reasons I don ’ t understand, I really do have a goal. And the goal is that the world be desirable and sustainable when my kids reach my age â and I think that ’ s â in other words, the next generation. I think that ’ s a goal that we probably all share. I think it ’ s a hopeless goal. Technologically, it ’ s achievable ; economically, it ’ s achievable ; politically, it means sort of the habits, institutions of people â it ’ s impossible. The institutions of the past with all their inertia are just irrelevant for the future, except they ’ re there and we have to deal with them. I spend about 15 percent of my time trying to save the world, the other 85 percent, the usual â and whatever else we devote ourselves to. And in that 15 percent, the main focus is on human mind, thinking skills, somehow trying to unleash kids from the straightjacket of school, which is putting information and dogma into them, get them so they really think, ask tough questions, argue about serious subjects, don ’ t believe everything that ’ s in the book, think broadly or creative. They can be. Our school systems are very flawed and do not reward you for the things that are important in life or for the survival of civilization ; they reward you for a lot of learning and sopping up stuff. We can ’ t go into that today because there isn ’ t time â it ’ s a broad subject. One thing for sure, in the future there is an essential feature â necessary, but not sufficient â which is doing more with less. We ’ ve got to be doing things with more efficiency using less energy, less material. Your great-great grandparents got by on muscle power, and yet we all think there ’ s this huge power that ’ s essential for our lifestyle. And with all the wonderful technology we have we can do things that are much more efficient : conserve, recycle, etc. Let me just rush very quickly through things that we ’ ve done. Human-powered airplane â Gossamer Condor sort of started me in this direction in 1976 and 77, winning the Kremer prize in aviation history, followed by the Albatross. And we began making various odd planes and creatures. Here ’ s a giant flying replica of a pterosaur that has no tail. Trying to have it fly straight is like trying to shoot an arrow with the feathered end forward. It was a tough job, and boy it made me have a lot of respect for nature. This was the full size of the original creature. We did things on land, in the air, on water â vehicles of all different kinds, usually with some electronics or electric power systems in them. I find they ' re all the same, whether its land, air or water. I ' ll be focusing on the air here. This is a solar-powered airplane â 165 miles carrying a person from France to England as a symbol that solar power is going to be an important part of our future. Then we did the solar car for General Motors â the Sunracer â that won the race in Australia. We got a lot of people thinking about electric cars, what you could do with them. A few years later, when we suggested to GM that now is the time and we could do a thing called the Impact, they sponsored it, and here ' s the Impact that we developed with them on their programs. This is the demonstrator. And they put huge effort into turning it into a commercial product. With that preamble, let ' s show the first two-minute videotape, which shows a little airplane for surveillance and moving to a giant airplane. Narrator : A tiny airplane, the AV Pointer serves for surveillance â in effect, a pair of roving eyeglasses. A cutting-edge example of where miniaturization can lead if the operator is remote from the vehicle. It is convenient to carry, assemble and launch by hand. Battery-powered, it is silent and rarely noticed. It sends high-resolution video **pictures** back to the operator. With onboard GPS, it can navigate autonomously, and it is rugged enough to self-land without damage. The modern sailplane is superbly efficient. Some can glide as flat as 60 **feet** forward for every **foot** of descent. They are powered only by the energy they can extract from the atmosphere â an atmosphere nature stirs up by solar energy. Humans and soaring birds have found nature to be generous in providing replenishable energy. Sailplanes have flown over 1, 000 miles, and the altitude record is over 50, 000 **feet**. The Solar Challenger was made to serve as a symbol that photovoltaic cells can produce real power and will be part of the world ' s energy future. In 1981, it flew 163 miles from Paris to England, solely on the power of sunbeams, and established a basis for the Pathfinder. The message from all these vehicles is that ideas and technology can be harnessed to produce remarkable gains in doing more with less â gains that can help us attain a desirable balance between technology and nature. The stakes are high as we speed toward a challenging future. Buckminster Fuller said it clearly :"there are no passengers on spaceship Earth, only crew. We, the crew, can and must do more with less â much less."Paul MacCready : If we could have the second video, the one-minute, put in as quickly as you can, which â this will show the Pathfinder airplane in some flights this past year in Hawaii, and will show a sequence of some of the beauty behind it after it had just flown to 71, 530 **feet** â higher than any propeller airplane has ever flown. It ' s amazing : just on the puny power of the sun â by having a super lightweight plane, you ' re able to get it up there. It ' s part of a long-term program NASA sponsored. And we worked very closely with the whole thing being a team effort, and with wonderful results like that flight. And we ' re working on a bigger plane â 220-foot span â and an intermediate-size, one with a regenerative fuel cell that can store excess energy during the day, feed it back at night, and stay up 65, 000 **feet** for months at a time. Ray Morgan ' s voice will come in here. There he ' s the project manager. Anything they do is certainly a team effort. He ran this program. Here ' s... some things he showed as a celebration at the very end. Ray Morgan : We ' d just ended a seven-month deployment of Hawaii. For those who live on the mainland, it was tough being away from home. The friendly support, the quiet confidence, congenial hospitality shown by our Hawaiian and military hosts â this is starting â made the experience enjoyable and unforgettable. PM : We have real-time IR **scans** going out through the Internet while the plane is flying. And it ’ s exploring without polluting the stratosphere. That ’ s its goal : the stratosphere, the blanket that really controls the radiation of the earth and permits life on earth to be the success that it is â probing that is very important. And also we consider it as a sort of poor man ’ s stationary satellite, because it can stay right overhead for months at a time, 2, 000 times closer than the real GFC synchronous satellite. We couldn ’ t bring one here to fly it and show you. But now let ’ s look at the other end. In the video you saw that nine-pound or eight-pound Pointer airplane surveillance drone that Keenan has developed and just done a remarkable job. Where some have servos that have gotten down to, oh, 18 or 25 grams, his weigh one-third of a gram. And what he ’ s going to bring out here is a surveillance drone that weighs about 2 ounces â that includes the video camera, the batteries that run it, the telemetry, the receiver and so on. And we ’ ll fly it, we hope, with the same success that we had last night when we did the practice. So Matt Keenan, just any time you ’ re â all right â ready to let her go. But first, we ’ re going to make sure that it ’ s appearing on the screen, so you see what it sees. You can imagine yourself being a mouse or fly inside of it, looking out of its camera. Matt Keenan : It ’ s switched on. PM : But now we ’ re trying to get the video. There we go. MK : Can you bring up the house lights? PM : Yeah, the house lights and we ’ ll see you all better and be able to fly the plane better. MK : All right, we ’ ll try to do a few laps around and bring it back in. Here we go. PM : The video worked right for the first few and I don ’ t know why it â there it goes. Oh, that was only a minute, but I think you ’ d be safe to have that near the end of the flight, perhaps. We get to do the classic. All right. If this hits you, it will not hurt you. OK. Thank you very much. Thank you. But now, as they say in infomercials, we have something much better for you, which we ’ re working on : planes that are only six inches â 15 centimeters â in size. And Matt ’ s plane was on the cover of Popular Science last month, showing what this can lead to. And in a while, something this size will have GPS and a video camera in it. We ’ ve had one of these fly nine miles through the air at 35 miles an hour with just a little battery in it. But there ’ s a lot of technology going. There are just milestones along the way of some remarkable things. This one doesn ’ t have the video in it, but you get a little feel from what it can do. OK, here we go. MK : Sorry. OK. PM : If you can pass it down when you ’ re done. Yeah, I think â I lost a little orientation ; I looked up into this light. It hit the building. And the building was poorly placed, actually. But you ’ re beginning to see what can be done. We ’ re working on projects now â even wing-flapping things the size of hawk moths â DARPA contracts, working with Caltech, UCLA. Where all this leads, I don ’ t know. Is it practical? I don ’ t know. But like any basic research, when you ’ re really forced to do things that are way beyond existing technology, you can get there with micro-technology, nanotechnology. You can do amazing things when you realize what nature has been doing all along. As you get to these small scales, you realize we have a lot to learn from nature â not with 747s â but when you get down to the nature ’ s realm, nature has 200 million years of experience. It never makes a mistake. Because if you make a mistake, you don ’ t leave any progeny. We should have nothing but success stories from nature, for you or for birds, and we ’ re learning a lot from its fascinating subjects. In concluding, I want to get back to the big **picture** and I have just two final slides to try and put it in perspective. The first I ’ ll just read. At last, I put in three sentences and had it say what I wanted. Over billions of years on a unique sphere, chance has painted a thin covering of life â complex, improbable, wonderful and fragile. Suddenly, we humans â a recently arrived species, no longer subject to the checks and balances inherent in nature â have grown in population, technology and intelligence to a position of terrible power. We now wield the paintbrush. And that ’ s serious : we ’ re not very bright. We ’ re short on wisdom ; we ’ re high on technology. Where ’ s it going to lead? Well, inspired by the sentences, I decided to wield the paintbrush. Every 25 years I do a **picture**. Here ’ s the one â tries to show that the world isn ’ t getting any bigger. Sort of a timeline, very non-linear scale, nature rates and trilobites and dinosaurs, and eventually we saw some humans with caves... Birds were flying overhead, after pterosaurs. And then we get to the civilization above the little TV set with a gun on it. Then traffic jams, and power systems, and some dots for digital. Where it ’ s going to lead â I have no idea. And so I just put robotic and natural cockroaches out there, but you can fill in whatever you want. This is not a forecast. This is a warning, and we have to think seriously about it. And that time when this is happening is not 100 years or 500 years. Things are going on this decade, next decade ; it ’ s a very short time that we have to decide what we are going to do. And if we can get some agreement on where we want the world to be â desirable, sustainable when your kids reach your age â I think we actually can reach it. Now, I said this was a warning, not a forecast. That was before â I painted this before we started in on making robotic versions of hawk moths and cockroaches, and now I ’ m beginning to wonder seriously â was this more of a forecast than I wanted? I personally think the surviving intelligent life form on earth is not going to be carbon-based ; it ’ s going to be silicon-based. And so where it all goes, I don ’ t know. The one final bit of sparkle we ’ ll put in at the very end here is an utterly impractical flight vehicle, which is a little ornithopter wing-flapping device that â rubber-band powered â that we ’ ll show you. MK : 32 gram. Sorry, one gram. PM : Last night we gave it a few too many turns and it tried to bash the **roof** out also. It ’ s about a gram. The tube there ’ s hollow, about paper-thin. And if this lands on you, I assure you it will not hurt you. But if you reach out to grab it or hold it, you will destroy it. So, be gentle, just act like a wooden Indian or something. And when it comes down â and we ’ ll see how it goes. We consider this to be sort of the spirit of TED. And you wonder, is it practical? And it turns out if I had not been â Unfortunately, we have some light bulb changes. We can probably get it down, but it ’ s possible it ’ s gone up to a greater destiny up there â â than it ever had. And I wanted to make â just â But I want to make just two points. One is, you think it ’ s frivolous ; there ’ s nothing to it. And yet if I had not been making ornithopters like that, a little bit cruder, in 1939 â a long, long time ago â there wouldn ’ t have been a Gossamer Condor, there wouldn ’ t have been an Albatross, a Solar Challenger, there wouldn ’ t be an Impact car, there wouldn ’ t be a mandate on zero-emission vehicles in California. A lot of these things â or similar â would have happened some time, probably a decade later. I didn ’ t realize at the time I was doing inquiry-based, hands-on things with teams, like they ’ re trying to get in education systems. So I think that, as a symbol, it ’ s important. And I believe that also is important. You can think of it as a sort of a symbol for learning and TED that somehow gets you thinking of technology and nature, and puts it all together in things that are â that make this conference, I think, more important than any that ’ s taken place in this country in this decade. Thank you.

About four years ago, the New Yorker published an article about a cache of

dodo bones that was found in a pit on the island of Mauritius. Now, the island of Mauritius is a small island off the east coast of Madagascar in the Indian Ocean, and it is the place where the dodo bird was discovered and extinguished, all within about 150 years. Everyone was very excited about this archaeological find, because it meant that they might finally be able to assemble a single dodo skeleton. See, while **museums** all over the world have dodo skeletons in their collection, nobody — not even the actual Natural History Museum on the island of Mauritius — has a skeleton that ' s made from the bones of a single dodo. Well, this isn ' t exactly true. The fact is, is that the British Museum had a complete specimen of a dodo in their collection up until the 18th century — it was actually mummified, skin and all — but in a fit of space-saving zeal, they actually cut off the head and they cut off the **feet** and they burned the rest in a bonfire. If you go look at their website today, they ' ll actually list these specimens, saying, the rest was lost in a fire. Not quite the whole truth. Anyway. The frontispiece of this article was this photo, and I ' m one of the people that thinks that Tina Brown was great for bringing photos to the New Yorker, because this photo completely rocked my world. I became obsessed with the object — not just the beautiful photograph itself, and the color, the shallow depth of field, the detail that ' s visible, the wire you can see on the beak there that the conservator used to put this skeleton together — there ' s an entire story here. And I thought to myself, wouldn ' t it be great if I had my own dodo skeleton? I want to point out here at this point that I ' ve spent my life obsessed by objects and the stories that they tell, and this was the very latest one. So I began looking around for — to see if anyone sold a kit, some kind of model that I could get, and I found lots of reference material, lots of lovely **pictures**. No dice : no dodo skeleton for me. But the damage had been done. I had saved a few hundred photos of dodo skeletons into my"Creative Projects"folder — it ' s a repository for my brain, everything that I could possibly be interested in. Any time I have an internet connection, there ' s a sluice of stuff moving into there, everything from beautiful rings to cockpit photos. The key that the Marquis du Lafayette sent to George Washington to celebrate the storming of the Bastille. Russian nuclear launch key : The one on the top is the **picture** of the one I found on eBay ; the one on the **bottom** is the one I made for myself, because I couldn ' t afford the one on eBay. Storm trooper costumes. Maps of Middle Earth — that ' s one I hand-drew myself. There ' s the dodo skeleton folder. This folder has 17, 000 photos — over 20 gigabytes of information — and it ' s growing constantly. And one day, a couple of weeks later, it might have been maybe a year later, I was in the art store with my kids, and I was buying some clay tools — we were going to have a craft day. I bought some Super Sculpeys, some armature wire, some various materials. And I looked down at this Sculpey, and I thought, maybe, yeah, maybe I could make my own dodo skull. I should point out at this time — I ' m not a sculptor ; I ' m a hard-edged model maker. You give me a **drawing**, you give me a prop to replicate, you give me a crane, scaffolding, parts from"Star Wars"— especially parts from"Star Wars"— I can do this stuff all day long. It ' s exactly how I made my living for 15 years. But you give me something like this — my friend Mike Murnane sculpted this ; it ' s a maquette for"Star Wars, Episode Two"— this is not my thing — this is something other people do — dragons, soft things. However, I felt like I had looked at enough photos of dodo skulls to actually be able to understand the topology and perhaps replicate it — I mean, it couldn ' t be that difficult. So, I started looking at the best photos I could find. I grabbed all the reference, and I found this lovely piece of reference. This is someone selling this on eBay ; it was clearly a woman—s hand, hopefully a woman ' s hand. Assuming it was roughly the size of my wife ' s hand, I made some measurements of her thumb, and I scaled them out to the size of the skull. I blew it up to the actual size, and I began using that, along with all the other reference that I had, comparing it to it as size reference for figuring out exactly how big the beak should be, exactly how long, etc. And over a few hours, I eventually achieved what was actually a pretty reasonable dodo skull. And I didn ' t mean to continue, I — it ' s kind of like, you know, you can only **clean** a super messy room by picking up one thing at a time ; you can ' t think about the totality. I wasn ' t thinking about a dodo skeleton ; I just noticed that as I finished this skull, the armature wire that I had been used to holding it up was sticking out of the back just where a spine would be. And one of the other things I ' d been interested in and obsessed with over the years is spines and skeletons, having collected a couple of hundred. I actually understood the mechanics of vertebrae enough to kind of start to imitate them. And so button by button, vertebrae by vertebrae, I built my way down. And actually, by the end of the day, I had a reasonable skull, a moderately good vertebrae and half of a pelvis. And again, I kept on going, looking for more reference, every bit of reference I could find — **drawings**, beautiful photos. This guy — I love this guy! He put a dodo leg bones on a scanner with a ruler. This is the kind of accuracy that I wanted, and I replicated every last bone and put it in. And after about six weeks, I finished, painted, mounted my own dodo skeleton. You can see that I even made a **museum** label for it that includes a brief history of the dodo. And TAP Plastics made me — although I didn ' t photograph it — a **museum** vitrine. I don ' t have the room for this in my house, but I had to finish what I had started. And this actually represented kind of a sea change to me. Again, like I said, my life has been about being **fascinated** by objects and the stories that they tell, and also making them for myself, obtaining them, appreciating them and diving into them. And in this folder,"Creative Projects,"there are tons of projects that I ' m currently working on, projects that I ' ve already worked on, things that I might want to work on some day, and things that I may just want to find and buy and have and look at and touch. But now there was potentially this new category of things that I could sculpt that was different, that I — you know, I have my own R2D2, but that ' s — honestly, relative to sculpting, to me, that ' s easy. And so I went back and looked through my"Creative Projects"folder, and I happened across the Maltese Falcon. Now, this is funny for me : to fall in love with an object from a Hammett novel, because if it ' s true that the world is divided into two types of people, Chandler people and Hammett people, I am absolutely a Chandler person. But in this case, it ' s not about the author, it ' s not about the book or the movie or the story, it ' s about the object in and of itself. And in this case, this object is — plays on a host of levels. First of all, there ' s the object in the world. This is the"Kniphausen Hawk."It is a ceremonial pouring vessel made around 1700 for a Swedish Count, and it is very likely the object from which Hammett drew his inspiration for the Maltese Falcon. Then there is the fictional bird, the one that Hammett created for the book. Built out of words, it is the engine that drives the plot of his book and also the movie, in which another object is created : a prop that has to represent the thing that Hammett created out of words, inspired by the Kniphausen Hawk, and this represents the falcon in the movie. And then there is this fourth level, which is a whole new object in the world : the prop made for the movie, the representative of the thing, becomes, in its own right, a whole other thing, a whole new object of desire. And so now it was time to do some research. I actually had done some research a few years before — it ' s why the folder was there. I ' d bought a replica, a really crappy replica, of the Maltese Falcon on eBay, and had downloaded enough **pictures** to actually have some reasonable reference. But I discovered, in researching further, really wanting precise reference, that one of the original lead birds had been sold at Christie ' s in 1994, and so I contacted an antiquarian bookseller who had the original Christie ' s catalogue, and in it I found this magnificent **picture**, which included a size reference. I was able to **scan** the **picture**, blow it up to exactly full size. I found other reference. Avi [Ara] Chekmayan, a New Jersey editor, actually found this resin Maltese Falcon at a flea market in 1991, although it took him five years to authenticate this bird to the auctioneers ' specifications, because there was a lot of controversy about it. It was made out of resin, which wasn ' t a common material for movie props about the time the movie was made. It ' s funny to me that it took a while to authenticate it, because I can see it compared to this thing, and I can tell you — it ' s real, it ' s the real thing, it ' s made from the exact same mold that this one is. In this one, because the auction was actually so controversial, Profiles in History, the auction house that sold this — I think in 1995 for about 100, 000 dollars — they actually included — you can see here on the **bottom** — not just a front elevation, but also a side, rear and other side elevation. So now, I had all the topology I needed to replicate the Maltese Falcon. What do they do, how do you start something like that? I really don ' t know. So what I did was, again, like I did with the dodo skull, I blew all my reference up to full size, and then I began cutting out the negatives and using those templates as shape references. So I took Sculpey, and I built a big block of it, and I passed it through until, you know, I got the right profiles. And then slowly, feather by feather, detail by detail, I worked out and achieved — working in front of the television and Super Sculpey — here ' s me sitting next to my wife — it ' s the only **picture** I took of the entire process. As I moved through, I achieved a very reasonable facsimile of the Maltese Falcon. But again, I am not a sculptor, and so I don ' t know a lot of the tricks, like, I don ' t know how my friend Mike gets beautiful, shiny surfaces with his Sculpey ; I certainly wasn ' t able to get it. So, I went down to my shop, and I molded it and I cast it in resin, because in the resin, then, I could absolutely get the glass smooth finished. Now there ' s a lot of ways to fill and get yourself a nice smooth finish. My preference is about 70 coats of this — matte black auto primer. I spray it on for about three or four days, it drips to **hell**, but it allows me a really, really nice gentle sanding surface and I can get it glass-smooth. Oh, finishing up with triple-zero steel wool. Now, the great thing about getting it to this point was that because in the movie, when they finally bring out the bird at the end, and they place it on the table, they actually spin it. So I was able to actually screen-shot and freeze-frame to make sure. And I ' m following all the light kicks on this thing and making sure that as I ' m holding the light in the same position, I ' m getting the same type of reflection on it — that ' s the level of detail I ' m going into this thing. I ended up with this : my Maltese Falcon. And it ' s beautiful. And I can state with authority at this point in time, when I ' d finished it, of all of the replicas out there — and there is a few — this is by far the most accurate representation of the original Maltese Falcon than anyone has sculpted. Now the original one, I should tell you, is sculpted by a guy named Fred Sexton. This is where it gets weird. Fred Sexton was a friend of this guy, George Hodel. Terrifying guy — agreed by many to be the killer of the Black Dahlia. Now, James Ellroy believes that Fred Sexton, the sculptor of the Maltese Falcon, killed James Elroy ' s mother. I ' ll go you one stranger than that : In 1974, during the production of a weird comedy sequel to"The Maltese Falcon,"called"The Black Bird,"starring George Segal, the Los Angeles County Museum of Art had a plaster original of the Maltese Falcon — one of the original six plasters, I think, made for the movie — stolen out of the **museum**. A lot of people thought it was a publicity stunt for the movie. John ' s Grill, which actually is seen briefly in"The Maltese Falcon,"is still a viable

San Francisco eatery, counted amongst its regular customers Elisha Cook, who played Wilmer Cook in the movie, and he gave them one of his original plasters of the Maltese Falcon. And they had it in their cabinet for about 15 years, until it got stolen in January of 2007. It would seem that the object of desire only comes into its own by disappearing repeatedly. So here I had this Falcon, and it was lovely. It looked really great, the light worked on it really well, it was better than anything that I could achieve or obtain out in the world. But there was a problem. And the problem was that : I wanted the entirety of the object, I wanted the weight behind the object. This thing was made of resin and it was too light. There ' s this group online that I frequent. It ' s a group of prop crazies just like me called the Replica Props Forum, and it ' s people who trade, make and travel in information about movie props. And it turned out that one of the guys there, a friend of mine that I never actually met, but befriended through some prop deals, was the manager of a local foundry. He took my master Falcon pattern, he actually did lost wax casting in bronze for me, and this is the bronze I got back. And this is, after some acid etching, the one that I ended up with. And this thing, it ' s deeply, deeply satisfying to me. Here, I ' m going to put it out there, later on tonight, and I want you to pick it up and handle it. You want to know how obsessed I am. This project ' s only for me, and yet I went so far as to buy on eBay a 1941 Chinese San Francisco-based newspaper, in order so that the bird could properly be wrapped... like it is in the movie. Yeah, I know! There you can see, it ' s weighing in at 27 and a half pounds. That ' s half the weight of my dog, Huxley. But there ' s a problem. Now, here ' s the most recent progression of Falcons. On the far left is a piece of crap — a replica I bought on eBay. There ' s my somewhat ruined Sculpey Falcon, because I had to get it back out of the mold. There ' s my first casting, there ' s my master and there ' s my bronze. There ' s a thing that happens when you mold and cast things, which is that every time you throw it into silicone and cast it in resin, you lose a little bit of volume, you lose a little bit of size. And when I held my bronze one up against my Sculpey one, it was shorter by three-quarters of an inch. Yeah, no, really, this was like aah — why didn ' t I remember this? Why didn ' t I start and make it bigger? So what do I do? I figure I have two options. One, I can fire a freaking **laser** at it, which I have already done, to do a 3D **scan** — there ' s a 3D **scan** of this Falcon. I had figured out the exact amount of shrinkage I achieved going from a wax master to a bronze master and blown this up big enough to make a 3D lithography master of this, which I will polish, then I will send to the mold maker and then I will have it done in bronze. Or : There are several people who own originals, and I have been attempting to contact them and reach them, hoping that they will let me spend a few minutes in the presence of one of the real birds, maybe to take a **picture**, or even to pull out the hand-held **laser** scanner that I happen to own that fits inside a cereal box, and could maybe, without even touching their bird, I swear, get a perfect 3D **scan**. And I ' m even willing to sign pages saying that I ' ll never let anyone else have it, except for me in my office, I promise. I ' ll give them one if they want it. And then, maybe, then I ' ll achieve the end of this exercise. But really, if we ' re all going to be honest with ourselves, I have to admit that achieving the end of the exercise was never the point of the exercise to begin with, was it. Thank you.

I was raised in Seoul, Korea, and moved to New York City in 1999 to attend college. I was pre-med at the time, and I thought I would become a surgeon because I was interested in anatomy and dissecting animals really piqued my curiosity. At the same time, I fell in love with New York City. I started to realize that I could look at the whole city as a living organism. I wanted to dissect it and look into its unseen layers. And the way to it, for me, was through artistic means. So, eventually I decided to pursue an MFA instead of an M. D. and in grad school I became interested in creatures that dwell in the hidden corners of the city. In New York City, rats are part of commuters ’ daily lives. Most people ignore them or are frightened of them. But I took a liking to them because they dwell on the fringes of society. And even though they ’ re used in labs to promote human lives, they ’ re also considered pests. I also started looking around in the city and trying to photograph them. One day, in the subway, I was snapping **pictures** of the tracks hoping to catch a rat or two, and a man came up to me and said,”You can ’ t take photographs here. The MTA will confiscate your camera.”I was quite shocked by that, and thought to myself,”Well, OK then. I ’ ll follow the rats.”Then I started going into the tunnels, which made me realize that there ’ s a whole new dimension to the city that I never saw before and most people don ’ t get to see. Around the same time, I met like-minded individuals who call themselves urban explorers, adventurers, spelunkers, guerrilla historians, etc. I was welcomed into this loose, Internet-based network of people who regularly explore urban ruins such as abandoned subway stations, tunnels, sewers, aqueducts, factories, hospitals, shipyards and so on. When I took photographs in these locations, I felt there was something missing in the **pictures**. Simply documenting these soon-to-be-demolished structures wasn ’ t enough for me. So I wanted to create a fictional character or an animal that dwells in these underground spaces, and the simplest way to do it, at the time, was to model myself. I decided against clothing because I wanted the figure to be without any cultural implications or time-specific elements. I wanted a simple way to represent a living body inhabiting these decaying, derelict spaces. This was taken in the Riviera Sugar Factory in Red Hook, Brooklyn. It ’ s now an empty, six-acre lot waiting for a shopping mall right across from the new Ikea. I was very fond of this space because it ’ s the first massive industrial complex I found on my own that is abandoned. When I first went in, I was scared, because I heard dogs barking and I thought they were guard dogs. But they happened to be wild dogs living there, and it was right by the water, so there were swans and ducks swimming around and trees growing everywhere and bees nesting in the sugar barrels. The nature had really reclaimed the whole complex. And, in a way, I wanted the human figure in the **picture** to become a part of that nature. When I got comfortable in the space, it also felt like a big playground. I would climb up the tanks and hop across exposed beams as if I went back in time and became a child again. This was taken in the old Croton Aqueduct, which supplied fresh water to New York City for the first time. The construction began in 1837. It lasted about five years. It got abandoned when the new Croton Aqueducts opened in 1890. When you go into spaces like this, you ’ re directly accessing the past, because they sit untouched for decades. I love feeling the aura of a space that has so much history. Instead of looking at reproductions of it at home, you ’ re actually feeling the hand-laid bricks and shimmying up and down narrow cracks and getting wet and muddy and walking in a dark tunnel with a flashlight. This is a tunnel underneath Riverside Park. It was built in the 1930s by Robert Moses. The murals were done by a graffiti artist to commemorate the hundreds of homeless people that got relocated from the tunnel in 1991 when the tunnel reopened for trains. Walking in this tunnel is very peaceful. There ’ s nobody around you, and you hear the kids playing in the **park** above you, completely unaware of what ’ s underneath. When I was going out a lot to these places, I was feeling a lot of anxiety and isolation because I was in a solitary phase in my life, and I decided to title my series"Naked City Spleen,"which references Charles Baudelaire."Naked City"is a nickname for New York, and"Spleen"embodies the melancholia and inertia that come from feeling alienated in an urban environment. This is the same tunnel. You see the sunbeams coming from the ventilation ducts and the train approaching. This is a tunnel that ' s abandoned in **Hell** ' s Kitchen. I was there alone, setting up, and a homeless man approached. I was basically intruding in his living space. I was really frightened at first, but I calmly explained to him that I was working on an art project and he didn ' t seem to mind and so I went ahead and put my camera on self-timer and ran back and forth. And when I was done, he actually offered me his shirt to wipe off my **feet** and kindly walked me out. It must have been a very unusual day for him. One thing that struck me, after this incident, was that a space like that holds so many deleted memories of the city. That homeless man, to me, really represented an element of the unconscious of the city. He told me that he was abused above ground and was once in Riker ' s Island, and at last he found peace and quiet in that space. The tunnel was once built for the prosperity of the city, but is now a sanctuary for outcasts, who are completely forgotten in the average urban dweller ' s everyday life. This is underneath my alma mater, Columbia University. The tunnels are famous for having been used during the development of the Manhattan Project. This particular tunnel is interesting because it shows the original foundations of Bloomingdale Insane Asylum, which was demolished in 1890 when Columbia moved in. This is the New York City Farm Colony, which was a poorhouse in Staten Island from the 1890s to the 1930s. Most of my photos are set in places that have been abandoned for decades, but this is an exception. This children ' s hospital was closed in 1997 ; it ' s located in Newark. When I was there three years ago, the windows were broken and the walls were peeling, but everything was left there as it was. You see the autopsy table, morgue trays, x-ray machines and even used utensils, which you see on the autopsy table. After exploring recently-abandoned buildings, I felt that everything could fall into ruins very fast : your home, your office, a shopping mall, a church — any man-made structures around you. I was reminded of how fragile our sense of security is and how vulnerable people truly are. I love to travel, and Berlin has become one of my favorite cities. It ' s full of history, and also full of underground bunkers and ruins from the war. This was taken under a homeless asylum built in 1885 to house 1, 100 people. I saw the structure while I was on the train, and I got off at the next station and met people there that gave me access to their catacomb-like basement, which was used for ammunition storage during the war and also, at some point, to hide groups of Jewish refugees. This is the actual catacombs in Paris. I explored there extensively in the off-limits areas and fell in love right away. There are more than 185 miles of tunnels, and only about a mile is open to the public as a **museum**. The first tunnels date back to 60 B. C. They were consistently dug as limestone quarries and by the 18th century, the caving-in of some of these quarries posed safety threats, so the government ordered reinforcing of the existing quarries and dug new observation tunnels in order to monitor and map the whole place. As you can see, the system is very complex and vast. It ' s very dangerous to get lost in there. And at the same time, there was a problem in the city with overflowing cemeteries. So the bones were moved from the cemeteries into the quarries, making them into the catacombs. The remains of over six million people are housed in there, some over 1, 300 years old. This was taken under the Montparnasse Cemetery where most of the ossuaries are located. There are also phone cables that were used in the ' 50s and many bunkers from the World War II era. This is a German bunker. Nearby there ' s a French bunker, and the whole tunnel system is so complex that the two parties never met. The tunnels are famous for having been used by the Resistance, which Victor Hugo wrote about in”Les Miserables.”And I saw a lot of graffiti from the 1800s, like this one. After exploring the underground of Paris, I decided to climb up, and I climbed a Gothic monument that ’ s right in the middle of Paris. This is the Tower of Saint Jacques. It was built in the early 1500s. I don ’ t recommend sitting on a gargoyle in the middle of January, naked. It was not very comfortable. And all this time, I never saw a single rat in any of these places, until recently, when I was in the London sewers. This was probably the toughest place to explore. I had to wear a **gas** mask because of the toxic fumes — I guess, except for in this **picture**. And when the tides of waste matter come in it sounds as if a whole storm is approaching you. This is a still from a **film** I worked on recently, called”Blind Door.”I ’ ve become more interested in capturing movement and texture. And the 16mm black- and-white **film** gave a different feel to it. And this is the first theater project I worked on. I adapted and produced”A Dream Play”by August Strindberg. It was performed last September one time only in the Atlantic Avenue tunnel in Brooklyn, which is considered to be the oldest underground train tunnel in the world, built in 1844. I ’ ve been leaning towards more collaborative projects like these, lately. But whenever I get a chance I still work on my series. The last place I visited was the Mayan ruins of Copan, Honduras. This was taken inside an archaeological tunnel in the main temple. I like doing more than just exploring these spaces. I feel an obligation to animate and humanize these spaces continually in order to preserve their memories in a creative way — before they ’ re lost forever. Thank you.

Text Sample 679: POS Dim 5 – 2008 – Score 9.00 – 2008/t000180.txt

I thought I ’ d start with telling you or showing you the people who started [Jet Propulsion Lab]. When they were a bunch of kids, they were kind of very imaginative, very adventurous, as they were trying at Caltech to mix chemicals and see which one blows up more. Well, I don ’ t recommend that you try to do that now. Naturally, they blew up a shack, and Caltech, well, then, hey, you go to the Arroyo and really do all your tests in there. So, that ’ s what we call our first five employees during the tea break, you know, in here. As I said, they were adventurous people. As a matter of fact, one of them, who was, kind of, part of a cult which was not too far from here on Orange Grove, and unfortunately he blew up himself because he kept mixing chemicals and trying to figure out which ones were the best chemicals. So, that gives you a kind of flavor of the kind of people we have there. We try to avoid blowing ourselves up. This one I thought I ’ d show you. Guess which one is a JPL employee in the heart of this crowd. I tried to come like him this morning, but as I walked out, then it was too cold, and I said, I ’ d better put my shirt back on. But more importantly, the reason I wanted to show this **picture** : look where the other people are looking, and look where he is looking. Wherever anybody else looks, look somewhere else, and go do something different, you know, and doing that. And that ’ s kind of what has been the spirit of what we are doing. And I want to tell you a quote from Ralph Emerson that one of my colleagues, you know, put on my wall in my office, and it says,”Do not go where the path may lead. Go instead where there is no path, and leave a trail.”And that ’ s my recommendation to all of you : look what everybody is doing, what they are doing ; go do something completely different. Don ’ t try to improve a little bit on what somebody else is doing, because that doesn ’ t get you very far. In our early days we used to work a lot on rockets, but we also used to have a lot of parties, you know. As you can see, one of our parties, you know, a few years ago. But then a big difference happened about 50 years ago, after Sputnik was launched. We launched the first American satellite, and that ' s the one you see on the left in there. And here we made 180 degrees change : we changed from a rocket house to be an exploration house. And that was done over a period of a couple of years, and now we are the leading organization, you know, exploring space on all of your behalf. But even when we did that, we had to remind ourselves, sometimes there are setbacks. So you see, on the **bottom**, that rocket was supposed to go upward ; somehow it ended going sideways. So that ' s what we call the misguided missile. But then also, just to celebrate that, we started an event at JPL for"Miss Guided Missile."So, we used to have a celebration every year and select — there used to be competition and parades and so on. It ' s not very appropriate to do it now. Some people tell me to do it ; I think, well, that ' s not really proper, you know, these days. So, we do something a little bit more serious. And that ' s what you see in the last Rose Bowl, you know, when we entered one of the floats. That ' s more on the play side. And on the right side, that ' s the Rover just before we finished its testing to take it to the Cape to launch it. These are the Rovers up here that you have on Mars now. So that kind of tells you about, kind of, the **fun** things, you know, and the serious things that we try to do. But I said I ' m going to show you a short clip of one of our employees to kind of give you an idea about some of the talent that we have. Video : Morgan Hendry : Beware of Safety is an instrumental rock band. It branches on more the experimental side. There ' s the improvisational side of jazz. There ' s the heavy-hitting sound of rock. Being able to treat sound as an instrument, and be able to dig for more abstract sounds and things to play live, mixing electronics and acoustics. The music ' s half of me, but the other half — I landed probably the best gig of all. I work for the Jet Propulsion Lab. I ' m building the next Mars Rover. Some of the most brilliant engineers I know are the ones who have that sort of artistic quality about them. You ' ve got to do what you want to do. And anyone who tells you you can ' t, you don ' t listen to them. Maybe they ' re right - I doubt it. Tell them where to put it, and then just do what you want to do. I ' m Morgan Hendry. I am NASA. Charles Elachi : Now, moving from the play stuff to the serious stuff, always people ask, why do we explore? Why are we doing all of these missions and why are we exploring them? Well, the way I think about it is fairly simple. Somehow, 13 billion years ago there was a Big Bang, and you ' ve heard a little bit about, you know, the origin of the universe. But somehow what strikes everybody ' s imagination — or lots of people ' s imagination — somehow from that original Big Bang we have this beautiful world that we live in today. You look outside : you have all that beauty that you see, all that life that you see around you, and here we have intelligent people like you and I who are having a conversation here. All that started from that Big Bang. So, the question is : How did that happen? How did that evolve? How did the universe form? How did the galaxies form? How did the planets form? Why is there a planet on which there is life which have evolved? Is that very common? Is there life on every planet that you can see around the stars? So we literally are all made out of stardust. We started from those stars ; we are made of stardust. So, next time you are really depressed, look in the mirror and you can look and say, hi, I ' m looking at a star here. You can skip the dust part. But literally, we are all made of stardust. So, what we are trying to do in our exploration is effectively write the book of how things have came about as they are today. And one of the first, or the easiest, places we can go and explore that is to go towards Mars. And the reason Mars takes particular attention : it ' s not very far from us. You know, it ' ll take us only six months to get there. Six to nine months at the right time of the year. It

’ s a planet somewhat similar to Earth. It ’ s a little bit smaller, but the land mass on Mars is about the same as the land mass on Earth, you know, if you don ’ t take the oceans into account. It has polar caps. It has an atmosphere somewhat thinner than ours, so it has weather. So, it ’ s very similar to some extent, and you can see some of the features on it, like the Grand Canyon on Mars, or what we call the Grand Canyon on Mars. It is like the Grand Canyon on Earth, except a **hell** of a lot larger. So it ’ s about the size, you know, of the United States. It has volcanoes on it. And that ’ s Mount Olympus on Mars, which is a kind of huge volcanic shield on that planet. And if you look at the height of it and you compare it to Mount Everest, you see, it ’ ll give you an idea of how large that Mount Olympus, you know, is, relative to Mount Everest. So, it basically dwarfs, you know, Mount Everest here on Earth. So, that gives you an idea of the tectonic events or volcanic events which have happened on that planet. Recently from one of our satellites, this shows that it ’ s Earth-like — we caught a landslide occurring as it was happening. So it is a dynamic planet, and activity is going on as we speak today. And these Rovers, people wonder now, what are they doing today, so I thought I would show you a little bit what they are doing. This is one very large crater. Geologists love craters, because craters are like digging a big hole in the ground without really working at it, and you can see what ’ s below the surface. So, this is called Victoria Crater, which is about a few football fields in size. And if you look at the top left, you see a little teeny dark dot. This **picture** was taken from an orbiting satellite. If I zoom on it, you can see : that ’ s the Rover on the surface. So, that was taken from orbit ; we had the camera zoom on the surface, and we actually saw the Rover on the surface. And we actually used the combination of the satellite images and the Rover to actually conduct science, because we can observe large areas and then you can get those Rovers to move around and basically go to a certain location. So, specifically what we are doing now is that Rover is going down in that crater. As I told you, geologists love craters. And the reason is, many of you went to the Grand Canyon, and you see in the wall of the Grand Canyon, you see these layers. And what these layers — that ’ s what the surface used to be a million years ago, 10 million years ago, 100 million years ago, and you get deposits on top of them. So if you can read the layers it ’ s like reading your book, and you can learn the history of what happened in the past in that location. So what you are seeing here are the layers on the wall of that crater, and the Rover is going down now, measuring, you know, the properties and analyzing the rocks as it ’ s going down, you know, that canyon. Now, it ’ s kind of a little bit of a challenge driving down a slope like this. If you were there you wouldn ’ t do it yourself. But we really made sure we tested those Rovers before we got them down — or that Rover — and made sure that it ’ s all working well. Now, when I came last time, shortly after the landing — I think it was, like, a hundred days after the landing — I told you I was surprised that those Rovers are lasting even a hundred days. Well, here we are four years later, and they ’ re still working. Now you say, Charles, you are really lying to us, and so on, but that ’ s not true. We really believed they were going to last 90 days or 100 days, because they are solar powered, and Mars is a dusty planet, so we expected the dust would start accumulating on the surface, and after a while we wouldn ’ t have enough power, you know, to keep them warm. Well, I always say it ’ s important that you are smart, but every once in a while it ’ s good to be lucky. And that ’ s what we found out. It turned out that every once in a while there are dust devils which come by on Mars, as you are seeing here, and when the dust devil comes over the Rover, it just **cleans** it up. It is like a brand new car that you have, and that ’ s literally why they have lasted so long. And now we designed them reasonably well, but that ’ s exactly why they are lasting that long and still providing all the science data. Now, the two Rovers, each one of them is, kind of, getting old. You know, one of them, one of the wheels is stuck, is not working, one of the front wheels, so what we are doing, we are driving it backwards. And the other one has arthritis of the shoulder joint, you know, it ’ s not working very well, so it ’ s walking like this, and we can move the arm, you know, that way. But still they are producing a lot of scientific data. Now, during that whole period, a number of people got excited, you know, outside the science community about these Rovers, so I thought I ’ d show you a video just to give you a reflection about how these Rovers are being viewed by people other than the science community. So let me go on the next short video. By the way, this video is pretty accurate of how the landing took place, you know, about four years ago. Video : Okay, we have parachute aligned. Okay, deploy the airbags. Open. Camera. We have a **picture** right now. Yeah! CE : That ’ s about what happened in the Houston operation room. It ’ s exactly like this. Video : Now, if there is life, the Dutch will find it. What is he doing? What is that? CE : Not too bad. So anyway, let me continue on showing you a little bit about the beauty of that planet. As I said earlier, it looked very much like Earth, so you see sand dunes. It looks like I could have told you these are **pictures** taken from the Sahara Desert or somewhere, and you ’ d have believed me, but these are **pictures** taken from Mars. But one area which is particularly intriguing for us is the northern region, you know, of Mars, close to the North Pole, because we see ice caps, and we see the ice caps shrinking and expanding, so it ’ s very much like you have in northern Canada. And we wanted to find out — and we see all kinds of glacial features on it. So, we wanted to find out, actually, what is that ice made of, and could that have embedded in it some organic, you know, material. So we have a spacecraft which is heading towards Mars, called Phoenix, and that spacecraft will land 17 days, seven hours and 20 seconds from now, so you can adjust your watch. So it ’ s on May 25 around just before five o ’ clock our time here on the West Coast, actually we will be landing on another planet. And as you can see, this is a **picture** of the spacecraft put on Mars, but I thought that just in case you ’ re going to miss that show, you know, in 17 days, I ’ ll show you, kind of, a little bit of what ’ s going to happen. Video : That ’ s what we call the seven minutes of terror. So the plan is to dig in the soil and take samples that we put them in an oven and actually heat them and look what **gases** will come from it. So this was launched about nine months ago. We ’ ll be coming in at 12, 000 miles per hour, and in seven minutes we have to stop and touch the surface very softly so we don ’ t break that lander. Ben Cichy : Phoenix is the first Mars Scout mission. It ’ s the first mission that ’ s going to try to land near the North Pole of Mars, and it ’ s the first mission that ’ s actually going to try and reach out and touch water on the surface of another planet. Lynn Craig : Where there tends to be water, at least on Earth, there tends to be life, and so it ’ s potentially a place where life could have existed on the planet in the past. Erik Bailey : The main purpose of EDL is to take a spacecraft that is traveling at 12, 500 miles an hour and bring it to a screeching halt in a soft way in a very short amount of time. BC : We enter the Martian atmosphere. We ’ re 70 miles above the surface of Mars. And our lander is safely tucked inside what we call an aeroshell. EB : Looks kind of like an ice cream cone, more or less. BC : And on the front of it is this heat shield, this saucer-looking thing that has about a half-inch of essentially what ’ s cork on the front of it, which is our heat shield. Now, this is really special cork, and this cork is what ’ s going to protect us from the violent atmospheric entry that we ’ re about to experience. Rob Grover : Friction really starts to build up on the spacecraft, and we use the friction when it ’ s flying through the atmosphere to our advantage to slow us down. BC : From this point, we ’ re going to decelerate from 12, 500 miles an hour down to 900 miles an hour. EB : The outside can get almost as hot as the surface of the Sun. RG : The temperature of the heat shield can reach 2, 600 degrees Fahrenheit. EB : The inside doesn ’ t get very hot. It probably gets about room temperature. Richard Kornfeld : There is this window of opportunity within which we can deploy the parachute. EB : If you fire the ’ chute too early, the parachute itself could fail. The fabric and the stitching could just pull apart. And that would be bad. BC : In the first 15 seconds after we deploy the parachute, we ’ ll decelerate from 900 miles an hour to a relatively slow 250 miles an hour. We no longer need the heat shield to protect us from the force of atmospheric entry, so we jettison the heat shield, exposing for the first time our lander to the atmosphere of Mars. LC : After the heat shield has been jettisoned and the legs are deployed, the next step is to have the radar system begin to detect how far Phoenix really is from the ground. BC : We ’ ve lost 99 percent of our entry velocity. So, we ’ re 99 percent of the way to where we want to be. But that last one percent, as it always seems to be, is the tricky part. EB : Now the spacecraft actually has to decide when it ’ s going to get rid of its parachute. BC : We separate from the lander going 125 miles an hour at roughly a kilometer above the surface of Mars : 3, 200 **feet**. That ’ s like taking two Empire State Buildings and stacking them on top of one another. EB : That ’ s when we separate from the back shell, and we ’ re now in free-fall. It ’ s a very scary moment ; a lot has to happen in a very short amount of time. LC : So it ’ s in a free-fall, but it ’ s also trying to use all of its actuators to make sure that it ’ s in the right position to land. EB : And then it has to light up its engines, right itself, and then slowly slow itself down and touch down on the ground safely. BC : Earth and Mars are so far apart that it takes over ten minutes for a signal from Mars to get to Earth. And EDL itself is all over in a matter of seven minutes. So by the time you even hear from the lander that EDL has started it ’ ll already be over. EB : We have to build large amounts of autonomy into the spacecraft so that it can land itself safely. BC : EDL is this immense, technically challenging problem. It ’ s about getting a spacecraft that ’ s hurtling through deep space and using all this bag of tricks to somehow figure out how to get it down to the surface of Mars at zero miles an hour. It ’ s this immensely exciting and challenging problem. CE : Hopefully it all will happen the way you saw it in here. So it will be a very tense moment, you know, as we are watching that spacecraft landing on another planet. So now let me talk about the next things that we are doing. So we are in the process, as we speak, of actually designing the next Rover that we are going to be sending to Mars. So I thought I would go a little bit and tell you, kind of, the steps we go through. It ’ s very similar to what you do when you design your product. As you saw a little bit earlier, when we were doing the Phoenix one, we have to take into account the heat that we are going to be facing. So we have to study all kinds of different materials, the shape that we want to do. In general we don ’ t try to please the customer here. What we want to do is to make sure we have an effective, you know, an efficient kind of machine. First we start by we want to have our employees to be as imaginative as they can. And we really love being close to the art center, because we have, as a matter of fact, one of the alumni from the art center, Eric Nyquist, had put a series of displays, far-out displays, you know, in our what we call mission design or spacecraft design room, just to get people to think wildly about things. We have a bunch of Legos. So, as I said, this is a playground for adults, where they sit down and try to play with different shapes and different designs. Then we get a little bit more serious, so we have what we call our CAD / CAMs and all the engineers who are involved, or scientists who are involved, who know about thermal properties, know about design, know about atmospheric interaction, parachutes, all of these things, which they work in a team effort and actually design a spacecraft in a computer to some extent, so to see, does that meet the requirement that we need. On the right, also, we have to take into account the environment of the planet where we are going. If you are going to Jupiter, you have a very high-radiation, you know, environment. It ’ s about the same radiation environment close by Jupiter as inside a nuclear reactor. So just imagine : you take your P. C. and throw it into a nuclear reactor and it still has to work. So these are kind of some of the little challenges, you know, that we have to face. If we are doing entry, we have to do tests of parachutes. You saw in the video a parachute breaking. That would be a bad day, you know, if that happened, so we have to test, because we are deploying this parachute at supersonic speeds. We are coming at extremely high speeds, and we are deploying them to slow us down. So we have to do all kinds of tests. To give you an idea of the size, you know, of that parachute relative to the people standing there. Next step, we go and actually build some kind of test models and actually test them, you know, in the lab at JPL, in what we call our Mars Yard. We kick them, we hit them, we drop them, just to make sure we understand how, where would they break. And then we back off, you know, from that point. And then we actually do the actual building and the flight. And this next Rover that we ’ re flying is about the size of a car. That big shield that you see outside, that ’ s a heat shield which is going to protect it. And that will be basically built over the next year, and it will be launched June a year from now. Now, in that case, because it was a very big Rover, we couldn ’ t use airbags. And I know many of you, kind of, last time afterwards said well, that was a cool thing to have — those airbags. Unfortunately this Rover is, like, ten times the size of the, you know, mass-wise, of the other Rover, or three times the mass. So we can ’ t use airbags. So we have to come up with another ingenious idea of how do we land it. And we didn ’ t want to take it propulsively all the way to the surface because we didn ’ t want to contaminate the surface ; we wanted the Rover to immediately land on its legs. So we came up with this ingenious idea, which is used here on Earth for helicopters. Actually, the lander will come down to about 100 **feet** and hover above that surface for 100 **feet**, and then we have a sky crane which will take that Rover and land it down on the surface. Hopefully it all will work, you know, it will work that way. And that Rover will be more kind of like a chemist. What we are going to be doing with that Rover as it drives around, it ’ s going to go and analyze the chemical composition of rocks. So it will have an arm which will take samples, put them in an oven, crush and analyze them. But also, if there is something that we cannot reach because it is too high on a cliff, we have a little **laser** system which will actually zap the rock, evaporate some of it, and actually analyze what ’ s coming from that rock. So it ’ s a little bit like”Star Wars,”you know, but it ’ s real. It ’ s real stuff. And also to help you, to help the community so you can do ads on that Rover, we are going to train that Rover to actually in addition to do this, to actually serve cocktails, you know, also on Mars. So that ’ s kind of giving you an idea of the kind of, you know, **fun** things we are doing on Mars. I thought I ’ d go to”The Lord of the Rings”now and show you some of the things we have there. Now,”The Lord of the Rings”has two things played through it. One, it ’ s a very attractive planet — it just has the beauty of the rings and so on. But for scientists, also the rings have a special meaning, because we believe they represent, on a small scale, how the Solar System actually formed. Some of the scientists believe that the way the Solar System formed, that the Sun when it collapsed and actually created the Sun, a lot of the dust around it created rings and then the particles in those rings accumulated together, and they formed bigger rocks, and then that ’ s how the planets, you know, were formed. So, the idea is, by watching Saturn we ’ re actually watching our solar system in real time being formed on a smaller scale, so it ' s like a test bed for it. So, let me show you a little bit on what that Saturnian system looks like. First, I ' m going to fly you over the rings. By the way, all of this is real stuff. This is not animation or anything like this. This is actually taken from the satellite that we have in orbit around Saturn, the Cassini. And you see the amount of detail that is in those rings, which are the particles. Some of them are agglomerating together to form larger particles. So that ' s why you have these gaps, is because a small satellite, you know, is being formed in that location. Now, you think that those rings are very large objects. Yes, they are very large in one dimension ; in the other dimension they are paper thin. Very, very thin. What you are seeing here is the shadow of the ring on Saturn itself. And that ' s one of the satellites which was actually formed on that one. So, think about it as a paper-thin, huge area of many hundreds of thousands of miles, which is rotating. And we have a wide variety of kind of satellites which will form, each one looking very different and very odd, and that keeps scientists busy for tens of years trying to explain this, and telling NASA we need more money so we can explain what these things look like, or why they formed that way. Well, there were two satellites which were particularly interesting. One of them is called Enceladus. It ' s a satellite which was all made of ice, and we measured it from orbit. Made of ice. But there was something bizarre about it. If you look at these stripes in here, what we call tiger stripes, when we flew over them, all of a sudden we saw an increase in the temperature, which said that those stripes are warmer than the rest of the planet. So as we flew by away from it, we looked back. And guess what? We saw geysers coming out. So this is a Yellowstone, you know, of Saturn. We are seeing geysers of ice which are coming out of that planet, which indicate that most likely there is an ocean, you know, below the surface. And somehow, through some dynamic effect, we ' re having these geysers which are being, you know, emitted from it. And the reason I showed the little arrow there, I think that should say 30 miles, we decided a few months ago to actually fly the spacecraft through the plume of that geyser so we can actually measure the material that it is made of. That was [unclear] also — you know, because we were worried about the risk of it, but it worked pretty well. We flew at the top of it, and we found that there is a fair amount of organic material which is being emitted in combination with the ice. And over the next few years, as we keep orbiting, you know, Saturn, we are planning to get closer and closer down to the surface and make more accurate measurements. Now, another satellite also attracted a lot of attention, and that ' s Titan. And the reason Titan is particularly interesting, it ' s a satellite bigger than our moon, and it has an atmosphere. And that atmosphere is very — as dense as our own atmosphere. So if you were on Titan, you would feel the same pressure that you feel in here. Except it ' s a lot colder, and that atmosphere is heavily made of methane. Now, methane gets people all excited, because it ' s organic material, so immediately people start thinking, could life have evolved in that location, when you have a lot of organic material. So people believe now that Titan is most likely what we call a pre-biotic planet, because it ' s so cold organic material did not get to the stage of becoming biological material, and therefore life could have evolved on it. So it could be Earth, frozen three billion years ago before life actually started on it. So that ' s getting a lot of interest, and to show you some example of what we did in there, we actually dropped a probe, which was developed by our colleagues in Europe, we dropped a probe as we were orbiting Saturn. We dropped a probe in the atmosphere of Titan. And this is a **picture** of an area as we were coming down. Just looked like the coast of California for me. You see the rivers which are coming along the coast, and you see that white area which looks like Catalina Island, and that looks like an ocean. And then with an instrument we have on board, a radar instrument, we found there are lakes like the Great Lakes in here, so it looks very much like Earth. It looks like there are rivers on it, there are oceans or lakes, we know there are clouds. We think it ’ s raining also on it. So it ’ s very much like the cycle on Earth except because it ’ s so cold, it could not be water, you know, because water would have frozen. What it turned out, that all that we are seeing, all this liquid, [is made of] hydrocarbon and ethane and methane, similar to what you put in your car. So here we have a cycle of a planet which is like our Earth, but is all made of ethane and methane and organic material. So if you were on Mars — sorry, on Titan, you don ’ t have to worry about four-dollar gasoline. You just drive to the nearest lake, stick your hose in it, and you ’ ve got your car filled up. On the other hand, if you light a match the whole planet will blow up. So in closing, I said I want to close by a couple of **pictures**. And just to kind of put us in perspective, this is a **picture** of Saturn taken with a spacecraft from behind Saturn, looking towards the Sun. The Sun is behind Saturn, so we see what we call”forward scattering,”so it highlights all the rings. And I ’ m going to zoom. There is a — I ’ m not sure you can see it very well, but on the top left, around 10 o ’ clock, there is a little teeny dot, and that ’ s Earth. You barely can see ourselves. So what I did, I thought I ’ d zoom on it. So as you zoom in, you know, you can see Earth, you know, just in the middle here. So we zoomed all the way on the art center. So thank you very much.

Welcome to 10, 000 **feet**. Let me explain why we are here and why some of you have a pine cone close to you. Once upon a time, I did a book called”How Buildings Learn.”Today ’ s event you might call”How Mountains Teach.”A little background : For 10 years I ’ ve been trying to figure out how to hack civilization so that we can get long-term thinking to be automatic and common instead of difficult and rare — or in some cases, non-existent. It would be helpful if humanity got into the habit of thinking of the now not just as next week or next quarter, but you know, next 10, 000 years and the last 10, 000 years — basically civilization ’ s story so far. So we have the Long Now Foundation in San Francisco. It ’ s an incubator for about a dozen projects, all having to do with continuity over the long term. Our core project is a rather ambitious folly — I suppose, a mythic undertaking : to build a 10, 000-year clock that can really keep good time for that long a period. And the design problems of a project like that are just absolutely delicious. Go to the clock. And what we have here is something many of you saw here three years ago. It ’ s the first working prototype of the clock. It ’ s about nine **feet** high. Designed by Danny Hillis and Alexander Rose. It ’ s presently in London, and is ticking away very deliberately at the science **museum** there. So the design problem for today is going to be, how do you house an eventual monumental clock like this so it can really tick, save time beautifully for 100 centuries? Well, this was the first solution. Alexander Rose came up with this idea of a spiraloid tower with continuous **sloping** ramps. And it looked like a way to go, until you start thinking about, what does deep time do to a building? Well, this is what deep time does to a building. This is the Parthenon. It ’ s only 2, 450 years old, and look what happened to it. Here ’ s a beautiful project. They really knew it ’ d last forever, because they ’ d build it out of absolutely huge stones. And now it ’ s a pathetic ruin and no one even knows what it was used for. That ’ s what happens to buildings. They ’ re vulnerable. Even the most durable and intactable buildings, like the pyramids of Giza, are in bad shape when you look up close. They ’ ve been looted inside and out. And they ’ re built to protect things but they don ’ t protect things. So we got to thinking, if you can ’ t put things safely in a building, where can you safely put them? We thought, OK, underground. How about underground with a view? Underground in a place that ’ s really solid. So the obvious answer was, we need a mountain. You don ’ t want just any mountain. You need absolutely the right mountain if you ’ re going to have a clock for 10, 000 years. So here ’ s an image of the long view of the search problem. And we got to thinking for various reasons it ought to be a desert mountain, so we got looking in the dry areas of the Southwest. We looked at mesas in New Mexico. We were looking at dead volcanoes in Arizona. Then Roger Kennedy, who was the director of the National Parks Service, led us to Eastern Nevada, to America ’ s newest and oldest national **park**, which is called Great Basin National Park. It ’ s right on the eastern border of Nevada. It ’ s the highest range in the state — over 13, 000 **feet**. And you ’ ll notice that on the left, on the left, on the west, it ’ s very steep, and on the right it ’ s gentle. This place is remote. It ’ s over 200 miles from any major city. It ’ s nowhere near any Interstate or **railroad**. And it ’ s — the only thing that goes by is what ’ s called America ’ s loneliest highway, U. S. 50. Now, inside the yellow line here, on the right is — that ’ s all national **park**. Inside the green line is national forest. And then over to the left is Bureau of Land Management land and some private land. Now, as it happened, that two- mile-long strip right in the middle, this vertical, was available because it was private land. And thanks to Jay Walker who was here and Mitch Kapor who was here, who started the process, Long Now was able to get that two-mile-long strip of land. And now let ’ s look at the grand truth of what ’ s there. We ’ re in Pole Canyon, looking west up the western escarpment of Mount Washington, which is 11, 600 **feet** on top. Those white cliffs are a dense Cambrian limestone. That ’ s a 2, 000-foot thick formation, and it might be a beautiful place to hide a clock. It would be a pilgrimage to get to it ; it would be a serious hike to get up to where the clock is. So last June, the Long Now board, some staff and some donors and advisors, made a two-week expedition to the mountain to explore it and investigate, one, if it ’ s the right mountain, and two, if it ’ s the right mountain, how it might actually work for us. Now Danny Hillis sort of framed the problem. He has a theory of how the overall clock experience should work. It ’ s what he calls the seven stages of a mythic adventure. It starts with the image. The image is a **picture** you have in your mind of the goal at the end of the journey. In this case it might well be an image of the clock. Then there ’ s the point of embarkation, that is, the point of transition from ordinary life to being a pilgrim on a quest. Then — this is a nice image of it, there ’ s the labyrinth. The labyrinth is a concept, it ’ s like a twilight zone, it ’ s a place where it ’ s difficult, where you get disoriented, maybe you get scared — but you have to go through it if you ’ re going to get to some kind of deep reintegration. Then there should always be in sight the draw — a kind of a beacon that draws you on through the labyrinth to finish the process of getting there. Now Brian Eno, who ’ s been in the thick of the Long Now process, spent two years making a C. D. called”January 7003,”and it ’ s”Bell Studies for the Clock of the Long Now.”Based on — parts of it are based on an algorithm that Danny Hillis developed, so that a peal of 10 bells makes a different peal every day for 10, 000 years. The Hillis algorithm. 10 factorial gives you that number. And in fact, pretty soon we ’ ll hear the sound. January 7003. There it is. OK, back to Danny ’ s list. Number five of the seven is the payoff. This is it. The climax. The goal. The main thing that you ’ re trying to get to. And then Danny says a really great journey will have a secret payoff. Something you didn ’ t expect that caps what you did expect. Then there ’ s the return. You ’ ve got to have a gradual return to the ordinary world, so you have time to assimilate what you ’ ve learned. And then, how about a memento? Number seven. At the end of it there ’ s something physical, a kind of reward that you take away. It might be a piece of a core drill of the mountain. Something that ’ s just yours. How do you study a mountain for the kinds of things we ’ re talking about? This is not a normal building project. What do you look for? What are the elements that will most affect your ideas and decisions? Start with borders. If you look on the left side of the cliffs here, that ’ s national **park**. That ’ s sacrosanct — you can ’ t do anything with that. To the right of it is national forest. There ’ s possibilities. The borders are important. Other elements were mines, weather, approaches and elevation. And especially trees. Look at those things up on top there. It turns out that Mount Washington is covered with bristlecone pines. They ’ re the world ’ s oldest living thing. People think they ’ re just the size of shrubs, but that ’ s not actually true. There are trees on that mountain that are 5, 000 years old and still living. The wood is so solid it ’ s like stone, and it lasts for a long time. So when you do tree ring studies of trunks that are on the mountain, some of them go back 10, 000 years. The stone itself is absolutely beautiful, sculpted by millennia of very tough winters up there. We had tree ring analysts from the University of Arizona join us on the expedition. Now, if you guys have a pine cone handy, now ’ s a good time to put it in your hand and feel it, especially on the end. That ’ s interesting. You ’ ll find out why it ’ s called a bristlecone pine. A little sensory experience. Here ’ s Danny Hillis in the midst of a bristlecone pine forest on Long Now land. I should say that the age of bristlecones was discovered, led by a theory. Edmund Schulman in the 1950s had been studying trees under great stress at Timberline, and came to the realization that he put in an article in Science magazine called,”Longevity under Adversity in Conifers.”And then, based on that principle, he started looking around at the various trees at Timberline, and realized that the bristlecone pines — he found some in the White Mountains that were over 4, 000 years old. Longevity under adversity is a pretty interesting design principle in its own right. OK, onto the mines. The first asking price for the property when we looked at it in 1998 was one billion dollars for 180 acres and a couple of mines. Because the owner said,”There ’ s one billion dollars of beryllium in that mountain.”And we said,”Wow, that ’ s great. Listen, we ’ ll counter. How about zero? And we ’ re a non-profit foundation, you can give us the property and take a **hell** of a tax deduction. All you have to do is prove to the government it ’ s worth a billion dollars.”Well, a few years went by and there was some kind of back and forth, and by and by, thanks to Mitch and Jay, we were able to buy the whole property for 140, 000 dollars. This is one of the mines. It doesn ’ t have any beryllium in it. It ’ s called the Pole Adit. And it does have tungsten, a little bit of tungsten, left over, that ’ s the kind of mine it was. But it goes a mile-and-a-half in a straight line, due east into the range, into very interesting territory — except that, as you ’ ll see when we go inside in a minute, we were hoping for limestone but in there is just shale. And shale is not quite completely competent rock. Competent rock is rock that will hold itself up without any shoring. The shale would like some shoring, and so parts of it are caved in in there. That ’ s Ben Roberts from — he ’ s the bat specialist from the National Park. But there are many wonders back in there, like this weird fungus on some of the collapsed timbers. OK, here ’ s another mine that ’ s up on top of the property, and it dates back to 1870. That ’ s what the property was originally built around — it was a set of mining claims. It was a very productive silver mine. In fact, it was the highest-operating mine in Nevada, and it ran year round. You can imagine what it was like in the winter at 10, 000 **feet**.

You may recognize a couple of the miners there. There ’ s Jeff Bezos on the right and Paul Saville on the left looking for galena, which is the lead-silver thing. They didn ’ t find any. They both kept their day jobs. Here ’ s the last mine. It ’ s called the Bonanza Adit. It ’ s down in a canyon. And Alexander Rose on the left there worked with a bunch of people from the National Park to survey the whole mine. It ’ s a mile deep. And they also found four species of bats in there. Now, almost all those mines, by the way, meet underneath the mountain. They don ’ t quite, but it ’ s something to think about. They don ’ t quite meet. Let ’ s go to weather. Mountains specialize in interesting weather. Way more interesting than Monterey even today. And so one Tuesday morning last June, there we were. Woke up in the morning — the mountain was covered with snow. That was a great time to go up and visit our weather station which again, thanks to Mitch Kapor, we ’ re building up there. And it ’ s a pretty interesting scene. This is, on the left there, the joyful lady is Pat Irwin, who ’ s the regional head of the National Forest Service, and they gave us the temporary use permit to be there. We want a temporary use permit for the clock, eventually — 10, 000-year temporary use permit. The weather station ’ s pretty interesting. Kurt Bollacker and Alexander Rose designed a radically wireless station. It runs on solar, and it sends a signal with that antenna and bounces it off of micrometeorite trails in the atmosphere to a place in Bozeman, Montana, where the data is taken down and then sent through landlines to San Francisco, where we put the data in real time up on our website. And there you see a week of weather at 9, 400 **feet** on Mount Washington. Let ’ s go to approaches. As it happens, there are no trails anywhere on Mount Washington, just a few old mining roads like this, so you have to bushwhack everywhere. But there ’ s no bears, and there ’ s no poison oak, and there ’ s basically no people because this place has been empty for a long time. You can hike for days and not encounter anybody. Well, here ’ s a potential approach. You need to come up the Lincoln Canyon. It ’ s this beautiful world all of its own, surrounded by cliffs, and it ’ s an easy hike to stroll up the canyon **bottom**, until you get to this barrier, and it actually presents a problem. So you can scratch Lincoln Canyon as an approach. Another possible approach is right up the western front of the mountain. You can see why we sometimes call it Long Mountain. And from where you ’ re standing at 6, 000 **feet** in the **valley**, it ’ s an easy hike up to the mature pinyon and juniper forest through that knoll at the front at 7, 600 **feet**. And you can carry right on up through meadows and steepening forest to the high base of the cliffs at 10, 500 **feet**, where there ’ s a bit of a problem. Now, Jeff Bezos advised us when he left at the end of the expedition,”Make the clock inaccessible. The harder it is to get to, the more people will value it.”And check — those are 600-foot vertical walls there. So Alexander Rose wanted to explore this route, and he started over here on the left from his pickup truck at 8, 900 **feet** and headed up the mountain. Now, as you gain elevation your IQ goes down — but your emotional affect goes up, which is great for having a mythic experience, whether you want to or not. In fact, Danny Hillis can estimate altitude by how much math he can ’ t do in his head. Now, I happened to be on the radio with Alexander when he got to this point at the base of the cliffs, and he said, quote,”There ’ s a hidden notch. I think I can get up a ways.”Now, he ’ s a rock climber, but you know, he ’ s our executive director. I don ’ t want him killed. I know he ’ s going to love cliffs. I ’ m saying,”Be careful, be careful, be careful.”Then he starts going up, and the next thing I hear is,”I ’ m half-way up. It ’ s like climbing stairs. I ’ m going up 60 degrees. It ’ s a secret passage. It ’ s like something from Tolkien.”And I ’ m going,”Careful, careful. Please be careful.”And then, of course, the next thing I hear is,”I ’ ve made it to the top. You can see all of creation from up here.”And he dashed across the top of the mountains. In fact, there he is. That ' s Alexander Rose. First ascent of the western face to Mount Washington, and a solo ascent at that. This discovery changed everything about our sense of these cliffs and what to do with them. We realized that we had to name this thing that Alexander discovered. How about Zander ' s Crevice? No. So we finally decided on Alexander ' s Siq. Zander ' s Siq is named after — some of you have been to Petra, there ' s this wonderful slot canyon that leads into Petra called the Siq, and so this is the Siq. And it really is hidden. I can ' t find it in this image, and I ' m not sure you can. Only when you get fresh snow can you see just along the rim there, and that brings it out. Now, Danny and I were up at this same area one day, and Danny looked over to the right and noticed something halfway up the cliffs, which is a kind of a porch or a cliff shelf with bristlecones on it, and supposed that people going up to the clock inside the mountain could come out onto that shelf and look down at the view. And the people toiling up the mountain could see them, these tiny little people up there, incredibly halfway up the cliff. How did they get there? Do I have to do that? And so that maybe becomes part of the draw and part of the labyrinth. You can get another angle on Danny ' s porch by going around to the south and looking north at the whole formation there. And you need to know that Danny ' s clock is to be kept accurate by a ray of sunshine, that perfect noon hitting it every sunny day, and the pulse of heat from that sets off a solar trigger which resets the clock to make it perfectly accurate. So even with the slowing of the rotation of the earth and so on, the clock will keep perfectly good time. So here we ' re looking from the south, look north. This is all Forest Service land. If you go up on top of those cliffs, that ' s some of the Long Now land in those trees. And if you go up there and look back, then you ' ll get a sense of what the view starts to be like from the top of the mountain. That ' s the long view. That ' s 80 miles to the horizon. And that ' s also timberline and those bristlecones really are shrubs. That ' s a different place to be. It ' s 11, 400 **feet** and it ' s exquisite. Now, if you go over to the right from this image to looking at the edge of the cliffs, it ' s 600 **foot**, just about a yard to the left of Kurt Bollacker ' s **foot**, there is a 600-foot drop. He ' s ambling on over to Zander ' s Siq. That ' s what it looks like looking down it. We should probably put in a rail or something. Over on the eastern side it ' s gentle, as you can see. And that ' s not snow — that ' s what the white limestone looks like. You also see there a bighorn sheep. Their herd was reintroduced from Wyoming. And they ' re doing pretty well, but they ' ve got a bit of trouble. This is Danny Hillis, and he ' s figuring out a design problem. he ' s trying to determine if where he is on a bit of Long Now land would appear from down in the **valley** to be the actual peak of the mountain. because the real peak is hidden around the corner. This is what in the infantry we used to call the military crest. And as it turned out the answer is, yes, that is from down below in the **valley** it does look like the peak, and that might be conjured with. We gradually realized we have three serious design domains to work on with this. One is the experience of the mountain. Another is the experience in the mountain. And the third is the experience from the mountain, which is really dominated by the view shed of the spring **valley** there behind Danny, and if you look off to the right, out there, 15 miles across to the Schell Creek range. In the front, there are 10 ranches strung right along the base of the mountains using the water from the mountains. In fact, there are artesian wells where water springs right into the air. One of the ranches is called the Kirkeby Ranch, and I ' ll take you there for a minute. It ' s a very nice ranch. Alfalfa and cattle, run by Paul and Ronnie Brenham, and it ' s pretty idyllic. It ' s also hard work. And most of these ranches are having trouble keeping going. This is their view to the west of the Schell Creek range. And if you go out to that line of trees at the far end, you ' ll see what the **valley** used to look like. This is Rocky Mountain junipers that have been there for thousands of years. And a scheme emerged that Long Now is looking to see if it might be possible to buy up the whole **valley**, because those 10 ranches with their 17, 000 acres dominate a 500 square mile **valley** with their grazing allotments and so on, and there ' s a possibility that you could get the whole thing for five million dollars and gradually restore it to its wild condition, and somewhere in the process turn it back over to the National Park, and it would double the size of Great Basin National Park. That would be swell. OK, let ' s take one more look at the mountain itself. The clock experience should be profound, but from the outside it should be invisible. Now, at the base of the high cliffs there ' s this natural cave. It ' s only about 12 **feet** deep, but what if it were deepened from inside? You excavated from somewhere, came up from inside and deepened it. And then you could have an entrance which was very rough and narrow as you first went in, that gradually becomes more refined and then actually quite exquisite. And this stone takes a perfect polish. You ' d have a polished set of passages and chambers in there eventually leading to the 10, 000 year clock. And it ' s not a mine. This would be a nuanced evocation of the basic structure of the mountain, and you would be appreciating it as much from inside as you do from outside. This is architecture not made by building, but by what you very carefully take away. So that ' s what the mountain taught us. Most of the amazingness of the clock we can borrow from the amazingness of the mountain. All we have to do is highlight its spectacular features and blend in with them. It ' s not a clock in a mountain — it ' s a mountain clock. Now, the Tewa Indians in the Southwest have a saying for what you need to do when you want to think long term about anything. They say,"pin peya obe"— welcome to the mountain. Thank you.

Text Sample 681: POS Dim 5 – 2004 – Score 8.00 – 2004/t000445.txt

If you ' d like to learn how to play the lobster, we have some here. And that ' s not a joke, we really do. So come up afterwards and I ' ll show you how to play a lobster. So, actually, I started working on what ' s called the mantis shrimp a few years ago because they make sound. This is a recording I made of a mantis shrimp that ' s found off the coast of California. And while that ' s an absolutely fascinating sound, it actually turns out to be a very difficult project. And while I was struggling to figure out how and why mantis shrimp, or stomatopods, make sound, I started to think about their appendages. And mantis shrimp are called"mantis shrimp"after the praying mantises, which also have a fast feeding appendage. And I started to think, well, maybe it will be interesting, while listening to their sounds, to figure out how these animals generate very fast feeding strikes. And so today I ' ll talk about the extreme stomatopod strike, work that I ' ve done in collaboration with Wyatt Korff and Roy Caldwell. So, mantis shrimp come in two varieties : there are spearers and smashers. And this is a spearing mantis shrimp, or stomatopod. And he lives in the sand, and he catches things that go by overhead. So, a quick strike like that. And if we slow it down a bit, this is the mantis shrimp — the same species — recorded at 1, 000 frames a second, played back at 15 frames per second. And you can see it ' s just a really spectacular extension of the limbs, exploding upward to actually just catch a dead piece of shrimp that I had offered it. Now, the other type of mantis shrimp is the smasher stomatopod, and these guys open up snails for a living. And so this guy gets the snail all set up and gives it a good whack. So, I ' ll play it one more time. He wiggles it in place, tugs it with his nose, and smash. And a few smashes later, the snail is broken open, and he ’ s got a good dinner. So, the smasher raptorial appendage can stab with a point at the end, or it can smash with the heel. And today I ’ ll talk about the smashing type of strike. And so the first question that came to mind was, well, how fast does this limb move? Because it ’ s moving pretty darn fast on that video. And I immediately came upon a problem. Every single high-speed video system in the biology department at Berkeley wasn ’ t fast enough to catch this movement. We simply couldn ’ t capture it on video. And so this had me stymied for quite a long period of time. And then a BBC crew came cruising through the biology department, looking for a story to do about new technologies in biology. And so we struck up a deal. I said,”Well, if you guys rent the high-speed video system that could capture these movements, you guys can **film** us collecting the data.”And believe it or not, they went for it. So we got this incredible video system. It ’ s very new technology — it just came out about a year ago — that allows you to **film** at extremely high speeds in low light. And low light is a critical issue with **filming** animals, because if it ’ s too high, you fry them. So this is a mantis shrimp. There are the eyes up here, and there ’ s that raptorial appendage, and there ’ s the heel. And that thing ’ s going to swing around and smash the snail. And the snail ’ s wired to a stick, so he ’ s a little bit easier to set up the shot. And — yeah. I hope there aren ’ t any snail rights activists around here. So this was **filmed** at 5, 000 frames per second, and I ’ m playing it back at 15. And so this is slowed down 333 times. And as you ’ ll notice, it ’ s still pretty gosh darn fast slowed down 333 times. It ’ s an incredibly powerful movement. The whole limb extends out. The body flexes backwards — just a spectacular movement. And so what we did is, we took a look at these videos, and we measured how fast the limb was moving to get back to that original question. And we were in for our first surprise. So what we calculated was that the limbs were moving at the peak speed ranging from 10 meters per second all the way up to 23 meters per second. And for those of you who prefer miles per hour, that ’ s over 45 miles per hour in water. And this is really darn fast. In fact, it ’ s so fast we were able to add a new point on the extreme animal movement spectrum. And mantis shrimp are officially the fastest measured feeding strike of any animal system. So our first surprise. So that was really cool and very unexpected. So, you might be wondering, well, how do they do it? And actually, this work was done in the 1960s by a famous biologist named Malcolm Burrows. And what he showed in mantis shrimp is that they use what ’ s called a”catch mechanism,”or”click mechanism.”And what this basically consists of is a large muscle that takes a good long time to contract, and a latch that prevents anything from moving. So the muscle contracts, and nothing happens. And once the muscle ’ s contracted completely, everything ’ s stored up — the latch flies upward, and you ’ ve got the movement. And that ’ s basically what ’ s called a”power amplification system.”It takes a long time for the muscle to contract, and a very short time for the limb to fly out. And so I thought that this was sort of the end of the story. This was how mantis shrimps make these very fast strikes. But then I took a trip to the National Museum of Natural History. And if any of you ever have a chance, backstage of the National Museum of Natural History is one of the world ’ s best collections of preserved mantis shrimp. And what — this is serious business for me. So, this — what I saw, on every single mantis shrimp limb, whether it ’ s a spearer or a smasher, is a beautiful saddle-shaped structure right on the top surface of the limb. And you can see it right here. It just looks like a saddle you ’ d put on a horse. It ’ s a very beautiful structure. And it ’ s surrounded by membranous areas. And those membranous areas suggested to me that maybe this is some kind of dynamically flexible structure. And this really sort of had me scratching my head for a while. And then we did a series of calculations, and what we were able to show is that these mantis shrimp have to have a spring. There needs to be some kind of spring-loaded mechanism in order to generate the amount of force that we observe, and the speed that we observe, and the output of the system. So we thought, OK, this must be a spring — the saddle could very well be a spring. And we went back to those high-speed videos again, and we could actually visualize the saddle compressing and extending. And I ' ll just do that one more time. And then if you take a look at the video — it ' s a little bit hard to see — it ' s outlined in yellow. The saddle is outlined in yellow. You can actually see it extending over the course of the strike, and actually hyperextending. So, we ' ve had very solid evidence showing that that saddle-shaped structure actually compresses and extends, and does, in fact, function as a spring. The saddle-shaped structure is also known as a"hyperbolic paraboloid surface,"or an"anticlastic surface."And this is very well known to engineers and **architects**, because it ' s a very strong surface in compression. It has **curves** in two directions, one **curve** upward and opposite transverse **curve** down the other, so any kind of perturbation spreads the forces over the surface of this type of shape. So it ' s very well known to engineers, not as well known to biologists. It ' s also known to quite a few people who make jewelry, because it requires very little material to build this type of surface, and it ' s very strong. So if you ' re going to build a thin gold structure, it ' s very nice to have it in a shape that ' s strong. Now, it ' s also known to **architects**. One of the most famous **architects** is Eduardo Catalano, who popularized this structure. And what ' s shown here is a saddle-shaped **roof** that he built that ' s 87 and a half **feet** spanwise. It ' s two and a half inches thick, and supported at two points. And one of the reasons why he designed **roofs** this way is because it ' s — he found it fascinating that you could build such a strong structure that ' s made of so few materials and can be supported by so few points. And all of these are the same principles that apply to the saddle-shaped spring in stomatopods. In biological systems it ' s important not to have a whole lot of extra material requirements for building it. So, very interesting parallels between the biological and the engineering worlds. And interestingly, this turns out — the stomatopod saddle turns out to be the first described biological hyperbolic paraboloid spring. That ' s a bit long, but it is sort of interesting. So the next and final question was, well, how much force does a mantis shrimp produce if they ' re able to break open snails? And so I wired up what ' s called a load cell. A load cell measures forces, and this is actually a piezoelectronic load cell that has a little crystal in it. And when this crystal is squeezed, the electrical properties change and it — which — in proportion to the forces that go in. So these animals are wonderfully aggressive, and are really hungry all the time. And so all I had to do was actually put a little shrimp paste on the front of the load cell, and they ' d smash away at it. And so this is just a regular video of the animal just smashing the heck out of this load cell. And we were able to get some force measurements out. And again, we were in for a surprise. I purchased a 100-pound load cell, thinking, no animal could produce more than 100 pounds at this size of an animal. And what do you know? They immediately overloaded the load cell. So these are actually some old data where I had to find the smallest animals in the lab, and we were able to measure forces of well over 100 pounds generated by an animal about this big. And actually, just last week I got a 300-pound load cell up and running, and I ' ve clocked these animals generating well over 200 pounds of force. And again, I think this will be a world record. I have to do a little bit more background reading, but I think this will be the largest amount of force produced by an animal of a given — per body mass. So, really incredible forces. And again, that brings us back to the importance of that spring in storing up and releasing so much energy in this system. But that was not the end of the story. Now, things — I ’ m making this sound very easy, this is actually a lot of work. And I got all these force measurements, and then I went and looked at the force output of the system. And this is just very simple — time is on the X- axis and the force is on the Y-axis. And you can see two peaks. And that was what really got me puzzled. The first peak, obviously, is the limb hitting the load cell. But there ’ s a really large second peak half a millisecond later, and I didn ’ t know what that was. So now, you ’ d expect a second peak for other reasons, but not half a millisecond later. Again, going back to those high-speed videos, there ’ s a pretty good hint of what might be going on. Here ’ s that same orientation that we saw earlier. There ’ s that raptorial appendage — there ’ s the heel, and it ’ s going to swing around and hit the load cell. And what I ’ d like you to do in this shot is keep your eye on this, on the surface of the load cell, as the limb comes flying through. And I hope what you are able to see is actually a flash of light. Audience : Wow. Sheila Patek : And so if we just take that one frame, what you can actually see there at the end of that yellow arrow is a vapor bubble. And what that is, is cavitation. And cavitation is an extremely potent fluid dynamic phenomenon which occurs when you have areas of water moving at extremely different speeds. And when this happens, it can cause areas of very low pressure, which results in the water literally vaporizing. And when that vapor bubble collapses, it emits sound, light and heat, and it ’ s a very destructive process. And so here it is in the stomatopod. And again, this is a situation where engineers are very familiar with this phenomenon, because it destroys boat propellers. People have been struggling for years to try and design a very fast rotating boat propeller that doesn ’ t cavitate and literally wear away the **metal** and put holes in it, just like these **pictures** show. So this is a potent force in fluid systems, and just to sort of take it one step further, I ’ m going to show you the mantis shrimp approaching the snail. This is taken at 20, 000 frames per second, and I have to give full credit to the BBC cameraman, Tim Green, for setting this shot up, because I could never have done this in a million years — one of the benefits of working with professional cameramen. You can see it coming in, and an incredible flash of light, and all this cavitation spreading over the surface of the snail. So really, just an amazing image, slowed down extremely, to extremely slow speeds. And again, we can see it in slightly different form there, with the bubble forming and collapsing between those two surfaces. In fact, you might have even seen some cavitation going up the edge of the limb. So to solve this quandary of the two force peaks : what I think was going on is : that first impact is actually the limb hitting the load cell, and the second impact is actually the collapse of the cavitation bubble. And these animals may very well be making use of not only the force and the energy stored with that specialized spring, but the extremes of the fluid dynamics. And they might actually be making use of fluid dynamics as a second force for breaking the snail. So, really fascinating double whammy, so to speak, from these animals. So, one question I often get after this talk — so I figured I ’ d answer it now — is, well, what happens to the animal? Because obviously, if it ’ s breaking snails, the poor limb must be disintegrating. And indeed it does. That ’ s the smashing part of the heel on both these images, and it gets worn away. In fact, I ’ ve seen them wear away their heel all the way to the flesh. But one of the convenient things about being an arthropod is that you have to molt. And every three months or so these animals molt, and they build a new limb and it ’ s no problem. Very, very convenient solution to that particular problem. So, I ’ d like to end on sort of a wacky note. Maybe this is all wacky to folks like you, I don ’ t know. So, the saddles — that saddle-shaped spring — has actually been well known to biologists for a long time, not as a spring but as a visual signal. And there ' s actually a spectacular colored dot in the center of the saddles of many species of stomatopods. And this is quite interesting, to find evolutionary origins of visual signals on what ' s really, in all species, their spring. And I think one explanation for this could be going back to the molting phenomenon. So these animals go into a molting period where they ' re unable to strike — their bodies become very soft. And they ' re literally unable to strike or they will self-destruct. This is for real. And what they do is, up until that time period when they can ' t strike, they become really obnoxious and awful, and they strike everything in sight ; it doesn ' t matter who or what. And the second they get into that time point when they can ' t strike any more, they just signal. They wave their legs around. And it ' s one of the classic examples in animal behavior of bluffing. It ' s a well-established fact of these animals that they actually bluff. They can ' t actually strike, but they pretend to. And so I ' m very curious about whether those colored dots in the center of the saddles are conveying some kind of information about their ability to strike, or their strike force, and something about the time period in the molting cycle. So sort of an interesting strange fact to find a visual structure right in the middle of their spring. So to conclude, I mostly want to acknowledge my two collaborators, Wyatt Korff and Roy Caldwell, who worked closely with me on this. And also the Miller Institute for Basic Research in Science, which gave me three years of funding to just do science all the time, and for that I ' m very grateful. Thank you very much.

You ' ll be happy to know that I ' ll be talking not about my own tragedy, but other people ' s tragedy. It ' s a lot easier to be lighthearted about other people ' s tragedy than your own, and I want to keep it in the spirit of the conference. So, if you believe the media accounts, being a drug dealer in the height of the crack cocaine epidemic was a very glamorous life, in the words of Virginia Postrel. There was money, there was drugs, guns, women, you know, you name it — jewelry, bling-bling — it had it all. What I ' m going to tell you today is that, in fact, based on 10 years of research, a unique opportunity to go inside a gang — to see the actual books, the financial records of the gang — that the answer turns out not to be that being in the gang was a glamorous life. But I think, more realistically, that being in a gang — selling drugs for a gang — is perhaps the worst job in all of America. And that ' s what I ' d like to convince you of today. So there are three things I want to do. First, I want to explain how and why crack cocaine had such a profound influence on inner-city gangs. Secondly, I want to tell you how somebody like me came to be able to see the inner workings of a gang — an interesting story, I think. And then third, I want to tell you, in a very superficial way, about some of the things we found when we actually got to look at the financial records, the books, of the gang. So before I do that, just one warning, which is that this presentation has been rated ' R ' by the Motion Picture Association of America. It contains adult themes, adult language. Given who is up on the stage, you ' ll be delighted to know that, in fact, there ' ll be no nudity — Unexpected wardrobe malfunctions aside. So let me start by talking about crack cocaine, and how it transformed the gang. To do that, you have to actually go back to a time before crack cocaine, in the early ' 80s, and look at it from the perspective of a gang leader. Being a gang leader in the inner city wasn ' t such a bad deal in the mid- ' 80s — the early ' 80s, let me say. Now, you had a lot of power, and you got to beat people up — you got a lot of prestige, a lot of respect. But the thing is, there was no money in it. The gang had no way to make money. You couldn ' t charge dues to the people in the gang, because the people in the gang didn ' t have any money. You couldn ' t really make any money selling marijuana — marijuana ' s too cheap, it turns out. You can ' t get rich selling marijuana. You couldn ' t sell cocaine ; cocaine ' s a great product — powdered cocaine — but you ' ve got to know rich white people. And most of the inner-city gang members didn ' t know any rich white people, so couldn ' t sell to that market. You couldn ' t really do petty crime, either. Turns out, petty crime ' s a terrible way to make a living. As a result, as a gang leader, you had, you know, power — it ' s a pretty good life — but the thing was, in the end, you were living at home with your mother. And so it wasn ' t really a career. There were limits to how powerful and important you could be if you had to live at home with your mother. Then along comes crack cocaine. And in the words of Malcolm Gladwell, crack cocaine was the extra-chunky version of tomato sauce for the inner city. Because crack cocaine was an unbelievable innovation. I don ' t have time to talk about it today, but if you think about it, I would say that in the last 25 years, of every invention or innovation that ' s occurred in this country, the biggest one in terms of impact on the well-being of people who live in the inner city, was crack cocaine. And for the worse — not for the better, but for the worse. It had a huge impact on life. So what was it about crack cocaine? It was a brilliant way of getting the brain high. Because you could smoke crack cocaine — you can ' t smoke powdered cocaine — and smoking is a much more efficient mechanism of delivering a high than snorting it. And it turned out there was this audience that didn ' t know it wanted crack cocaine, but when it came, it really did. And it was a perfect drug ; you could buy the cocaine that went into it for a dollar, sell it for five dollars. Highly addictive — the high was very short. So for fifteen minutes, you get this great high, and then when you come down, all you want to do is get high again. It created a wonderful market. And for the people who were there running the gang, it was a great way, seemingly, to make a lot of money. At least for the people on the top. So this is where we enter the **picture**. Not really me — I ' m really a bit player in all this. My co-author, Sudhir Venkatesh, is the main character. He was a math major in college who had a good heart, and decided he wanted to get a sociology PhD, came to the University of Chicago. Now, the three months before he came to Chicago, he had spent following the Grateful Dead. And in his own words, he"looked like a freak."He ' s a South Asian — very dark-skinned South Asian. Big man, and he had hair, in his words,"down to his ass."Defied all kinds of boundaries : Was he black or white? Was he man or woman? He was really a curious sight to be seen. So he showed up at the University of Chicago, and the famous sociologist William Julius Wilson was doing a book that involved surveying people all across Chicago. He took one look at Sudhir, who was going to go do some surveys for him, and decided he knew exactly the place to send him, which was to one of the toughest, most notorious housing projects not just in Chicago, but in the entire United States. So Sudhir, the suburban boy who had never really been in the inner city, dutifully took his clipboard and walked down to this housing project, gets to the first building. The first building? Well, there ' s nobody there. But he hears some voices up in the stairwell, so he climbs up the stairwell, comes around the corner, and finds a group of young African-American men playing dice. This is about 1990, peak of the crack epidemic. This is a very dangerous job, being in a gang. You don ' t like to be surprised. You don ' t like to be surprised by people who come around the corner. And the mantra was : shoot first ; ask questions later. Now, Sudhir was lucky — he was such a freak, and that clipboard probably saved his life, because they figured no other rival gang member would be coming up to shoot at them with a clipboard. So his greeting was not particularly warm, but they did say, well, OK — let ' s hear your questions on your survey. So — I kid you not — the first question on the survey that he was sent to ask was :"How do you feel about being poor and Black in America?"Makes you wonder about academics. So the choice of answers were : [A) Very Good B) Good C) Bad D) Very Bad] What Sudhir found out is, in fact, that the real answer was the following : [A) Very Good B) Good C) Bad D) Very Bad E) Fuck you] The survey was not, in the end, going to be what got Sudhir off the hook. He was held hostage overnight in the stairwell. There was a lot of gunfire, there were a lot of philosophical discussions he had with the gang members. By morning, the gang leader arrived, checked out Sudhir, decided he was no threat, and they let him go home. So Sudhir went home, took a shower, took a nap. And you and I, probably, faced with the situation, would think,"I guess I ' m going to write my dissertation on The Grateful Dead, I ' ve been following them for the last three months."Sudhir, on the other hand, got right back, walked down to the housing project, went up to the second floor, and said :"Hey, guys, I had so much **fun** hanging out with you last night, I wonder if I could do it again tonight."And that was the beginning of what turned out to be a beautiful relationship that involved Sudhir living in the housing project on and off for 10 years, hanging out in crack houses, going to jail with the gang members, having the windows shot out of his car, having the police break into his apartment and steal his computer disks — you name it. But ultimately, the story has a happy ending for Sudhir, who became one of the most respected sociologists in the country. And especially for me, as I sat in my office with my Excel spreadsheet open, waiting for Sudhir to come and deliver to me the latest load of data that he would get from the gang. It was one of the most unequal co-authoring relationships ever — But I was glad to be the beneficiary of it. So what did we find? What did we find in the gang? Well, let me say one thing : We really got access to everybody in the gang. We got an inside look at the gang, from the very **bottom** up to the very top. They trusted Sudhir, in ways that really no academic has ever — or really anybody, any outsider — has ever earned the trust of these gangs, to the point where they actually opened up what was most interesting for me — their books, the financial records they kept. They made them available to us, and we not only could study them, but we could ask them questions about what was in them. So if I have to kind of summarize very quickly in the short time I have what the **bottom** line of what I take away from the gang is, it ' s that, if I had to draw a parallel between the gang and any other organization, it would be that the gang is just like McDonald ' s, in a lot of different respects — the restaurant McDonald ' s. So first, in one way, which isn ' t maybe the most interesting way, but it ' s a good way to start — is in the way it ' s organized, the hierarchy of the gang, the way it looks. So here ' s what the org chart of the gang looks like. I don ' t know if you know much about org charts, but if you were to assign a stripped- down and simplified McDonald ' s org chart, this is exactly what it would look like. It ' s amazing, but the top level of the gang, they actually call themselves the"Board of Directors."And Sudhir says it ' s not like these guys had a very sophisticated view of what happened in American corporate life, but they had seen movies like"Wall Street,"and they had learned a little bit about what it was like to be in the real world. Now, below that board of directors, you ' ve got essentially what are regional VPs — people who control, say, the South Side of Chicago, or the West Side of Chicago. Sudhir got to know very well the guy who had the unfortunate assignment of trying to take the Iowa franchise, which, it turned out, for this black gang, was not one of the more brilliant financial endeavors they undertook. But the thing that really makes the gang seem like McDonald ' s is its franchisees. The guys who are running the local gangs — the four-square-block by four-square-block areas — they ' re just like the guys, in some sense, who are running the McDonald ’ s. They are the entrepreneurs. They get the exclusive property rights to control the drug-selling. They get the name of the gang behind them, for merchandising and marketing. And they ’ re the ones who basically make the profit or lose a profit, depending on how good they are at running the business. Now, the group I really want you to think about, though, are the ones at the **bottom** — the **foot** soldiers. These are the teenagers, typically, who ’ d be standing out on the street corner, selling the drugs. Extremely dangerous work. And important to note is that almost all of the weight, all of the people in this organization are at the **bottom** — just like McDonald ’ s. So in some sense, the **foot** soldiers are a lot like the people who are taking your order at McDonald ’ s, and it ’ s not just by chance that they ’ re like them. In fact, in these neighborhoods, they ’ d be the same people. So the same kids who are working in the gang were actually, at the very same time, typically working part-time at a place like McDonald ’ s. Which already foreshadows the main result that I ’ ve talked about, about what a crappy job it was, being in the gang. Because obviously, if being in the gang were such a wonderful, lucrative job, why in the world would these guys moonlight at McDonald ’ s? So what do the wages look like? You might be surprised. But based on being able to talk to them and to see their records, this is what it looks like in terms of the wages. The hourly wage the **foot** soldiers were earning was $3. 50 an hour. It was below the minimum wage. And this is well-documented. It ’ s easy to see by the patterns of consumption they have. It really is not fiction — it ’ s fact. There was very little money in the gang, especially at the **bottom**. Now if you managed to rise up, say, and be that local leader, the guy who ’ s the equivalent of the McDonald ’ s franchisee, you ’ d be making 100, 000 dollars a year. And that, in some ways, was the best job you could hope to get if you were growing up in one of these neighborhoods as a young black male. If you managed to rise to the very top, 200, 000 or 400, 000 dollars a year is what you ’ d hope to make. Truly, you would be a great success story. And one of the sad parts of this is that, indeed, among the many other ramifications of crack cocaine is that the most talented individuals in these communities — this is what they were striving for. They weren ’ t trying to make it in legitimate ways, because there were no legitimate channels out. This was the best way out. And it actually was the right choice, probably, to try to make it out this way. You look at this, the relationship to McDonald ’ s breaks down here. The money looks about the same. Why is it such a bad job? Well, the reason it ’ s such a bad job is that there ’ s somebody shooting at you a lot of the time. So, with shooting at you, what are the death rates? We found, in our gang — and admittedly, this was not really a standard situation ; this was a time of intense violence, of a lot of gang wars, as this gang actually became quite successful. But there were costs. And so the death rate — not to mention the rate of being arrested, sent to prison, being wounded — the death rate in our sample was seven percent per person per year. You ’ re in the gang for four years, you expect to die with about a 25 percent likelihood. That is about as high as you can get. So for comparison ’ s purposes, let ’ s think about some other walk of life you may expect might be extremely risky. Let ’ s say that you were a murderer and you were convicted of murder, and you ’ re sent to death row. It turns out, the death rates on death row from all causes, including execution : two percent a year. So it ’ s a lot safer being on death row than it is selling drugs out on the street. That gives you some pause, for those of you who believe that a death penalty ’ s going to have an enormous deterrent effect on crime. To give you a sense of just how bad the inner city was during crack — and I ’ m not really focusing on the negatives, but really, there ’ s another story to tell you there — if you look at the death rates just of random, young black males growing up in the inner city in the United States, the death rates during crack were about one percent. That ’ s extremely high. And this is violent death — it ’ s unbelievable, in some sense. To put it into perspective : if you compare this to the soldiers in Iraq, for instance, right now fighting the war : 0. 5 percent. So in some very literal way, the young black men who were growing up in this country were living in a war zone, very much in the sense that the soldiers over in Iraq are fighting in a war. So why in the world, you might ask, would anybody be willing to stand out on a street corner selling drugs for $3. 50 an hour, with a 25 percent chance of dying over the next four years? Why would they do that? And I think there are a couple answers. I think the first one is that they got fooled by history. It used to be the gang was a rite of passage ; that the young people controlled the gang ; that as you got older, you dropped out of the gang. So what happened was, the people who happened to be in the right place at the right time — the people who happened to be leading the gang in the mid-to-late- ’ 80s — became very, very wealthy. And so the logical thing to think was that they are going to age out of the gang like everybody else has, and the next generation is going to take over and get the wealth. There are striking similarities, I think, to the Internet boom. The first set of people in Silicon Valley got very, very rich. And then all of my friends said,”Maybe I should go do that, too.”And they were willing to work very cheap for stock options that never came. In some sense, that ’ s what happened, exactly, to the set of people we were looking at. They were willing to start at the **bottom**, just like, say, a first-year lawyer at a law firm is willing to start at the **bottom**, work 80-hour weeks for not that much money, because they think they ’ re going to make partner. But the rules changed, and they never got to make partner. Indeed, the same people who were running all of the major gangs in the late 1980s are still running the major gangs in Chicago today. They never passed on any of the wealth, So everybody got stuck at that $3. 50-an-hour job, and it turned out to be a disaster. The other thing the gang was very good at was marketing and trickery. And so for instance, one thing the gang would do is — the gang leaders would have big entourages, and they ’ d drive fancy cars and have fancy jewelry. So what Sudhir eventually realized as he hung out with them more, is that, really, they didn ’ t own those cars — they just leased them, because they couldn ’ t afford to own the fancy cars. And they didn ’ t really have gold jewelry, they had gold- plated jewelry. It goes back to, you know, the real-real versus the fake-real. And really, they did all sorts of things to trick the young people into thinking what a great deal the gang was going to be. So for instance, they would give a 14-year-old kid a whole roll of bills to hold. That 14-year-old kid would say to his friends,”Hey, look at all the money I got in the gang.”It wasn ’ t his money — until he spent it, and then he was in debt to the gang, and was sort of an indentured servant for a while. So I have a couple minutes. Let me do one last thing I hadn ’ t thought I ’ d have time to do, which is to talk about what we learned more generally about economics, from the study of the gang. So, economists tend to talk in technical words. Often, our theories fail quite miserably when we over the data, but what ’ s kind of interesting is that in this setting, it turned out that some of the economic theories that worked not so well in the real economy worked very well in the drug economy, in some sense, because it ’ s unfettered capitalism. Here ’ s an economic principle. This is one of the basic ideas in labor economics, called a”compensating differential.”It ’ s the idea that the increment to wages that a worker requires to leave him indifferent between performing two tasks, one which is more unpleasant than the other. Compensating differential — it ’ s why we think garbagemen might be paid more than people who work in **parks**. The words of one of the members of the gang, I think, make this clear. So it turns out — I ’ m sort of getting ahead of myself — it turns out, in the gang, when there ’ s a war going on, they actually pay the **foot** soldiers twice as much money. It ’ s exactly this concept. Because they ’ re not willing to be at risk. And the words of a gang member capture it quite nicely, he says :”Would you stand around here when all this shit...”— the shooting —”... if all this shit ’ s going on? No, right? So if I gonna be asked to put my life on the line, then front me the cash, man.”I think the gang member says it much more articulately than the economist, about what ’ s going on. Here ’ s another one. Economists talk about game theory, that every two-person game has a Nash equilibrium. Here ’ s the translation you get from the gang member. They ’ re talking about the decision of why they don ’ t go shoot — One thing that turns out to be a great business tactic in the gang : if you go and just shoot guns in the air in the other gang ’ s territory — people are afraid to go buy drugs there, they ’ re going to come into your neighborhood. Here ’ s what he says about why they don ’ t do that :”If we start shooting around there, the other gang ’ s territory, nobody, I mean, you dig it, nobody gonna step on their turf. But we gotta be careful, ’ cause they can shoot around here too and then we all fucked.”So that ’ s the same concept. Then again, sometimes economists get it wrong. One thing we observed in the data is that it looked like — the gang leader always got paid. No matter how bad it was economically, he always got himself paid. We had some theories related to cash flow, and lack of access to capital markets, and things like that. Then we asked the gang member,”Why is it you always get paid and your workers don ’ t always get paid?”His response is,”You got all these niggers below you who want your job, you dig? If you start taking losses, they see you as weak and shit.”And I thought about it and said,”CEOs often pay themselves million-dollar bonuses, even when companies are losing a lot of money. And it never would really occur to an economist that this idea of ’ weak and shit ’ could really be important.”Maybe”weak and shit”is an important hypothesis that needs more analysis. Thank you very much.

Text Sample 683: POS Dim 5 – 2006 – Score 7.00 – 2006/t000417.txt

I just want to say, over the last few years I ’ ve been â had the opportunity to do this closing conference. And I ’ ve had some incredible warm-up acts. About eight years ago, Billy Graham opened for me. And I thought that there was â I thought that there was absolutely no way in **hell** to top that. But I just wanted to say â and I mean this without irony â I think I can speak for everybody in the audience when I say that I wish to God that you were the President of the United States. OK, this is the title of my talk today. I just want to give you a quick overview. First of all, please remember I ’ m completely politically correct, and I mean everything with great affection. If any of you have sensitive stomachs or are feeling queasy, now is the time to check your Blackberry. Just to review, this is my TEDTalk. We ’ re going to do some jokes, some gags, some little skits â and then we ’ re going to talk about the L1 point. So, one of the questions I ask myself is, was this the most distressing TED ever? Let ’ s try and sum things up, shall we? Images of limb regeneration and faces filled with smallpox : 21 percent of the conference. Mentions of polar bears drowning : four percent. Images of the earth being wiped out by flood or bird flu : 64 percent. And David Pogue singing show tunes. Because this is the most distressing TED ever, I ’ ve been working with Neil Gershenfeld on next year ’ s TED Bag. And if the â if the conference is anywhere near this distressing, then we ’ re going to have a scream bag next year. It ’ s going to be a cradle-to-cradle scream bag, of course. So you ’ re going to be able to go like this. Bring it over here and open it up. Aaaah! Meanwhile, back at TED University, this wonderful woman is teaching you how to chop Sun Chips. So Robert Wright â I don ’ t know, I felt like if there was anyone that Helen needed to give antidepressants to, it might have been him. I want to deliberately interfere with his dopamine levels. He was talking about morality. Economy class morality is, we want to bomb you back to the Stone Age. Business class morality is, don ’ t bomb Japan â they built my car. And first-class morality is, don ’ t bomb Mexico â they **clean** my house. Yes, it is politically incorrect. All right, now I want to do a little bit of a thing for you... All right, now these are the wha â I ’ d say, [mumble, mumble â mumble, mumble, mumble, mumble, mumble] â ahh! So I wanted to show you guys â I wanted to talk about a revolutionary new computer interface that lets you work with images just as easily as you â as a completely natural user interface. And you can â you can use really natural hand gestures to like, go like this. Now we had a Harvard professor here â she was from Harvard, I just wanted to mention and â and she was actually a professor from Harvard. And she was talking about seven-dimensional, inverted universes. With, you know, of course, there ’ s the gravity brain. There ’ s the weak brain. And then there ’ s my weak brain, which is too â too â absolutely too weak to understand what the fuck she was talking about. Now â one of the things that is very important to me is to try and figure out what on Earth am I here for. And that ’ s why I went out and I picked up a best-selling business book. You know, it basically uses as its central premise Greek mythology. And it ’ s by a guy named Pastor Rick Warren, and it ’ s called”The Porpoise Driven Life.”And Rick is as a pagan god, which I thought was kind of appropriate, in a certain way. And now we ’ re going to have kind of a little more visualization about Rick Warren. OK. All right. Now, red is Rick Warren, and green is Daniel Dennett, OK? The scales here are religiosity from zero percent, or atheist, to 100 percent, Bible literally true. And then this is books sold â the logarithmic scale. 30, 000, 300, 000, three million, 30 million, 300 million. OK, now they ’ re duking it out. Now they ’ re duking it out. And Rick Warren ’ s kind of pulling ahead, kind of pulling ahead. Yup, and his installed base is getting a little bigger. But Darwin ’ s dangerous idea is coming back. It ’ s coming back. Let me turn the trails on, so you can see that a little bit better. Now, one of the things that ’ s very important is, Nicholas Negroponte talked to us about one lap dance per â I ’ m sorry â about One Laptop Per Child. Now let ’ s talk about some of the characteristics that are important for this revolutionary device. I ’ ll tell you a little bit about the design parameters, and then I ’ ll show it to you in person. First of all, it needs to be small. It needs to be flat, so it ’ s transportable. Lightweight. Portable. Uses very, very little power. Very, very high resolution. Has to be visible in bright daylight. Will work anywhere. And broadly applicable across many platforms. Now, we ’ ve actually done some research â Neil Gershenfeld and the Fab Labs went out into the market. They did some research ; we came back ; and we think we have the perfect prototype of what the students in the field are actually asking for. And here it is, the $100 computer. OK, OK, OK, OK â excellent, excellent. Now, I bought this device from Clifford Stoll for about 900 bucks. And he and his team of junior-high school students were doing real science. So we ’ re trying to check and trying to douse here, and see who uses marijuana. See who uses marijuana. Are we going to be able to find any marijuana, Jim Young? Only if we open enough locker doors. OK, now smallpox is an extremely distressing illness. We had Dr. Larry Brilliant talking about how we eradicated smallpox. I wanted to show you the stages of smallpox. We start. This is day one. Day two. Day three, she gets a massively big pox on her shoulder. Day three. Day four. Day five and day six. Now the good news is, because I ’ m a trained medical professional, I know that even though she ’ ll be scarred for life, she ’ s going to make a full recovery. Now the good news about **Architects** for Humanity is they ’ re really kind of the most amazing group. They ’ ve been sponsoring a design competition to come up with innovative medical housing solutions, clinic solutions, in Africa, and they ’ ve had a design competition. Now the wonderful thing is, Larry Brilliant was just appointed the head of the Google Foundation, and so he decided that he would support â he would support Cameron ’ s work. And the way he decided to support that work was by shipping over 50, 000 shipping containers of Google snacks. So I want to show you some prototypes. The U. N. â you know, they took 20 years just to add a flap to a tent, but I think we have some more exciting things. This is a home made entirely out of Fruit Roll-Ups. And those roll-up cookies coated with white chocolate. And the really wonderful thing about this is, when you ’ re done, well â you can eat it. But the thing that I ’ m really, really excited about is this incredible granola house. And the granola house has a special Sun Chip **roof** to collect water and recycle it. And it ’ s â well, on this side it has regular Sour Patch Kids and Gummy Bears to let in the light. But on this side, it has sugary Gummy Bears, to diffuse the light more slightly. And we â we wanted just to show you what this might look like in situ. So, Einstein â Einstein, tell me â what ’ s your favorite song? No, I said what ’ s your favorite song? No, I said what ’ s your favorite song?”Free Bird.”OK, so, Einstein, what ’ s your favorite singing group? Could you say that again? What ’ s your favorite singing group? OK, one more time â I ’ m just going to give you a little help. Your favorite singing group â it ’ s Diana Ross and the â Audience : Supremes! Tom Reilly : Exactly. Could we have the sound up on the laptop, please?”Free Bird”kind of reminds me that if you â if you listen to”Free Bird”backwards, this is what you might hear. Computer : Satan. Satan. Satan. Satan. Satan. Satan. Satan. TR : Now it ’ s a little hard to hear the whole message, so I wanted to â so I wanted to help you a little bit. Computer : My sweet Satan. Dan Dennett worships Satan. Buy”The Purpose-Driven Life,”or Satan will take your soul. TR : So, we ’ ve talked a lot about global warming, but, you know, as Jill said, it sounds kind of nice â good weather in the wintertime, and New York City. And as Jay Walker pointed out, that is just not scary enough. So Al, I actually think I ’ m rather good at branding. So I ’ ve tried to figure out a good design process to come up with a new term to replace”global warming.”So we started with Babel Fish. We put in global warming. And then we decided that we ’ d change it from English to Dutch â into”Het globale Verwarmen.”From Dutch to [Korean], into”Hordahordaneecheewa.”[Korean] to Portuguese : Aquecer-se Global. Then Portuguese to Pig Latin. Aquecer-se ucked-fay. And then finally back into the English, which is, we ’ re totally fucked. Now I don ’ t know about you, but Michael Shermer talked about the willingness for human beings â evolutionarily, they ’ re designed to see patterns in things. For example, in cheese sandwiches. Now can you look at that carefully and see if you see the Virgin Mary? I tried to make it a little bit clearer. Is it the Virgin Mary? Or is it Mena Trott? So, I talked to Josh Prince-Ramus about the convention center and the conferences. It ’ s getting awfully big. It ’ s getting just a little bit too big. It ’ s bursting at the seams here a little bit. So we tried to come up with a program â how we could remake this structure to better accommodate TED. So first of all we decided â that we needed about one-third bookstore, one-third Google cafe, about 20 percent registration, 80 percent luxury hotel, about five percent for restrooms. And then of course, we wanted to have the simulcast lounge, the lobby and the Steinbeck forum. Now let me show you how that literally translated into the design program. So first, one of the problems with Monterey is that if there is global warming and

Greenland melts as you say, the ocean level is going to rise 20 **feet** and flood the **hell** out of the convention center. So we ’ re going to build this new building on stilts. So we build this building on stilts, then up here â is where we ’ re going to put the new Steinbeck auditorium. And the wonderful thing about the new bookstore is, it ’ s going to be shaped in a spiral that ’ s organized by the Dewey Decimal System. Then we ’ re going to make an escalator that helps you get up there. And finally, we ’ re going to put the Marriott Hotel and the Portola Plaza on the top. Now I don ’ t know about you, but sometimes I have these images in my head of separated at birth. I don ’ t know about you, but when I see Aubrey de Grey, I immediately go to Gandalf the Grey. OK. Now, we ’ ve heard, of course, that we ’ re all soldiers here. So what I ’ d really, really like you to do now is, pick up your white piece of paper. Does everybody have their white piece of paper? And I want you to get out a pen, and I want you to write a terrorist note. If we put up the ELMO for a moment â if we put up the ELMO, then we ’ ll get, you know, I ’ ll give you a model that you can work from, OK? And then I want you to fold that note into a paper airplane. And once you ’ ve folded it into a paper airplane, I want you to take some anthrax â and I want you to put that in the paper airplane. And then I want you to throw it on Jim Young. Luckily, I was the recipient of the TED Prize this year. And I wanted to see â I want to dedicate this **film** to my father, Homer. OK. Now this **film** isn ’ t really hard enough, so I wanted to make it a little bit harder. So I ’ m going to try and do this while reciting pi. 3. 1415, 2657, 753, 8567, 24972 â â 85871, 25871, 3928, 5657, 2592, 5624. Can we cue the music please? Now I wanted to use this talk to talk about global warming a little bit. Back in 1968, you can see that the mountain range of Brokeback Mountain was covered in 151 inches of snow pack. Parenthetically, over there on the slopes, I did want to show you that black men ski. But over the years, 10 years later, the snow packs eroded, and, if you notice, the trees have started turning yellow. The water level of the lake has started drying up. A few years later, there ’ s no snow left at all. And all the trees have turned brown. This year, unfortunately the lakebed ’ s turned into an absolute cracked dry bed. And I fear, if we do nothing for our planet, in 20 years, it ’ s going to look like this. Mr. Vice President, I wish I knew how to quit you. Thank you very much.

My name is Ursus Wehrli, and I would like to talk to you this morning about my project, Tidying Up Art. First of all â any questions so far? First of all, I have to say I ’ m not from around here. I ’ m from a completely different cultural area, maybe you noticed? I mean, I ’ m wearing a tie, first. And then secondly, I ’ m a little bit nervous because I ’ m speaking in a foreign language, and I want to apologize in advance, for any mistakes I might make. Because I ’ m from Switzerland, and I just don ’ t hope you think this is Swiss German I ’ m speaking now here. This is just what it sounds like if we Swiss try to speak American. But don ’ t worry â I don ’ t have trouble with English, as such. I mean, it ’ s not my problem, it ’ s your language after all. I am fine. After this presentation here at TED, I can simply go back to Switzerland, and you have to go on talking like this all the time. So I ’ ve been asked by the organizers to read from my book. It ’ s called”Tidying Up Art”and it ’ s, as you can see, it ’ s more or less a **picture** book. So the reading would be over very quickly. But since I ’ m here at TED, I decided to hold my talk here in a more modern way, in the spirit of TED here, and I managed to do some slides here for you. I ’ d like to show them around so we can just, you know â Actually, I managed to prepare for you some enlarged **pictures** â even better. So Tidying Up Art, I mean, I have to say, that ’ s a relatively new term. You won ’ t be familiar with it. I mean, it ’ s a hobby of mine that I ’ ve been indulging in for the last few years, and it all started out with this **picture** of the American artist, Donald Baechler I had hanging at home. I had to look at it every day and after a while I just couldn ’ t stand the mess anymore this guy was looking at all day long. Yeah, I kind of felt sorry for him. And it seemed to me even he felt really bad facing these unorganized red squares day after day. So I decided to give him a little support, and brought some order into neatly stacking the blocks on top of each other. Yeah. And I think he looks now less miserable. And it was great. With this experience, I started to look more closely at modern art. Then I realized how, you know, the world of modern art is particularly topsy-turvy. And I can show here a very good example. It ’ s actually a simple one, but it ’ s a good one to start with. It ’ s a **picture** by Paul Klee. And we can see here very clearly, it ’ s a confusion of color. Yeah. The artist doesn ’ t really seem to know where to put the different colors. The various **pictures** here of the various elements of the **picture** â the whole thing is unstructured. We don ’ t know, maybe Mr. Klee was probably in a hurry, I mean â â maybe he had to catch a plane, or something. We can see here he started out with orange, and then he already ran out of orange, and here we can see he decided to take a break for a square. And I would like to show you here my tidied up version of this **picture**. We can see now what was barely recognizable in the original : 17 red and orange squares are juxtaposed with just two green squares. Yeah, that ’ s great. So I mean, that ’ s just tidying up for beginners. I would like to show you here a **picture** which is a bit more advanced. What can you say? What a mess. I mean, you see, everything seems to have been scattered aimlessly around the space. If my room back home had looked like this, my mother would have grounded me for three days. So I ’ d like to â I wanted to reintroduce some structure into that **picture**. And that ’ s really advanced tidying up. Yeah, you ’ re right. Sometimes people clap at this point, but that ’ s actually more in Switzerland. We Swiss are famous for chocolate and cheese. Our trains run on time. We are only happy when things are in order. But to go on, here is a very good example to see. This is a **picture** by Joan Miro. And yeah, we can see the artist has drawn a few lines and shapes and dropped them any old way onto a yellow background. And yeah, it ’ s the sort of thing you produce when you ’ re doodling on the phone. And this is my â â you can see now the whole thing takes up far less space. It ’ s more economical and also more efficient. With this method Mr. Miro could have saved canvas for another **picture**. But I can see in your faces that you ’ re still a little bit skeptical. So that you can just appreciate how serious I am about all this, I brought along the patents, the specifications for some of these works, because I ’ ve had my working methods patented at the EidgenĂśssische Amt fĂźr Geistiges Eigentum in Bern, Switzerland. I ’ ll just quote from the specification.”Laut den KunstprĂźfer Dr. Albrecht â”It ’ s not finished yet.”Laut den KunstprĂźfer Dr. Albrecht GĂśtz von Ohlenhusen wird die Verfahrensweise rechtlich geschĂźtzt welche die Kunst durch spezifisch aufgerĂ¤umte RegelmĂ¤ssigkeiten **des** allgemeinen Formenschatzes neue Wirkungen zu erzielen mĂśglich wird.”Ja, well I could have translated that, but you would have been none the wiser. I ’ m not sure myself what it means but it sounds good anyway. I just realized it ’ s important how one introduces new ideas to people, that ’ s why these patents are sometimes necessary. I would like to do a short test with you. Everyone is sitting in quite an orderly fashion here this morning. So I would like to ask you all to raise your right hand. Yeah. The right hand is the one we write with, apart from the left-handers. And now, I ’ ll count to three. I mean, it still looks very orderly to me. Now, I ’ ll count to three, and on the count of three I ’ d like you all to shake hands with the person behind you. OK? One, two, three. You can see now, that ’ s a good example : even behaving in an orderly, systematic way can sometimes lead to complete chaos. So we can also see that very clearly in this next painting. This is a painting by the artist, Niki de Saint Phalle. And I mean, in the original it ’ s completely unclear to see what this tangle of colors and shapes is supposed to depict. But in the tidied up version, it ’ s plain to see that it ’ s a sunburnt woman playing volleyball. Yeah, it ’ s a â this one here, that ’ s much better. That ’ s a **picture** by Keith Haring. I think it doesn ’ t matter. So, I mean, this **picture** has not even got a proper title. It ’ s called”Untitled”and I think that ’ s appropriate. So, in the tidied-up version we have a sort of Keith Haring spare parts shop. This is Keith Haring looked at statistically. One can see here quite clearly, you can see we have 25 pale green elements, of which one is in the form of a circle. Or here, for example, we have 27 pink squares with only one pink **curve**. I mean, that ’ s interesting. One could extend this sort of statistical analysis to cover all Mr. Haring ’ s various works, in order to establish in which period the artist favored pale green circles or pink squares. And the artist himself could also benefit from this sort of listing procedure by using it to estimate how many pots of paint he ’ s likely to need in the future. One can obviously also make combinations. For example, with the Keith Haring circles and Kandinsky ’ s dots. You can add them to all the squares of Paul Klee. In the end, one has a list with which one then can arrange. Then you categorize it, then you file it, put that file in a filing cabinet, put it in your office and you can make a living doing it. Yeah, from my own experience. So I ’ m â Actually, I mean, here we have some artists that are a bit more structured. It ’ s not too bad. This is Jasper Johns. We can see here he was practicing with his ruler. But I think it could still benefit from more discipline. And I think the whole thing adds up much better if you do it like this. And here, that ’ s one of my favorites. Tidying up Rene Magritte â this is really **fun**. You know, there is a â I ’ m always being asked what inspired me to embark on all this. It goes back to a time when I was very often staying in hotels. So once I had the opportunity to stay in a ritzy, five-star hotel. And you know, there you had this little sign â I put this little sign outside the door every morning that read,”Please tidy room.”I don ’ t know if you have them over here. So actually, my room there hasn ’ t been tidied once daily, but three times a day. So after a while I decided to have a little **fun**, and before leaving the room each day I ’ d scatter a few things around the space. Like books, clothes, toothbrush, etc. And it was great. By the time I returned everything had always been neatly returned to its place. But then one morning, I hang the same little sign onto that **picture** by Vincent van Gogh. And you have to say this room hadn ’ t been tidied up since 1888. And when I returned it looked like this. Yeah, at least it is now possible to do some vacuuming. OK, I mean, I can see there are always people that like reacting that one or another **picture** hasn ’ t been properly tidied up. So we can make a short test with you. This is a **picture** by Rene Magritte, and I ’ d like you all to inwardly â like in your head, that is â to tidy that up. So it ’ s possible that some of you would make it like this. Yeah? I would actually prefer to do it more this way. Some people would make apple pie out of it. But it ’ s a very good example to see that the whole work was more of a handicraft endeavor that involved the very time-consuming job of cutting out the various elements and sticking them back in new arrangements. And it ’ s not done, as many people imagine, with the computer, otherwise it would look like this. So now I ’ ve been able to tidy up **pictures** that I ’ ve wanted to tidy up for a long time. Here is a very good example. Take Jackson Pollock, for example. It ’ s â oh, no, it ’ s â that ’ s a really hard one. But after a while, I just decided here to go all the way and put the paint back into the cans. Or you could go into three-dimensional art. Here we have the fur cup by Meret Oppenheim. Here I just brought it back to its original state. But yeah, and it ’ s great, you can even go, you know â Or we have this pointillist movement for those of you who are into art. The pointillist movement is that kind of paintings where everything is broken down into dots and pixels. And then I â this sort of thing is **ideal** for tidying up. So I once applied myself to the work of the inventor of that method, Georges Seurat, and I collected together all his dots. And now they ’ re all in here. You can count them afterwards, if you like. You see, that ’ s the wonderful thing about the tidy up art idea : it ’ s new. So there is no existing tradition in it. There is no textbooks, I mean, not yet, anyway. I mean, it ’ s”the future we will create.”But to round things up I would like to show you just one more. This is the village square by Pieter Bruegel. That ’ s how it looks like when you send everyone home. Yeah, maybe you ’ re asking yourselves where old Bruegel ’ s people went? Of course, they ’ re not gone. They ’ re all here. I just piled them up. So I ’ m â yeah, actually I ’ m kind of finished at that moment. And for those who want to see more, I ’ ve got my book downstairs in the bookshop. And I ’ m happy to sign it for you with any name of any artist. But before leaving I would like to show you, I ’ m working right now on another â in a related field with my tidying up art method. I ’ m working in a related field. And I started to bring some order into some flags. Here â that ’ s just my new proposal here for the Union Jack. And then maybe before I leave you... yeah, I think, after you have seen that I have to leave anyway. Yeah, that was a hard one. I couldn ’ t find a way to tidy that up properly, so I just decided to make it a little bit more simpler. Thank you very much.

Text Sample 685: POS Dim 5 – 2006 – Score 6.00 – 2006/t000181.txt

I grew up in Northern Ireland, right up in the very, very north end of it there, where it ’ s absolutely freezing cold. This was me running around in the back garden mid-summer. I couldn ’ t pick a career. In Ireland the obvious choice is the military, but to be honest it actually kind of sucks. My mother wanted me to be a dentist. But the problem was that people kept blowing everything up. So I actually went to school in Belfast, which was where all the action happened. And this was a pretty common sight. The school I went to was pretty boring. They forced us to learn things like Latin. The school teachers weren ’ t having much **fun**, the sports were very dirty or very painful. So I cleverly chose rowing, which I got very good at. And I was actually rowing for my school here until this fateful day, and I flipped over right in front of the entire school. And that was the finishing post right there. So this was extremely embarrassing. But our school at that time got a grant from the government, and they got an incredible computer — the research machine 3DZ — and they left the programming manuals lying around. And so students like myself with nothing to do, we would learn how to program it. Also around this time, at home, this was the computer that people were buying. It was called the Sinclair ZX80. This was a 1K computer, and you ’ d buy your programs on cassette **tape**. Actually I ’ m just going to pause for one second, because I heard that there ’ s a prerequisite to speak here at TED — you had to have a **picture** of yourself from the old days with big hair. So I brought a **picture** with big hair.. I just want to get that out of the way. So after the Sinclair ZX80 came along the very cleverly named Sinclair ZX81. And — you see the **picture** at the **bottom**? There ’ s a **picture** of a guy doing homework with his son. That ’ s what they thought they had built it for. The reality is we got the programming manual and we started making games for it. We were programming in BASIC, which is a pretty awful language for games, so we ended up learning Assembly language so we could really take control of the hardware. This is the guy that invented it, Sir Clive Sinclair, and he ’ s showing his machine. You had this same thing in America, it was called the Timex Sinclair1000. To play a game in those days you had to have an imagination to believe that you were really playing”Battlestar Galactica.”The graphics were just horrible. You had to have an even better imagination to play this game,”Death Rider.”But of course the scientists couldn ’ t help themselves. They started making their own video games. This is one of my favorite ones here, where they have rabbit breeding, so males choose the lucky rabbit. It was around this time we went from 1K to 16K, which was quite the leap. And if you ’ re wondering how much 16K is, this eBay logo here is 16K. And in that amount of memory someone programmed a full flight simulation program. And that ’ s what it looked like. I spent ages flying this flight simulator, and I honestly believed I could fly airplanes by the end of it. Here ’ s Clive Sinclair now launching his color computer. He ’ s recognized as being the father of video games in Europe. He ’ s a multi-millionaire, and I think that ’ s why he ’ s smiling in this photograph. So I went on for the next 20 years or so making a lot of different games. Some of the highlights were things like”The Terminator,””Aladdin,”the”Teenage Mutant Hero Turtles.”Because I was from the United Kingdom, they thought the word ninja was a little too mean for children, so they decided to call it hero instead. I personally preferred the Spanish version, which was”Tortugas Ninja.”That was much better. Then the last game I did was based on trying to get the video game industry and Hollywood to actually work together on something — instead of licensing from each other, to actually work. Now, Chris did ask me to bring some statistics with me, so I ’ ve done that. The video game industry in 2005 became a 29 billion dollar business. It grows every year. Last year was the biggest year. By 2008, we ’ re going to kick the butt of the music industry. By 2010, we ’ re going to hit 42 billion. 43 percent of gamers are female. So there ’ s a lot more female gamers than people are really aware. The average age of gamers? Well, obviously it ’ s for children, right? Well, no, actually it ’ s 30 years old. And interestingly, the people who buy the most games are 37. So 37 is our target audience. All video games are violent. Of course the newspapers love to beat on this. But 83 percent of games don ’ t have any mature content whatsoever, so it ’ s just not true. Online gaming statistics. I brought some stuff on”World of Warcraft.”It ’ s 5. 5 million players. It makes about 80 million bucks a month in subscriptions. It costs 50 bucks just to install it on your computer, making the publisher about another 275 million. The game costs about 80 million dollars to make, so basically it pays for itself in about a month. A player in a game called”Project Entropia”actually bought his own island for 26, 500 dollars. You have to remember that this is not a real island. He didn ’ t actually buy anything, just some data. But he got great terms on it. This purchase included mining and hunting rights, ownership of all land on the island, and a castle with no furniture included. This market is now estimated at over 800 million dollars annually. And what ’ s interesting about it is the market was actually created by the gamers themselves. They found clever ways to trade items and to sell their accounts to each other so that they could make money while they were playing their games. I dove onto eBay a couple of days ago just to see what was gong on, typed in World of Warcraft, got 6, 000 items. I liked this one the best : a level 60 Warlock with lots of epics for 174, 000 dollars. It ’ s like that guy obviously had some pain while making it. So as far as popularity of games, what do you think these people are doing here? It turns out they ’ re actually in Hollywood Bowl in Los Angeles listening to the L. A. Philharmonic playing video game music. That

’ s what the show looks like. You would expect it to be cheesy, but it ’ s not. It ’ s very, very epic and a very beautiful concert. And the people that went there absolutely loved it. What do you think these people are doing? They ’ re actually bringing their computers so they can play games against each other. And this is happening in every city around the world. This is happening in your local cities too, you ’ re probably just not aware of it. Now, Chris told me that you had a timeline video a few years ago here just to show how video game graphics have been improving. I wanted to update that video and give you a new look at it. But what I want you to do is to try to understand it. We ’ re on this **curve**, and the graphics are getting so ridiculously better. And I ’ m going to show you up to maybe 2007. But I want you to try and think about what games could look like 10 years from now. So we ’ re going to start that video. Video : Throughout human history people have played games. As man ’ s intellect and technology have evolved so too have the games he plays. David Perry : The thing again I want you to think about is, don ’ t look at these graphics and think of that ’ s the way it is. Think about that ’ s where we are right now, and the **curve** that we ’ re on means that this is going to continue to get better. This is an example of the kind of graphics you need to be able to draw if you wanted to get a job in the video game industry today. You need to be really an incredible artist. And once we get enough of those guys, we ’ re going to want more fantasy artists that can create places we ’ ve never been to before, or characters that we ’ ve just never seen before. So the obvious thing for me to talk about today is graphics and audio. But if you were to go to a game developers conference, what they ’ re all talking about is emotion, purpose, meaning, understanding and feeling. You ’ ll hear about talks like, can a video game make you cry? And these are the kind of topics we really actually care about. I came across a student who ’ s absolutely excellent at expressing himself, and this student agreed that he would not show his video to anybody until you here at TED had seen it. So I ’ d like to play this video. So this is a student ’ s opinion on what his experience of games are. Video : I, like many of you, live somewhere between reality and video games. Some part of me — a true living, breathing person — has become programmed, electronic and virtual. The boundary of my brain that divides real from fantasy has finally begun to crumble. I ’ m a video game addict and this is my story. In the year of my birth the Nintendo Entertainment System also went into development. I played in the backyard, learned to read, and even ate some of my vegetables. Most of my childhood was spent playing with Legos. But as was the case for most of my generation, I spent a lot of time in front of the TV. Mr. Rogers, Walt Disney, Nick Junior, and roughly half a million commercials have undoubtedly left their mark on me. When my parents bought my sister and I our first Nintendo, whatever inherent addictive quality this early interactive electronic entertainment possessed quickly took hold of me. At some point something clicked. With the combination of simple, interactive stories and the warmth of the TV set, my simple 16-bit Nintendo became more than just an escape. It became an alternate existence, my virtual reality. I ’ m a video game addict, and it ’ s not because of a certain number of hours I have spent playing, or nights I have gone without sleep to finish the next level. It is because I have had life-altering experiences in virtual space, and video games had begun to erode my own understanding of what is real and what is not. I ’ m addicted, because even though I know I ’ m losing my grip on reality, I still crave more. From an early age I learned to invest myself emotionally in what unfolded before me on screen. Today, after 20 years of watching TV geared to make me emotional, even a decent insurance commercial can bring tears to my eyes. I am just one of a new generation that is growing up. A generation who may experience much more meaning through video games than they will through the real world. Video games are nearing an evolutionary leap, a point where game worlds will look and feel just as real as the **films** we see in theatres, or the news we watch on TV. And while my sense of free will in these virtual worlds may still be limited, what I do learn applies to my real life. Play enough video games and eventually you will really believe you can snowboard, fly a plane, drive a nine-second quarter mile, or kill a man. I know I can. Unlike any pop culture phenomenon before it, video games actually allow us to become part of the machine. They allow us to sublimate into the culture of interactive, downloaded, streaming, HD reality. We are interacting with our entertainment. I have come to expect this level of interaction. Without it, the problems faced in the real world — poverty, war, disease and genocide — lack the levity they should. Their importance blends into the sensationalized drama of prime time TV. But the beauty of video games today lies not in the lifelike graphics, the vibrating joysticks or virtual surround sound. It lies in that these games are beginning to make me emotional. I have fought in wars, feared for my own survival, watched my cohorts die on beaches and woods that look and feel more real than any textbook or any news story. The people who create these games are smart. They know what makes me scared, excited, panicked, proud or sad. Then they use these emotions to dimensionalize the worlds they create. A well-designed video game will seamlessly weave the user into the fabric of the virtual experience. As one becomes more experienced the awareness of physical control melts away. I know what I want and I do it. No buttons to push, no triggers to pull, just me and the game. My fate and the fate of the world around me lie inside my hands. I know violent video games make my mother worry. What troubles me is not that video game violence is becoming more and more like real life violence, but that real life violence is starting to look more and more like a video game. These are all troubles outside of myself. I, however, have a problem very close to home. Something has happened to my brain. Perhaps there is a single part of our brain that holds all of our gut instincts, the things we know to do before we even think. While some of these instincts may be innate, most are learned, and all of them are hardwired into our brains. These instincts are essential for survival in both real and virtual worlds. Only in recent years has the technology behind video games allowed for a true overlap in stimuli. As gamers we are now living by the same laws of physics in the same cities and doing many of the same things we once did in real life, only virtually. Consider this — my real life car has about 25, 000 miles on it. In all my driving games, I ’ ve driven a total of 31, 459 miles. To some degree I ’ ve learned how to drive from the game. The sensory cues are very similar. It ’ s a funny feeling when you have spent more time doing something on the TV than you have in real life. When I am driving down a road at sunset all I can think is, this is almost as beautiful as my games are. For my virtual worlds are perfect. More beautiful and rich than the real world around us. I ’ m not sure what the implications of my experience are, but the potential for using realistic video game stimuli in repetition on a vast number of loyal participants is frightening to me. Today I believe Big Brother would find much more success brainwashing the masses with video games rather than just simply TVs. Video games are **fun**, engaging, and leave your brain completely vulnerable to re-programming. But maybe brainwashing isn ’ t always bad. Imagine a game that teaches us to respect each other, or helps us to understand the problems we ’ re all facing in the real world. There is a potential to do good as well. It is critical, as these virtual worlds continue to mirror the real world we live in, that game developers realize that they have tremendous responsibilities before them. I ’ m not sure what the future of video games holds for our civilization. But as virtual and real world experiences increasingly overlap there is a greater and greater potential for other people to feel the same way I do. What I have only recently come to realize is that beyond the graphics, sound, game play and emotion it is the power to break down reality that is so fascinating and addictive to me. I know that I am losing my grip. Part of me is just waiting to let go. I know though, that no matter how amazing video games may become, or how flat the real world may seem to us, that we must stay aware of what our games are teaching us and how they leave us feeling when we finally do unplug. DP : Wow. I found that video very, very thought provoking, and that ' s why I wanted to bring it here for you guys to see. And what was interesting about it is the obvious choice for me to talk about was graphics and audio. But as you heard, Michael talked about all these other elements as well. Video games give an awful lot of other things too, and that ' s why people get so addicted. The most important one being **fun**. The name of this track is"The Magic To Come."Who is that going to come from? Is it going to come from the best directors in the world as we thought it probably would? I don ' t think so. I think it ' s going to come from the children who are growing up now that aren ' t stuck with all of the stuff that we remember from the past. They ' re going to do it their way, using the tools that we ' ve created. The same with students or highly creative people, writers and people like that. As far as colleges go, there ' s about 350 colleges around the world teaching video game courses. That means there ' s literally thousands of new ideas. Some of the ideas are really dreadful and some of them are great. There ' s nothing worse than having to listen to someone try and pitch you a really bad video game idea. Chris Anderson : You ' re off, you ' re off. That ' s it. He ' s out of time. DP : I ' ve just got a little tiny bit more if you ' ll indulge me. CA : Go ahead. I ' m going to stay right here though. DP : This is just a cool shot, because this is students coming to school after class. The school is closed ; they ' re coming back at midnight because they want to pitch their video game ideas. I ' m sitting at the front of the class, and they ' re actually pitching their ideas. So it ' s hard to get students to come back to class, but it is possible. This is my daughter, her name ' s Emma, she ' s 17 months old. And I ' ve been asking myself, what is Emma going to experience in the video game world? And as I ' ve shown here, we have the audience. She ' s never going to know a world where you can ' t press a button and have millions of people ready to play. You know, we have the technology. She ' s never going to know a world where the graphics just aren ' t stunning and really immersive. And as the student video showed, we can impact and move. She ' s never going to know a world where video games aren ' t incredibly emotional and will probably make her cry. I just hope she likes video games. So, my closing thought. Games on the surface seem simple entertainment, but for those that like to look a little deeper, the new paradigm of video games could open entirely new frontiers to creative minds that like to think big. Where better to challenge those minds than here at TED? Thank you. Chris Anderson : David Perry. That was awesome.

Text Sample 686: POS Dim 5 – 2003 – Score 8.00 – 2003/t000434.txt

Good morning everyone. First of all, it ' s been fantastic being here over these past few days. And secondly, I feel it ' s a great honor to kind of wind up this extraordinary gathering of people, these amazing talks that we ' ve had. I feel that I ' ve fitted in, in many ways, to some of the things that I ' ve heard. I came directly here from the deep, deep tropical rainforest in Ecuador, where I was out — you could only get there by a plane — with indigenous people with paint on their faces and parrot feathers on their headdresses, where these people are fighting to try and keep the oil companies, and keep the roads, out of their forests. They ’ re fighting to develop their own way of living within the forest in a world that ’ s **clean**, a world that isn ’ t contaminated, a world that isn ’ t polluted. And what was so amazing to me, and what fits right in with what we ’ re all talking about here at TED, is that there, right in the middle of this rainforest, was some solar **panels** — the first in that part of Ecuador — and that was mainly to bring water up by pump so that the women wouldn ’ t have to go down. The water was **cleaned**, but because they got a lot of batteries, they were able to store a lot of electricity. So every house — and there were, I think, eight houses in this little community — could have light for, I think it was about half an hour each evening. And there is the Chief, in all his regal finery, with a laptop computer. And this man, he has been outside, but he ’ s gone back, and he was saying,”You know, we have suddenly jumped into a whole new era, and we didn ’ t even know about the white man 50 years ago, and now here we are with laptop computers, and there are some things we want to learn from the modern world. We want to know about health care. We want to know about what other people do — we ’ re interested in it. And we want to learn other languages. We want to know English and French and perhaps Chinese, and we ’ re good at languages.”So there he is with his little laptop computer, but fighting against the might of the pressures — because of the debt, the foreign debt of Ecuador — fighting the pressure of World Bank, IMF, and of course the people who want to exploit the forests and take out the oil. And so, coming directly from there to here. But, of course, my real field of expertise lies in an even different kind of civilization — I can ’ t really call it a civilization. A different way of life, a different being. We ’ ve talked earlier — this wonderful talk by Wade Davis about the different cultures of the humans around the world — but the world is not composed only of human beings ; there are also other animal beings. And I propose to bring into this TED conference, as I always do around the world, the voice of the animal kingdom. Too often we just see a few slides, or a bit of **film**, but these beings have voices that mean something. And so, I want to give you a greeting, as from a chimpanzee in the forests of Tanzania — Ooh, ooh, ooh, ooh, ooh, ooh, ooh, ooh, ooh, ooh, ooh, ooh, ooh, ooh, ooh! I ’ ve been studying chimpanzees in Tanzania since 1960. During that time, there have been modern technologies that have really transformed the way that field biologists do their work. For example, for the first time, a few years ago, by simply collecting little fecal samples we were able to have them analyzed — to have DNA profiling done — so for the first time, we actually know which male chimps are the fathers of each individual infant. Because the chimps have a very promiscuous mating society. So this opens up a whole new **avenue** of research. And we use GSI — geographic whatever it is, GSI — to determine the range of the chimps. And we ’ re using — you can see that I ’ m not really into this kind of stuff — but we ’ re using satellite imagery to look at the deforestation in the area. And of course, there ’ s developments in infrared, so you can watch animals at night, and equipment for recording by video, and **tape** recording is getting lighter and better. So in many, many ways, we can do things today that we couldn ’ t do when I began in 1960. Especially when chimpanzees, and other animals with large brains, are studied in captivity, modern technology is helping us to search for the upper levels of cognition in some of these non-human animals. So that we know today, they ’ re capable of performances that would have been thought absolutely impossible by science when I began. I think the chimpanzee in captivity who is the most skilled in intellectual performance is one called Ai in Japan — her name means love — and she has a wonderfully sensitive partner working with her. She loves her computer — she ’ ll leave her big group, and her running water, and her trees and everything. And she ’ ll come in to sit at this computer — it ’ s like a video game for a kid ; she ’ s hooked. She ’ s 28, by the way, and she does things with her computer screen and a touch pad that she can do faster than most humans. She does very complex tasks, and I haven ’ t got time to go into them, but the amazing thing about this female is she doesn ’ t like making mistakes. If she has a bad run, and her score isn ’ t good, she ’ ll come and reach up and tap on the glass — because she can ’ t see the experimenter — which is asking to have another go. And her concentration — she ’ s already concentrated hard for 20 minutes or so, and now she wants to do it all over again, just for the satisfaction of having done it better. And the food is not important — she does get a tiny reward, like one raisin for a correct response — but she will do it for nothing, if you tell her beforehand. So here we are, a chimpanzee using a computer. Chimpanzees, gorillas, orangutans also learn human sign language. But the point is that when I was first in Gombe in 1960 — I remember so well, so vividly, as though it was yesterday — the first time, when I was going through the vegetation, the chimpanzees were still running away from me, for the most part, although some were a little bit acclimatized — and I saw this dark shape, hunched over a termite mound, and I peered with my binoculars. It was, fortunately, one adult male whom I ’ d named David Greybeard — and by the way, science at that time was telling me that I shouldn ’ t name the chimps ; they should all have numbers ; that was more scientific. Anyway, David Greybeard — and I saw that he was picking little pieces of grass and using them to fish termites from their underground nest. And not only that — he would sometimes pick a leafy twig and strip the leaves — modifying an object to make it suitable for a specific purpose — the beginning of tool-making. The reason this was so exciting and such a breakthrough is at that time, it was thought that humans, and only humans, used and made tools. When I was at school, we were defined as man, the toolmaker. So that when Louis Leakey, my mentor, heard this news, he said,”Ah, we must now redefine ’ man, ’ redefine ’ tool, ’ or accept chimpanzees as humans.”We now know that at Gombe alone, there are nine different ways in which chimpanzees use different objects for different purposes. Moreover, we know that in different parts of Africa, wherever chimps have been studied, there are completely different tool-using behaviors. And because it seems that these patterns are passed from one generation to the next, through observation, imitation and practice — that is a definition of human culture. What we find is that over these 40-odd years that I and others have been studying chimpanzees and the other great apes, and, as I say, other mammals with complex brains and social systems, we have found that after all, there isn ’ t a sharp line dividing humans from the rest of the animal kingdom. It ’ s a very wuzzy line. It ’ s getting wuzzier all the time as we find animals doing things that we, in our arrogance, used to think was just human. The chimps — there ’ s no time to discuss their fascinating lives — but they have this long childhood, five years of suckling and sleeping with the mother, and then another three, four or five years of emotional dependence on her, even when the next child is born. The importance of learning in that time, when behavior is flexible — and there ’ s an awful lot to learn in chimpanzee society. The long-term affectionate supportive bonds that develop throughout this long childhood with the mother, with the brothers and sisters, and which can last through a lifetime, which may be up to 60 years. They can actually live longer than 60 in captivity, so we ’ ve only done 40 years in the wild so far. And we find chimps are capable of true compassion and altruism. We find in their non-verbal communication — this is very rich — they have a lot of sounds, which they use in different circumstances, but they also use touch, posture, gesture, and what do they do? They kiss ; they embrace ; they hold hands.

They pat one another on the back ; they swagger ; they shake their fist — the kind of things that we do, and they do them in the same kind of context. They have very sophisticated cooperation. Sometimes they hunt — not that often, but when they hunt, they show sophisticated cooperation, and they share the prey. We find that they show emotions, similar to — maybe sometimes the same — as those that we describe in ourselves as happiness, sadness, fear, despair. They know mental as well as physical suffering. And I don ' t have time to go into the information that will prove some of these things to you, save to say that there are very bright students, in the best universities, studying emotions in animals, studying personalities in animals. We know that chimpanzees and some other creatures can recognize themselves in mirrors —"self"as opposed to"other."They have a sense of humor, and these are the kind of things which traditionally have been thought of as human prerogatives. But this teaches us a new respect — and it ' s a new respect not only for the chimpanzees, I suggest, but some of the other amazing animals with whom we share this planet. Once we ' re prepared to admit that after all, we ' re not the only beings with personalities, minds and above all feelings, and then we start to think about ways we use and abuse so many other sentient, sapient creatures on this planet, it really gives cause for deep shame, at least for me. So, the sad thing is that these chimpanzees — who ' ve perhaps taught us, more than any other creature, a little humility — are in the wild, disappearing very fast. They ' re disappearing for the reasons that all of you in this room know only too well. The deforestation, the growth of human populations, needing more land. They ' re disappearing because some timber companies go in with clear-cutting. They ' re disappearing in the heart of their range in Africa because the big multinational logging companies have come in and made roads — as they want to do in Ecuador and other parts where the forests remain untouched — to take out oil or timber. And this has led in Congo basin, and other parts of the world, to what is known as the bush- meat trade. This means that although for hundreds, perhaps thousands of years, people have lived in those forests, or whatever habitat it is, in harmony with their world, just killing the animals they need for themselves and their families — now, suddenly, because of the roads, the hunters can go in from the towns. They shoot everything, every single thing that moves that ' s bigger than a small rat ; they sun-dry it or smoke it. And now they ' ve got transport ; they take it on the logging trucks or the mining trucks into the towns where they sell it. And people will pay more for bush-meat, as it ' s called, than for domestic meat — it ' s culturally preferred. And it ' s not sustainable, and the huge logging camps in the forest are now demanding meat, so the Pygmy hunters in the Congo basin who ' ve lived there with their wonderful way of living for so many hundreds of years are now corrupted. They ' re given weapons ; they shoot for the logging camps ; they get money. Their culture is being destroyed, along with the animals upon whom they depend. So, when the logging camp moves, there ' s nothing left. We talked already about the loss of human cultural diversity, and I ' ve seen it happening with my own eyes. And the grim **picture** in Africa — I love Africa, and what do we see in Africa? We see deforestation ; we see the desert spreading ; we see massive hunger ; we see disease and we see population growth in areas where there are more people living on a certain piece of land than the land can possibly support, and they ' re too poor to buy food from elsewhere. Were the people that we heard about yesterday, on the Easter Island, who cut down their last tree — were they stupid? Didn ' t they know what was happening? Of course, but if you ' ve seen the crippling poverty in some of these parts of the world it isn ' t a question of"Let ' s leave the tree for tomorrow.""How am I going to feed my family today? Maybe I can get just a few dollars from this last tree which will keep us going a little bit longer, and then we ’ ll pray that something will happen to save us from the inevitable end.”So, this is a pretty grim **picture**. The one thing we have, which makes us so different from chimpanzees or other living creatures, is this sophisticated spoken language — a language with which we can tell children about things that aren ’ t here. We can talk about the distant past, plan for the distant future, discuss ideas with each other, so that the ideas can grow from the accumulated wisdom of a group. We can do it by talking to each other ; we can do it through video ; we can do it through the written word. And we are abusing this great power we have to be wise stewards, and we ’ re destroying the world. In the developed world, in a way, it ’ s worse, because we have so much access to knowledge of the stupidity of what we ’ re doing. Do you know, we ’ re bringing little babies into a world where, in many places, the water is poisoning them? And the air is harming them, and the food that ’ s grown from the contaminated land is poisoning them. And that ’ s not just in the far-away developing world ; that ’ s everywhere. Do you know we all have about 50 chemicals in our bodies we didn ’ t have about 50 years ago? And so many of these diseases, like asthma and certain kinds of cancers, are on the increase around places where our filthy toxic waste is dumped. We ’ re harming ourselves around the world, as well as harming the animals, as well as harming nature herself — Mother Nature, that brought us into being ; Mother Nature, where I believe we need to spend time, where there ’ s trees and flowers and birds for our good psychological development. And yet, there are hundreds and hundreds of children in the developed world who never see nature, because they ’ re growing up in concrete and all they know is virtual reality, with no opportunity to go and lie in the sun, or in the forest, with the dappled sun-specks coming down from the canopy above. As I was traveling around the world, you know, I had to leave the forest — that ’ s where I love to be. I had to leave these fascinating chimpanzees for my students and field staff to continue studying because, finding they dwindled from about two million 100 years ago to about 150, 000 now, I knew I had to leave the forest to do what I could to raise awareness around the world. And the more I talked about the chimpanzees ’ plight, the more I realized the fact that everything ’ s interconnected, and the problems of the developing world so often stem from the greed of the developed world, and everything was joining together, and making — not sense, hope lies in sense, you said — it ’ s making a nonsense. How can we do it? Somebody said that yesterday. And as I was traveling around, I kept meeting young people who ’ d lost hope. They were feeling despair, they were feeling,”Well, it doesn ’ t matter what we do ; eat, drink and be merry, for tomorrow we die. Everything is hopeless — we ’ re always being told so by the media.”And then I met some who were angry, and anger that can turn to violence, and we ’ re all familiar with that. And I have three little grandchildren, and when some of these students would say to me at high school or university, they ’ d say,”We ’ re angry,”or”We ’ re filled with despair, because we feel you ’ ve compromised our future, and there ’ s nothing we can do about it.”And I looked in the eyes of my little grandchildren, and think how much we ’ ve harmed this planet since I was their age. I feel this deep shame, and that ’ s why in 1991 in Tanzania, I started a program that ’ s called Roots and Shoots. There ’ s little brochures all around outside, and if any of you have anything to do with children and care about their future, I beg that you pick up that brochure. And Roots and Shoots is a program for hope. Roots make a firm foundation. Shoots seem tiny, but to reach the sun they can break through brick walls. See the brick walls as all the problems that we ’ ve inflicted on this planet. Then, you see, it is a message of hope. Hundreds and thousands of young people around the world can break through, and can make this a better world. And the most important message of Roots and Shoots is that every single individual makes a difference. Every individual has a role to play. Every one of us impacts the world around us everyday, and you scientists know that you can ' t actually — even if you stay in bed all day, you ' re breathing oxygen and giving out CO_2, and probably going to the loo, and things like that — you ' re making a difference in the world. So, the Roots and Shoots program involves youth in three kinds of projects. And these are projects to make the world around them a better place. One project to show care and concern for your own human community. One for animals, including domestic animals — and I have to say, I learned everything I know about animal behavior even before I got to Gombe and the chimps from my dog, Rusty, who was my childhood companion. And the third kind of project : something for the local environment. So what the kids do depends first of all, how old are they — and we go now from pre-school right through university. It ' s going to depend whether they ' re inner-city or rural. It ' s going to depend if they ' re wealthy or impoverished. It ' s going to depend which part, say, of America they ' re in. We ' re in every state now, and the problems in Florida are different from the problems in New York. It ' s going to depend on which country they ' re in — and we ' re already in 60-plus countries, with about 5, 000 active groups — and there are groups all over the place that I keep hearing about that I ' ve never even heard of, because the kids are taking the program and spreading it themselves. Why? Because they ' re buying into it, and they ' re the ones who get to decide what they ' re going to do. It isn ' t something that their parents tell them, or their teachers tell them. That ' s effective, but if they decide themselves,"We want to **clean** this river and put the fish back that used to be there. We want to clear away the toxic soil from this area and have an organic garden. We want to go and spend time with the old people and hear their stories and record their oral histories. We want to go and work in a dog shelter. We want to learn about animals. We want..."You know, it goes on and on, and this is very hopeful for me. As I travel around the world 300 days a year, everywhere there ' s a group of Roots and Shoots of different ages. Everywhere there are children with shining eyes saying,"Look at the difference we ' ve made."And now comes the technology into it, because with this new way of communicating electronically these kids can communicate with each other around the world. And if anyone is interested to help us, we ' ve got so many ideas but we need help — we need help to create the right kind of system that will help these young people to communicate their excitement. But also — and this is so important — to communicate their despair, to say,"We ' ve tried this and it doesn ' t work, and what shall we do?"And then, lo and behold, there ' s another group answering these kids who may be in America, or maybe this is a group in Israel, saying,"Yeah, you did it a little bit wrong. This is how you should do it."The philosophy is very simple. We do not believe in violence. No violence, no bombs, no guns. That ' s not the way to solve problems. Violence leads to violence, at least in my view. So how do we solve? The tools for solving the problems are knowledge and understanding. Know the facts, but see how they fit in the big **picture**. Hard work and persistence — don ' t give up — and love and compassion leading to respect for all life. How many more minutes? Two, one? Chris Anderson : One — one to two. Jane Goodall : Two, two, I ' m going to take two. Are you going to come and drag me off? Anyway — so basically, Roots and Shoots is beginning to change young people ' s lives. It ' s what I ' m devoting most of my energy to. And I believe that a group like this can have a very major impact, not just because you can share technology with us, but because so many of you have children. And if you take this program out, and give it to your children, they have such a good opportunity to go out and do good, because they ' ve got parents like you. And it ’ s been so clear how much you all care about trying to make this world a better place. It ’ s very encouraging. But the kids do ask me — and this won ’ t take more than two minutes, I promise — the kids say,”Dr. Jane, do you really have hope for the future? You travel, you see all these horrible things happening.”Firstly, the human brain — I don ’ t need to say anything about that. Now that we know what the problems are around the world, human brains like yours are rising to solve those problems. And we ’ ve talked a lot about that. Secondly, the **resilience** of nature. We can destroy a river, and we can bring it back to life. We can see a whole area desolated, and it can be brought back to bloom again, with time or a little help. And thirdly, the last speaker talked about — or the speaker before last, talked about the indomitable human spirit. We are surrounded by the most amazing people who do things that seem to be absolutely impossible. Nelson Mandela — I take a little piece of limestone from Robben Island Prison, where he labored for 27 years, and came out with so little bitterness, he could lead his people from the horror of apartheid without a bloodbath. Even after the 11th of September — and I was in New York and I felt the fear — nevertheless, there was so much human courage, so much love and so much compassion. And then as I went around the country after that and felt the fear — the fear that was leading to people feeling they couldn ’ t worry about the environment any more, in case they seemed not to be patriotic — and I was trying to encourage them, somebody came up with a little quotation from Mahatma Gandhi,”If you look back through human history, you see that every evil regime has been overcome by good.”And just after that a woman brought me this little bell, and I want to end on this note. She said,”If you ’ re talking about hope and peace, ring this. This bell is made from **metal** from a defused landmine, from the killing fields of Pol Pot — one of the most evil regimes in human history — where people are now beginning to put their lives back together after the regime has crumbled. So, yes, there is hope, and where is the hope? Is it out there with the politicians? It ’ s in our hands. It ’ s in your hands and my hands and those of our children. It ’ s really up to us. We ’ re the ones who can make a difference. If we lead lives where we consciously leave the lightest possible ecological footprints, if we buy the things that are ethical for us to buy and don ’ t buy the things that are not, we can change the world overnight. Thank you.

When you think about **resilience** and technology it ’ s actually much easier. You ’ re going to see some other speakers today, I already know, who are going to talk about breaking-bones stuff, and, of course, with technology it never is. So it ’ s very easy, comparatively speaking, to be resilient. I think that, if we look at what happened on the Internet, with such an incredible last half a dozen years, that it ’ s hard to even get the right analogy for it. A lot of how we decide, how we ’ re supposed to react to things and what we ’ re supposed to expect about the future depends on how we bucket things and how we categorize them. And so I think the tempting analogy for the boom-bust that we just went through with the Internet is a gold rush. It ’ s easy to think of this analogy as very different from some of the other things you might pick. For one thing, both were very real. In 1849, in that Gold Rush, they took over $700 million worth of gold out of California. It was very real. The Internet was also very real. This is a real way for humans to communicate with each other. It ’ s a big deal. Huge boom. Huge boom. Huge bust. Huge bust. You keep going, and both things are lots of hype. I don ’ t have to remind you of all the hype that was involved with the Internet — like GetRich. com. But you had the same thing with the Gold Rush."Gold. Gold. Gold."Sixty-eight rich men on the Steamer Portland. Stacks of yellow **metal**. Some have 5, 000. Many have more. A few bring out 100, 000 dollars each. People would get very excited about this when they read these articles."The Eldorado of the United States of America : the discovery of inexhaustible gold mines in California."And the parallels between the Gold Rush and the Internet Rush continue very strongly. So many people left what they were doing. And what would happen is — and the Gold Rush went on for years. People on the East Coast in 1849, when they first started to get the news, they thought,"Ah, this isn ' t real."But they keep hearing about people getting rich, and then in 1850 they still hear that. And they think it ' s not real. By about 1852, they ' re thinking,"Am I the stupidest person on Earth by not rushing to California?"And they start to decide they are. These are community affairs, by the way. Local communities on the East Coast would get together and whole teams of 10, 20 people would caravan across the United States, and they would form companies. These were typically not solitary efforts. But no matter what, if you were a lawyer or a banker, people dropped what they were doing, no matter what skill set they had, to go pan for gold. This guy on the left, Dr. Richard Beverley Cole, he lived in Philadelphia and he took the Panama route. They would take a ship down to Panama, across the isthmus, and then take another ship north. This guy, Dr. Toland, went by covered wagon to California. This has its parallels, too. Doctors leaving their practices. These are both very successful — a physician in one case, a surgeon in the other. Same thing happened on the Internet. You get DrKoop. com. In the Gold Rush, people literally jumped ship. The San Francisco harbor was clogged with 600 ships at the peak because the ships would get there and the crews would abandon to go search for gold. So there were literally 600 captains and 600 ships. They turned the ships into hotels, because they couldn ' t sail them anywhere. You had dotcom fever. And you had gold fever. And you saw some of the excesses that the dotcom fever created and the same thing happened. The fort in San Francisco at the time had about 1, 300 soldiers. Half of them deserted to go look for gold. And they wouldn ' t let the other half out to go look for the first half because they were afraid they wouldn ' t come back. And one of the soldiers wrote home, and this is the sentence that he put :"The struggle between right and six dollars a month and wrong and 75 dollars a day is a rather severe one."They had bad burn rate in the Gold Rush. A very bad burn rate. This is actually from the Klondike Gold Rush. This is the White Pass Trail. They loaded up their mules and their horses. And they didn ' t plan right. And they didn ' t know how far they would really have to go, and they overloaded the horses with hundreds and hundreds of pounds of stuff. In fact it was so bad that most of the horses died before they could get where they were going. It got renamed the"Dead Horse Trail."And the Canadian Minister of the Interior wrote this at the time :"Thousands of pack horses lie dead along the way, sometimes in bunches under the cliffs, with pack saddles and packs where they ' ve fallen from the rock above, sometimes in tangled masses, filling the mud holes and furnishing the only footing for our poor pack animals on the march, often, I regret to say, exhausted, but still alive, a fact we were unaware of, until after the miserable wretches turned beneath the hooves of our cavalcade. The eyeless sockets of the pack animals everywhere account for the myriads of ravens along the road. The inhumanity which this trail has been witness to, the heartbreak and suffering which so many have undergone, cannot be imagined. They certainly cannot be described."And you know, without the smell that would have accompanied that, we had the same thing on the Internet : very bad burn rate calculations. I ' ll just play one of these and you

’ ll remember it. This is a commercial that was played on the Super Bowl in the year 2000. : Bride #1 : You said you had a large selection of invitations. Clerk : But we do. Bride #2 : Then why does she have my invitation? Announcer : What may be a little thing to some... Bride #3 : You are mine, little man. Announcer : Could be a really big deal to you. Husband #1 : Is that your wife? Husband #2 : Not for another 15 minutes. Announcer : After all, it ’ s your special day. OurBeginning. com. Life ’ s an event. Announce it to the world. Jeff Bezos : It ’ s very difficult to figure out what that ad is for. But they spent three and a half million dollars in the 2000 Super Bowl to air that ad, even though, at the time, they only had a million dollars in annual revenue. Now, here ’ s where our analogy with the Gold Rush starts to diverge, and I think rather severely. And that is, in a gold rush, when it ’ s over, it ’ s over. Here ’ s this guy :”There are many men in Dawson at the present time who feel keenly disappointed. They ’ ve come thousands of miles on a perilous trip, risked life, health and property, spent months of the most arduous labor a man can perform and at length with expectations raised to the highest pitch have reached the coveted goal only to discover the fact that there is nothing here for them.”And that was, of course, the very common story. Because when you take out that last piece of gold — and they did incredibly quickly. I mean, if you look at the 1849 Gold Rush — the entire American river region, within two years — every stone had been turned. And after that, only big companies who used more sophisticated mining technologies started to take gold out of there. So there ’ s a much better analogy that allows you to be incredibly optimistic and that analogy is the electric industry. And there are a lot of similarities between the Internet and the electric industry. With the electric industry you actually have to — one of them is that they ’ re both sort of thin, horizontal, enabling layers that go across lots of different industries. It ’ s not a specific thing. But electricity is also very, very broad, so you have to sort of narrow it down. You know, it can be used as an incredible means of transmitting power. It ’ s an incredible means of coordinating, in a very fine-grained way, information flows. There ’ s a bunch of things that are interesting about electricity. And the part of the electric revolution that I want to focus on is sort of the golden age of appliances. The killer app that got the world ready for appliances was the light bulb. So the light bulb is what wired the world. And they weren ’ t thinking about appliances when they wired the world. They were really thinking about — they weren ’ t putting electricity into the home ; they were putting lighting into the home. And, but it really — it got the electricity. It took a long time. This was a huge — as you would expect — a huge capital build out. All the streets had to be torn up. This is work going on down in lower Manhattan where they built some of the first electric power generating stations. And they ’ re tearing up all the streets. The Edison Electric Company, which became Edison General Electric, which became General Electric, paid for all of this digging up of the streets. It was incredibly expensive. But that is not the — and that ’ s not the part that ’ s really most similar to the Web. Because, remember, the Web got to stand on top of all this heavy infrastructure that had been put in place because of the long-distance phone network. So all of the cabling and all of the heavy infrastructure — I ’ m going back now to, sort of, the explosive part of the Web in 1994, when it was growing 2, 300 percent a year. How could it grow at 2, 300 percent a year in 1994 when people weren ’ t really investing in the Web? Well, it was because that heavy infrastructure had already been laid down. So the light bulb laid down the heavy infrastructure, and then home appliances started coming into being. And this was huge. The first one was the electric fan — this was the 1890 electric fan. And the appliances, the golden age of appliances really lasted — it depends how you want to measure it — but it ’ s anywhere from 40 to 60 years. It goes on a long time. It starts about 1890. And the electric fan was a big success. The electric iron, also very big. By the way, this is the beginning of the asbestos lawsuit. There ' s asbestos under that handle there. This is the first vacuum cleaner, the 1905 Skinner Vacuum, from the Hoover Company. And this one weighed 92 pounds and took two people to operate and cost a quarter of a car. So it wasn ' t a big seller. This was truly, truly an early-adopter product — the 1905 Skinner Vacuum. But three years later, by 1908, it weighed 40 pounds. Now, not all these things were highly successful. This is the electric tie press, which never really did catch on. People, I guess, decided that they would not wrinkle their ties. These never really caught on either : the electric shoe warmer and drier. Never a big seller. This came in, like, six different colors. I don ' t know why. But I thought, you know, sometimes it ' s just not the right time for an invention ; maybe it ' s time to give this one another shot. So I thought we could build a Super Bowl ad for this. We ' d need the right partner. And I thought that really — I thought that would really work, to give that another shot. Now, the toaster was huge because they used to make toast on open fires, and it took a lot of time and attention. I want to point out one thing. This is — you guys know what this is. They hadn ' t invented the electric socket yet. So this was — remember, they didn ' t wire the houses for electricity. They wired them for lighting. So your — your appliances would plug in. They would — each room typically had a light bulb socket at the top. And you ' d plug it in there. In fact, if you ' ve seen the Carousel of Progress at Disney World, you ' ve seen this. Here are the cables coming up into this light fixture. All the appliances plug in there. And you would just unscrew your light bulb if you wanted to plug in an appliance. The next thing that really was a big, big deal was the washing machine. Now, this was an object of much envy and lust. Everybody wanted one of these electric washing machines. On the **left-hand** side, this was the soapy water. And there ' s a rotor there — that this motor is spinning. And it would **clean** your clothes. This is the **clean** rinse-water. So you ' d take the clothes out of here, put them in here, and then you ' d run the clothes through this electric wringer. And this was a big deal. You ' d keep this on your porch. It was a little bit messy and kind of a pain. And you ' d run a long cord into the house where you could screw it into your light socket. And that ' s actually kind of an important point in my presentation, because they hadn ' t invented the off switch. That was to come much later — the off switch on appliances — because it didn ' t make any sense. I mean, you didn ' t want this thing clogging up a light socket. So you know, when you were done with it, you unscrewed it. That ' s what you did. You didn ' t turn it off. And as I said before, they hadn ' t invented the electric outlet either, so the washing machine was a particularly dangerous device. And there are — when you research this, there are gruesome descriptions of people getting their hair and clothes caught in these devices. And they couldn ' t yank the cord out because it was screwed into a light socket inside the house. And there was no off switch, so it wasn ' t very good. And you might think that that was incredibly stupid of our ancestors to be plugging things into a light socket like this. But, you know, before I get too far into condemning our ancestors, I thought I ' d show you : this is my conference room. This is a total kludge, if you ask me. First of all, this got installed upside down. This light socket — and so the cord keeps falling out, so I **taped** it in. This is supposed — don ' t even get me started. But that ' s not the worst one. This is what it looks like under my desk. I took this **picture** just two days ago. So we really haven ' t progressed that much since 1908. It ' s a total, total mess. And, you know, we think it ' s getting better, but have you tried to install 802. 11 yourself? I challenge you to try. It ' s very hard. I know Ph. D. s in Computer Science — this process has brought them to tears, absolute tears. And that ’ s assuming you already have DSL in your house. Try to get DSL installed in your house. The engineers who do it everyday can ’ t do it. They have to — typically, they come three times. And one friend of mine was telling me a story : not only did they get there and have to wait, but then the engineers, when they finally did get there, for the third time, they had to call somebody. And they were really happy that the guy had a speakerphone because then they had to wait on hold for an hour to talk to somebody to give them an access code after they got there. So we ’ re not — we ’ re pretty kludge-y ourselves. By the way, DSL is a kludge. I mean, this is a twisted pair of copper that was never designed for the purpose it ’ s being put to — you know it ’ s the whole thing — we ’ re very, very primitive. And that ’ s kind of the point. Because, you know, **resilience** — if you think of it in terms of the Gold Rush, then you ’ d be pretty depressed right now because the last nugget of gold would be gone. But the good thing is, with innovation, there isn ’ t a last nugget. Every new thing creates two new questions and two new opportunities. And if you believe that, then you believe that where we are — this is what I think — I believe that where we are with the incredible kludge — and I haven ’ t even talked about user interfaces on the Web — but there ’ s so much kludge, so much terrible stuff — we are at the 1908 Hurley washing machine stage with the Internet. That ’ s where we are. We don ’ t get our hair caught in it, but that ’ s the level of primitiveness of where we are. We ’ re in 1908. And if you believe that, then stuff like this doesn ’ t bother you. This is 1996 :”All the negatives add up to making the online experience not worth the trouble.”1998 :”Amazon. toast.”In 1999 :”Amazon. bomb.”My mom hates this **picture**. She — but you know, if you really do believe that it ’ s the very, very beginning, if you believe it ’ s the 1908 Hurley washing machine, then you ’ re incredibly optimistic. And I do think that that ’ s where we are. And I do think there ’ s more innovation ahead of us than there is behind us. And in 1917, Sears — I want to get this exactly right. This was the advertisement that they ran in 1917. It says :”Use your electricity for more than light.”And I think that ’ s where we are. We ’ re very, very early. Thank you very much.

Text Sample 688: POS Dim 5 – 2003 – Score 7.00 – 2003/t000364.txt

I am known best for human-powered flight, but that was just one thing that got me going in the sort of things that I ’ m working in now. As a youngster, I was very interested in model airplanes, ornithopters, autogyros, helicopters, gliders, power planes, indoor models, outdoor models, everything, which I just thought was a lot of **fun**, and wondered why most other people didn ’ t share my same enthusiasm with them. And then, navy pilot training, and, after college, I got into sailplane flying, power plane flying, and considered the sailplanes as a sort of hobby and **fun**, but got tangled up with some great professor types, who convinced me and everybody else in the field that this was a good way to get into really deep science. While this was all going on, I was in the field of weather modification, although getting a Ph. D. in aeronautics. The weather modification subject was getting started, and as a graduate student, I could go around to the various talks that were being given, on a hitchhiker ride to the East Coast, and so on. And everybody would talk to me, but all the professionals in the field hated each other, and they wouldn ’ t communicate. And as a result, I got the absolutely unique background in that field, and started a company, which did more research in weather modification than anybody, and there are a lot of things that I just can ’ t go into. But then, 1971 started AeroVironment, with no employees — then one or two, three, and sort of fumbled along on trying to get interesting projects. We had AirDynamisis, who, like I, did not want to work for aerospace companies on some big, many year project, and so we did our small projects, and the company slowly grew. The thing that is exciting was, in 1976, I suddenly got interested in the human-powered airplane because I ’ d made a made a loan to a friend of 100, 000 dollars, or I guaranteed the money at the bank. He needed them — he needed the money for starting a company. The company did not succeed, and he couldn ’ t pay the money back, and I was the guarantor of the note. So, I had a $100, 000 debt, and I noticed that the Kramer prize for human-powered flight, which had then been around for — — 17 years at the time, was 50, 000 pounds, which, at the exchange rate, was just about 100, 000 dollars. So suddenly, I was interested in human-powered flight — — and did not — the way I approached it, first, thinking about ways to make the planes, was just like they ’ d been doing in England, and not succeeding, and I gave it up. I figured, nah, there isn ’ t any simple, easy way. But then, got off on a vacation trip, and was studying bird flight, just for the **fun** of it, and you can watch a bird soaring around in circles, and measure the time, and estimate the bank angle, and immediately, figure out its speed, and the turning radius, and so on, which I could do in the car, as we ’ re driving along on a vacation trip — — with my three sons, young sons, helping me, but ridiculing the whole thing very much. But that began thinking about how birds went around, and then how airplanes would, how hang gliders would fly, and then other planes, and the idea of the Gossamer-Condor-type airplane quickly emerged, was so logical, one should have thought of it in the first place, but one didn ’ t. And it was just, keep the weight down — 70 pounds was all it weighed — but let the size swell up, like a hang glider, but three times the span, three times the cord. You ’ re down to a third of the speed, a third of the power, and a good bicyclist can put out that power, and that worked, and we won the prize a year later. We didn ’ t — a lot of flying, a lot of experiments, a lot of things that didn ’ t work, and ones that did work, and the plane kept getting a little better, a little better. Got a good pilot, Brian Allen, to operate it, and finally, succeeded. But unfortunately, about 65, 000 dollars was spent on the project. And there was only about 30 to help retire the debt. But fortunately, Henry Kramer, who put up the prize for — that was a one-mile flight — put up a new prize for flying the English Channel, 21 miles. And he thought it would take another 18 years for somebody to win that. We realized that if you just **cleaned** up our Gossamer Condor a little bit, the power to fly would be decreased a little bit, and if you decrease the power required a little, the pilot can fly a much longer period of time. And Brian Allen was able, in a miraculous flight, to get the Gossamer Albatross across the English Channel, and we won the 100, 000-pound, 200, 000-dollar prize for that. And when all expenses were paid, the debt was handled, and everything was fine. It turned out that giving the planes to the **museum** was worth much more than the debt, so for five years, six years, I only had to pay one third income tax. So, there were good economic reasons for the project, but — — that ’ s not, well, the project was done entirely for economic reasons, and we have not been involved in any human-powered flight since then — — because the prizes are all over. But that sure started me thinking about various things, and immediately, we began making a solar-powered plane because we felt solar power was going to be so important for the country and the world, we didn ’ t want the small funding in the government to be decreased, which is what the government was trying to do with it. And we thought a solar-powered plane wouldn ’ t really make sense, but you could do it and it would get a lot of publicity for solar power and maybe help that field. And that project continued, did succeed, and we then got into other projects in aviation and **mechanical** things and ground devices. But while this was going on, in 1982, I got a prize from the Lindbergh Foundation — their annual prize — and I had to prepare a paper on it, which collected all my varied thoughts and varied interests over the years. This was the one chance that I had to focus on what I, really, was after, and what was important. And to my surprise, I realized the importance of environmental issues, which Charles Lindbergh devoted the last third of his life to, and preparing that paper did me a lot of good. I thought back about if I was a space traveler, and came and visited Earth every 5, 000 years. And for a few thousand visits, I would see the same thing every time, the little differences in the Earth. But this last time, just coming round, right now, suddenly, there ’ d be huge changes in the environment, in the concentration of people, and it was just unbelievable, the amount of — all the change in it. I wanted to — well, one of the biggest changes is, 200 years ago, we began using coal from underground, which has a lot of pollution, and 100 years ago, began getting gasoline from underground, with a lot of pollution. And gasoline consumption, or production, will reach its limit in about ten years, and then go down, and we wonder what ’ s going to happen with transportation. I wanted to show the slide — this slide, I think, is the most important one any of you will see, ever, because — — it shows nature versus humans, and goes from 1850 to 2050. And so, the year 2000, you see there. And this is the weight of all air and land vertebrates. Humans and muskrats and giraffes and birds and so on, are — the red line goes up. That ’ s the humans and livestock and pets portion. The green line goes down. That ’ s the wild nature portion. Humans, livestock and pets are, now, 98 percent of the total world ’ s mass of vertebrates on land and air. And you don ’ t know what the future will hold, but it ’ s not going to get a lower percentage. Ten thousand years ago, the humans and livestock and pets were not even one tenth of one percent and wouldn ’ t even have been visible on such a **curve**. Now they are 98 percent, and it, I think, shows human domination of the Earth. I give a talk to some remarkable high school students each summer, and ask them, after they ’ ve asked me questions, and I give them a talk and so on. Then I ask them questions. What ’ s the population of the Earth? What ’ s the population of the Earth going to be when you ’ re the age of your parents? Which I ’ d never, really — they had never, really, thought about but, now, they think about it. And then, what population of the Earth would be an equilibrium that could continue on, and be for 2050, 2100, 2150? And they form little groups, all fighting with each other, and when I leave, two hours later, most of them are saying about 2 billion people, and they don ’ t have any clue about how to get down to 2 billion, nor do I, but I think they ’ re right and this is a serious problem. Rachel Carson was thinking of these, and came out with”Silent Spring,”way back.”Solar Manifesto”by Hermann Scheer, in Germany, claims all energy on Earth can be derived, for every country, from solar energy and water, and so on. You don ’ t need to dig down for these chemicals, and we can do things much more efficiently. Let ’ s have the next slide. So this just summarizes it.”Over billions of years, on a unique sphere, chance has painted a thin covering of life — complex and probable, wonderful and fragile. Suddenly, we humans, a recently arrived species, no longer subject to the checks and balances inherent in nature, have grown in population, technology and intelligence to a position of terrible power. We, now, wield the paintbrush.”We ’ re in charge. It ’ s frightening. And I do a painting every 20 or 25 years. This is the last one. And [it] shows the Earth in a time flag : on the right, in trilobites and dinosaurs and so on ; and over the triangle, we now get to civilization and TV and traffic jams and so on. I have no idea of what comes next, so I just used robotic and natural cockroaches as the future, as a little warning. And two weeks after this **drawing** was done, we actually had our first project contract, at AeroVironment, on robotic cockroaches, which was very frightening to me. Well, that ’ ll be all the slides. As time went on, we stopped our environmental programs. We focused more on the really serious energy problems of the future, and we produced products for the company. And we developed the impact car that General Motors made, the EV1, out of — and got the Air Resources Board to have the regulations that stimulated the electric cars, but they ’ ve since come apart. And we ’ ve done a lot of things, small drone airplanes and so on. I have a Helios. We have the first video. Narrator : With a wingspan of 247 **feet**, this makes her larger than a Boeing 747. Her designers ’ attention to detail and her construction gives Helios ’ structure the flexibility and strength to deal with the turbulence encountered in the atmosphere. This enables her to easily ride through the air currents as if she ’ s sliding along on the ocean waves. Paul MacCready : The wings could touch together on top and not break. We think. Narrator : And Helios now begins the process of turning her back to the sun, to maximize the power from her solar array. As the sky gets darker, and the outside air temperatures drop below minus 100 degrees Fahrenheit, the most environmentally hostile segment of Helios ’ s journey has gone by without notice, except for being recorded by specially designed data acquisition systems and their associated sensors. Approaching a peak radar altitude of 96, 863 **feet**, at 4:12 p. m., Helios is standing on top of 98 percent of the Earth ’ s atmosphere. This is more than 10, 000 **feet** higher than the previous world ’ s altitude record held by the SR-71 Blackbird. PM : That plane has many purposes, but it ’ s aimed for communications, and it can fly so slowly that it ’ ll just stay up at 65, 000 **feet**. Eventually, it will be able to have to stay up day, night, day, night, for six months at a time, acting like the synchronous satellite, but only ten miles above the Earth. Let ’ s have the next video. This shows the other end of the spectrum. Narrator : A tiny airplane, the AV Pointer serves for surveillance. In effect a pair of roving eyeglasses, a cutting-edge example of where miniaturization can lead if the operator is remote from the vehicle. It is convenient to carry, assemble, and launch by hand. Battery-powered, it is silent and rarely noticed. It sends high-resolution video **pictures** back to the operator. With onboard GPS, it can navigate autonomously, and it is rugged enough to self-land without damage. PM : Okay, and let ’ s have the next. That plane is widely used by the military, now, in all their operations. Let ’ s have the next video. Alan Alda : He ’ s got it, he ’ s got it, he ’ s got it on his head. We ’ re going to end our visit with Paul MacCready ’ s flying circus by meeting his son, Tyler, who, with his two brothers, helped build the Gossamer Condor, 25 years ago. Tyler MacCready : You can chase it, like this, for hours. AA : When they got bored with their father ’ s project, they invented an extraordinary little plane of their own. TM : And I can control it by putting the lift on one side of the wing, or on the other. AA : They called it their Walkalong Glider. I ’ ve never seen anything like that. How old were you when you invented that? TM : Oh, 10, 11. TM : 12, something like that. PM : And Tyler ’ s here to show you the Walkalong. TM : All right. You all got a couple of these in your gift bags, and one of the first things, the production version seemed to dive a little bit, and so I would just suggest you bend the wing tips up a little bit before you try flying it. I ’ ll give you a demonstration of how it works. The idea is that it soars on the lift over your body, like a seagull soaring on a cliff. As the wind comes up, it has to go over the cliff, so as you walk through the air, it goes around your body, some has to go over you. And so you just keep the glider positioned in that up current. The launch is the difficult part : you ’ ve got to hold it high up, over your head, and you start walking forward, and just let go of it, and you can control it like that. And then also, like it said in the video, you can turn it left or right just by putting the lift under one wing or another. So I can do it —

oops, that was going to be a right turn. Okay, this one will be a left turn. Here, but — — anyway. And that ' s it, so you can just control it, wherever you want, and it ' s just hours of **fun**. And these are no longer in production, so you have real collector ' s items. And this, we just wanted to show you — if we can get the video running on this, yeah — just an example of a little video surveillance. This was flying around in the party last night, and — — you can see how it just can fly around, and you can spy on anybody you want. And that ' s it. I was going to bring an airplane, but I was worried about hitting people in here, so I thought this would be a little bit more gentle. And that ' s it, yeah, just a few inventions. All right.

So I really consider myself a storyteller. But I don ' t really tell stories in the usual way, in the sense that I don ' t usually tell my own stories. Instead, I ' m really interested in building tools that allow large numbers of other people to tell their stories, people all around the world. I do this because I think that people actually have a lot in common. I think people are very similar, but I also think that we have trouble seeing that. You know, as I look around the world I see a lot of gaps, and I think we all see a lot of gaps. And we define ourselves by our gaps. There ' s language gaps, there ' s ethnicity and racial gaps, there ' s age gaps, there ' s gender gaps, there ' s sexuality gaps, there ' s wealth and money gaps, there ' s education gaps, there ' s also religious gaps. You know, we have all these gaps and I think we like our gaps because they make us feel like we identify with something, some smaller community. But I think that actually, despite our gaps, we really have a lot in common. And I think one thing we have in common is a very deep need to express ourselves. I think this is a very old human desire. It ' s nothing new. But the thing about self-expression is that there ' s traditionally been this imbalance between the desire that we have to express ourselves and the number of sympathetic friends who are willing to stand around and listen. This, also, is nothing new. Since the dawn of human history, we ' ve tried to rectify this imbalance by making art, writing poems, singing songs, scripting editorials and sending them in to a newspaper, gossiping with friends. This is nothing new. What ' s new is that in the last several years a lot of these very traditional physical human activities, these acts of self-expression, have been moving onto the Internet. And as that ' s happened, people have been leaving behind footprints, footprints that tell stories of their moments of self-expression. And so what I do is, I write computer programs that study very large sets of these footprints, and then try to draw conclusions about the people who left them — what they feel, what they think, what ' s different in the world today than usual, these sorts of questions. One project that explores these ideas, which was made about a year ago, is a piece called We Feel Fine. This is a piece that every two or three minutes **scans** the world ' s newly-posted blog entries for occurrences of the phrases"I feel"or"I am feeling."And when it finds one of those phrases, it grabs the sentence up to the period, and then automatically tries to deduce the age, gender and geographical location of the person that wrote that sentence. Then, knowing the geographical location and the time, we can also then figure out the weather when that person wrote the sentence. All of this information is saved in a database that collects about 20, 000 feelings a day. It ' s been running for about a year and a half. It ' s reached about seven-and-a-half million human feelings now. And I ' ll show you a glimpse of how this information is then visualized. So this is We Feel Fine. What you see here is a madly swarming mass of particles, each of which represents a single human feeling that was stated in the last few hours. The color of each particle corresponds to the type of feeling inside — so that happy, positive feelings are brightly colored. And sad, negative feelings are darkly colored. The diameter of each dot represents the length of the sentence inside, so that the large dots contain large sentences, and the small dots contain small sentences. Any dot can be clicked and expanded. And we see here,"I would just feel so much better if I could curl up in his arms right now and feel his affection for me in the embrace of his body and the tenderness of his lips."So it gets pretty hot and steamy sometimes in the world of human emotions. And all of these are stated by people :"I know that objectively it really doesn ' t mean much, but after spending so many years as a small fish in a big pond, it ' s nice to feel bigger again."The dots exhibit human qualities. They kind of have their own physics, and they swarm wildly around, kind of exploring the world of life. And then they also exhibit curiosity. You can see a few of them are swarming around the cursor right now. You can see some other ones are swarming around the **bottom** left corner of the screen around six words. Those six words represent the six movements of We Feel Fine. We ' re currently seeing Madness. There ' s also Murmurs, Montage, Mobs, Metrics and Mounds. And I ' ll walk you through a few of those now. Murmurs causes all of the feelings to fly to the ceiling. And then, one by one, in reverse chronological order, they excuse themselves, entering the scrolling list of feelings."I feel a bit better now.""I feel confused and unsure of what the **hell** I want to do.""I feel gypped out of something awesome here.""I feel so free ; I feel so good.""I feel like I ' m in this fog of depression that I can ' t get out of."And you can click any of these to go out and visit the blog from which it was collected. And in that way, you can connect with the authors of these statements if you feel some degree of empathy. The next movement is called Montage. Montage causes all of the feelings that contain photographs to become extracted and display themselves in a grid. This grid is then said to represent the **picture** of the world ' s feelings in the last few hours, if you will. Each of these can be clicked and we can blow it up. We see,"I just feel like I ' m not going to have **fun** if it ' s not the both of us."That was from someone in Michigan. We see,"I feel like I have been at a computer all day."These are automatically constructed using the found objects :"I think I feel a little full."The next movement is called mobs. Mobs provides different statistical breakdowns of the population of the world ' s feelings in the last few hours. We see that"better"is the most frequent feeling right now, followed by"good,""bad,""guilty,""right,""down,""sick"and so on. We can also get a gender breakdown. And we see that women are slightly more prolific talking about their emotions in the last few hours than men. We can do an age breakdown, which gives us a histogram of the world ' s emotional distribution by age. We see people in their twenties are the most prolific, followed by teenagers, and then people in their thirties, and it dies out very quickly from there. In weather, the feelings assume the physical characteristics of the weather that they represent, so that the ones collected on a sunny day swirl around as if they ' re part of the sun. The cloudy ones float along as if they ' re on a breeze. The rainy ones fall down as if they ' re in a rainstorm, and the snowy ones kind of flutter to the ground. Finally, location causes the feelings to move to their positions on a world map showing the geographical distribution of feelings. Metrics provides more numerical views on the data. We see that the world is feeling"used"at 3. 3 times the normal level right now. They ' re feeling"warm"at 2. 9 times the normal level, and so on. Other views are also available. Here are gender, age, weather, location. The final movement is called Mounds. It ' s a bit different from the others. Mounds visualizes the entire dataset as large, gelatinous blobs which kind of jiggle. And if I hold down my cursor, they do a little dance. We see”better”is the most frequent feeling, followed by”bad.”And then if I go over here, the list begins to scroll, and there are actually thousands of feelings that have been collected. You can see the little pink cursor moving along, representing our position. Here we see people that feel”slipping,””nauseous,””responsible.”There ’ s also a search capability, if you ’ re interested in finding out about a certain population. For instance, you could find women who feel”addicted”in their 20s when it was cloudy in Bangladesh. But I ’ ll spare you that. So here are some of my favorite montages that have been collected :”I feel so much of my dad alive in me that there isn ’ t even room for me.””I feel very lonely.””I need to be in some backwoods redneck town so that I can feel beautiful.””I feel invisible to you.””I wouldn ’ t hide it if society didn ’ t make me feel like I needed to.””I feel in love with Carolyn.””I feel so naughty.””I feel these weirdoes are actually an asset to college life.””I love how I feel today.”So as you can see, We Feel Fine uses a technique that I call”passive observation.”What I mean by that is that it passively observes people as they live their lives. It **scans** the world ’ s blogs and looks at what people are writing, and these people don ’ t know they ’ re being watched or interviewed. And because of that, you end up getting very honest, candid, sincere responses that are often very moving. And this is a technique that I usually prefer in my work because people don ’ t know they ’ re being interviewed. They ’ re just living life, and they end up just acting like that. Another technique is directly questioning people. And this is a technique that I explored in a different project, the Yahoo! Time Capsule, which was designed to take a fingerprint of the world in 2006. It was divided into ten very simple themes — love, anger, sadness and so on — each of which contained a single, very open-ended question put to the world : What do you love? What makes you angry? What makes you sad? What do you believe in? And so on. The time capsule was available for one month online, translated into 10 languages, and this is what it looked like. It ’ s a spinning globe, the surface of which is entirely composed of the **pictures** and words and **drawings** of people that submitted to the time capsule. The ten themes radiate out and orbit the time capsule. You can sift through this data and see what people have submitted. This is in response to, What ’ s beautiful?”Miss World.”There are two modes to the time capsule. There ’ s One World, which presents the spinning globe, and Many Voices, which splits the data out into **film** strips and lets you sift through them one by one. So this project was punctuated by a really amazing event, which was held in the desert outside Albuquerque in New Mexico at the Jemez Pueblo, where for three consecutive nights, the contents of the capsule were projected onto the sides of the ancient Red Rock Canyon walls, which stand about 200 **feet** tall. It was really incredible. And we also projected the contents of the time capsule as binary code using a 35-watt **laser** into outer space. You can see the orange line leaving the desert floor at about a 45 degree angle there. This was amazing because the first night I looked at all this information and really started seeing the gaps that I talked about earlier — the differences in age, gender and wealth and so on. But, you know, as I looked at this more and more and more, and saw these images go across the rocks, I realized I was seeing the same archetypal events depicted again and again and again. You know : weddings, births, funerals, the first car, the first kiss, the first camel or horse — depending on the culture. And it was really moving. And this **picture** here was taken the final night from a distant cliff about two miles away, where the contents of the capsule were being beamed into space. And there was something very moving about all of this human expression being shot off into the night sky. And it started to make me think a lot about the night sky, and how humans have always used the night sky to project their great stories. You know, as a child in Vermont, on a farm where I grew up, I would often look up into the dark sky and see the three star belt of Orion, the Hunter. And as an adult, I ’ ve been more aware of the great Greek myths playing out in the sky overhead every night. You know, Orion facing the roaring bull. Perseus flying to the rescue of Andromeda. Zeus battling Chronos for control of Mount Olympus. I mean, these are the great tales of the Greeks. And it caused me to wonder about our world today. And it caused me to wonder specifically, if we could make new constellations today, what would those look like? What would those be? If we could make new **pictures** in the sky, what would we draw? What are the great stories of today? And those are the questions that inspired my new project, which is debuting here today at TED. Nobody ’ s seen this yet, publicly. It ’ s called Universe : Revealing Our Modern Mythology. And it uses this **metaphor** of an interactive night sky. So, it ’ s my great pleasure now to show this to you. So, Universe will open here. And you ’ ll see that it leads with a shifting star field, and there ’ s an Aurora Borealis in the background, kind of morphing with color. The color of the Aurora Borealis can be controlled using this single bar of color at the **bottom**, and we ’ ll put it down here to red. So you see this kind of — these stars moving along. Now, these aren ’ t just little points of light, little pixels. Each of those stars actually represents a specific event in the real world — a quote that was stated by somebody, an image, a news story, a person, a company. You know, some kind of heroic personality. And you might notice that as the cursor begins to touch some of these stars, that shapes begin to emerge. We see here there ’ s a little man walking along, or maybe a woman. And we see here a photograph with a head. You can start to see words emerging here. And those are the constellations of today. And I can turn them all on, and you can see them moving across the sky now. This is the universe of 2007, the last two months. The data from this is global news coverage from thousands of news sources around the world. It ’ s using the API of a really great company that I work with in New York, actually, called Daylife. And it ’ s kind of the zeitgeist view at this level of the world ’ s current mythology over the last couple of months. So we can see where it ’ s emerging here, like President Ford, Iraq, Bush. And we can actually isolate just the words — I call them secrets — and we can cause them to form an alphabetical list. And we see Anna Nicole Smith playing a big role recently. President Ford — this is Gerald Ford ’ s funeral. We can actually click anything in Universe and have it become the center of the universe, and everything else will enter its orbit. So, we ’ ll click Ford, and now that becomes the center. And the things that relate to Ford enter its orbit and swirl around it. We can isolate just the photographs, and we now see those. We can click on one of those and have the photograph be the center of the universe. Now the things that relate to it are swirling around. We can click on this and we see this iconic image of Betty Ford kissing her husband ’ s coffin. In Universe, there ’ s kind of no end. It just goes infinitely, and you can just kind of click on stuff. This is a photographic representation, called Snapshots. But we can actually be more specific in defining our universe. So, if we want to, let ’ s check out what Bill Clinton ’ s universe looks like. And let ’ s see, in the past week, what he ’ s been up to. So now, we have a new universe, which is just constrained to all things Bill Clinton. We can have his constellations emerge here. We can pull out his secrets, and we see that it has a lot to do with candidates, Hillary, presidential, Barack Obama. We can see the stories that Bill Clinton is taking part in right now. Any of those can be opened up. So we see Obama and the Clintons meet in Alabama. You can see that this is an important story ; there are a lot of things in its orbit. If we open this up, we get different perspectives on this story. You can click any of those to go out and read the article at the source. This one ’ s from Al Jazeera. We can also see the superstars. These would be the people that are kind of the looming heroes and heroines in the universe of Bill Clinton. So there ’ s Bill Clinton, Hillary, Iraq, George Bush, Barack Obama, Scooter Libby — these are kind of the people of Bill Clinton. We can also see a world map, so this shows us the geographic reach of Bill Clinton in the last week or so. We can see he ’ s been focused in America because he ’ s been campaigning, probably, but a little bit of action over here in the Middle East. And then we can also see a timeline. So we see that he was a bit quiet on Saturday, but he was back to work on Sunday morning, and actually been tapering off since then this week. And it ’ s not limited to just people or dates, but we can actually put in concepts also. So if I put in climate change for all of 2006, we ’ ll see what that universe looks like. Here we have our star field. Here we have our shapes. Here we have our secrets. So we see again, climate change is large : Nairobi, global conference, environmental. And there are also quotes that you can see, if you ’ re interested in reading about quotes on climate change. You know, this is really an infinite thing. The superstars of climate change in 2006 : United States, Britain, China. You know, these are the towering countries that kind of define this concept. So this is a piece that demands exploration. This will be online in several days, probably next Tuesday. And you ’ ll all be able to use it and kind of explore what your own personal mythology might be. You ’ ll notice that in Daylife — rather, in Universe — it supports both the notion of a global mythology, which is represented by something as broad as, say, 2007, and also a personal mythology. As you search for the things that are important to you in your world, and then see what the constellations of those might look like. So it ’ s been a pleasure. Thank you very much.

Now, have any of y ’ all ever looked up this word? You know, in a dictionary? Yeah, that ’ s what I thought. How about this word? Here, I ’ ll show it to you. Lexicography : the practice of compiling dictionaries. Notice â we ’ re very specific â that word”compile.”The dictionary is not carved out of a piece of granite, out of a lump of rock. It ’ s made up of lots of little bits. It ’ s little discrete â that ’ s spelled D-I-S-C-R-E-T-E â bits. And those bits are words. Now one of the perks of being a lexicographer â besides getting to come to TED â is that you get to say really **fun** words, like lexicographical. Lexicographical has this great pattern : it ’ s called a double dactyl. And just by saying double dactyl, I ’ ve sent the geek needle all the way into the red. But”lexicographical”is the same pattern as”higgledy- piggledy.”Right? It ’ s a **fun** word to say, and I get to say it a lot. Now, one of the non-perks of being a lexicographer is that people don ’ t usually have a kind of warm, fuzzy, snuggly image of the dictionary. Right? Nobody hugs their dictionaries. But what people really often think about the dictionary is, they think more like this. Just to let you know, I do not have a lexicographical whistle. But people think that my job is to let the good words make that difficult **left-hand** turn into the dictionary, and keep the bad words out. But the thing is, I don ’ t want to be a traffic cop. For one thing, I just do not do uniforms. And for another, deciding what words are good and what words are bad is actually not very easy. And it ’ s not very **fun**. And when parts of your job are not easy or **fun**, you kind of look for an excuse not to do them. So if I had to think of some kind of occupation as a **metaphor** for my work, I would much rather be a fisherman. I want to throw my big net into the deep, blue ocean of English and see what marvelous creatures I can drag up from the **bottom**. But why do people want me to direct traffic, when I would much rather go fishing? Well, I blame the Queen. Why do

I blame the Queen? Well, first of all, I blame the Queen because it ’ s funny. But secondly, I blame the Queen because dictionaries have really not changed. Our idea of what a dictionary is has not changed since her reign. The only thing that Queen Victoria would not be amused by in modern dictionaries is our inclusion of the F-word, which has happened in American dictionaries since 1965. So, there ’ s this guy, right? Victorian era. James Murray, first editor of the Oxford English Dictionary. I do not have that hat. I wish I had that hat. So he ’ s really responsible for a lot of what we consider modern in dictionaries today. When a guy who looks like that, in that hat, is the face of modernity, you have a problem. And so, James Murray could get a job on any dictionary today. There ’ d be virtually no learning **curve**. And of course, a few of us are saying : okay, computers! Computers! What about computers? The thing about computers is, I love computers. I mean, I ’ m a huge geek, I love computers. I would go on a hunger strike before I let them take away Google Book Search from me. But computers don ’ t do much else other than speed up the process of compiling dictionaries. They don ’ t change the end result. Because what a dictionary is, is it ’ s Victorian design merged with a little bit of modern propulsion. It ’ s steampunk. What we have is an electric velocipede. You know, we have Victorian design with an engine on it. That ’ s all! The design has not changed. And OK, what about online dictionaries, right? Online dictionaries must be different. This is the Oxford English Dictionary Online, one of the best online dictionaries. This is my favorite word, by the way. Erinaceous : pertaining to the hedgehog family ; of the nature of a hedgehog. Very useful word. So, look at that. Online dictionaries right now are paper thrown up on a screen. This is flat. Look how many links there are in the actual entry : two! Right? Those little buttons, I had them all expanded except for the date chart. So there ’ s not very much going on here. There ’ s not a lot of clickiness. And in fact, online dictionaries replicate almost all the problems of print, except for searchability. And when you improve searchability, you actually take away the one advantage of print, which is serendipity. Serendipity is when you find things you weren ’ t looking for, because finding what you are looking for is so damned difficult. So â□□ â□□ now, when you think about this, what we have here is a ham butt problem. Does everyone know the ham butt problem? Woman ’ s making a ham for a big, family dinner. She goes to cut the butt off the ham and throw it away, and she looks at this piece of ham and she ’ s like,”This is a perfectly good piece of ham. Why am I throwing this away?”She thought,”Well, my mom always did this.”So she calls up mom, and she says,”Mom, why ’ d you cut the butt off the ham, when you ’ re making a ham?”She says,”I don ’ t know, my mom always did it!”So they call grandma, and grandma says,”My pan was too small!”So, it ’ s not that we have good words and bad words. We have a pan that ’ s too small! You know, that ham butt is delicious! There ’ s no reason to throw it away. The bad words â□□ see, when people think about a place and they don ’ t find a place on the map, they think,”This map sucks!”When they find a nightspot or a bar, and it ’ s not in the guidebook, they ’ re like,”Ooh, this place must be cool! It ’ s not in the guidebook.”When they find a word that ’ s not in the dictionary, they think,”This must be a bad word.”Why? It ’ s more likely to be a bad dictionary. Why are you blaming the ham for being too big for the pan? So, you can ’ t get a smaller ham. The English language is as big as it is. So, if you have a ham butt problem, and you ’ re thinking about the ham butt problem, the conclusion that it leads you to is inexorable and counterintuitive : paper is the enemy of words. How can this be? I mean, I love books. I really love books. Some of my best friends are books. But the book is not the best shape for the dictionary. Now they ’ re going to think”Oh, boy. People are going to take away my beautiful, paper dictionaries?”No. There will still be paper dictionaries. When we had cars â when cars became the dominant mode of transportation, we didn ’ t round up all the horses and shoot them. You know, there ’ re still going to be paper dictionaries, but it ’ s not going to be the dominant dictionary. The book-shaped dictionary is not going to be the only shape dictionaries come in. And it ’ s not going to be the prototype for the shapes dictionaries come in. So, think about it this way : if you ’ ve got an artificial constraint, artificial constraints lead to arbitrary distinctions and a skewed worldview. What if biologists could only study animals that made people go,”Aww.”Right? What if we made aesthetic judgments about animals, and only the ones we thought were cute were the ones that we could study? We ’ d know a whole lot about charismatic megafauna, and not very much about much else. And I think this is a problem. I think we should study all the words, because when you think about words, you can make beautiful expressions from very humble parts. Lexicography is really more about material science. We are studying the tolerances of the materials that you use to build the structure of your expression : your speeches and your writing. And then, often people say to me,”Well, OK, how do I know that this word is real?”They think,”OK, if we think words are the tools that we use to build the expressions of our thoughts, how can you say that screwdrivers are better than hammers? How can you say that a sledgehammer is better than a ball- peen hammer?”They ’ re just the right tools for the job. And so people say to me,”How do I know if a word is real?”You know, anybody who ’ s read a children ’ s book knows that love makes things real. If you love a word, use it. That makes it real. Being in the dictionary is an artificial distinction. It doesn ’ t make a word any more real than any other way. If you love a word, it becomes real. So if we ’ re not worrying about directing traffic, if we ’ ve transcended paper, if we are worrying less about control and more about description, then we can think of the English language as being this beautiful mobile. And any time one of those little parts of the mobile changes, is touched, any time you touch a word, you use it in a new context, you give it a new connotation, you verb it, you make the mobile move. You didn ’ t break it. It ’ s just in a new position, and that new position can be just as beautiful. Now, if you ’ re no longer a traffic cop â the problem with being a traffic cop is there can only be so many traffic cops in any one intersection, or the cars get confused. Right? But if your goal is no longer to direct the traffic, but maybe to count the cars that go by, then more eyeballs are better. You can ask for help! If you ask for help, you get more done. And we really need help. Library of Congress : 17 million books, of which half are in English. If only one out of every 10 of those books had a word that ’ s not in the dictionary in it, that would be equivalent to more than two unabridged dictionaries. And I find an un-dictionaried word â a word like”un-dictionaried,”for example â in almost every book I read. What about newspapers? Newspaper archive goes back to 1759, 58. 1 million newspaper pages. If only one in 100 of those pages had an un-dictionaried word on it, it would be an entire other OED. That ’ s 500, 000 more words. So that ’ s a lot. And I ’ m not even talking about magazines. I ’ m not talking about blogs â and I find more new words on BoingBoing in a given week than I do Newsweek or Time. There ’ s a lot going on there. And I ’ m not even talking about polysemy, which is the greedy habit some words have of taking more than one meaning for themselves. So if you think of the word”set,”a set can be a badger ’ s burrow, a set can be one of the pleats in an Elizabethan ruff, and there ’ s one numbered definition in the OED. The OED has 33 different numbered definitions for set. Tiny, little word, 33 numbered definitions. One of them is just labeled”miscellaneous technical senses.”Do you know what that says to me? That says to me, it was Friday afternoon and somebody wanted to go down the pub. That ’ s a lexicographical cop out, to say,”miscellaneous technical senses.”So, we have all these words, and we really need help! And the thing is, we could ask for help â asking for help ’ s not that hard. I mean, lexicography is not rocket science. See, I just gave you a lot of words and a lot of numbers, and this is more of a visual explanation. If we think of the dictionary as being the map of the English language, these bright spots are what we know about, and the dark spots are where we are in the dark. If that was the map of all the words in American English, we don ’ t know very much. And we don ’ t even know the shape of the language. If this was the dictionary â if this was the map of American English â look, we have a kind of lumpy idea of Florida, but there ’ s no California! We ’ re missing California from American English. We just don ’ t know enough, and we don ’ t even know that we ’ re missing California. We don ’ t even see that there ’ s a gap on the map. So again, lexicography is not rocket science. But even if it were, rocket science is being done by dedicated amateurs these days. You know? It can ’ t be that hard to find some words! So, enough scientists in other disciplines are really asking people to help, and they ’ re doing a good job of it. For instance, there ’ s eBird, where amateur birdwatchers can upload information about their bird sightings. And then, ornithologists can go and help track populations, migrations, etc. And there ’ s this guy, Mike Oates. Mike Oates lives in the U. K. He ’ s a director of an electroplating company. He ’ s found more than 140 comets. He ’ s found so many comets, they named a comet after him. It ’ s kind of out past Mars. It ’ s a hike. I don ’ t think he ’ s getting his **picture** taken there anytime soon. But he found 140 comets without a telescope. He downloaded data from the NASA SOHO satellite, and that ’ s how he found them. If we can find comets without a telescope, shouldn ’ t we be able to find words? Now, y ’ all know where I ’ m going with this. Because I ’ m going to the Internet, which is where everybody goes. And the Internet is great for collecting words, because the Internet ’ s full of collectors. And this is a little-known technological fact about the Internet, but the Internet is actually made up of words and enthusiasm. And words and enthusiasm actually happen to be the recipe for lexicography. Isn ’ t that great? So there are a lot of really good word- collecting sites out there right now, but the problem with some of them is that they ’ re not scientific enough. They show the word, but they don ’ t show any context. Where did it come from? Who said it? What newspaper was it in? What book? Because a word is like an archaeological artifact. If you don ’ t know the provenance or the source of the artifact, it ’ s not science, it ’ s a pretty thing to look at. So a word without its source is like a cut flower. You know, it ’ s pretty to look at for a while, but then it dies. It dies too fast. So, this whole time I ’ ve been saying,”The dictionary, the dictionary, the dictionary, the dictionary.”Not”a dictionary,”or”dictionaries.”And that ’ s because, well, people use the dictionary to stand for the whole language. They use it synecdochically. And one of the problems of knowing a word like”synecdochically”is that you really want an excuse to say”synecdochically.”This whole talk has just been an excuse to get me to the point where I could say”synecdochically”to all of you. So I ’ m really sorry. But when you use a part of something â like the dictionary is a part of the language, or a flag stands for the United States, it ’ s a symbol of the country â then you ’ re using it synecdochically. But the thing is, we could make the dictionary the whole language. If we get a bigger pan, then we can put all the words in. We can put in all the meanings. Doesn ’ t everyone want more meaning in their lives? And we can make the dictionary not just be a symbol of the language â we can make it be the whole language. You see, what I ’ m really hoping for is that my son, who turns seven this month â I want him to barely remember that this is the form factor that dictionaries used to come in. This is what dictionaries used to look like. I want him to think of this kind of dictionary as an eight-track **tape**. It ’ s a format that died because it wasn ’ t useful enough. It wasn ’ t really what people needed. And the thing is, if we can put in all the words, no longer have that artificial distinction between good and bad, we can really describe the language like scientists. We can leave the aesthetic judgments to the writers and the speakers. If we can do that, then I can spend all my time fishing, and I don ’ t have to be a traffic cop anymore. Thank you very much for your kind attention.

We really need to put the best we have to offer within reach of our children. If we don ’ t do that, we ’ re going to get the generation we deserve. They ’ re going to learn from whatever it is they have around them. And we, as now the elite, parents, librarians, professionals, whatever it is, a bunch of our activities are, in fact, in trying to get the best we have to offer within reach of those around us, or as broadly as we can. I ’ m going to start and end this talk with a couple things that are carved in stone. One is what ’ s on the Boston Public Library. Carved above their door is,”Free to All.”It ’ s kind of an inspiring statement, and I ’ ll go back at the end of this. I ’ m a librarian, and what I ’ m trying to do is bring all of the works of knowledge to as many people as want to read it. And the idea of using technology is perfect for us. I think we have the opportunity to one-up the Greeks. It ’ s not easy to one-up the Greeks. But with the industriousness of the Egyptians, they were able to build the Library of Alexandria — the idea of a copy of every book of all the peoples of the world. The problem was you actually had to go to Alexandria to go to it. On the other hand, if you did, then great things happened. I think we can one-up the Greeks and achieve something. And I ’ m going to try to argue only one point today : that universal access to all knowledge is within our grasp. So if I ’ m successful, then you ’ ll actually come away thinking, yeah, we could actually achieve the great vision of everything ever published, everything that was ever meant for distribution, available to anybody in the world that ’ s ever wanted to have access to it. Yes, there ’ s issues about how money should be distributed, and that ’ s still being refigured out. But I ’ d say there ’ s plenty of money, and there ’ s plenty of demand, so we can actually achieve that. But I ’ m going to go over the technological, social and sort of where are we as a whole, trying to get to that particular vision. And the way I ’ m going to try to do this is do it like the Amazon. com website, the books, music, video and just go step — media type by media type, just go and say, all right, how ’ re we doing on this? So if we start with books, you know, sort of where are we? Well, first you have to, as an engineer, scope the problem. How big is it? If you wanted to put all of the published works online so that anybody could have it available, well, how big a problem is it? Well, we don ’ t really know, but the largest print library in the world is the Library of Congress. It ’ s 26 million volumes, 26 million volumes. It is, by far and away, the largest print library in the world. And a book, if you had a book, is about a megabyte, so — you know, if you had it in Microsoft Word. So a megabyte, 26 million megabytes is 26 terabytes — it goes mega-, giga-, tera-. 26 terabytes. 26 terabytes fits in a computer system that ’ s about this big, on spinning Linux drives, and it costs about 60, 000 dollars. So for the cost of a house — or around here, a garage — you can put, you can have spinning all of the words in the Library of Congress. That ’ s pretty neat. Then the question is, what do you get? You know, is it worth trying to get there? Do you actually want it online? Some of the first things that people do is they make book readers that allow you to search inside the books, and that ’ s kind of **fun**.

And you can download these things, and look around them in new and different ways. And you can get at them remotely, if you happen to have a laptop. There ’ s starting to be some of these sort of page turn-y interfaces that look a whole lot like books in certain ways, and you can search them, make little tabs, and it ’ s kind of cute — still very book-like — on your laptop. But I don ’ t know, reading things on a laptop — whenever I pull up my laptop, it always feels like work. I think that ’ s one of the reasons why the Kindle is so great. I don ’ t have to feel like I ’ m at work to read a Kindle. It ’ s starting to be a little bit more specified. But I have to say that there ’ s older technologies that I tend to like. I like the physical book. And I think we can go and use our technology to go and digitize things, put them on the Net, and then download, print them and bind them, and end up with books again. And we sort of said, well, how hard is this? And it turns out to not be very hard. We actually went off to make a bookmobile. And a bookmobile — the size of a van with a satellite dish, a printer, binder and cutter, and kids make their own books. It costs about three dollars to download, print and bind a normal, old book. And they actually come out kind of nice looking. You can actually get really good-looking books for on the order of one penny per page, sort of the parts cost for doing this. So the idea of — this technology actually may end up putting books back in people ’ s hands again. There are some other bookmobiles running around. This is Eric Eldred making books at Walden Pond — Thoreau ’ s works. This is just before he got kicked out by the Parks Services, for competing with the bookstore there. In India, they ’ ve got another couple bookmobiles running around. And this is the opening day at the Library of Alexandria, the new Library of Alexandria, in Egypt. It was quite popularly attended. And kids starting to make their own books, and a happy kid with the first book that he ’ s ever owned. So the idea of being able to use this technology to end up with paper where I can handle sort of sounds a little retro, but I think it still has its place. And being from the Silicon Valley, sort of utopian sort of world, we thought, if we can make this technology work in rural Uganda, we might have something. So we actually got some funding from the World Bank to try it out. And we found in about 30 days we could go and take a couple folks from Silicon Valley, fly them to Uganda, buy a car, set up the first Internet connection at the National Library of Uganda, figure out what they wanted, and get a program going making books in rural Uganda. And it actually — so technologically, it works. What we found out of this is we didn ’ t have the right books. So the books were in the library. We could get it to people, if they ’ re digitized, but we didn ’ t know how to quite get them digitized. Everybody thought the answer is, send things to India and China. And so we ’ ve tried that, and I ’ ll go over that in a moment. There are some newer technologies for delivering that have happened that are actually quite exciting as well. One is a print-on-demand machine that looks like a Rube Goldberg machine. We have one of these things now. It ’ s completely cool. It ’ s all conveyor belt, and it makes a book. And it ’ s called the”Espresso Book Machine,”and in about 10 minutes, you can press a button and make a book. Something else I ’ m quite excited about in this particular domain, beyond these sort of kiosk-y things where you can get books on demand, is some of these new little screens that are coming out. And one of my favorites in this is the $100 laptop. And I don ’ t mean to steal any thunder here, but we ’ ve gone and used one of these things to be an e-book reader. So here ’ s one of the beta units and you can — it actually turns out to be a really good-looking e-book reader. And we have a quick hack that we did to try to put one of our books on it, and it turns out that 200 dots per inch means that you can put **scanned** books on them that look really good. At 200 dots per inch, it ’ s kind of the equivalent of a 300 dot print **laser** printer. We ’ re in good enough shape. You actually can go and read **scanned** books quite easily. So the idea of electronic books is starting to come about. But how do you go about doing all this **scanning**? So we thought, okay, well, let ' s try out this send books to India thing. And there was a project with, funded by the National Science Foundation — sent a bunch of scanners, and the American libraries were supposed to send books. Well, they didn ' t. They didn ' t want to send their books. So we bought 100, 000 books and sent them to India. And then we learned why you don ' t want to send books to India. The lesson we learned out of this is, **scan** your own books. If you really care about books, you ' re going to **scan** them better, especially if they ' re valuable books. If they ' re new books and you can just, you know, butcher them, because you could just buy another one, that ' s not such a big deal in terms of doing high-quality **scanning**. But do things that you love. But the Indians have been **scanning** a lot of their own books — about 300, 000 now — doing very well. The Chinese did over a million, and the Egyptians are about 30, 000. But we sent — thought, OK, if we ' re going to need to do this, let ' s do it in- library. How do we go and do this, and how do we get it down so that it ' s a cost point that we could afford? And we sort of picked the price point of 10 cents a page. If it ' s basically the cost of xeroxing to basically digitize, OCR, package it up, make it so that you could download, print and bind it — the whole shebang — we would have achieved something. So we started out trying to figure out. How do we get to 10 cents? And we tried these robot things, and they worked pretty well — sort of these auto-page-turning things. If we can have Mars Rovers, you ' d think you could turn pages. But it actually turns out to be pretty hard to turn pages, and the volume isn ' t there. So anyway — so we ended up making our own book scanner, and with two digital, high-grade, professional digital cameras, controlled **museum** lighting, so even if it ' s a black and white book, you can go and get the proper intonation. So you basically do a beautiful, respectful job. This is not a fax, this is — the idea is to do a beautiful job as you ' re going through these libraries. And we ' ve been able to achieve 10 cents a page if we run things in volume. This is what it looks like at the University of Toronto. And actually, it turns out to, you know, pay a living wage. People seem to love it. Yes, it ' s a little boring, but some people kind of get into the Zen of it. And especially if it ' s kind of interesting books that you care about, in languages that you can read. We actually have been able to do a pretty good job of this, at getting 10 cents a page. So 10 cents a page, 300 pages in your average book, 30 dollars a book. The Library of Congress, if you did the whole darn thing — 26 million books — is about 750 million dollars, right? But a million books, I think, actually would be a pretty good start, and that would cost 30 million dollars. That ' s not that big a bill. And what we ' ve been able to do is get into libraries. We ' ve now got eight of these **scanning** centers in three countries, and libraries are up for having their books **scanned**. The Getty here is moving their books to the UCLA, which is where we have one these **scanning** centers, and **scanning** their out-of-copyright books, which is fabulous. So we ' re starting to get the institutional responsibility. The thing we ' re missing is the 10 cents. If we can get the 10 cents, all the rest of it flows. We ' ve **scanned** about 200, 000 books. Now we ' re **scanning** about 15, 000 books a month, and it ' s starting to gear up another factor of two from there. So all in all, that ' s going very well. And we ' re starting to move out of the just out-of-copyright into the out-of-print world. So I think of — we ' re kind of going from the out-of-copyright, library stuff, and Amazon. com is coming from the in-print world. And I think we ' ll meet in the middle some place, and have the classic thing that you have, which is a publishing system and a library system working in parallel. And so we ' re starting up a program to do out-of-print works, but loaning them. Exactly what loaning means, I ' m not quite sure. But anyway, loaning out-of-print works from the Boston Public Library, the Woods Hole Oceanographic Institute and a few other libraries that are starting to participate in this program, to try out this model of where does a library stop and where does the bookstore take over. So all in all, it ' s possible to do this in large scale. We ' re also going back over microfilm and getting that online. So, we can do 10 cents a page, we ' re going 15, 000 books a month and we ' ve got about 250, 000 books online, counting all the other projects that are starting to add in. So what I wanted to argue is, books are within our grasp. The idea of taking on the whole ball of wax is not that big a deal. Yes, it costs tens of millions, low hundreds of millions, but one time shot and we ' ve got basically the history of printed literature online. And then, there ' s business model issues about how to try to effectively market it and get it to people. But it is within our grasp, technologically and law-wise, at least for the out of print and out of copyright, we suggest, to be able to get the whole darn thing online. Now let ' s go for audio, and I ' m going to go through these. So how much is there? Well, as best we can tell, there are about two to three million disks having been published — so 78s, long-playing records and CDs — or at least that ' s the largest archives of published materials we ' ve been able to sort of point at. It costs about 10 dollars a piece to go and take a disk and put it online, if you ' re doing things in volume. But we ' ve found that the rights issues are really quite thorny. This is a fairly heavily litigated area, so we ' ve found that there are niches in the music world that aren ' t served terribly well by the classic commercial publishing system. And we ' ve been starting to make these available by going and offering shelf space on the Net. In the United States, it doesn ' t cost you to give something away. Right? If you give something to a charity or to the public, you get a pat on the back and a tax donation — except on the Net, where you can go broke. If you put up a video of your garage band, and it starts getting heavily accessed, you can lose your guitars or your house. This doesn ' t make any sense. So we ' ve offered unlimited storage, unlimited bandwidth, forever, for free, to anybody that has something to share that belongs in a library. And we ' ve been getting a lot of takers. One is the rock ' n ' rollers. The rock ' n ' rollers had a tradition of sharing, as long as nobody made any money. You could — concert recordings, it ' s not the commercial recordings, but concert recordings, started by the Grateful Dead. And we get about two or three bands a day signing up. They give permission, and we get about 40 or 50 concerts a day. We have about 40, 000 concerts, everything the Grateful Dead ever did, up on the Net, so that people can see it and listen to this material. So audio is possible to put up, but the rights issues are really pretty thorny. We ' ve got a lot of collections now — a couple hundred thousand items — and it ' s growing over time. Moving images : if you think of theatrical releases, there are not that many of them. As best we can tell, there are about 150, 000 to 200, 000 movies ever that are really meant for a large-scale theatrical distribution. It ' s just not that many. But half of those were Indian. But anyway, it ' s doable, but we ' ve only found about a thousand of these things that — to be out of copyright. So we ' ve digitized those and made those available. But we ' ve found that there ' s lots of other types of movies that haven ' t really seen the light of day — archival **films**. We ' ve found, also, a lot of political **films**, a lot of amateur **films**, all sorts of things that are basically needing a home, a permanent home. So we ' ve been starting to make these available and it ' s grown to be very popular. We ' re not quite a YouTube. We tended towards longer-term things and also things that people can reuse and make into new movies, which has just been great **fun**. Television comes quite a bit larger. We started recording 20 channels of television 24 hours a day. It ' s sort of the biggest TiVo box you ' ve ever seen. It ’ s about a petabyte, so far, of worldwide television — Russian, Chinese, Japanese, Iraqi, Al Jazeera, BBC, CNN, ABC, CBS, NBC — 24 hours a day. We only put one week up, which is mostly for cost reasons, which is the 9 / 11, sort of from 9 / 11 / 2001. For one week, what did the world see? CNN was saying that Palestinians were dancing in the streets. Were they? Let ’ s look at the Palestinian television and find out. How can we have critical thinking without being able to quote and being able to compare what happened in the past? And television is dreadfully unrecorded and unquotable, except by Jon Stewart, who does a fabulous job. So anyway, television is, I would suggest, within our grasp. So 15 dollars per video hour, and also about 100 dollars to 150 dollars per celluloid hour, we ’ re able to go and get materials online very inexpensively and have them up on the Net. And we ’ ve got, now, a lot of these materials. So we ’ ve got about 100, 000 pieces up there. So books, music, video, software. There ’ s only 50, 000 titles of it. Mostly the issues there are legal issues and breaking copy protections. But we ’ ve worked through some of those, but we ’ ve still got real problems in Washington. Well, we ’ re best known as the World Wide Web. We ’ ve been archiving the World Wide Web since 1996. We take a snapshot of every website and all of the pages on it, every two months. And actually, it ’ s really been pioneered by Alexa Internet, which donates this collection to the Internet Archive. And it ’ s been growing along for the last 11 years, and it ’ s a fantastic resource. And we ’ ve made a Wayback Machine that you can then go and see old websites kind of the way they were. If you go and search on something — this is Google. com, the different versions of it that we have, this is what it looks like when it was an alpha release, and this is what it looked like at Stanford. So anyway, you ’ ve got basically an idea of where things came from. Mostly, people want to see their old stuff out of this. If there ’ s one thing that we want to learn from the Library of Alexandria version one, which is probably best known for burning, is, don ’ t just have one copy. So we ’ ve started to — we ’ ve made another copy of all of this and we actually put it back in the Library of Alexandria. So this is a **picture** of the Internet Archive at the Library of Alexandria. And we now have also another copy building up in Amsterdam. So, we should put it in the San Andreas Fault Line in San Francisco, flood zone in Amsterdam and in the Middle East. Right, so anyway... so we ’ re hedging our bets here. If we go and put it in a couple more places, I think we ’ ll be in good shape. There ’ s a political and social question out of this. Is all of this, as we go digital, is it going to be public or private? There ’ s some large companies that have seen this vision, that are doing large-scale digitization, but they ’ re locking up the public domain. The question is, is that the world that we really want to live in? What ’ s the role of the public versus the private as things go forward? How do we go and have a world where we both have libraries and publishing in the future, just as we basically benefited as we were growing up? So universal access to all knowledge — I think it can be one of the greatest achievements of humankind, like the man on the moon, or the Gutenberg Bible, or the Library of Alexandria. It could be something that we ’ re remembered for, for millennia, for having achieved. And as I said before, I ’ ll end with something that ’ s carved above the door of the Carnegie Library. Carnegie — one of the great capitalists of this country — carved above his legacy,”Free to the People.”Thank you very much.

Text Sample 692: POS Dim 5 – 2010 – Score 9.00 – 2010/t002718.txt
Thank you very much. I have a few **pictures**, and I ’ ll talk a little bit about how

I ’ m able to do what I do. All these houses are built from between 70 and 80 percent recycled material, stuff that was headed to the mulcher, the landfill, the burn pile. It was all just gone. This is the first house I built. This double front door here with the three-light transom, that was headed to the landfill. Have a little turret there. And then these buttons on the corbels here — right there — those are hickory nuts. And these buttons there — those are chicken eggs. Of course, first you have breakfast, and then you fill the shell full of Bondo and paint it and nail it up, and you have an architectural button in just a fraction of the time. This is a look at the inside. You can see the three-light transom there with the eyebrow windows. Certainly an architectural antique headed to the landfill — even the lockset is probably worth 200 dollars. Everything in the kitchen was salvaged. There ’ s a 1952 O ’ Keefe & Merritt stove, if you like to cook — cool stove. This is going up into the turret. I got that staircase for 20 dollars, including delivery to my lot. Then, looking up in the turret, you see there are bulges and pokes and sags and so forth. Well, if that ruins your life, well, then, you shouldn ’ t live there. This is a laundry chute. And this right here is a shoe last — those are those cast-iron things you see at antique shops. So I had one of those, so I made some low-tech gadgetry, where you just stomp on the shoe last, and then the door flies open and you throw your laundry down. And then if you ’ re smart enough, it goes on a basket on top of the washer. If not, it goes into the toilet. This is a bathtub I made, made out of scrap two-by-four. Started with the rim, and then glued and nailed it up into a flat, corbeled it up and flipped it over, then did the two profiles on this side. It ’ s a two-person tub. After all, it ’ s not just a question of hygiene, but there ’ s a possibility of recreation as well. Then, this faucet here is just a piece of Osage orange. It looks a little phallic, but after all, it ’ s a bathroom. This is a house based on a Budweiser can. It doesn ’ t look like a can of beer, but the design take-offs are absolutely unmistakable : the barley hops design worked up into the eaves, then the dentil work comes directly off the can ’ s red, white, blue and silver. Then, these corbels going down underneath the eaves are that little design that comes off the can. I just put a can on a copier and kept enlarging it until I got the size I want. Then, on the can it says,”This is the famous Budweiser beer, we know of no other beer, blah, blah, blah.”So we changed that and put,”This is the famous Budweiser house. We don ’ t know of any other house...”and so forth and so on. This is a deadbolt. It ’ s a fence from a 1930s shaper, which is a very angry woodworking machine. And they gave me the fence, but they didn ’ t give me the shaper, so we made a deadbolt out of it. That ’ ll keep bull elephants out, I promise. And sure enough, we ’ ve had no problems with bull elephants. The shower is intended to simulate a glass of beer. We ’ ve got bubbles going up there, then suds at the top with lumpy tiles. Where do you get lumpy tiles? Well, of course, you don ’ t. But I get a lot of toilets, and so you just dispatch a toilet with a hammer, and then you have lumpy tiles. And then the faucet is a beer tap. Then, this **panel** of glass is the same **panel** of glass that occurs in every middle-class front door in America. We ’ re getting tired of it. It ’ s kind of clichd now. If you put it in the front door, your design fails. So don ’ t put it in the front door ; put it somewhere else. It ’ s a pretty **panel** of glass. But if you put it in the front door, people say,”Oh, you ’ re trying to be like those guys, and you didn ’ t make it.”So don ’ t put it there. Then, another bathroom upstairs. This light up here is the same light that occurs in every middle-class foyer in America. Don ’ t put it in the foyer. Put it in the shower, or in the closet, but not in the foyer. Then, somebody gave me a bidet, so it got a bidet. This little house here, those branches there are made out of Bois d ’ arc or Osage orange. These **pictures** will keep scrolling as I talk a little bit. In order to do what I do, you have to understand what causes waste in the building industry.

Our housing has become a commodity, and I ’ ll talk a little bit about that. But the first cause of waste is probably even buried in our DNA. Human beings have a need for maintaining consistency of the apperceptive mass. What does that mean? What it means is, for every perception we have, it needs to tally with the one like it before, or we don ’ t have continuity, and we become a little bit disoriented. So I can show you an object you ’ ve never seen before. Oh, that ’ s a cell phone. But you ’ ve never seen this one before. What you ’ re doing is sizing up the pattern of structural features, and then you go through your databanks : Cell phone. Oh! That ’ s a cell phone. If I took a bite out of it, you ’ d go,”Wait a second.”That ’ s not a cell phone. That ’ s one of those new chocolate cell phones.”You ’ d have to start a new category, right between cell phones and chocolate. That ’ s how we process information. You translate that to the building industry. If we have a wall of windowpanes and one pane is cracked, we go,”Oh, dear. That ’ s cracked. Let ’ s repair it. Let ’ s take it out and throw it away so nobody can use it and put a new one in.”Because that ’ s what you do with a cracked pane. Never mind that it doesn ’ t affect our lives at all. It only rattles that expected pattern and unity of structural features. However, if we took a small hammer, and we added cracks to all the other windows — then we have a pattern. Because Gestalt psychology emphasizes recognition of pattern over parts that comprise a pattern. We ’ ll go,”Ooh, that ’ s nice.”So, that serves me every day. Repetition creates pattern. If I have 100 of these, 100 of those, it makes no difference what these and those are. If I can repeat anything, I have the possibility of a pattern, from hickory nuts and chicken eggs, shards of glass, branches. It doesn ’ t make any difference. That causes a lot of waste in the building industry. The second cause is, Friedrich Nietzsche, along about 1885, wrote a book titled”The Birth of Tragedy.”And in there, he said cultures tend to swing between one of two perspectives : on the one hand, we have an Apollonian perspective, which is very crisp and premeditated and intellectualized and perfect. On the other end of the spectrum, we have a Dionysian perspective, which is more given to the passions and intuition, tolerant of organic texture and human gesture. So the way the Apollonian personality takes a **picture** or hangs a **picture** is, they ’ ll get out a transit and a **laser** level and a micrometer.”OK, honey. A thousandth of an inch to the left. That ’ s where we want the **picture**. Right. Perfect!”Predicated on plumb level, square and centered. The Dionysian personality takes the **picture** and goes : That ’ s the difference. I feature blemish. I feature organic process. Dead center John Dewey. Apollonian mindset creates mountains of waste. If something isn ’ t perfect, if it doesn ’ t line up with that premeditated model? Dumpster.”Oops. Scratch. Dumpster.””Oops”this,”oops”that. Landfill, landfill, landfill. The third thing is arguably — The Industrial Revolution started in the Renaissance with the rise of humanism, then got a little jump start along about the French Revolution. By the middle of the 19th century, it ’ s in full flower. And we have dumaflaches and gizmos and contraptions that will do anything that we, up to that point, had to do by hand. So now we have standardized materials. Well, trees don ’ t grow two inches by four inches, eight, ten and twelve **feet** tall. We create mountains of waste. And they ’ re doing a pretty good job there in the forest, working all the byproduct of their industry — with OSB and particle board and so forth and so on — but it does no good to be responsible at the point of harvest in the forest if consumers are wasting the harvest at the point of consumption. And that ’ s what ’ s happening. And so if something isn ’ t standard,”Oops, dumpster.””Oops”this.”Oops, warped.”If you buy a two-by- four and it ’ s not straight, you can take it back.”Oh, I ’ m so sorry, sir. We ’ ll get you a straight one.”Well, I feature all those warped things because repetition creates pattern, and it ’ s from a Dionysian perspective. The fourth thing is labor is disproportionately more expensive than materials. Well, that ' s just a myth. And there ' s a story : Jim Tulles, one of the guys I trained — I said,"Jim, it ' s time now. I got a job for you as a foreman on a framing crew. Time for you to go.""Dan, I just don ' t think I ' m ready.""Jim, now it ' s time. You ' re the down — oh!"So we hired on. And he was out there with a **tape** measure, going through the trash heap, looking for header material, or the board that goes over a door, thinking he ' d impress his boss — that ' s how we taught him to do it. The superintendent walked up and said,"What are you doing?""Oh, just looking for header material,"waiting for that kudos. He said,"I ' m not paying you to go through the trash. Get back to work."And Jim had the wherewithal to say,"You know, if you were paying me 300 dollars an hour, I can see how you might say that. But right now, I ' m saving you five dollars a minute. Do the math.""Good call, Tulles. From now on, you guys hit this pile first."And the irony is that he wasn ' t very good at math. But once in a while, you get access to the control room, and then you can kind of mess with the dials. And that ' s what happened there. The fifth thing is that maybe, after 2, 500 years, Plato is still having his way with us in his notion of perfect forms. He said that we have in our noggin the perfect idea of what we want, and we force environmental resources to accommodate that. So we all have in our head the perfect house, the American dream, which is a house, the dream house. The problem is we can ' t afford it. So we have the American dream look-alike, which is a mobile home. Now there ' s a blight on the planet. It ' s a chattel mortgage, just like furniture, just like a car. You write the check, and instantly, it depreciates 30 percent. After a year, you can ' t get insurance on everything you have in it, only on 70 percent. Wired with 14-Gauge wire, typically. Nothing wrong with that, unless you ask it to do what 12-Gauge wire ' s supposed to do, and that ' s what happens. It out-gasses formaldehyde — so much so that there is a federal law in place to warn new mobile home buyers of the formaldehyde atmosphere danger. Are we just being numbingly stupid? The walls are this thick. The whole thing has the structural value of corn."So... I thought Palm Harbor Village was over there.""No, no. We had a wind last night. It ' s gone now."Then when they degrade, what do you do with them? Now, all that — that Apollonian, Platonic model — is what the building industry is predicated on, and there are a number of things that exacerbate that. One is that all the professionals, all the tradesmen, vendors, inspectors, engineers, **architects** all think like this. And then it works its way back to the consumer, who demands the same model. It ' s a self-fulfilling prophecy. We can ' t get out of it. Then here come the marketeers and the advertisers."Woo. Woo-hoo."We buy stuff we didn ' t know we needed. All we have to do is look at what one company did with carbonated prune juice. How disgusting. But you know what they did? They hooked a **metaphor** into it and said,"I drink Dr. Pepper..."And pretty soon, we ' re swilling that stuff by the lake-ful, by the billions of gallons. It doesn ' t even have real prunes! Doesn ' t even keep you regular. My oh my, that makes it worse. And we get sucked into that faster than anything. Then, a man named Jean-Paul Sartre wrote a book titled"Being and Nothingness."It ' s a pretty quick read. You can snap through it in maybe — maybe two years, if you read eight hours a day. In there, he talked about the divided self. He said human beings act differently when they know they ' re alone than when they know somebody else is around. So if I ' m eating spaghetti, and I know I ' m alone, I can eat like a backhoe. I can wipe my mouth on my sleeve, **napkin** on the table, chew with my mouth open, make little noises, scratch wherever I want. But as soon as you walk in, I go,"Oops! Lil ' spaghetti sauce there."**Napkin** in my lap, half-bites, chew with my mouth closed, no scratching. Now, what I ' m doing is fulfilling your expectations of how I should live my life. I feel that expectation, and so I accommodate it, and I ’ m living my life according to what you expect me to do. That happens in the building industry as well. That ’ s why all subdivisions look the same. Sometimes, we even have these formalized cultural expectations. I ’ ll bet all your shoes match. Sure enough, we all buy into that... And with gated communities, we have a formalized expectation, with a homeowners ’ association. Sometimes those guys are Nazis, my oh my. That exacerbates and continues this model. The last thing is gregariousness. Human beings are a social species. We like to hang together in groups, just like wildebeests, just like lions. Wildebeests don ’ t hang with lions, because lions eat wildebeests. Human beings are like that. We do what that group does that we ’ re trying to identify with. You see this in junior high a lot. Those kids, they ’ ll work all summer long — kill themselves — so that they can afford one pair of designer jeans. So along about September, they can stride in and go,”I ’ m important today. See? Don ’ t touch my designer jeans! I see you don ’ t have designer jeans. You ’ re not one of the beautiful — See, I ’ m one of the beautiful people. See my jeans?”Right there is reason enough to have uniforms. And so that happens in the building industry as well. We have confused Maslow ’ s hierarchy of needs, just a little bit. On the **bottom** tier, we have basic needs : shelter, clothing, food, water, mating and so forth. Second : security. Third : relationships. Fourth : status, self-esteem — that is, vanity — and we ’ re taking vanity and shoving it down here. And so we end up with vain decisions, and we can ’ t even afford our mortgage. We can ’ t afford to eat anything except beans ; that is, our housing has become a commodity. And it takes a little bit of nerve to dive into those primal, terrifying parts of ourselves and make our own decisions and not make our housing a commodity, but make it something that bubbles up from seminal sources. That takes a little bit of nerve, and, darn it, once in a while, you fail. But that ’ s okay. If failure destroys you, then you can ’ t do this. I fail all the time, every day, and I ’ ve had some whopping failures, I promise — big, public, humiliating, embarrassing failures. Everybody points and laughs, and they say,”He tried it a fifth time, and it still didn ’ t work! What a moron!”Early on, contractors come by and say,”Dan, you ’ re a cute little bunny, but you know, this just isn ’ t going to work. What don ’ t you do this? Why don ’ t you do that?”And your instinct is to say,”Well, why don ’ t you suck an egg?”But you don ’ t say that, because they ’ re the guys you ’ re targeting. And so what we ’ ve done — and this isn ’ t just in housing ; it ’ s in clothing and food and our transportation needs, our energy — we sprawl just a little bit. And when I get a little bit of press, I hear from people all over the world. And we may have invented excess, but the problem of waste is worldwide. We ’ re in trouble. And I don ’ t wear ammo belts crisscrossing my chest and a red bandana. But we ’ re clearly in trouble. And what we need to do is reconnect with those really primal parts of ourselves and make some decisions and say,”You know, I think I would like to put CDs across the wall there. What do you think, honey?”If it doesn ’ t work, take it down. What we need to do is reconnect with who we really are, and that ’ s thrilling indeed. Thank you very much.

Text Sample 693: POS Dim 5 – 2010 – Score 7.00 – 2010/t002603.txt

My name is Arvind Gupta, and I ’ m a toymaker. I ’ ve been making toys for the last 30 years. The early ’ 70s, I was in college. It was a very revolutionary time. It was a political ferment, so to say â students out in the streets of Paris, revolting against authority. America was jolted by the anti-Vietnam movement, the Civil Rights movement. In India, we had the Naxalite movement, the [unclear] movement. But you know, when there is a political churning of society, it unleashes a lot of energy. The National Movement of India was testimony to that. Lots of people resigned from well-paid jobs and jumped into the National Movement. Now in the early ’ 70s, one of the great programs in India was to revitalize primary science in village schools. There was a person, Anil Sadgopal, did a Ph. D. from Caltech and returned back as a molecular biologist in India ’ s cutting-edge research institute, the TIFR. At 31, he was not able to relate the kind of [unclear] research, which he was doing with the lives of the ordinary people. So he designed and went and started a village science program. Many people were inspired by this. The slogan of the early ’ 70s was”Go to the people. Live with them ; love them. Start from what they know. Build on what they have.”This was kind of the defining slogan. Well I took one year. I joined Telco, made TATA trucks, pretty close to Pune. I worked there for two years, and I realized that I was not born to make trucks. Often one doesn ’ t know what one wants to do, but it ’ s good enough to know what you don ’ t want to do. So I took one year off, and I went to this village science program. And it was a turning point. It was a very small village â a weekly bazaar where people, just once in a week, they put in all the vats. So I said,”I ’ m going to spend a year over here.”So I just bought one specimen of everything which was sold on the roadside. And one thing which I found was this black rubber. This is called a cycle valve tube. When you pump in air in a bicycle, you use a bit of this. And some of these models â so you take a bit of this cycle valve tube, you can put two matchsticks inside this, and you make a flexible joint. It ’ s a joint of tubes. You start by teaching angles â an acute angle, a right angle, an obtuse angle, a straight angle. It ’ s like its own little coupling. If you have three of them, and you loop them together, well you make a triangle. With four, you make a square, you make a pentagon, you make a hexagon, you make all these kind of polygons. And they have some wonderful properties. If you look at the hexagon, for instance, it ’ s like an amoeba, which is constantly changing its own profile. You can just pull this out, this becomes a rectangle. You give it a push, this becomes a parallelogram. But this is very shaky. Look at the pentagon, for instance, pull this out â it becomes a boat shape trapezium. Push it and it becomes house shaped. This becomes an isosceles triangle â again, very shaky. This square might look very square and prim. Give it a little push â this becomes a rhombus. It becomes kite-shaped. But give a child a triangle, he can ’ t do a thing to it. Why use triangles? Because triangles are the only rigid structures. We can ’ t make a bridge with squares because the train would come, it would start doing a jig. Ordinary people know about this because if you go to a village in India, they might not have gone to engineering college, but no one makes a **roof** placed like this. Because if they put tiles on top, it ’ s just going to crash. They always make a triangular **roof**. Now this is people science. And if you were to just poke a hole over here and put a third matchstick, you ’ ll get a T joint. And if I were to poke all the three legs of this in the three vertices of this triangle, I would make a tetrahedron. So you make all these 3D shapes. You make a tetrahedron like this. And once you make these, you make a little house. Put this on top. You can make a joint of four. You can make a joint of six. You just need a ton. Now this was â you make a joint of six, you make an icosahedron. You can play around with it. This makes an igloo. Now this is in 1978. I was a 24-year-old young engineer. And I thought this was so much better than making trucks. If you, as a matter of fact, put four marbles inside, you simulate the molecular structure of methane, CH4. Four atoms of hydrogen, the four points of the tetrahedron, which means the little carbon atom. Well since then, I just thought that I ’ ve been really privileged to go to over 2, 000 schools in my country â village schools, government schools, municipal schools, Ivy League schools â I ' ve been invited by most of them. And every time I go to a school, I see a gleam in the eyes of the children. I see hope. I see happiness in their faces. Children want to make things. Children want to do things. Now this, we make lots and lots of pumps. Now this is a little pump with which you could inflate a balloon. It ' s a real pump. You could actually pop the balloon. And we have a slogan that the best thing a child can do with a toy is to break it. So all you do is â it ' s a very kind of provocative statement â this old bicycle tube and this old plastic [unclear] This filling cap will go very snugly into an old bicycle tube. And this is how you make a valve. You put a little sticky **tape**. This is one-way traffic. Well we make lots and lots of pumps. And this is the other one â that you just take a straw, and you just put a stick inside and you make two half-cuts. Now this is what you do, is you bend both these legs into a triangle, and you just wrap some **tape** around. And this is the pump. And now, if you have this pump, it ' s like a great, great sprinkler. It ' s like a centrifuge. If you spin something, it tends to fly out. Well in terms of â if you were in Andhra Pradesh, you would make this with the palmyra leaf. Many of our folk toys have great science principles. If you spin-top something, it tends to fly out. If I do it with both hands, you can see this **fun** Mr. Flying Man. Right. This is a toy which is made from paper. It ' s amazing. There are four **pictures**. You see insects, you see frogs, snakes, eagles, butterflies, frogs, snakes, eagles. Here ' s a paper which you could [unclear] â designed by a mathematician at Harvard in 1928, Arthur Stone, documented by Martin Gardner in many of his many books. But this is great **fun** for children. They all study about the food chain. The insects are eaten by the frogs ; the frogs are eaten by the snakes ; the snakes are eaten by the eagles. And this can be, if you had a whole photocopy paper â A4 size paper â you could be in a municipal school, you could be in a government school â a paper, a scale and a pencil â no glue, no scissors. In three minutes, you just fold this up. And what you could use it for is just limited by your imagination. If you take a smaller paper, you make a smaller flexagon. With a bigger one, you make a bigger one. Now this is a pencil with a few slots over here. And you put a little fan here. And this is a hundred-year-old toy. There have been six major research papers on this. There ' s some grooves over here, you can see. And if I take a reed â if I rub this, something very amazing happens. Six major research papers on this. As a matter of fact, Feynman, as a child, was very **fascinated** by this. He wrote a paper on this. And you don ' t need the three billion-dollar Hadron Collider for doing this. This is there for every child, and every child can enjoy this. If you want to put a colored disk, well all these seven colors coalesce. And this is what Newton talked about 400 years back, that white light ' s made of seven colors, just by spinning this around. This is a straw. What we ' ve done, we ' ve just sealed both the ends with **tape**, nipped the right corner and the **bottom** left corner, so there ' s holes in the opposite corners, there ' s a little hole over here. This is a kind of a blowing straw. I just put this inside this. There ' s a hole here, and I shut this. And this costs very little money to make â great **fun** for children to do. What we do is make a very simple electric motor. Now this is the simplest motor on Earth. The most expensive thing is the battery inside this. If you have a battery, it costs five cents to make it. This is an old bicycle tube, which gives you a broad rubber band, two safety pins. This is a permanent magnet. Whenever current flows through the coil, this becomes an electromagnet. It ' s the interaction of both these magnets which makes this motor spin. We made 30, 000. Teachers who have been teaching science for donkey years, they just muck up the definition and they spit it out. When teachers make it, children make it. You can see a gleam in their eye. They get a thrill of what science is all about. And this science is not a rich man ’ s game. In a democratic country, science must reach to our most oppressed, to the most marginalized children. This program started with 16 schools and spread to 1, 500 government schools. Over 100, 000 children learn science this way. And we ’ re just trying to see possibilities. Look, this is the tetrapak â awful materials from the point of view of the environment. There are six layers â three layers of plastic, aluminum â which are are sealed together. They are fused together, so you can ’ t separate them. Now you can just make a little network like this and fold them and stick them together and make an icosahedron. So something which is trash, which is choking all the seabirds, you could just recycle this into a very, very joyous â all the platonic solids can be made with things like this. This is a little straw, and what you do is you just nip two corners here, and this becomes like a baby crocodile ’ s mouth. You put this in your mouth, and you blow. It ’ s children ’ s delight, a teacher ’ s envy, as they say. You ’ re not able to see how the sound is produced, because the thing which is vibrating goes inside my mouth. I ’ m going to keep this outside, to blow out. I ’ m going to suck in air. So no one actually needs to muck up the production of sound with wire vibrations. The other is that you keep blowing at it, keep making the sound, and you keep cutting it. And something very, very nice happens. And when you get a very small one â This is what the kids teach you. You can also do this. Well before I go any further, this is something worth sharing. This is a touching slate meant for blind children. This is strips of Velcro, this is my **drawing** slate, and this is my **drawing** pen, which is basically a **film** box. It ’ s basically like a fisherman ’ s line, a fishing line. And this is wool over here. If I crank the handle, all the wool goes inside. And what a blind child can do is to just draw this. Wool sticks on Velcro. There are 12 million blind children in our country â who live in a world of darkness. And this has come as a great boon to them. There ’ s a factory out there making our children blind, not able to provide them with food, not able to provide them with vitamin A. But this has come as a great boon for them. There are no patents. Anyone can make it. This is very, very simple. You can see, this is the generator. It ’ s a crank generator. These are two magnets. This is a large pulley made by sandwiching rubber between two old CDs. Small pulley and two strong magnets. And this fiber turns a wire attached to an LED. If I spin this pulley, the small one ’ s going to spin much faster. There will be a spinning magnetic field. Lines, of course, would be cut, the force will be generated. And you can see, this LED is going to glow. So this is a small crank generator. Well, this is, again, it ’ s just a ring, a steel ring with steel nuts. And what you can do is just, if you give it a twirl, well they just keep going on. And imagine a bunch of kids standing in a circle and just waiting for the steel ring to be passed on. And they ’ d be absolutely joyous playing with this. Well in the end, what we can also do : we use a lot of old newspapers to make caps. This is worthy of Sachin Tendulkar. It ’ s a great cricket cap. When first you see Nehru and Gandhi, this is the Nehru cap â just half a newspaper. We make lots of toys with newspapers, and this is one of them. And this is â you can see â this is a flapping bird. All of our old newspapers, we cut them into little squares. And if you have one of these birds â children in Japan have been making this bird for many, many years. And you can see, this is a little fantail bird. Well in the end, I ’ ll just end with a story. This is called”The Captain ’ s Hat Story.”The captain was a captain of a sea-going ship. It goes very slowly. And there were lots of passengers on the ship, and they were getting bored, so the captain invited them on the deck.”Wear all your colorful clothes and sing and dance, and I ’ ll provide you with good food and drinks.”And the captain would wear a cap everyday and join in the regalia. The first day, it was a huge umbrella cap, like a captain ’ s cap. That night, when the passengers would be sleeping, he would give it one more fold, and the second day, he would be wearing a fireman ’ s cap â with a little shoot just like a designer cap, because it protects the spinal cord. And the second night, he would take the same cap and give it another fold. And the third day, it would be a Shikari cap â just like an adventurer ’ s cap. And the third night, he would give it two more folds â and this is a very, very famous cap. If you ’ ve seen any of our Bollywood **films**, this is what the policeman wears, it ’ s called a zapalu cap. It ’ s been catapulted to international glory. And we must not forget that he was the captain of the ship. So that ’ s a ship. And now the end : everyone was enjoying the journey very much. They were singing and dancing. Suddenly there was a storm and huge waves. And all the ship can do is to dance and pitch along with the waves. A huge wave comes and slaps the front and knocks it down. And another one comes and slaps the aft and knocks it down. And there ’ s a third one over here. This swallows the bridge and knocks it down. And the ship sinks, and the captain has lost everything, but for a life jacket. Thank you so much.

Text Sample 694: POS Dim 5 – 2010 – Score 7.00 – 2010/t002785.txt

So I ’ m going to talk to you about you about the political chemistry of oil spills and why this is an incredibly important, long, oily, hot summer, and why we need to keep ourselves from getting distracted. But before I talk about the political chemistry, I actually need to talk about the chemistry of oil. This is a photograph from when I visited Prudhoe Bay in Alaska in 2002 to watch the Minerals Management Service testing their ability to burn oil spills in ice. And what you see here is, you see a little bit of crude oil, you see some ice cubes, and you see two sandwich baggies of napalm. The napalm is burning there quite nicely. And the thing is, is that oil is really an **abstraction** for us as the American consumer. We ’ re four percent of the world ’ s population ; we use 25 percent of the world ’ s oil production. And we don ’ t really understand what oil is, until you check out its molecules, And you don ’ t really understand that until you see this stuff burn. So this is what happens as that burn gets going. It takes off. It ’ s a big woosh. I highly recommend that you get a chance to see crude oil burn someday, because you will never need to hear another poli sci lecture on the geopolitics of oil again. It ’ ll just bake your retinas. So there it is ; the retinas are baking. Let me tell you a little bit about this chemistry of oil. Oil is a stew of hydrocarbon molecules. It starts of with the very small ones, which are one carbon, four hydrogen — that ’ s methane — it just floats off. Then there ’ s all sorts of intermediate ones with middle amounts of carbon. You ’ ve probably heard of benzene rings ; they ’ re very carcinogenic. And it goes all the way over to these big, thick, galumphy ones that have hundreds of carbons, and they have thousands of hydrogens, and they have vanadium and heavy **metals** and sulfur and all kinds of craziness hanging off the sides of them. Those are called the asphaltenes ; they ’ re an ingredient in asphalt. They ’ re very important in oil spills. Let me tell you a little bit about the chemistry of oil in water. It is this chemistry that makes oil so disastrous. Oil doesn ’ t sink, it floats. If it sank, it would be a whole different story as far as an oil spill. And the other thing it does is it spreads out the moment it hits the water. It spreads out to be really thin, so you have a hard time corralling it. The next thing that happens is the light ends evaporate, and some of the toxic things float into the water column and kill fish eggs and smaller fish and things like that, and shrimp. And then the asphaltenes — and this is the **crucial** thing — the asphaltenes get whipped by the waves into a frothy emulsion, something like mayonnaise. It triples the amount of oily, messy goo that you have in the water, and it makes it very hard to handle. It also makes it very viscous. When the Prestige sank off the coast of Spain, there were big, floating cushions the size of sofa cushions of emulsified oil, with the consistency, or the viscosity, of chewing gum. It ' s incredibly hard to **clean** up. And every single oil is different when it hits water. When the chemistry of the oil and water also hits our politics, it ' s absolutely explosive. For the first time, American consumers will kind of see the oil supply chain in front of themselves. They have a"eureka!"moment, when we suddenly understand oil in a different context. So I ' m going to talk just a little bit about the origin of these politics, because it ' s really **crucial** to understanding why this summer is so important, why we need to stay focused. Nobody gets up in the morning and thinks,"Wow! I ' m going to go buy some three- carbon-to-12-carbon molecules to put in my tank and drive happily to work."No, they think,"Ugh. I have to go buy **gas**. I ' m so angry about it. The oil companies are ripping me off. They set the prices, and I don ' t even know. I am helpless over this."And this is what happens to us at the **gas** pump — and actually, **gas** pumps are specifically designed to diffuse that anger. You might notice that many **gas** pumps, including this one, are designed to look like ATMs. I ' ve talked to engineers. That ' s specifically to diffuse our anger, because supposedly we feel good about ATMs. That shows you how bad it is. But actually, I mean, this feeling of helplessness comes in because most Americans actually feel that oil prices are the result of a conspiracy, not of the vicissitudes of the world oil market. And the thing is, too, is that we also feel very helpless about the amount that we consume, which is somewhat reasonable, because in fact, we have designed this system where, if you want to get a job, it ' s much more important to have a car that runs, to have a job and keep a job, than to have a GED. And that ' s actually very perverse. Now there ' s another perverse thing about the way we buy **gas**, which is that we ' d rather be doing anything else. This is BP ' s **gas** station in downtown Los Angeles. It is green. It is a shrine to greenishness."Now,"you think,"why would something so lame work on people so smart?"Well, the reason is, is because, when we ' re buying **gas**, we ' re very invested in this sort of cognitive dissonance. I mean, we ' re angry at the one hand and we want to be somewhere else. We don ' t want to be buying oil ; we want to be doing something green. And we get kind of in on our own con. I mean — and this is funny, it looks funny here. But in fact, that ' s why the slogan"beyond petroleum"worked. But it ' s an inherent part of our energy policy, which is we don ' t talk about reducing the amount of oil that we use. We talk about energy independence. We talk about hydrogen cars. We talk about biofuels that haven ' t been invented yet. And so, cognitive dissonance is part and parcel of the way that we deal with oil, and it ' s really important to dealing with this oil spill. Okay, so the politics of oil are very moral in the United States. The oil industry is like a huge, gigantic octopus of engineering and finance and everything else, but we actually see it in very moral terms. This is an early- on photograph — you can see, we had these gushers. Early journalists looked at these spills, and they said,"This is a filthy industry."But they also saw in it that people were getting rich for doing nothing. They weren ' t farmers, they were just getting rich for stuff coming out of the ground. It ' s the"Beverly Hillbillies,"basically. But in the beginning, this was seen as a very morally problematic thing, long before it became funny. And then, of course, there was John D. Rockefeller. And the thing about John D. is that he went into this chaotic wild-east of oil industry, and he rationalized it into a vertically integrated company, a multinational. It was terrifying ; you think Walmart is a terrifying business model now, imagine what this looked like in the 1860s or 1870s. And it also the kind of root of how we see oil as a conspiracy. But what ’ s really amazing is that Ida Tarbell, the journalist, went in and did a big expos of Rockefeller and actually got the whole antitrust laws put in place. But in many ways, that image of the conspiracy still sticks with us. And here ’ s one of the things that Ida Tarbell said — she said,”He has a thin nose like a thorn. There were no lips. There were puffs under the little colorless eyes with creases running from them.”Okay, so that guy is actually still with us. I mean, this is a very pervasive — this is part of our DNA. And then there ’ s this guy, okay. So, you might be wondering why it is that, every time we have high oil prices or an oil spill, we call these CEOs down to Washington, and we sort of pepper them with questions in public and we try to shame them. And this is something that we ’ ve been doing since 1974, when we first asked them,”Why are there these obscene profits?”And we ’ ve sort of personalized the whole oil industry into these CEOs. And we take it as, you know — we look at it on a moral level, rather than looking at it on a legal and financial level. And so I ’ m not saying these guys aren ’ t liable to answer questions — I ’ m just saying that, when you focus on whether they are or are not a bunch of greedy bastards, you don ’ t actually get around to the point of making laws that are either going to either change the way they operate, or you ’ re going to get around to really reducing the amount of oil and reducing our dependence on oil. So I ’ m saying this is kind of a distraction. But it makes for good theater, and it ’ s powerfully cathartic as you probably saw last week. So the thing about water oil spills is that they are very politically galvanizing. I mean, these **pictures** — this is from the Santa Barbara spill. You have these **pictures** of birds. They really influence people. When the Santa Barbara spill happened in 1969, it formed the environmental movement in its modern form. It started Earth Day. It also put in place the National Environmental Policy Act, the Clean Air Act, the Clean Water Act. Everything that we are really stemmed from this period. I think it ’ s important to kind of look at these **pictures** of the birds and understand what happens to us. Here we are normally ; we ’ re standing at the **gas** pump, and we ’ re feeling kind of helpless. We look at these **pictures** and we understand, for the first time, our role in this supply chain. We connect the dots in the supply chain. And we have this kind of — as voters, we have kind of a”eureka!”moment. This is why these moments of these oil spills are so important. But it ’ s also really important that we don ’ t get distracted by the theater or the morals of it. We actually need to go in and work on the roots of the problem. One of the things that happened with the two previous oil spills was that we really worked on some of the symptoms. We were very reactive, as opposed to being proactive about what happened. And so what we did was, actually, we made moratoriums on the east and west coasts on drilling. We stopped drilling in ANWR, but we didn ’ t actually reduce the amount of oil that we consumed. In fact, it ’ s continued to increase. The only thing that really reduces the amount of oil that we consume is much higher prices. As you can see, our own production has fallen off as our reservoirs have gotten old and expensive to drill out. We only have two percent of the world ’ s oil reserves ; 65 percent of them are in the Persian Gulf. One of the things that ’ s happened because of this is that, since 1969, the country of Nigeria, or the part of Nigeria that pumps oil, which is the delta — which is two times the size of Maryland — has had thousands of oil spills a year. I mean, we ’ ve essentially been exporting oil spills when we import oil from places without tight environmental regulations. That has been the equivalent of an Exxon Valdez spill every year since 1969. And we can wrap our heads around the spills, because that ’ s what we see here, but in fact, these guys actually live in a war zone. There ’ s a thousand battle-related deaths a year in this area twice the size of Maryland, and it ’ s all related to the oil. And these guys, I mean, if they were in the U. S., they might be actually here in this room. They have degrees in political science, degrees in business — they ’ re entrepreneurs. They don ’ t actually want to be doing what they ’ re doing. And it ’ s sort of one of the other groups of people who pay a price for us. The other thing that we ’ ve done, as we ’ ve continued to increase demand, is that we kind of play a shell game with the costs. One of the places we put in a big oil project in Chad, with Exxon. So the U. S. taxpayer paid for it ; the World Bank, Exxon paid for it. We put it in. There was a tremendous banditry problem. I was there in 2003. We were driving along this dark, dark road, and the guy in the green stepped out, and I was just like,”Ahhh! This is it.”And then the guy in the Exxon uniform stepped out, and we realized it was okay. They have their own private sort of army around them at the oil fields. But at the same time, Chad has become much more unstable, and we are not paying for that price at the pump. We pay for it in our taxes on April 15th. We do the same thing with the price of policing the Persian Gulf and keeping the shipping lanes open. This is 1988 — we actually bombed two Iranian oil platforms that year. That was the beginning of an escalating U. S. involvement there that we do not pay for at the pump. We pay for it on April 15th, and we can ’ t even calculate the cost of this involvement. The other place that is sort of supporting our dependence on oil and our increased consumption is the Gulf of Mexico, which was not part of the moratoriums. Now what ’ s happened in the Gulf of Mexico — as you can see, this is the Minerals Management diagram of wells for **gas** and oil. It ’ s become this intense industrialized zone. It doesn ’ t have the same resonance for us that the Arctic National Wildlife Refuge has, but it should, I mean, it ’ s a bird sanctuary. Also, every time you buy gasoline in the United States, half of it is actually being refined along the coast, because the Gulf actually has about 50 percent of our refining capacity and a lot of our marine terminals as well. So the people of the Gulf have essentially been subsidizing the rest of us through a less-clean environment. And finally, American families also pay a price for oil. Now on the one hand, the price at the pump is not really very high when you consider the actual cost of the oil, but on the other hand, the fact that people have no other transit options means that they pay a large amount of their income into just getting back and forth to work, generally in a fairly crummy car. If you look at people who make $50, 000 a year, they have two kids, they might have three jobs or more, and then they have to really commute. They ’ re actually spending more on their car and fuel than they are on taxes or on health care. And the same thing happens at the 50th percentile, around 80, 000. Gasoline costs are a tremendous drain on the American economy, but they ’ re also a drain on individual families and it ’ s kind of terrifying to think about what happens when prices get higher. So, what I ’ m going to talk to you about now is : what do we have to do this time? What are the laws? What do we have to do to keep ourselves focused? One thing is — we need to stay away from the theater. We need to stay away from the moratoriums. We need to focus really back again on the molecules. The moratoriums are fine, but we do need to focus on the molecules on the oil. One of the things that we also need to do, is we need to try to not kind of fool ourselves into thinking that you can have a green world, before you reduce the amount of oil that we use. We need to focus on reducing the oil. What you see in this top **drawing** is a schematic of how petroleum gets used in the U. S. economy. It comes in on the side — the useful stuff is the dark gray, and the un-useful stuff, which is called the rejected energy — the waste, goes up to the top. Now you can see that the waste far outweighs the actually useful amount. And one of the things that we need to do is, not only fix the fuel efficiency of our vehicles and make them much more efficient, but we also need to fix the economy in general. We need to remove the perverse incentives to use more fuel. For example, we have an insurance system where the person who drives 20, 000 miles a year pays the same insurance as somebody who drives 3, 000. We actually encourage people to drive more. We have policies that reward sprawl — we have all kinds of policies. We need to have more mobility choices. We need to make the **gas** price better reflect the real cost of oil. And we need to shift subsidies from the oil industry, which is at least 10 billion dollars a year, into something that allows middle-class people to find better ways to commute. Whether that ' s getting a much more efficient car and also kind of building markets for new cars and new fuels down the road, this is where we need to be. We need to kind of rationalize this whole thing, and you can find more about this policy. It ' s called STRONG, which is"Secure Transportation Reducing Oil Needs Gradually,"and the idea is instead of being helpless, we need to be more strong. They ' re up at NewAmerica. net. What ' s important about these is that we try to move from feeling helpless at the pump, to actually being active and to really sort of thinking about who we are, having kind of that special moment, where we connect the dots actually at the pump. Now supposedly, oil taxes are the third rail of American politics — the no- fly zone. I actually — I agree that a dollar a gallon on oil is probably too much, but I think that if we started this year with three cents a gallon on gasoline, and upped it to six cents next year, nine cents the following year, all the way up to 30 cents by 2020, that we could actually significantly reduce our gasoline consumption, and at the same time we would give people time to prepare, time to respond, and we would be raising money and raising consciousness at the same time. Let me give you a little sense of how this would work. This is a **gas** receipt, hypothetically, for a year from now. The first thing that you have on the tax is — you have a tax for a stronger America — 33 cents. So you ' re not helpless at the pump. And the second thing that you have is a kind of warning sign, very similar to what you would find on a cigarette pack. And what it says is,"The National Academy of Sciences estimates that every gallon of **gas** you burn in your car creates 29 cents in health care costs."That ' s a lot. And so this — you can see that you ' re paying considerably less than the health care costs on the tax. And also, the hope is that you start to be connected to the whole greater system. And at the same time, you have a number that you can call to get more information on commuting, or a low-interest loan on a different kind of car, or whatever it is you ' re going to need to actually reduce your gasoline dependence. With this whole sort of suite of policies, we could actually reduce our gasoline consumption — or our oil consumption — by 20 percent by 2020. So, three million barrels a day. But in order to do this, one of the things we really need to do, is we need to remember we are people of the hydrocarbon. We need to keep or minds on the molecules and not get distracted by the theater, not get distracted by the cognitive dissonance of the green possibilities that are out there. We need to kind of get down and do the gritty work of reducing our dependence upon this fuel and these molecules. Thank you.

I am a papercutter. I cut stories. So my process is very straightforward. I take a piece of paper, I visualize my story, sometimes I sketch, sometimes I don ' t. And as my image is already inside the paper, I just have to remove what ' s not from that story. So I didn ' t come to papercutting in a straight line. In fact, I see it more as a spiral. I was not born with a blade in my hand. And I don ' t remember papercutting as a child. As a teenager, I was sketching, drawing, and I wanted to be an artist. But I was also a rebel. And I left everything and went for a long series of odd jobs. So among them, I have been a shepherdess, a truck driver, a factory worker, a cleaning lady. I worked in tourism for one year in Mexico, one year in Egypt. I moved for two years in Taiwan. And then I settled in New York where I became a tour guide. And I still worked as a tour leader, traveled back and forth in China, Tibet and Central Asia. So of course, it took time, and I was nearly 40, and I decided it ' s time to start as an artist. I chose papercutting because paper is cheap, it ' s light, and you can use it in a lot of different ways. And I chose the language of silhouette because graphically it ' s very efficient. And it ' s also just getting to the essential of things. So the word"silhouette"comes from a minister of finance, Etienne de Silhouette. And he slashed so many budgets that people said they couldn ' t afford paintings anymore, and they needed to have their portrait"a la silhouette."So I made series of images, cuttings, and I assembled them in portfolios. And people told me — like these 36 views of the Empire State building — they told me,"You ' re making artist books."So artist books have a lot of definitions. They come in a lot of different shapes. But to me, they are **fascinating** objects to visually narrate a story. They can be with words or without words. And I have a passion for images and for words. I love pun and the relation to the unconscious. I love oddities of languages. And everywhere I lived, I learned the languages, but never mastered them. So I ' m always looking for the false cognates or identical words in different languages. So as you can guess, my mother tongue is French. And my daily language is English. So I did a series of work where it was identical words in French and in English. So one of these works is the"Spelling Spider."So the Spelling Spider is a cousin of the spelling bee. But it ' s much more connected to the Web. And this spider spins a bilingual alphabet. So you can read"architecture active"or"active architecture."So this spider goes through the whole alphabet with identical adjectives and substantives. So if you don ' t know one of these languages, it ' s instant learning. And one ancient form of the book is scrolls. So scrolls are very convenient, because you can create a large image on a very small table. So the unexpected consequences of that is that you only see one part of your image, so it makes a very freestyle architecture. And I ' m making all those kinds of windows. So it ' s to look beyond the surface. It ' s to have a look at different worlds. And very often I ' ve been an outsider. So I want to see how things work and what ' s happening. So each window is an image and is a world that I often revisit. And I revisit this world thinking about the image or clich about what we want to do, and what are the words, colloquialisms, that we have with the expressions. It ' s all if. So what if we were living in balloon houses? It would make a very uplifting world. And we would leave a very low footprint on the planet. It would be so light. So sometimes I view from the inside, like EgoCentriCity and the inner circles. Sometimes it ' s a global view, to see our common roots and how we can use them to catch dreams. And we can use them also as a safety net. And my inspirations are very eclectic. I ' m influenced by everything I read, everything I see. I have some stories that are humorous, like"Dead Beats."Other ones are historical. Here it ' s"CandyCity."It ' s a non-sugar- coated history of sugar. It goes from slave trade to over-consumption of sugar with some sweet moments in between. And sometimes I have an emotional response to news, such as the 2010 Haitian earthquake. Other times, it ' s not even my stories. People tell me their lives, their memories, their aspirations, and I create a mindscape. I channel their history [so that] they have a place to go back to look at their life and its possibilities. I call them Freudian cities. I cannot speak for all my images, so I ' ll just go through a few of my worlds just with the title."ModiCity.""ElectriCity.""MAD Growth on Columbus Circle.""ReefCity.""A Web of Time.""Chaos City.""Daily Battles.""FeliCity.""Floating Islands."And at one point, I had to do"The Whole Nine Yards."So it ' s actually a papercut that ' s nine yards long. So in life and in papercutting, everything is connected. One story leads to another. I was also interested in the physicality of this format, because you have to walk to see it. And parallel to my cutting is my running. I started with small images, I started with a few miles. Larger images, I started to run marathons. Then I went to run 50K, then 60K. Then I ran 50 miles — ultramarathons. And I still feel I ' m running, it ' s just the training to become a long-distance papercutter. And running gives me a lot of energy. Here is a three-week papercutting marathon at the Museum of Arts and Design in New York City. The result is"Hells and Heavens."It ' s two **panels** 13 ft. high. They were installed in the **museum** on two floors, but in fact, it ' s a continuous image. And I call it"Hells and Heavens"because it ' s daily **hells** and daily heavens. There is no border in between. Some people are born in **hells**, and against all odds, they make it to heavens. Other people make the opposite trip. That ' s the border. You have sweatshops in **hells**. You have people renting their wings in the heavens. And then you have all those individual stories where sometimes we even have the same action, and the result puts you in **hells** or in heavens. So the whole"Hells and Heavens"is about free will and determinism. And in papercutting, you have the **drawing** as the structure itself. So you can take it off the wall. Here it ' s an artist book installation called"Identity Project."It ' s not autobiographical identities. They are more our social identities. And then you can just walk behind them and try them on. So it ' s like the different layers of what we are made of and what we present to the world as an identity. That ' s another artist book project. In fact, in the **picture**, you have two of them. It ' s one I ' m wearing and one that ' s on exhibition at the Center for Books Arts in New York City. Why do I call it a book? It ' s called"Fashion Statement,"and there are quotes about fashion, so you can read it, and also, because the definition of artist book is very generous. So artist books, you take them off the wall. You take them for a walk. You can also install them as public art. Here it ' s in Scottsdale, Arizona, and it ' s called"Floating Memories."So it ' s regional memories, and they are just randomly moved by the wind. I love public art. And I entered competitions for a long time. After eight years of rejection, I was thrilled to get my first commission with the Percent for Art in New York City. It was for a merger station for emergency workers and firemen. I made an artist book that ' s in stainless steel instead of paper. I called it"Working in the Same Direction."But I added weathervanes on both sides to show that they cover all directions. With public art, I could also make cut glass. Here it ' s faceted glass in the Bronx. And each time I make public art, I want something that ' s really relevant to the place it ' s installed. So for the subway in New York, I saw a correspondence between riding the subway and reading. It is travel in time, travel on time. And Bronx literature, it ' s all about Bronx writers and their stories. Another glass project is in a public library in San Jose, California. So I made a vegetable point of view of the growth of San Jose. So I started in the center with the acorn for the Ohlone Indian civilization. Then I have the fruit from Europe for the ranchers. And then the fruit of the world for Silicon Valley today. And it ' s still growing. So the technique, it ' s cut, sandblasted, etched and printed glass into architectural glass. And outside the library, I wanted to make a place to cultivate your mind. I took library material that had fruit in their title and I used them to make an orchard walk with these fruits of knowledge. I also planted the bibliotree. So it ' s a tree, and in its trunk you have the roots of languages. And it ' s all about international writing systems. And on the branches you have library material growing. You can also have function and form with public art. So in Aurora, Colorado it ' s a bench. But you have a bonus with this bench. Because if you sit a long time in summer in shorts, you will walk away with temporary branding of the story element on your thighs.

Another functional work, it ’ s in the south side of Chicago for a subway station. And it ’ s called”Seeds of the Future are Planted Today.”It ’ s a story about transformation and connections. So it acts as a screen to protect the rail and the commuter, and not to have objects falling on the rails. To be able to change fences and window guards into flowers, it ’ s fantastic. And here I ’ ve been working for the last three years with a South Bronx developer to bring art to life to low-income buildings and affordable housing. So each building has its own personality. And sometimes it ’ s about a legacy of the neighborhood, like in Morrisania, about the jazz history. And for other projects, like in Paris, it ’ s about the name of the street. It ’ s called Rue **des** Prairies — Prairie Street. So I brought back the rabbit, the dragonfly, to stay in that street. And in 2009, I was asked to make a poster to be placed in the subway cars in New York City for a year. So that was a very captive audience. And I wanted to give them an escape. I created”All Around Town.”It is a papercutting, and then after, I added color on the computer. So I can call it techno-crafted. And along the way, I ’ m kind of making papercuttings and adding other techniques. But the result is always to have stories. So the stories, they have a lot of possibilities. They have a lot of scenarios. I don ’ t know the stories. I take images from our global imagination, from clich, from things we are thinking about, from history. And everybody ’ s a narrator, because everybody has a story to tell. But more important is everybody has to make a story to make sense of the world. And in all these universes, it ’ s like imagination is the vehicle to be transported with, but the destination is our minds and how we can reconnect with the essential and with the magic. And it ’ s what story cutting is all about.

I ’ m a contemporary artist with a bit of an unexpected background. I was in my 20s before I ever went to an art **museum**. I grew up in the middle of nowhere on a dirt road in rural Arkansas, an hour from the nearest movie theater. And I think it was a great place to grow up as an artist because I grew up around quirky, colorful characters who were great at making with their hands. And my childhood is more hick than I could ever possibly relate to you, and also more intellectual than you would ever expect. For instance, me and my sister, when we were little, we would compete to see who could eat the most squirrel brains. But on the other side of that, though, we were big readers in our house. And if the TV was on, we were watching a documentary. And my dad is the most voracious reader I know. He can read a novel or two a day. But when I was little, I remember, he would kill flies in our house with my BB gun. And what was so amazing to me about that — well he would be in his recliner, would holler for me to fetch the BB gun, and I ’ d go get it. And what was amazing to me — well it was pretty kickass ; he was killing a fly in the house with a gun — but what was so amazing to me was that he knew just enough how to pump it. And he could shoot it from two rooms away and not damage what it was on because he knew how to pump it just enough to kill the fly and not damage what it landed on. So I should talk about art. Or we ’ ll be here all day with my childhood stories. I love contemporary art, but I ’ m often really frustrated with the contemporary art world and the contemporary art scene. A few years ago, I spent months in Europe to see the major international art exhibitions that have the pulse of what is supposed to be going on in the art world. And I was struck by going to so many, one after the other, with some clarity of what it was that I was longing for. And I was longing for several things that I wasn ’ t getting, or not getting enough of. But two of the main things :

one of it, I was longing for more work that was appealing to a broad public, that was accessible. And the second thing that I was longing for was some more exquisite craftsmanship and technique. So I started thinking and listing what all it was that I thought would make a perfect biennial. So I decided, I ' m going to start my own biennial. I ' m going to organize it and direct it and get it going in the world. So I thought, okay, I have to have some criteria of how to choose work. So amongst all the criteria I have, there ' s two main things. One of them, I call my Mimaw ' s Test. And what that is is I imagine explaining a work of art to my grandmother in five minutes, and if I can ' t explain it in five minutes, then it ' s too obtuse or esoteric and it hasn ' t been refined enough yet. It needs to worked on until it can speak fluently. And then my other second set of rules — I hate to say"rules"because it ' s art — my criteria would be the three H ' s, which is head, heart and hands. And great art would have"head": it would have interesting intellectual ideas and concepts. It would have"heart"in that it would have passion and heart and soul. And it would have"hand"in that it would be greatly crafted. So I started thinking about how am I going to do this biennial, how am I going to travel the world and find these artists? And then I realized one day, there ' s an easier solution to this. I ' m just going to make the whole thing myself. And so this is what I did. So I thought, a biennial needs artists. I ' m going to do an international biennial ; I need artists from all around the world. So what I did was I invented a hundred artists from around the world. I figured out their bios, their passions in life and their art styles, and I started making their work. I felt, oh this is the kind of project that I could spend my whole life doing. So I decided, I ' m going to make this a real biennial. It ' s going to be two years of studio work. And I ' m going to create this in two years, and I have. So I should start to talk about these guys. Well the range is quite a bit. And I ' m such a technician, so I loved this project, getting to play with all the techniques. So for example, in realist paintings, it ranges from this, which is kind of old masters style, to really realistic still-life, to this type of painting where I ' m painting with a single hair. And then at the other end, there ' s performance and short **films** and indoor installations like this indoor installation and this one, and outdoor installations like this one and this one. I know I should mention : I ' m making all these things. This isn ' t Photoshopped. I ' m under the river with those fish. So now let me introduce some of my fictional artists to you. This is Nell Remmel. Nell is interested in agricultural processes, and her work is based in these practices. This piece, which is called"Flipped Earth"— she was interested in taking the sky and using it to cleanse barren ground. And by taking giant mirrors — and here she ' s taking giant mirrors and pulling them into the dirt. And this is 22 **feet** long. And what I loved about her work is, when I would walk around it and look down into the sky, looking down to watch the sky, and it unfolded in a new way. And probably the best part of this piece is at dusk and dawn when the twilight wedge has fallen and the ground ' s dark, but there ' s still the light above, bright above. And so you ' re standing there and everything else is dark, but there ' s this portal that you want to jump in. This piece was great. This is in my parents ' backyard in Arkansas. And I love to dig a hole. So this piece was great **fun** because it was two days of digging in soft dirt. The next artist is Kay Overstry, and she ' s interested in ephemerality and transience. And in her most recent project, it ' s called"Weather I Made."And she ' s making weather on her body ' s scale. And this piece is"Frost."And what she did was she went out on a cold, dry night and breathed back and forth on the lawn to leave — to leave her life ' s mark, the mark of her life. And so this is five-foot, five-inches of frost that she left behind. The sun rises, and it melts away. And that was played by my mom. So the next artist, this is a group of Japanese artists, a collective of Japanese artists — in Tokyo. And they were interested in developing a new, alternative art space, and they needed funding for it, so they decided to come up with some interesting fundraising projects. One of these is scratch-off masterpieces. And so what they ' re doing — each of these artists on a nine-by-seven-inch card, which they sell for 10 bucks, they drew original works of art. And you buy one, and maybe you get a real piece, and maybe not. Well this has sparked a craze in Japan, because everyone ' s wanting a masterpiece. And the ones that are the most sought after are the ones that are only barely scratched off. And all these works, in some way, talk about luck or fate or chance. Those first two are portraits of mega- jackpot winners years before and after their win. And in this one it ' s called"Drawing the Short Stick."I love this piece because I have a little cousin at home who introduced me — which I think is such a great introduction — to a friend one day as,"This is my cousin Shea. He draws sticks real good."Which is one of the best compliments ever. This artist is Gus Weinmueller, and he ' s doing a project, a large project, called"Art for the Peoples."And within this project, he ' s doing a smaller project called"Artists in Residence."And what he does is — he spends a week at a time with a family. And he shows up on their porch, their doorstep, with a toothbrush and pajamas, and he ' s ready to spend the week with them. And using only what ' s present, he goes in and makes a little abode studio to work out of. And he spends that week talking to the family about what do they think great art is. He has all these discussions with their family, and he digs through everything they have, and he finds materials to make work. And he makes a work that answers what they think great art is. For this family, he made this still-life painting. And whatever he makes somehow references nesting and space and personal property. This next project, this is by Jaochim Parisvega, and he ' s interested in — he believes art is everywhere waiting — that it just needs a little bit of a push to happen. And he provides this push by harnessing natural forces, like in his series where he used rain to make paintings. This project is called"Love Nests."What he did was to get wild birds to make his art for him. So he put the material in places where the birds were going to collect them, and they crafted his nests for him. And this one ' s called"Lovelock ' s Nest."This one ' s called"Mixtape Love Song ' s Nest."And this one ' s called"Lovemaking Nest."Next is Sylvia Slater. Sylvia ' s interested in art training. She ' s a very serious Swiss artist. And she was thinking about her friends and family who work in chaos-ridden places and developing countries, and she was thinking, what can I make that would be of value to them, in case something bad happens and they have to buy their way across the border or pay off a gunman? And so she came up with creating these pocket-sized artworks that are portraits of the person that would carry them. And you would carry this around with you, and if everything went to **hell**, you could make payments and buy your life. So this life price is for an irrigation non-profit director. So hopefully what happens is you never use it, and it ' s an heirloom that you pass down. And she makes them so they could either be broken up into payments, or they could be like these, which are leaves that can be payments. And so they ' re valuable. This is precious **metals** and gemstones. And this one had to get broken up. He had to break off a piece to get out of Egypt recently. This is by a duo, Michael Abernathy and Bud Holland. And they ' re interested in creating culture, just tradition. So what they do is they move into an area and try to establish a new tradition in a small geographic area. So this is in Eastern Tennessee, and what they decided was that we need a positive tradition that goes with death. So they came up with"dig jigs."And a dig jig — a dig jig is where, for a milestone anniversary or a birthday, you gather all your friends and family together and you dance on where you ' re going to be buried. And we got a lot of attention when we did it. I talked my family into doing this, and they didn ’ t know what I was doing. And I was like,”Get dressed for a funeral. We ’ re going to go do some work.”And so we got to the grave and made this, which was hilarious — the attention that we got. So what happens is you dance on the grave, and after you ’ ve done your dance, everyone toasts you and tells you how great you are. And you in essence have a funeral that you get to be present for. That ’ s my mom and dad. This is by Jason Birdsong. He is interested in how we see as an animal, how we are interested in mimicry and camouflage. You know, we look down a dark alley or a jungle path, trying to make out a face or a creature. We just have that natural way of seeing. And he plays with this idea. And this piece : those aren ’ t actually leaves. They ’ re butterfly specimens who have a natural camouflage. So he pairs these up. There ’ s another pile of leaves. Those are actually all real butterfly specimens. And he pairs these up with paintings. Like this is a painting of a snake in a box. So you open the box and you think,”Whoa, there ’ s a snake in there.”But it ’ s actually a painting. So he makes these interesting conversations about realism and mimicry and our drive to be fooled by great camouflage. The next artist is Hazel Clausen. Hazel Clausen is an anthropologist who took a sabbatical and decided,”You know, I would learn a lot about culture if I created a culture that doesn ’ t exist from scratch.”So that ’ s what she did. She created the Swiss people named the Uvulites, and they have this distinctive yodeling song that they use the uvula for. And also they reference how the uvula — everything they say is fallen because of the forbidden fruit. And that ’ s the symbol of their culture. And this is from a documentary called”Sexual Practices and Populations Control Among the Uvulites.”This is a typical angora embroidery for them. This is one of their founders, Gert Schaeffer. And actually this is my Aunt Irene. It was so funny having a fake person who was making fake things. And I crack up at this piece, because when I see it I know that ’ s French angora and all antique German ribbons and wool that I got in a Nebraska mill and carried around for 10 years and then antique Chinese skirts. The next is a collective of artists called the Silver Dobermans, and their motto is to spread pragmatism one person at a time. And they ’ re really interested in how over-coddled we ’ ve become. So this is one of their comments on how over-coddled we ’ ve become. And what they ’ ve done is they put a warning sign on every single barb on this fence. And this is called”Horse Sense Fence.”The next artist is K. M. Yoon, a really interesting South Korean artist. And he ’ s reworking a Confucian art tradition of scholar stones. Next is Maynard Sipes. And I love Maynard Sipes, but he ’ s off in his own world, and, bless his heart, he ’ s so paranoid. Next is Roy Penig, a really interesting Kentucky artist, and he ’ s the nicest guy. He even once traded a work of art for a block of government cheese because the person wanted it so badly. Next is an Australian artist, Janeen Jackson, and this is from a project of hers called”What an Artwork Does When We ’ re Not Watching.”Next is by a Lithuanian fortune teller, Jurgi Petrauskas. Next is Ginger Cheshire. This is from a short **film** of hers called”The Last Person.”And that ’ s my cousin and my sister ’ s dog, Gabby. The next, this is by Sam Sandy. He ’ s an Australian Aboriginal elder, and he ’ s also an artist. And this is from a large traveling sculpture project that he ’ s doing. This is from Estelle Willoughsby. She heals with color. And she ’ s one of the most prolific of all these hundred artists, even though she ’ s going to be 90 next year. This is by Z. Zhou, and he ’ s interested in stasis. Next is by Hilda Singh, and she ’ s doing a whole project called”Social Outfits.”Next is by Vera Sokolova. And I have to say, Vera kind of scares me. You can ’ t look her directly in the eyes because she ’ s kind of scary. And it ’ s good that she ’ s not real ; she ’ d be mad that I said that. And she ’ s an optometrist in St. Petersburg, and she plays with optics. Next, this is by Thomas Swifton. This is from a short **film**,"Adventures with Skinny."And this is by Cicily Bennett, and it ' s from a series of short **films**. And after this one, there ' s 77 other artists. And all together with those other 77 you ' re not seeing, that ' s my biennial. Thank you. Thank you. Thanks. Thank you. Thanks.

Text Sample 697: POS Dim 5 – 2011 – Score 7.00 – 2011/t002591.txt

I ' d like to begin with a thought experiment. Imagine that it ' s 4, 000 years into the future. Civilization as we know it has ceased to exist â no books, no electronic devices, no Facebook or Twitter. All knowledge of the English language and the English alphabet has been lost. Now imagine archeologists digging through the rubble of one of our cities. What might they find? Well perhaps some rectangular pieces of plastic with strange symbols on them. Perhaps some circular pieces of **metal**. Maybe some cylindrical containers with some symbols on them. And perhaps one archeologist becomes an instant celebrity when she discovers â buried in the hills somewhere in North America â massive versions of these same symbols. Now let ' s ask ourselves, what could such artifacts say about us to people 4, 000 years into the future? This is no hypothetical question. In fact, this is exactly the kind of question we ' re faced with when we try to understand the Indus Valley civilization, which existed 4, 000 years ago. The Indus civilization was roughly contemporaneous with the much better known Egyptian and the Mesopotamian civilizations, but it was actually much larger than either of these two civilizations. It occupied the area of approximately one million square kilometers, covering what is now Pakistan, Northwestern India and parts of Afghanistan and Iran. Given that it was such a vast civilization, you might expect to find really powerful rulers, kings, and huge monuments glorifying these powerful kings. In fact, what archeologists have found is none of that. They ' ve found small objects such as these. Here ' s an example of one of these objects. Well obviously this is a replica. But who is this person? A king? A god? A priest? Or perhaps an ordinary person like you or me? We don ' t know. But the Indus people also left behind artifacts with writing on them. Well no, not pieces of plastic, but stone seals, copper tablets, pottery and, surprisingly, one large sign board, which was found buried near the gate of a city. Now we don ' t know if it says Hollywood, or even Bollywood for that matter. In fact, we don ' t even know what any of these objects say, and that ' s because the Indus script is undeciphered. We don ' t know what any of these symbols mean. The symbols are most commonly found on seals. So you see up there one such object. It ' s the square object with the unicorn-like animal on it. Now that ' s a magnificent piece of art. So how big do you think that is? Perhaps that big? Or maybe that big? Well let me show you. Here ' s a replica of one such seal. It ' s only about one inch by one inch in size â pretty tiny. So what were these used for? We know that these were used for stamping clay tags that were attached to bundles of goods that were sent from one place to the other. So you know those packing slips you get on your FedEx boxes? These were used to make those kinds of packing slips. You might wonder what these objects contain in terms of their text. Perhaps they ' re the name of the sender or some information about the goods that are being sent from one place to the other â we don ' t know. We need to decipher the script to answer that question. Deciphering the script is not just an intellectual puzzle ; it ' s actually become a question that ' s become deeply intertwined with the politics and the cultural history of South Asia. In fact, the script has become a battleground of sorts between three different groups of people. First, there ' s a group of people who are very passionate in their belief that the Indus script does not represent a language at all. These people believe that the symbols are very similar to the kind of symbols you find on traffic signs or the emblems you find on shields. There ’ s a second group of people who believe that the Indus script represents an Indo-European language. If you look at a map of India today, you ’ ll see that most of the languages spoken in North India belong to the Indo-European language family. So some people believe that the Indus script represents an ancient Indo-European language such as Sanskrit. There ’ s a last group of people who believe that the Indus people were the ancestors of people living in South India today. These people believe that the Indus script represents an ancient form of the Dravidian language family, which is the language family spoken in much of South India today. And the proponents of this theory point to that small pocket of Dravidian-speaking people in the North, actually near Afghanistan, and they say that perhaps, sometime in the past, Dravidian languages were spoken all over India and that this suggests that the Indus civilization is perhaps also Dravidian. Which of these hypotheses can be true? We don ’ t know, but perhaps if you deciphered the script, you would be able to answer this question. But deciphering the script is a very challenging task. First, there ’ s no Rosetta Stone. I don ’ t mean the software ; I mean an ancient artifact that contains in the same text both a known text and an unknown text. We don ’ t have such an artifact for the Indus script. And furthermore, we don ’ t even know what language they spoke. And to make matters even worse, most of the text that we have are extremely short. So as I showed you, they ’ re usually found on these seals that are very, very tiny. And so given these formidable obstacles, one might wonder and worry whether one will ever be able to decipher the Indus script. In the rest of my talk, I ’ d like to tell you about how I learned to stop worrying and love the challenge posed by the Indus script. I ’ ve always been **fascinated** by the Indus script ever since I read about it in a middle school textbook. And why was I **fascinated**? Well it ’ s the last major undeciphered script in the ancient world. My career path led me to become a computational neuroscientist, so in my day job, I create computer models of the brain to try to understand how the brain makes predictions, how the brain makes decisions, how the brain learns and so on. But in 2007, my path crossed again with the Indus script. That ’ s when I was in India, and I had the wonderful opportunity to meet with some Indian scientists who were using computer models to try to analyze the script. And so it was then that I realized there was an opportunity for me to collaborate with these scientists, and so I jumped at that opportunity. And I ’ d like to describe some of the results that we have found. Or better yet, let ’ s all collectively decipher. Are you ready? The first thing that you need to do when you have an undeciphered script is try to figure out the direction of writing. Here are two texts that contain some symbols on them. Can you tell me if the direction of writing is right to left or left to right? I ’ ll give you a couple of seconds. Okay. Right to left, how many? Okay. Okay. Left to right? Oh, it ’ s almost 50 / 50. Okay. The answer is : if you look at the **left-hand** side of the two texts, you ’ ll notice that there ’ s a cramping of signs, and it seems like 4, 000 years ago, when the scribe was writing from right to left, they ran out of space. And so they had to cram the sign. One of the signs is also below the text on the top. This suggests the direction of writing was probably from right to left, and so that ’ s one of the first things we know, that directionality is a very key aspect of linguistic scripts. And the Indus script now has this particular property. What other properties of language does the script show? Languages contain patterns. If I give you the letter Q and ask you to predict the next letter, what do you think that would be? Most of you said U, which is right. Now if I asked you to predict one more letter, what do you think that would be? Now there ’ s several thoughts. There ’ s E. It could be I. It could be A, but certainly not B, C or D, right? The Indus script also exhibits similar kinds of patterns. There ’ s a lot of text that start with this diamond-shaped symbol. And this in turn tends to be followed by this quotation marks-like symbol. And this is very similar to a Q and U example. This symbol can in turn be followed by these fish-like symbols and some other signs, but never by these other signs at the **bottom**. And furthermore, there ’ s some signs that really prefer the end of texts, such as this jar-shaped sign, and this sign, in fact, happens to be the most frequently occurring sign in the script. Given such patterns, here was our idea. The idea was to use a computer to learn these patterns, and so we gave the computer the existing texts. And the computer learned a statistical model of which symbols tend to occur together and which symbols tend to follow each other. Given the computer model, we can test the model by essentially quizzing it. So we could deliberately erase some symbols, and we can ask it to predict the missing symbols. Here are some examples. You may regard this as perhaps the most ancient game of Wheel of Fortune. What we found was that the computer was successful in 75 percent of the cases in predicting the correct symbol. In the rest of the cases, typically the second best guess or third best guess was the right answer. There ’ s also practical use for this particular procedure. There ’ s a lot of these texts that are damaged. Here ’ s an example of one such text. And we can use the computer model now to try to complete this text and make a best guess prediction. Here ’ s an example of a symbol that was predicted. And this could be really useful as we try to decipher the script by generating more data that we can analyze. Now here ’ s one other thing you can do with the computer model. So imagine a monkey sitting at a keyboard. I think you might get a random jumble of letters that looks like this. Such a random jumble of letters is said to have a very high entropy. This is a physics and information theory term. But just imagine it ’ s a really random jumble of letters. How many of you have ever spilled coffee on a keyboard? You might have encountered the stuck-key problem â so basically the same symbol being repeated over and over again. This kind of a sequence is said to have a very low entropy because there ’ s no variation at all. Language, on the other hand, has an intermediate level of entropy ; it ’ s neither too rigid, nor is it too random. What about the Indus script? Here ’ s a graph that plots the entropies of a whole bunch of sequences. At the very top you find the uniformly random sequence, which is a random jumble of letters â and interestingly, we also find the DNA sequence from the human genome and instrumental music. And both of these are very, very flexible, which is why you find them in the very high range. At the lower end of the scale, you find a rigid sequence, a sequence of all A ’ s, and you also find a computer program, in this case in the language Fortran, which obeys really strict rules. Linguistic scripts occupy the middle range. Now what about the Indus script? We found that the Indus script actually falls within the range of the linguistic scripts. When this result was first published, it was highly controversial. There were people who raised a hue and cry, and these people were the ones who believed that the Indus script does not represent language. I even started to get some hate mail. My students said that I should really seriously consider getting some protection. Who ’ d have thought that deciphering could be a dangerous profession? What does this result really show? It shows that the Indus script shares an important property of language. So, as the old saying goes, if it looks like a linguistic script and it acts like a linguistic script, then perhaps we may have a linguistic script on our hands. What other evidence is there that the script could actually encode language? Well linguistic scripts can actually encode multiple languages. So for example, here ’ s the same sentence written in English and the same sentence written in Dutch using the same letters of the alphabet. If you don ’ t know Dutch and you only know English and I give you some words in Dutch, you ’ ll tell me that these words contain some very unusual patterns. Some things are not right, and you ’ ll say these words are probably not English words. The same thing happens in the case of the Indus script. The computer found several texts â two of them are shown here â that have very unusual patterns. So for example the first text : there ’ s a doubling of this jar-shaped sign. This sign is the most frequently-occurring sign in the Indus script, and it ’ s only in this text that it occurs as a doubling pair. Why is that the case? We went back and looked at where these particular texts were found, and it turns out that they were found very, very far away from the Indus Valley. They were found in present day Iraq and Iran. And why were they found there? What I haven ’ t told you is that the Indus people were very, very enterprising. They used to trade with people pretty far away from where they lived, and so in this case, they were traveling by sea all the way to Mesopotamia, present-day Iraq. And what seems to have happened here is that the Indus traders, the merchants, were using this script to write a foreign language. It ’ s just like our English and Dutch example. And that would explain why we have these strange patterns that are very different from the kinds of patterns you see in the text that are found within the Indus Valley. This suggests that the same script, the Indus script, could be used to write different languages. The results we have so far seem to point to the conclusion that the Indus script probably does represent language. If it does represent language, then how do we read the symbols? That ’ s our next big challenge. So you ’ ll notice that many of the symbols look like **pictures** of humans, of insects, of fishes, of birds. Most ancient scripts use the rebus principle, which is, using **pictures** to represent words. So as an example, here ’ s a word. Can you write it using **pictures**? I ’ ll give you a couple seconds. Got it? Okay. Great. Here ’ s my solution. You could use the **picture** of a bee followed by a **picture** of a leaf â and that ’ s”belief,”right. There could be other solutions. In the case of the Indus script, the problem is the reverse. You have to figure out the sounds of each of these **pictures** such that the entire sequence makes sense. So this is just like a crossword puzzle, except that this is the mother of all crossword puzzles because the stakes are so high if you solve it. My colleagues, Iravatham Mahadevan and Asko Parpola, have been making some headway on this particular problem. And I ’ d like to give you a quick example of Parpola ’ s work. Here ’ s a really short text. It contains seven vertical strokes followed by this fish-like sign. And I want to mention that these seals were used for stamping clay tags that were attached to bundles of goods, so it ’ s quite likely that these tags, at least some of them, contain names of merchants. And it turns out that in India there ’ s a long tradition of names being based on horoscopes and star constellations present at the time of birth. In Dravidian languages, the word for fish is”meen”which happens to sound just like the word for star. And so seven stars would stand for”elu meen,”which is the Dravidian word for the Big Dipper star constellation. Similarly, there ’ s another sequence of six stars, and that translates to”aru meen,”which is the old Dravidian name for the star constellation Pleiades. And finally, there ’ s other combinations, such as this fish sign with something that looks like a **roof** on top of it. And that could be translated into”mey meen,”which is the old Dravidian name for the planet Saturn. So that was pretty exciting. It looks like we ’ re getting somewhere. But does this prove that these seals contain Dravidian names based on planets and star constellations? Well not yet. So we have no way of validating these particular readings, but if more and more of these readings start making sense, and if longer and longer sequences appear to be correct, then we know that we are on the right track. Today, we can write a word such as TED in Egyptian hieroglyphics and in cuneiform script, because both of these were deciphered in the 19th century. The decipherment of these two scripts enabled these civilizations to speak to us again directly. The Mayans started speaking to us in the 20th century, but the Indus civilization remains silent. Why should we care? The Indus civilization does not belong to just the South Indians or the North Indians or the Pakistanis ; it belongs to all of us. These are our ancestors â yours and mine. They were silenced by an unfortunate accident of history. If we decipher the script, we would enable them to speak to us again. What would they tell us? What would we find out about them? About us? I can ’ t wait to find out. Thank you.

The public debate about architecture quite often just stays on contemplating the final result, the architectural object. Is the latest tower in London a gherkin or a sausage or a sex tool? So recently, we asked ourselves if we could invent a format that could actually tell the stories behind the projects, maybe combining images and **drawings** and words to actually sort of tell stories about architecture. And we discovered that we didn ’ t have to invent it, it already existed in the form of a comic book. So we basically copied the format of the comic book to actually tell the stories of behind the scenes, how our projects actually evolve through adaptation and improvisation. Sort of through the turmoil and the opportunities and the incidents of the real world. We call this comic book”Yes is More,”which is obviously a sort of evolution of the ideas of some of our heroes. In this case it ’ s Mies van der Rohe ’ s Less is More. He triggered the modernist revolution. After him followed the post-modern counter-revolution, Robert Venturi saying,”Less is a bore.”After him, Philip Johnson sort of introduced you could say promiscuity, or at least openness to new ideas with,”I am a whore.”Recently, Obama has introduced optimism at a sort of time of global financial crisis. And what we ’ d like to say with”Yes is More”is basically trying to question this idea that the architectural avant-garde is almost always negatively defined, as who or what we are against. The cliche of the radical **architect** is the sort of angry young man rebelling against the establishment. Or this idea of the misunderstood genius, frustrated that the world doesn ’ t fit in with his or her ideas. Rather than revolution, we ’ re much more interested in evolution, this idea that things gradually evolve by adapting and improvising to the changes of the world. In fact, I actually think that Darwin is one of the people who best explains our design process. His famous evolutionary tree could almost be a diagram of the way we work. As you can see, a project evolves through a series of generations of design meetings. At each meeting, there ’ s way too many ideas. Only the best ones can survive. And through a process of architectural selection, we might choose a really beautiful model or we might have a very functional model. We mate them. They have sort of mutant offspring. And through these sort of generations of design meetings we arrive at a design. A very literal way of showing it is a project we did for a library and a hotel in Copenhagen. The design process was really tough, almost like a struggle for survival, but gradually an idea evolved : this sort of idea of a rational tower that melts together with the surrounding city, sort of expanding the public space onto what we refer to as a Scandinavian version of the Spanish Steps in Rome, but sort of public on the outside, as well as on the inside, with the library. But Darwin doesn ’ t only explain the evolution of a single idea. As you can see, sometimes a subspecies branches off. And quite often we sit in a design meeting and we discover that there is this great idea. It doesn ’ t really work in this context. But for another client in another culture, it could really be the right answer to a different question. So as a result, we never throw anything out. We keep our office almost like an archive of architectural biodiversity. You never know when you might need it. And what I ’ d like to do now, in an act of warp-speed storytelling, is tell the story of how two projects evolved by adapting and improvising to the happenstance of the world. The first story starts last year when we went to Shanghai to do the competition for the Danish National Pavilion for the World Expo in 2010. And we saw this guy, Haibao. He ’ s the mascot of the expo, and he looks strangely familiar. In fact he looked like a building we had designed for a hotel in the north of Sweden. When we submitted it for the Swedish competition we thought it was a really cool scheme, but it didn ’ t exactly look like something from the north of Sweden. The Swedish jury didn ’ t think so either. So we lost. But then we had a meeting with a Chinese businessman who saw our design and said,”Wow, that ’ s the Chinese character for the word ’ people. ’”So, apparently this is how you write”people,”as in the People ’ s Republic of China. We even double checked. And at the same time, we got invited to exhibit at the Shanghai Creative Industry Week. So we thought like, this is too much of an opportunity, so we hired a feng shui master. We scaled the building up three times to Chinese proportions, and went to China. So the People ’ s Building, as we called it. This is our two interpreters, sort of reading the architecture. It went on the cover of the Wen Wei Po newspaper, which got Mr. Liangyu Chen, the mayor of Shanghai, to visit the exhibition. And we had the chance to explain the project. And he said,”Shanghai is the city in the world with most skyscrapers,”but to him it was as if the connection to the roots had been cut over. And with the People ’ s Building, he saw an architecture that could bridge the gap between the ancient wisdom of China and the progressive future of China. So we obviously profoundly agreed with him. Unfortunately, Mr. Chen is now in prison for corruption. But like I said, Haibao looked very familiar, because he is actually the Chinese character for”people.”And they chose this mascot because the theme of the expo is”Better City, Better Life.”Sustainability. And we thought, sustainability has grown into being this sort of neo-Protestant idea that it has to hurt in order to do good. You know, you ’ re not supposed to take long, warm showers. You ’ re not supposed to fly on holidays because it ’ s bad for the environment. Gradually, you get this idea that sustainable life is less **fun** than normal life. So we thought that maybe it could be interesting to focus on examples where a sustainable city actually increases the quality of life. We also asked ourselves, what could Denmark possibly show China that would be relevant? You know, it ’ s one of the biggest countries in the world, one of the smallest. China symbolized by the dragon. Denmark, we have a national bird, the swan. China has many great poets, but we discovered that in the People ’ s Republic public school curriculum, they have three fairy tales by An Tu Sheng, or Hans Christian Anderson, as we call him. So that means that all 1. 3 billion Chinese have grown up with”The Emperor ’ s New Clothes,””The Matchstick Girl”and”The Little Mermaid.”It ’ s almost like a fragment of Danish culture integrated into Chinese culture. The biggest tourist attraction in China is the Great Wall. The Great Wall is the only thing that can be seen from the moon. The big tourist attraction in Denmark is The Little Mermaid. That can actually hardly be seen from the canal tours. And it sort of shows the difference between these two cities. Copenhagen, Shanghai, modern, European. But then we looked at recent urban development, and we noticed that this is like a Shanghai street, 30 years ago. All bikes, no cars. This is how it looks today ; all traffic jam. Bicycles have become forbidden many places. Meanwhile, in Copenhagen we ’ re actually expanding the bicycle lanes. A third of all the people commute by bike. We have a free system of bicycles called the City Bike that you can borrow if you visit the city. So we thought, why don ’ t we reintroduce the bicycle in China? We donate 1, 000 bikes to Shanghai. So if you come to the expo, go straight to the Danish pavilion, get a Danish bike, and then continue on that to visit the other pavilions. Like I said, Shanghai and Copenhagen are both port cities, but in Copenhagen the water has gotten so **clean** that you can actually swim in it. One of the first projects we ever did was the harbor bath in Copenhagen, sort of continuing the public realm into the water. So we thought that these expos quite often have a lot of state financed propaganda, images, statements, but no real experience. So just like with a bike, we don ’ t talk about it. You can try it. Like with the water, instead of talking about it, we ’ re going to sail a million liters of harbor water from Copenhagen to Shanghai, so the Chinese who have the courage can actually dive in and feel how **clean** it is. This is where people normally object that it doesn ’ t sound very sustainable to sail water from Copenhagen to China. But in fact, the container ships go full of goods from China to Denmark, and then they sail empty back. So quite often you load water for ballast. So we can actually hitch a ride for free. And in the middle of this sort of harbor bath, we ’ re actually going to put the actual Little Mermaid. So the real Mermaid, the real water, and the real bikes. And when she ’ s gone, we ’ re going to invite a Chinese artist to reinterpret her. The architecture of the pavilion is this sort of loop of exhibition and bikes. When you go to the exhibition, you ’ ll see the Mermaid and the pool. You ’ ll walk around, start looking for a bicycle on the **roof**, jump on your ride and then continue out into the rest of the expo. So when we actually won the competition we had to do an exhibition in China explaining the project. And to our surprise we got one of our boards back with corrections from the Chinese state censorship. The first thing, the China map missed Taiwan. It ’ s a very serious political issue in China. We will add on. The second thing, we had compared the swan to the dragon, and then the Chinese state said,”Suggest change to panda.”So, when it came out in Denmark that we were actually going to move our national monument, the National People ’ s Party sort of rebelled against it. They tried to pass a law against moving the Mermaid. So for the first time, I got invited to speak at the National Parliament. It was kind of interesting because in the morning, from 9 to 11, they were discussing the bailout package — how many billions to invest in saving the Danish economy. And then at 11 o ’ clock they stopped talking about these little issues. And then from 11 to 1, they were debating whether or not to send the Mermaid to China. But to conclude, if you want to see the Mermaid from May to December next year, don ’ t come to Copenhagen, because she ’ s going to be in Shanghai. If you do come to Copenhagen, you will probably see an installation by Ai Weiwei, the Chinese artist. But if the Chinese government intervenes, it might even be a panda. So the second story that I ’ d like to tell is, actually starts in my own house. This is my apartment. This is the view from my apartment, over the sort of landscape of triangular balconies that our client called the Leonardo DiCaprio balcony. And they form this sort of vertical backyard where, on a nice summer day, you ’ ll actually get introduced to all your neighbors in a vertical radius of 10 meters. The house is sort of a distortion of a square block. Trying to zigzag it to make sure that all of the apartments look at the straight views, instead of into each other. Until recently, this was the view from my apartment, onto this place where our client actually bought the neighbor site. And he said that he was going to do an apartment block next to a parking structure. And we thought, rather than doing a traditional stack of apartments looking straight into a big boring block of cars, why don ’ t we turn all the apartments into penthouses, put them on a podium of cars. And because Copenhagen is completely flat, if you want to have a nice south- facing slope with a view, you basically have to do it yourself. Then we sort of cut up the volume, so we wouldn ’ t block the view from my apartment. And essentially the parking is sort of occupying the deep space underneath the apartments. And up in the sun, you have a single layer of apartments that combine all the splendors of a suburban lifestyle, like a house with a garden with a sort of metropolitan view, and a sort of dense urban location. This is our first architectural model. This is an aerial photo taken last summer. And essentially, the apartments cover the parking. They are accessed through this diagonal elevator. It ’ s actually a stand-up product from Switzerland, because in Switzerland they have a natural need for diagonal elevators. And the facade of the parking, we wanted to make the parking naturally ventilated, so we needed to perforate it. And we discovered that by controlling the size of the holes, we could actually turn the entire facade into a gigantic, naturally ventilated, rasterized image. And since we always refer to the project as The Mountain, we commissioned this Japanese Himalaya photographer to give us this beautiful photo of Mount Everest, making the entire building a 3, 000 square meter artwork. So if you go back into the parking, into the corridors, it ’ s almost like traveling into a parallel universe from cars and colors, into this sort of south-facing urban oasis. The wood of your apartment continues outside becoming the facades. If you go even further, it turns into this green garden. And all the rainwater that drops on the Mountain is actually accumulated. And there is an automatic irrigation system that makes sure that this sort of landscape of gardens, in one or two years it will sort of transform into a Cambodian temple ruin, completely covered in green. So, the Mountain is like our first built example of what we like to refer to as architectural alchemy. This idea that you can actually create, if not gold, then at least added value by mixing traditional ingredients, like normal apartments and normal parking, and in this case actually offer people the chance that they don ’ t have to choose between a life with a garden or a life in the city. They can actually have both. As an **architect**, it ’ s really hard to set the agenda. You can ’ t just say that now I ’ d like to do a sustainable city in central Asia, because that ’ s not really how you get commissions. You always have to sort of adapt and improvise to the opportunities and accidents that happen, and the sort of turmoil of the world. One last example is that recently we, like last summer, we won the competition to design a Nordic national bank. This was the director of the bank when he was still smiling. It was in the middle of the capital so we were really excited by this opportunity. Unfortunately, it was the national bank of Iceland. At the same time, we actually had a visitor — a minister from Azerbaijan came to our office. We took him to see the Mountain. And he got very excited by this idea that you could actually make mountains out of architecture, because Azerbaijan is known as the Alps of Central Asia. So he asked us if we could actually imagine an urban master plan on an island outside the capital that would recreate the silhouette of the seven most significant mountains of Azerbaijan. So we took the commission. And we made this small movie that I ’ d like to show. We quite often make little movies. We always argue a lot about the soundtrack, but in this case it was really easy to choose the song. So basically, Baku is this sort of crescent bay overlooking the island of Zira, the island that we are planning — almost like the diagram of their flag. And our main idea was to sort of sample the seven most significant mountains of the topography of Azerbaijan and reinterpret them into urban and architectural structures, inhabitable of human life. Then we place these mountains on the island, surrounding this sort of central green **valley**, almost like a central **park**. And what makes it interesting is that the island right now is just a piece of desert. It has no vegetation.

It has no water. It has no energy, no resources. So we actually sort of designed the entire island as a single ecosystem, exploiting wind energy to drive the desalination plants, and to use the thermal properties of water to heat and cool the buildings. And all the sort of excess freshwater wastewater is filtered organically into the landscape, gradually transforming the desert island into sort of a green, lush landscape. So, you can say where an urban development normally happens at the expense of nature, in this case it ’ s actually creating nature. And the buildings, they don ’ t only sort of invoke the imagery of the mountains, they also operate like mountains. They create shelter from the wind. They accumulate the solar energy. They accumulate the water. So they actually transform the entire island into a single ecosystem. So we recently presented the master plan, and it has gotten approved. And this summer we are starting the construction documents of the two first mountains, in what ’ s going to be the first carbon-neutral island in Central Asia. Yes, maybe just to round off. So in a way you can see how the Mountain in Copenhagen sort of evolved into the Seven Peaks of Azerbaijan. With a little luck and some more evolution, maybe in 10 years it could be the Five Mountains on Mars. Thank you.

Text Sample 699: POS Dim 5 – 2009 – Score 7.00 – 2009/t000114.txt

I was speaking to a group of about 300 kids, ages six to eight, at a children ’ s **museum**, and I brought with me a bag full of legs, similar to the kinds of things you see up here, and had them laid out on a table for the kids. And, from my experience, you know, kids are naturally curious about what they don ’ t know, or don ’ t understand, or is foreign to them. They only learn to be frightened of those differences when an adult influences them to behave that way, and maybe censors that natural curiosity, or you know, reins in the question-asking in the hopes of them being polite little kids. So I just **pictured** a first grade teacher out in the lobby with these unruly kids, saying,”Now, whatever you do, don ’ t stare at her legs.”But, of course, that ’ s the point. That ’ s why I was there, I wanted to invite them to look and explore. So I made a deal with the adults that the kids could come in without any adults for two minutes on their own. The doors open, the kids descend on this table of legs, and they are poking and prodding, and they ’ re wiggling toes, and they ’ re trying to put their full weight on the sprinting leg to see what happens with that. And I said,”Kids, really quickly — I woke up this morning, I decided I wanted to be able to jump over a house — nothing too big, two or three stories — but, if you could think of any animal, any superhero, any cartoon character, anything you can dream up right now, what kind of legs would you build me?”And immediately a voice shouted,”Kangaroo!””No, no, no! Should be a frog!””No. It should be Go Go Gadget!””No, no, no! It should be the Incredibles.”And other things that I don ’ t — aren ’ t familiar with. And then, one eight- year-old said,”Hey, why wouldn ’ t you want to fly too?”And the whole room, including me, was like,”Yeah.”And just like that, I went from being a woman that these kids would have been trained to see as”disabled”to somebody that had potential that their bodies didn ’ t have yet. Somebody that might even be super-abled. Interesting. So some of you actually saw me at TED, 11 years ago. And there ’ s been a lot of talk about how life-changing this conference is for both speakers and attendees, and I am no exception. TED literally was the launch pad to the next decade of my life ’ s exploration. At the time, the legs I presented were groundbreaking in prosthetics. I had woven carbon fiber sprinting legs modeled after the hind leg of a cheetah, which you may have seen on stage yesterday. And also these very life-like, intrinsically painted silicone legs. So at the time, it was my opportunity to put a call out to innovators outside the traditional medical prosthetic community to come bring their talent to the science and to the art of building legs. So that we can stop compartmentalizing form, function and aesthetic, and assigning them different values. Well, lucky for me, a lot of people answered that call. And the journey started, funny enough, with a TED conference attendee — Chee Pearlman, who hopefully is in the audience somewhere today. She was the editor then of a magazine called ID, and she gave me a cover story. This started an incredible journey. Curious encounters were happening to me at the time ; I ’ d been accepting numerous invitations to speak on the design of the cheetah legs around the world. And people would come up to me after the conference, after my talk, men and women. And the conversation would go something like this,”You know Aimee, you ’ re very attractive. You don ’ t look disabled.”I thought,”Well, that ’ s amazing, because I don ’ t feel disabled.”And it really opened my eyes to this conversation that could be explored, about beauty. What does a beautiful woman have to look like? What is a sexy body? And interestingly, from an identity standpoint, what does it mean to have a disability? I mean, people — Pamela Anderson has more prosthetic in her body than I do. Nobody calls her disabled. So this magazine, through the hands of graphic designer Peter Saville, went to fashion designer Alexander McQueen, and photographer Nick Knight, who were also interested in exploring that conversation. So, three months after TED I found myself on a plane to London, doing my first fashion shoot, which resulted in this cover —”Fashionable”? Three months after that, I did my first runway show for Alexander McQueen on a pair of hand-carved wooden legs made from solid ash. Nobody knew — everyone thought they were wooden boots. Actually, I have them on stage with me : grapevines, magnolias — truly stunning. Poetry matters. Poetry is what elevates the banal and neglected object to a realm of art. It can transform the thing that might have made people fearful into something that invites them to look, and look a little longer, and maybe even understand. I learned this firsthand with my next adventure. The artist Matthew Barney, in his **film** opus called the”The Cremaster Cycle.”This is where it really hit home for me — that my legs could be wearable sculpture. And even at this point, I started to move away from the need to replicate human-ness as the only aesthetic **ideal**. So we made what people lovingly referred to as glass legs even though they ’ re actually optically clear polyurethane, a. k. a. bowling ball material. Heavy! Then we made these legs that are cast in soil with a potato root system growing in them, and beetroots out the top, and a very lovely brass toe. That ’ s a good close-up of that one. Then another character was a half-woman, half-cheetah — a little homage to my life as an athlete. 14 hours of prosthetic make-up to get into a creature that had articulated paws, claws and a tail that whipped around, like a gecko. And then another pair of legs we collaborated on were these — look like jellyfish legs, also polyurethane. And the only purpose that these legs can serve, outside the context of the **film**, is to provoke the senses and ignite the imagination. So whimsy matters. Today, I have over a dozen pair of prosthetic legs that various people have made for me, and with them I have different negotiations of the terrain under my **feet**, and I can change my height — I have a variable of five different heights. Today, I ’ m 6 ’ 1”. And I had these legs made a little over a year ago at Dorset Orthopedic in England and when I brought them home to Manhattan, my first night out on the town, I went to a very fancy party. And a girl was there who has known me for years at my normal 5 ’ 8”. Her mouth dropped open when she saw me, and she went,”But you ’ re so tall!”And I said,”I know. Isn ’ t it **fun**?”I mean, it ’ s a little bit like wearing stilts on stilts, but I have an entirely new relationship to door jams that I never expected I would ever have. And I was having **fun** with it. And she looked at me, and she said,"But, Aimee, that ' s not fair."And the incredible thing was she really meant it. It ' s not fair that you can change your height, as you want it. And that ' s when I knew — that ' s when I knew that the conversation with society has changed profoundly in this last decade. It is no longer a conversation about overcoming deficiency. It ' s a conversation about augmentation. It ' s a conversation about potential. A prosthetic limb doesn ' t represent the need to replace loss anymore. It can stand as a symbol that the wearer has the power to create whatever it is that they want to create in that space. So people that society once considered to be disabled can now become the **architects** of their own identities and indeed continue to change those identities by designing their bodies from a place of empowerment. And what is exciting to me so much right now is that by combining cutting-edge technology — robotics, bionics — with the age-old poetry, we are moving closer to understanding our collective humanity. I think that if we want to discover the full potential in our humanity, we need to celebrate those heartbreaking strengths and those glorious disabilities that we all have. I think of Shakespeare ' s Shylock :"If you prick us, do we not bleed, and if you tickle us, do we not laugh?"It is our humanity, and all the potential within it, that makes us beautiful. Thank you.

The substance of things unseen. Cities, past and future. In Oxford, perhaps we can use Lewis Carroll and look in the looking glass that is New York City to try and see our true selves, or perhaps pass through to another world. Or, in the words of F. Scott Fitzgerald,"As the moon rose higher, the inessential houses began to melt away until gradually I became aware of the old island here that once flowered for Dutch sailors ' eyes, a fresh green breast of the new world."My colleagues and I have been working for 10 years to rediscover this lost world in a project we call The Mannahatta Project. We ' re trying to discover what Henry Hudson would have seen on the afternoon of September 12th, 1609, when he sailed into New York harbor. And I ' d like to tell you the story in three acts, and if I have time still, an epilogue. So, Act I : A Map Found. So, I didn ' t grow up in New York. I grew up out west in the Sierra Nevada Mountains, like you see here, in the Red Rock Canyon. And from these early experiences as a child I learned to love landscapes. And so when it became time for me to do my graduate studies, I studied this emerging field of landscape ecology. Landscape ecology concerns itself with how the stream and the meadow and the forest and the cliffs make habitats for plants and animals. This experience and this training lead me to get a wonderful job with the Wildlife Conservation Society, which works to save wildlife and wild places all over the world. And over the last decade, I traveled to over 40 countries to see jaguars and bears and elephants and tigers and rhinos. But every time I would return from my trips I ' d return back to New York City. And on my weekends I would go up, just like all the other tourists, to the top of the Empire State Building, and I ' d look down on this landscape, on these ecosystems, and I ' d wonder,"How does this landscape work to make habitat for plants and animals? How does it work to make habitat for animals like me?"I ' d go to Times Square and I ' d look at the amazing ladies on the wall, and wonder why nobody is looking at the historical figures just behind them. I ' d go to Central Park and see the rolling topography of Central Park come up against the abrupt and sheer topography of midtown Manhattan. I started reading about the history and the geography in New York City. I read that New York City was the first mega-city, a city of 10 million people or more, in 1950. I started seeing paintings like this. For those of you who are from New York, this is 125th street under the West Side Highway. It was once a beach. And this painting has John James Audubon, the painter, sitting on the rock. And it ' s looking up on the wooded heights of Washington Heights to Jeffrey ' s Hook, where the George Washington Bridge goes across today. Or this painting, from the 1740s, from Greenwich Village. Those are two students at King ' s College — later Columbia University — sitting on a hill, overlooking a **valley**. And so I ' d go down to Greenwich Village and I ' d look for this hill, and I couldn ' t find it. And I couldn ' t find that palm tree. What ' s that palm tree doing there? So, it was in the course of these investigations that I ran into a map. And it ' s this map you see here. It ' s held in a geographic information system which allows me to zoom in. This map isn ' t from Hudson ' s time, but from the American Revolution, 170 years later, made by British military cartographers during the occupation of New York City. And it ' s a remarkable map. It ' s in the National Archives here in Kew. And it ' s 10 **feet** long and three and a half **feet** wide. And if I zoom in to lower Manhattan you can see the extent of New York City as it was, right at the end of the American Revolution. Here ' s Bowling Green. And here ' s Broadway. And this is City Hall Park. So the city basically extended to City Hall Park. And just beyond it you can see features that have vanished, things that have disappeared. This is the Collect Pond, which was the fresh water source for New York City for its first 200 years, and for the Native Americans for thousands of years before that. You can see the Lispenard Meadows draining down through here, through what is TriBeCa now, and the beaches that come up from the Battery, all the way to 42nd St. This map was made for military reasons. They ' re mapping the roads, the buildings, these fortifications that they built. But they ' re also mapping things of ecological interest, also military interest : the hills, the marshes, the streams. This is Richmond Hill, and Minetta Water, which used to run its way through Greenwich Village. Or the swamp at Gramercy Park, right here. Or Murray Hill. And this is the Murrays ' house on Murray Hill, 200 years ago. Here is Times Square, the two streams that came together to make a wetland in Times Square, as it was at the end of the American Revolution. So I saw this remarkable map in a book. And I thought to myself,"You know, if I could georeference this map, if I could place this map in the grid of the city today, I could find these lost features of the city, in the block-by-block geography that people know, the geography of where people go to work, and where they go to live, and where they like to eat."So, after some work we were able to georeference it, which allows us to put the modern streets on the city, and the buildings, and the open spaces, so that we can zoom in to where the Collect Pond is. We can digitize the Collect Pond and the streams, and see where they actually are in the geography of the city today. So this is **fun** for finding where things are relative to the old topography. But I had another idea about this map. If we take away the streets, and if we take away the buildings, and if we take away the open spaces, then we could take this map. If we pull off the 18th century features we could drive it back in time. We could drive it back to its ecological fundamentals : to the hills, to the streams, to the basic hydrology and shoreline, to the beaches, the basic aspects that make the ecological landscape. Then, if we added maps like the geology, the bedrock geology, and the surface geology, what the glaciers leave, if we make the soil map, with the 17 soil classes, that are defined by the National Conservation Service, if we make a digital elevation model of the topography that tells us how high the hills were, then we can calculate the slopes. We can calculate the aspect. We can calculate the winter wind exposure — so, which way the winter winds blow across the landscape.

The white areas on this map are the places protected from the winter winds. We compiled all the information about where the Native Americans were, the Lenape. And we built a probability map of where they might have been. So, the red areas on this map indicate the places that are best for human sustainability on Manhattan, places that are close to water, places that are near the harbor to fish, places protected from the winter winds. We know that there was a Lenape settlement down here by the Collect Pond. And we knew that they planted a kind of horticulture, that they grew these beautiful gardens of corn, beans, and squash, the"Three Sisters"garden. So, we built a model that explains where those fields might have been. And the old fields, the successional fields that go. And we might think of these as abandoned. But, in fact, they ' re grassland habitats for grassland birds and plants. And they have become successional shrub lands, and these then mix in to a map of all the ecological communities. And it turns out that Manhattan had 55 different ecosystem types. You can think of these as neighborhoods, as distinctive as TriBeCa and the Upper East Side and Inwood — that these are the forest and the wetlands and the marine communities, the beaches. And 55 is a lot. On a per-area basis, Manhattan had more ecological communities per acre than Yosemite does, than Yellowstone, than Amboseli. It was really an extraordinary landscape that was capable of supporting an extraordinary biodiversity. So, Act II : A Home Reconstructed. So, we studied the fish and the frogs and the birds and the bees, the 85 different kinds of fish that were on Manhattan, the Heath hens, the species that aren ' t there anymore, the beavers on all the streams, the black bears, and the Native Americans, to study how they used and thought about their landscape. We wanted to try and map these. And to do that what we did was we mapped their habitat needs. Where do they get their food? Where do they get their water? Where do they get their shelter? Where do they get their reproductive resources? To an ecologist, the intersection of these is habitat, but to most people, the intersection of these is their home. So, we would read in field guides, the standard field guides that maybe you have on your shelves, you know, what beavers need is,"A slowly meandering stream with aspen trees and alders and willows, near the water."That ' s the best thing for a beaver. So we just started making a list. Here is the beaver. And here is the stream, and the aspen and the alder and the willow. As if these were the maps that we would need to predict where you would find the beaver. Or the bog turtle, needing wet meadows and insects and sunny places. Or the bobcat, needing rabbits and beavers and den sites. And rapidly we started to realize that beavers can be something that a bobcat needs. But a beaver also needs things. And that having it on either side means that we can link it together, that we can create the network of the habitat relationships for these species. Moreover, we realized that you can start out as being a beaver specialist, but you can look up what an aspen needs. An aspen needs fire and dry soils. And you can look at what a wet meadow needs. And it need beavers to create the wetlands, and maybe some other things. But you can also talk about sunny places. So, what does a sunny place need? Not habitat per se. But what are the conditions that make it possible? Or fire. Or dry soils. And that you can put these on a grid that ' s 1, 000 columns long across the top and 1, 000 rows down the other way. And then we can visualize this data like a network, like a social network. And this is the network of all the habitat relationships of all the plants and animals on Manhattan, and everything they needed, going back to the geology, going back to time and space at the very core of the web. We call this the Muir Web. And if you zoom in on it it looks like this. Each point is a different species or a different stream or a different soil type. And those little gray lines are the connections that connect them together. They are the connections that actually make nature resilient.

And the structure of this is what makes nature work, seen with all its parts. We call these Muir Webs after the Scottish-American naturalist John Muir, who said,"When we try to pick out anything by itself, we find that it ' s bound fast by a thousand invisible cords that cannot be broken, to everything in the universe."So then we took the Muir webs and we took them back to the maps. So if we wanted to go between 85th and 86th, and Lex and Third, maybe there was a stream in that block. And these would be the kind of trees that might have been there, and the flowers and the lichens and the mosses, the butterflies, the fish in the stream, the birds in the trees. Maybe a timber rattlesnake lived there. And perhaps a black bear walked by. And maybe Native Americans were there. And then we took this data. You can see this for yourself on our website. You can zoom into any block on Manhattan, and see what might have been there 400 years ago. And we used it to try and reveal a landscape here in Act III. We used the tools they use in Hollywood to make these fantastic landscapes that we all see in the movies. And we tried to use it to visualize Third Avenue. So we would take the landscape and we would build up the topography. We ' d lay on top of that the soils and the waters, and illuminate the landscape. We would lay on top of that the map of the ecological communities. And feed into that the map of the species. So that we would actually take a photograph, flying above Times Square, looking toward the Hudson River, waiting for Hudson to come. Using this technology, we can make these fantastic georeferenced views. We can basically take a **picture** out of any window on Manhattan and see what that landscape looked like 400 years ago. This is the view from the East River, looking up Murray Hill at where the United Nations is today. This is the view looking down the Hudson River, with Manhattan on the left, and New Jersey out on the right, looking out toward the Atlantic Ocean. This is the view over Times Square, with the beaver pond there, looking out toward the east. So we can see the Collect Pond, and Lispenard Marshes back behind. We can see the fields that the Native Americans made. And we can see this in the geography of the city today. So when you ' re watching"Law and Order,"and the lawyers walk up the steps they could have walked back down those steps of the New York Court House, right into the Collect Pond, 400 years ago. So these images are the work of my friend and colleague, Mark Boyer, who is here in the audience today. And I ' d just like, if you would give him a hand, to call out for his fine work. There is such power in bringing science and visualization together, that we can create images like this, perhaps looking on either side of a looking glass. And even though I ' ve only had a brief time to speak, I hope you appreciate that Mannahatta was a very special place. The place that you see here on the left side was interconnected. It was based on this diversity. It had this **resilience** that is what we need in our modern world. But I wouldn ' t have you think that I don ' t like the place on the right, which I quite do. I ' ve come to love the city and its kind of diversity, and its **resilience**, and its dependence on density and how we ' re connected together. In fact, that I see them as reflections of each other, much as Lewis Carroll did in"Through the Looking Glass."We can compare these two and hold them in our minds at the same time, that they really are the same place, that there is no way that cities can escape from nature. And I think this is what we ' re learning about building cities in the future. So if you ' ll allow me a brief epilogue, not about the past, but about 400 years from now, what we ' re realizing is that cities are habitats for people, and need to supply what people need : a sense of home, food, water, shelter, reproductive resources, and a sense of meaning. This is the particular additional habitat requirement of humanity. And so many of the talks here at TED are about meaning, about bringing meaning to our lives in all kinds of different ways, through technology, through art, through science, so much so that I think we focus so much on that side of our lives, that we haven ’ t given enough attention to the food and the water and the shelter, and what we need to raise the kids. So, how can we envision the city of the future? Well, what if we go to Madison Square Park, and we imagine it without all the cars, and bicycles instead and large forests, and streams instead of sewers and storm drains? What if we imagined the Upper East Side with green **roofs**, and streams winding through the city, and windmills supplying the power we need? Or if we imagine the New York City metropolitan area, currently home to 12 million people, but 12 million people in the future, perhaps living at the density of Manhattan, in only 36 percent of the area, with the areas in between covered by farmland, covered by wetlands, covered by the marshes we need. This is the kind of future I think we need, is a future that has the same diversity and abundance and dynamism of Manhattan, but that learns from the sustainability of the past, of the ecology, the original ecology, of nature with all its parts. Thank you very much.

When the Industrial Revolution started, the amount of carbon sitting underneath Britain in the form of coal was as big as the amount of carbon sitting under Saudi Arabia in the form of oil. This carbon powered the Industrial Revolution, it put the”Great”in Great Britain, and led to Britain ’ s temporary world domination. And then, in 1918, coal production in Britain peaked, and has declined ever since. In due course, Britain started using oil and **gas** from the North Sea, and in the year 2000, oil and **gas** production from the North Sea also peaked, and they ’ re now on the decline. These observations about the finiteness of easily accessible, local, secure fossil fuels, is a motivation for saying,”Well, what ’ s next? What is life after fossil fuels going to be like? Shouldn ’ t we be thinking hard about how to get off fossil fuels?”Another motivation, of course, is climate change. And when people talk about life after fossil fuels and climate change action, I think there ’ s a lot of fluff, a lot of greenwash, a lot of misleading advertising, and I feel a duty as a physicist to try to guide people around the claptrap and help people understand the actions that really make a difference, and to focus on ideas that do add up. Let me illustrate this with what physicists call a back-of-envelope calculation. We love back-of-envelope calculations. You ask a question, write down some numbers, and get an answer. It may not be very accurate, but it may make you say,”Hmm.”So here ’ s a question : Imagine if we said,”Oh yes, we can get off fossil fuels. We ’ ll use biofuels. Problem solved. Transport... We don ’ t need oil anymore.”Well, what if we grew the biofuels for a road on the grass verge at the edge of the road? How wide would the verge have to be for that to work out? OK, so let ’ s put in some numbers. Let ’ s have our cars go at 60 miles per hour. Let ’ s say they do 30 miles per gallon. That ’ s the European average for new cars. Let ’ s say the productivity of biofuel plantations is 1, 200 liters of biofuel per hectare per year. That ’ s true of European biofuels. And let ’ s imagine the cars are spaced 80 meters apart from each other, and they ’ re perpetually going along this road. The length of the road doesn ’ t matter, because the longer the road, the more biofuel plantation. What do we do with these numbers? Take the first number, divide by the other three, and get eight kilometers. And that ’ s the answer. That ’ s how wide the plantation would have to be, given these assumptions. And maybe that makes you say,”Hmm. Maybe this isn ’ t going to be quite so easy.”And it might make you think, perhaps there ’ s an issue to do with areas. And in this talk, I ’ d like to talk about land areas, and ask : Is there an issue about areas? The answer is going to be yes, but it depends which country you are in. So let ' s start in the United Kingdom, since that ' s where we are today. The energy consumption of the United Kingdom, the total energy consumption — not just transport, but everything — I like to quantify it in lightbulbs. It ' s as if we ' ve all got 125 lightbulbs on all the time, 125 kilowatt-hours per day per person is the energy consumption of the UK. So there ' s 40 lightbulbs ' worth for transport, 40 lightbulbs ' worth for heating, and 40 lightbulbs ' worth for making electricity, and other things are relatively small, compared to those three big fish. It ' s actually a bigger footprint if we take into account the embodied energy in the stuff we import into our country as well. And 90 percent of this energy, today, still comes from fossil fuels, and 10 percent, only, from other, greener — possibly greener — sources, like nuclear power and renewables. So. That ' s the UK. The population density of the UK is 250 people per square kilometer. I ' m now going to show you other countries by these same two measures. On the vertical axis, I ' m going to show you how many lightbulbs — what our energy consumption per person is. We ' re at 125 lightbulbs per person, and that little blue dot there is showing you the land area of the United Kingdom. The population density is on the horizontal axis, and we ' re 250 people per square kilometer. Let ' s add European countries in blue, and you can see there ' s quite a variety. I should emphasize, both of these axes are logarithmic ; as you go from one gray bar to the next gray bar, you ' re going up a factor of 10. Next, let ' s add Asia in red, the Middle East and North Africa in green, sub-Saharan Africa in blue, black is South America, purple is Central America, and then in pukey-yellow, we have North America, Australia and New Zealand. You can see the great diversity of population densities and of per capita consumptions. Countries are different from each other. Top left, we have Canada and Australia, with enormous land areas, very high per capita consumption — 200 or 300 lightbulbs per person — and very low population densities. Top right : Bahrain has the same energy consumption per person, roughly, as Canada — over 300 lightbulbs per person, but their population density is a factor of 300 times greater, 1, 000 people per square kilometer. **Bottom** right : Bangladesh has the same population density as Bahrain, but consumes 100 times less per person. **Bottom** left : well, there ' s no one. But there used to be a whole load of people. Here ' s another message from this diagram. I ' ve added on little blue tails behind Sudan, Libya, China, India, Bangladesh. That ' s 15 years of progress. Where were they 15 years ago, and where are they now? And the message is, most countries are going to the right, and they ' re going up. Up and to the right : bigger population density and higher per capita consumption. So, we may be off in the top right-hand corner, slightly unusual, the United Kingdom accompanied by Germany, Japan, South Korea, the Netherlands, and a bunch of other slightly odd countries, but many other countries are coming up and to the right to join us. So we ' re a **picture**, if you like, of what the future energy consumption might be looking like in other countries, too. I ' ve also added in this diagram now some pink lines that go down and to the right. Those are lines of equal power consumption per unit area, which I measure in watts per square meter. So, for example, the middle line there, 0. 1 watts per square meter, is the energy consumption per unit area of Saudi Arabia, Norway, Mexico in purple, and Bangladesh 15 years ago. Half of the world ' s population lives in countries that are already above that line. The United Kingdom is consuming 1. 25 watts per square meter. So is Germany, and Japan is consuming a bit more. So, let ' s now say why this is relevant. Why is it relevant? Well, we can measure renewables in the same units and other forms of power production in the same units. Renewables is one of the leading ideas for how we could get off our 90 percent fossil-fuel habit.

So here come some renewables. Energy crops deliver half a watt per square meter in European climates. What does that mean? You might have anticipated that result, given what I told you about the biofuel plantation a moment ago. Well, we consume 1. 25 watts per square meter. What this means is, even if you covered the whole of the United Kingdom with energy crops, you couldn ’ t match today ’ s energy consumption. Wind power produces a bit more — 2. 5 watts per square meter. But that ’ s only twice as big as 1. 25 watts per square meter. So that means if you wanted, literally, to produce total energy consumption in all forms, on average, from wind farms, you need wind farms half the area of the UK. I ’ ve got data to back up all these assertions, by the way. Next, let ’ s look at solar power. Solar **panels**, when you put them on a **roof**, deliver about 20 watts per square meter in England. If you really want to get a lot from solar **panels**, you need to adopt the traditional Bavarian farming method, where you leap off the **roof**, and coat the countryside with solar **panels**, too. Solar **parks**, because of the gaps between the **panels**, deliver less. They deliver about 5 watts per square meter of land area. And here ’ s a solar **park** in Vermont, with real data, delivering 4. 2 watts per square meter. Remember where we are, 1. 25 watts per square meter, wind farms 2. 5, solar **parks** about five. So whichever of those renewables you pick, the message is, whatever mix of those renewables you ’ re using, if you want to power the UK on them, you ’ re going to need to cover something like 20 percent or 25 percent of the country with those renewables. I ’ m not saying that ’ s a bad idea ; we just need to understand the numbers. I ’ m absolutely not anti-renewables. I love renewables. But I ’ m also pro-arithmetic. Concentrating solar power in deserts delivers larger powers per unit area, because you don ’ t have the problem of clouds. So, this facility delivers 14 watts per square meter ; this one 10 watts per square meter ; and this one in Spain, 5 watts per square meter. Being generous to concentrating solar power, I think it ’ s perfectly credible it could deliver 20 watts per square meter. So that ’ s nice. Of course, Britain doesn ’ t have any deserts. Yet. So here ’ s a summary so far : All renewables, much as I love them, are diffuse. They all have a small power per unit area, and we have to live with that fact. And that means, if you do want renewables to make a substantial difference for a country like the United Kingdom on the scale of today ’ s consumption, you need to be imagining renewable facilities that are country-sized. Not the entire country, but a fraction of the country, a substantial fraction. There are other options for generating power as well, which don ’ t involve fossil fuels. So there ’ s nuclear power, and on this ordinance survey map, you can see there ’ s a Sizewell B inside a blue square kilometer. That ’ s one gigawatt in a square kilometer, which works out to 1, 000 watts per square meter. So by this particular metric, nuclear power isn ’ t as intrusive as renewables. Of course, other metrics matter, too, and nuclear power has all sorts of popularity problems. But the same goes for renewables as well. Here ’ s a photograph of a consultation exercise in full swing in the little town of Penicuik just outside Edinburgh, and you can see the children of Penicuik celebrating the burning of the effigy of the windmill. So — People are anti-everything, and we ’ ve got to keep all the options on the table. What can a country like the UK do on the supply side? Well, the options are, I ’ d say, these three : power renewables, and recognizing that they need to be close to country-sized ; other people ’ s renewables, so we could go back and talk very politely to the people in the top **left-hand** side of the diagram and say,”Uh, we don ’ t want renewables in our backyard, but, um, please could we put them in yours instead?”And that ’ s a serious option. It ’ s a way for the world to handle this issue. So countries like Australia, Russia, Libya, Kazakhstan, could be our best friends for renewable production. And a third option is nuclear power. So that ’ s some supply-side options. In addition to the supply levers that we can push — and remember, we need large amounts, because at the moment, we get 90 percent of our energy from fossil fuels — in addition to those levers, we could talk about other ways of solving this issue. Namely, we could reduce demand, and that means reducing population — I ' m not sure how to do that — or reducing per capita consumption. So let ' s talk about three more big levers that could really help on the consumption side. First, transport. Here are the physics principles that tell you how to reduce the energy consumption of transport. People often say,"Technology can answer everything. We can make vehicles that are 100 times more efficient."And that ' s almost true. Let me show you. The energy consumption of this typical tank here is 80 kilowatt hours per hundred person kilometers. That ' s the average European car. Eighty kilowatt hours. Can we make something 100 times better by applying the physics principles I just listed? Yes. Here it is. It ' s the bicycle. It ' s 80 times better in energy consumption, and it ' s powered by biofuel, by Weetabix. And there are other options in between, because maybe the lady in the tank would say,"No, that ' s a lifestyle change. Don ' t change my lifestyle, please."We could persuade her to take a train, still a lot more efficient than a car, but that might be a lifestyle change. Or there ' s the EcoCAR, top-left. It comfortably accommodates one teenager and it ' s shorter than a traffic cone, and it ' s almost as efficient as a bicycle, as long as you drive it at 15 miles per hour. In between, perhaps some more realistic options on the transport lever are electric vehicles, so electric bikes and electric cars in the middle, perhaps four times as energy efficient as the standard petrol-powered tank. Next, there ' s the heating lever. Heating is a third of our energy consumption in Britain, and quite a lot of that is going into homes and other buildings, doing space heating and water heating. So here ' s a typical crappy British house. It ' s my house, with a Ferrari out front. What can we do to it? Well, the laws of physics are written up there, which describe how the power consumption for heating is driven by the things you can control. The things you can control are the temperature difference between the inside and the outside. There ' s this remarkable technology called a thermostat : you grasp it, rotate it to the left, and your energy consumption in the home will decrease. I ' ve tried it. It works. Some people call it a lifestyle change. You can also get the fluff men in to reduce the leakiness of your building — put fluff in the walls, fluff in the **roof**, a new front door, and so forth. The sad truth is, this will save you money. That ' s not sad, that ' s good. But the sad truth is, it ' ll only get about 25 percent of the leakiness of your building if you do these things, which are good ideas. If you really want to get a bit closer to Swedish building standards with a crappy house like this, you need to be putting external insulation on the building, as shown by this block of flats in London. You can also deliver heat more efficiently using heat pumps, which use a smaller bit of high-grade energy like electricity to move heat from your garden into your house. The third demand-side option I want to talk about, the third way to reduce energy consumption is : read your meters. People talk a lot about smart meters, but you can do it yourself. Use your own eyes and be smart. Read your meter, and if you ' re anything like me, it ' ll change your life. Here ' s a graph I made. I was writing a book about sustainable energy, and a friend asked me,"How much energy do you use at home?"I was embarrassed ; I didn ' t actually know. And so I started reading the meter every week. The old meter readings are shown in the top half of the graph, and then 2007 is shown in green at the **bottom**. That was when I was reading the meter every week. And my life changed, because I started doing experiments and seeing what made a difference. My **gas** consumption plummeted, because I started tinkering with the thermostat and the timing on the heating system, and I knocked more than half off my **gas** bills. There ’ s a similar story for my electricity consumption, where switching off the DVD players, the stereos, the computer peripherals that were on all the time, and just switching them on when I needed them, knocked another third off my electricity bills, too. So we need a plan that adds up. I ’ ve described for you six big levers. We need big action, because we get 90 percent of our energy from fossil fuels, and so you need to push hard on most, if not all, of these levers. Most of these levers have popularity problems, and if there is a lever you don ’ t like the use of, well, please do bear in mind that means you need even stronger effort on the other levers. So I ’ m a strong advocate of having grown-up conversations that are based on numbers and facts. And I want to close with this map that just visualizes for you the requirement of land and so forth in order to get just 16 lightbulbs per person from four of the big possible sources. So, if you wanted to get 16 lightbulbs — remember, today our total energy consumption is 125 lightbulbs ’ worth — if you wanted 16 from wind, this map visualizes a solution for the UK. It ’ s got 160 wind farms, each 100 square kilometers in size, and that would be a twentyfold increase over today ’ s amount of wind. Nuclear power : to get 16 lightbulbs per person, you ’ d need two gigawatts at each of the purple dots on the map. That ’ s a fourfold increase over today ’ s levels of nuclear power. Biomass : to get 16 lightbulbs per person, you ’ d need a land area something like three and a half Wales ’ worth, either in our country, or in someone else ’ s country, possibly Ireland, possibly somewhere else. And a fourth supply-side option : concentrating solar power in other people ’ s deserts. If you wanted to get 16 lightbulbs ’ worth, then we ’ re talking about these eight hexagons down at the **bottom** right. The total area of those hexagons is two Greater London ’ s worth of someone else ’ s Sahara, and you ’ ll need power lines all the way across Spain and France to bring the power from the Sahara to Surrey. We need a plan that adds up. We need to stop shouting and start talking. And if we can have a grown-up conversation, make a plan that adds up and get building, maybe this low-carbon revolution will actually be **fun**. Thank you very much for listening.

Text Sample 702: POS Dim 5 – 2012 – Score 7.00 – 2012/t002286.txt

My passions are music, technology and making things. And it ’ s the combination of these things that has led me to the hobby of sound visualization, and, on occasion, has led me to play with fire. This is a Rubens ’ tube. It ’ s one of many I ’ ve made over the years, and I have one here tonight. It ’ s about an 8-foot-long tube of **metal**, it ’ s got a hundred or so holes on top, on that side is the speaker, and here is some lab tubing, and it ’ s connected to this tank of propane. So, let ’ s fire it up and see what it does. So let ’ s play a 550-herz frequency and watch what happens. Thank you. It ’ s okay to applaud the laws of physics, but essentially what ’ s happening here — — is the energy from the sound via the air and **gas** molecules is influencing the combustion properties of propane, creating a visible waveform, and we can see the alternating regions of compression and rarefaction that we call frequency, and the height is showing us amplitude. So let ’ s change the frequency of the sound, and watch what happens to the fire. So every time we hit a resonant frequency we get a standing wave and that emergent sine **curve** of fire. So let ’ s turn that off. We ’ re indoors. Thank you. I also have with me a flame table. It ’ s very similar to a Rubens ’ tube, and it ’ s also used for visualizing the physical properties of sound, such as eigenmodes, so let ’ s fire it up and see what it does. Ooh. Okay. Now, while the table comes up to pressure, let me note here that the sound is not traveling in perfect lines. It ’ s actually traveling in all directions, and the Rubens ’ tube ’ s a little like bisecting those waves with a line, and the flame table ’ s a little like bisecting those waves with a plane, and it can show a little more subtle complexity, which is why I like to use it to watch Geoff Farina play guitar. All right, so it ’ s a delicate dance. If you watch closely — If you watch closely, you may have seen some of the eigenmodes, but also you may have seen that jazz music is better with fire. Actually, a lot of things are better with fire in my world, but the fire ’ s just a foundation. It shows very well that eyes can hear, and this is interesting to me because technology allows us to present sound to the eyes in ways that accentuate the strength of the eyes for seeing sound, such as the removal of time. So here, I ’ m using a rendering algorithm to paint the frequencies of the song”Smells Like Teen Spirit”in a way that the eyes can take them in as a single visual impression, and the technique will also show the strengths of the visual cortex for pattern recognition. So if I show you another song off this album, and another, your eyes will easily pick out the use of repetition by the band Nirvana, and in the frequency distribution, the colors, you can see the clean- dirty-clean sound that they are famous for, and here is the entire album as a single visual impression, and I think this impression is pretty powerful. At least, it ’ s powerful enough that if I show you these four songs, and I remind you that this is”Smells Like Teen Spirit,”you can probably correctly guess, without listening to any music at all, that the song a die hard Nirvana fan would enjoy is this song,”I ’ ll Stick Around”by the Foo Fighters, whose lead singer is Dave Grohl, who was the drummer in Nirvana. The songs are a little similar, but mostly I ’ m just interested in the idea that someday maybe we ’ ll buy a song because we like the way it looks. All right, now for some more sound data. This is data from a skate **park**, and this is Mabel Davis skate **park** in Austin, Texas. And the sounds you ’ re hearing came from eight microphones attached to obstacles around the **park**, and it sounds like chaos, but actually all the tricks start with a very distinct slap, but successful tricks end with a pop, whereas unsuccessful tricks more of a scratch and a tumble, and tricks on the rail will ring out like a gong, and voices occupy very unique frequencies in the skate **park**. So if we were to render these sounds visually, we might end up with something like this. This is all 40 minutes of the recording, and right away the algorithm tells us a lot more tricks are missed than are made, and also a trick on the rails is a lot more likely to produce a cheer, and if you look really closely, we can tease out traffic patterns. You see the skaters often trick in this direction. The obstacles are easier. And in the middle of the recording, the mics pick this up, but later in the recording, this kid shows up, and he starts using a line at the top of the **park** to do some very advanced tricks on something called the tall rail. And it ’ s fascinating. At this moment in time, all the rest of the skaters turn their lines 90 degrees to stay out of his way. You see, there ’ s a subtle etiquette in the skate **park**, and it ’ s led by key influencers, and they tend to be the kids who can do the best tricks, or wear red pants, and on this day the mics picked that up. All right, from skate physics to theoretical physics. I ’ m a big fan of Stephen Hawking, and I wanted to use all eight hours of his Cambridge lecture series to create an homage. Now, in this series he ’ s speaking with the aid of a computer, which actually makes identifying the ends of sentences fairly easy. So I wrote a steering algorithm. It listens to the lecture, and then it uses the amplitude of each word to move a point on the x-axis, and it uses the inflection of sentences to move a same point up and down on the y-axis. And these trend lines, you can see, there ’ s more questions than answers in the laws of physics, and when we reach the end of a sentence, we place a star at that location. So there ’ s a lot of sentences, so a lot of stars, and after rendering all of the audio, this is what we get. This is

Stephen Hawking ’ s universe. It ’ s all eight hours of the Cambridge lecture series taken in as a single visual impression, and I really like this image, but a lot of people think it ’ s fake. So I made a more interactive version, and the way I did that is I used their position in time in the lecture to place these stars into 3D space, and with some custom software and a Kinect, I can walk right into the lecture. I ’ m going to wave through the Kinect here and take control, and now I ’ m going to reach out and I ’ m going to touch a star, and when I do, it will play the sentence that generated that star. Stephen Hawking : There is one, and only one, arrangement in which the pieces make a complete **picture**. Jared Ficklin : Thank you. There are 1, 400 stars. It ’ s a really **fun** way to explore the lecture, and, I hope, a fitting homage. All right. Let me close with a work in progress. I think, after 30 years, the opportunity exists to create an enhanced version of closed captioning. Now, we ’ ve all seen a lot of TEDTalks online, so let ’ s watch one now with the sound turned off and the closed captioning turned on. There ’ s no closed captioning for the TED theme song, and we ’ re missing it, but if you ’ ve watched enough of these, you hear it in your mind ’ s ear, and then applause starts. It usually begins here, and it grows and then it falls. Sometimes you get a little star applause, and then I think even Bill Gates takes a nervous breath, and the talk begins. All right, so let ’ s watch this clip again. This time, I ’ m not going to talk at all. There ’ s still going to be no audio, but what I am going to do is I ’ m going to render the sound visually in real time at the **bottom** of the screen. So watch closely and see what your eyes can hear. This is fairly amazing to me. Even on the first view, your eyes will successfully pick out patterns, but on repeated views, your brain actually gets better at turning these patterns into information. You can get the tone and the timbre and the pace of the speech, things that you can ’ t get out of closed captioning. That famous scene in horror movies where someone is walking up from behind is something you can see, and I believe this information would be something that is useful at times when the audio is turned off or not heard at all, and I speculate that deaf audiences might actually even be better at seeing sound than hearing audiences. I don ’ t know. It ’ s a theory right now. Actually, it ’ s all just an idea. And let me end by saying that sound moves in all directions, and so do ideas. Thank you.

Text Sample 703: POS Dim 5 – 2012 – Score 7.00 – 2012/t002287.txt

So the machine I ’ m going to talk you about is what I call the greatest machine that never was. It was a machine that was never built, and yet, it will be built. It was a machine that was designed long before anyone thought about computers. If you know anything about the history of computers, you will know that in the ’ 30s and the ’ 40s, simple computers were created that started the computer revolution we have today, and you would be correct, except for you ’ d have the wrong century. The first computer was really designed in the 1830s and 1840s, not the 1930s and 1940s. It was designed, and parts of it were prototyped, and the bits of it that were built are here in South Kensington. That machine was built by this guy, Charles Babbage. Now, I have a great affinity for Charles Babbage because his hair is always completely unkempt like this in every single **picture**. He was a very wealthy man, and a sort of, part of the aristocracy of Britain, and on a Saturday night in Marylebone, were you part of the intelligentsia of that period, you would have been invited round to his house for a soiree — and he invited everybody : kings, the Duke of Wellington, many, many famous people — and he would have shown you one of his **mechanical** machines. I really miss that era, you know, where you could go around for a soiree and see a **mechanical** computer get demonstrated to you. But Babbage, Babbage himself was born at the end of the 18th century, and was a fairly famous mathematician. He held the post that Newton held at Cambridge, and that was recently held by Stephen Hawking. He ' s less well known than either of them because he got this idea to make **mechanical** computing devices and never made any of them. The reason he never made any of them, he ' s a classic nerd. Every time he had a good idea, he ' d think,"That ' s brilliant, I ' m going to start building that one. I ' ll spend a fortune on it. I ' ve got a better idea. I ' m going to work on this one. And I ' m going to do this one."He did this until Sir Robert Peel, then Prime Minister, basically kicked him out of Number 10 Downing Street, and kicking him out, in those days, that meant saying,"I bid you good day, sir."The thing he designed was this monstrosity here, the analytical engine. Now, just to give you an idea of this, this is a view from above. Every one of these circles is a cog, a stack of cogs, and this thing is as big as a steam locomotive. So as I go through this talk, I want you to imagine this gigantic machine. We heard those wonderful sounds of what this thing would have sounded like. And I ' m going to take you through the architecture of the machine — that ' s why it ' s computer architecture — and tell you about this machine, which is a computer. So let ' s talk about the memory. The memory is very like the memory of a computer today, except it was all made out of **metal**, stacks and stacks of cogs, 30 cogs high. Imagine a thing this high of cogs, hundreds and hundreds of them, and they ' ve got numbers on them. It ' s a decimal machine. Everything ' s done in decimal. And he thought about using binary. The problem with using binary is that the machine would have been so tall, it would have been ridiculous. As it is, it ' s enormous. So he ' s got memory. The memory is this bit over here. You see it all like this. This monstrosity over here is the CPU, the chip, if you like. Of course, it ' s this big. Completely **mechanical**. This whole machine is **mechanical**. This is a **picture** of a prototype for part of the CPU which is in the Science Museum. The CPU could do the four fundamental functions of arithmetic — so addition, multiplication, subtraction, division — which already is a bit of a feat in **metal**, but it could also do something that a computer does and a calculator doesn ' t : this machine could look at its own internal memory and make a decision. It could do the"if then"for basic programmers, and that fundamentally made it into a computer. It could compute. It couldn ' t just calculate. It could do more. Now, if we look at this, and we stop for a minute, and we think about chips today, we can ' t look inside a silicon chip. It ' s just so tiny. Yet if you did, you would see something very, very similar to this. There ' s this incredible complexity in the CPU, and this incredible regularity in the memory. If you ' ve ever seen an electron microscope **picture**, you ' ll see this. This all looks the same, then there ' s this bit over here which is incredibly complicated. All this cog wheel mechanism here is doing is what a computer does, but of course you need to program this thing, and of course, Babbage used the technology of the day and the technology that would reappear in the ' 50s, ' 60s and ' 70s, which is punch cards. This thing over here is one of three punch card readers in here, and this is a program in the Science Museum, just not far from here, created by Charles Babbage, that is sitting there — you can go see it — waiting for the machine to be built. And there ' s not just one of these, there ' s many of them. He prepared programs anticipating this would happen. Now, the reason they used punch cards was that Jacquard, in France, had created the Jacquard loom, which was weaving these incredible patterns controlled by punch cards, so he was just repurposing the technology of the day, and like everything else he did, he ' s using the technology of his era, so 1830s, 1840s, 1850s, cogs, steam, **mechanical** devices. Ironically, born the same year as Charles Babbage was Michael Faraday, who would completely revolutionize everything with the dynamo, transformers, all these sorts of things. Babbage, of course, wanted to use proven technology, so steam and things. Now, he needed accessories. Obviously, you ' ve got a computer now. You ' ve got punch cards, a CPU and memory. You need accessories you ' re going to come with. You ' re not just going to have that, So, first of all, you had sound. You had a bell, so if anything went wrong — — or the machine needed the attendant to come to it, there was a bell it could ring. And there ' s actually an instruction on the punch card which says"Ring the bell."So you can imagine this"Ting!"You know, just stop for a moment, imagine all those noises, this thing,"Click, clack click click click,"steam engine,"Ding,"right? You also need a printer, obviously, and everyone needs a printer. This is actually a **picture** of the printing mechanism for another machine of his, called the Difference Engine No. 2, which he never built, but which the Science Museum did build in the ' 80s and ' 90s. It ' s completely **mechanical**, again, a printer. It prints just numbers, because he was obsessed with numbers, but it does print onto paper, and it even does word wrapping, so if you get to the end of the line, it goes around like that. You also need graphics, right? I mean, if you ' re going to do anything with graphics, so he said,"Well, I need a plotter. I ' ve got a big piece of paper and an ink pen and I ' ll make it plot."So he designed a plotter as well, and, you know, at that point, I think he got pretty much a pretty good machine. Along comes this woman, Ada Lovelace. Now, imagine these soirees, all these great and good comes along. This lady is the daughter of the mad, bad and dangerous-to-know Lord Byron, and her mother, being a bit worried that she might have inherited some of Lord Byron ' s madness and badness, thought,"I know the solution : Mathematics is the solution. We ' ll teach her mathematics. That ' ll calm her down."Because of course, there ' s never been a mathematician that ' s gone crazy, so, you know, that ' ll be fine. Everything ' ll be fine. So she ' s got this mathematical training, and she goes to one of these soirees with her mother, and Charles Babbage, you know, gets out his machine. The Duke of Wellington is there, you know, get out the machine, obviously demonstrates it, and she gets it. She ' s the only person in his lifetime, really, who said,"I understand what this does, and I understand the future of this machine."And we owe to her an enormous amount because we know a lot about the machine that Babbage was intending to build because of her. Now, some people call her the first programmer. This is actually from one of — the paper that she translated. This is a program written in a particular style. It ' s not, historically, totally accurate that she ' s the first programmer, and actually, she did something more amazing. Rather than just being a programmer, she saw something that Babbage didn ' t. Babbage was totally obsessed with mathematics. He was building a machine to do mathematics, and Lovelace said,"You could do more than mathematics on this machine."And just as you do, everyone in this room already ' s got a computer on them right now, because they ' ve got a phone. If you go into that phone, every single thing in that phone or computer or any other computing device is mathematics. It ' s all numbers at the **bottom**. Whether it ' s video or text or music or voice, it ' s all numbers, it ' s all, underlying it, mathematical functions happening, and Lovelace said,"Just because you ' re doing mathematical functions and symbols doesn ' t mean these things can ' t represent other things in the real world, such as music."This was a huge leap, because Babbage is there saying,"We could compute these amazing functions and print out tables of numbers and draw graphs,"— — and Lovelace is there and she says,"Look, this thing could even compose music if you told it a representation of music numerically."So this is what I call Lovelace ' s Leap. When you say she ' s a programmer, she did do some, but the real thing is to have said the future is going to be much, much more than this. Now, a hundred years later, this guy comes along, Alan Turing, and in 1936, and invents the computer all over again. Now, of course, Babbage ’ s machine was entirely **mechanical**. Turing ’ s machine was entirely theoretical. Both of these guys were coming from a mathematical perspective, but Turing told us something very important. He laid down the mathematical foundations for computer science, and said,”It doesn ’ t matter how you make a computer.”It doesn ’ t matter if your computer ’ s **mechanical**, like Babbage ’ s was, or electronic, like computers are today, or perhaps in the future, cells, or, again, **mechanical** again, once we get into nanotechnology. We could go back to Babbage ’ s machine and just make it tiny. All those things are computers. There is in a sense a computing essence. This is called the Church—Turing thesis. And so suddenly, you get this link where you say this thing Babbage had built really was a computer. In fact, it was capable of doing everything we do today with computers, only really slowly. To give you an idea of how slowly, it had about 1k of memory. It used punch cards, which were being fed in, and it ran about 10, 000 times slower the first ZX81. It did have a RAM pack. You could add on a lot of extra memory if you wanted to. So, where does that bring us today? So there are plans. Over in Swindon, the Science Museum archives, there are hundreds of plans and thousands of pages of notes written by Charles Babbage about this analytical engine. One of those is a set of plans that we call Plan 28, and that is also the name of a charity that I started with Doron Swade, who was the curator of computing at the Science Museum, and also the person who drove the project to build a difference engine, and our plan is to build it. Here in South Kensington, we will build the analytical engine. The project has a number of parts to it. One was the **scanning** of Babbage ’ s archive. That ’ s been done. The second is now the study of all of those plans to determine what to build. The third part is a computer simulation of that machine, and the last part is to physically build it at the Science Museum. When it ’ s built, you ’ ll finally be able to understand how a computer works, because rather than having a tiny chip in front of you, you ’ ve got to look at this humongous thing and say,”Ah, I see the memory operating, I see the CPU operating, I hear it operating. I probably smell it operating.”But in between that we ’ re going to do a simulation. Babbage himself wrote, he said, as soon as the analytical engine exists, it will surely guide the future course of science. Of course, he never built it, because he was always fiddling with new plans, but when it did get built, of course, in the 1940s, everything changed. Now, I ’ ll just give you a little taste of what it looks like in motion with a video which shows just one part of the CPU mechanism working. So this is just three sets of cogs, and it ’ s going to add. This is the adding mechanism in action, so you imagine this gigantic machine. So, give me five years. Before the 2030s happen, we ’ ll have it. Thank you very much.

Text Sample 704: POS Dim 5 – 2013 – Score 7.00 – 2013/t002089.txt

I ’ m almost like a crazy evangelical. I ’ ve always known that the age of design is upon us, almost like a rapture. If the day is sunny, I think,”Oh, the gods have had a good design day.”Or, I go to a show and I see a beautiful piece by an artist, particularly beautiful, I say he ’ s so good because he clearly looked to design to understand what he needed to do. So I really do believe that design is the highest form of creative expression. That ’ s why I ’ m talking to you today about the age of design, and the age of design is the age in which design is still cute furniture, is still posters, is still fast cars, what you see at MoMA today. But in truth, what I really would like to explain to the public and to the audiences of MoMA is that the most interesting chairs are the ones that are actually made by a robot, like this beautiful chair by Dirk Vander Kooij, where a robot deposits a toothpaste-like slur of recycled refrigerator parts, as if he were a big candy, and makes a chair out of it. Or good design is digital fonts that we use all the time and that become part of our identity. I want people to understand that design is so much more than cute chairs, that it is first and foremost everything that is around us in our life. And it ' s interesting how so much of what we ' re talking about tonight is not simply design but interaction design. And in fact, interaction design is what I ' ve been trying to insert in the collection of the Museum of Modern Art for a few years, starting not very timidly but just pointedly with works, for instance, by Martin Wattenberg — the way a machine plays chess with itself, that you see here, or Lisa Strausfeld and her partners, the Sugar interface for One Laptop Per Child, Toshio Iwai ' s Tenori-On musical instruments, and Philip Worthington ' s Shadow Monsters, and John Maeda ' s Reactive Books, and also Jonathan Harris and Sep Kamvar ' s I Want You To Want Me. These were some of the first acquisitions that really introduced the idea of interaction design to the public. But more recently, I ' ve been trying really to go even deeper into interaction design with examples that are emotionally really suggestive and that really explain interaction design at a level that is almost undeniable. The Wind Map, by Wattenberg and Fernanda Vigas, I don ' t know if you ' ve ever seen it — it ' s really fantastic. It looks at the territory of the United States as if it were a wheat field that is procured by the winds and that is really giving you a pictorial image of what ' s going on with the winds in the United States. But also, more recently, we started acquiring video games, and that ' s where all **hell** broke loose in a really interesting way. There are still people that believe that there ' s a high and there ' s a low. And that ' s really what I find so intriguing about the reactions that we ' ve had to the anointment of video games in the MoMA collection. We ' ve — No, first of all, New York Magazine always gets it. I love them. So we are in the right quadrant. We are in the Highbrow — that ' s daring, that ' s courageous — and Brilliant, which is great. Timidly, we ' ve been higher on the diagonal in other situations, but it ' s okay. It ' s good. It ' s good. It ' s good. But here comes the art critic. Oh, that was fantastic. So the first was Jonathan Jones from The Guardian."Sorry, MoMA, video games are not art."Did I ever say they were art? I was talking about interaction design. Excuse me."Exhibiting Pac-Man and Tetris alongside Picasso and Van Gogh"— They ' re two floors away. —"will mean game over for any real understanding of art."I ' m bringing in the end of the world. You know? We were talking about the rapture? It ' s coming. And Jonathan Jones is making it happen. So the same Guardian rebuts,"Are video games art : the debate that shouldn ' t be. Last week, Guardian art critic blah blah suggested that games cannot qualify as art. But is he right? And does it matter?"Thank you. Does it matter? You know, it ' s like once again there ' s this whole problem of design being often misunderstood for art, or the idea that is so diffuse that designers want to aspire to, would like to be called, artists. No. Designers aspire to be really great designers. Thank you very much. And that ' s more than enough. So my knight in shining armor, John Maeda, without any prompt, came out with this big declaration on why video games belong in the MoMA. And that was fantastic. And I thought that was it. But then there was another wonderfully pretentious article that came out in The New Republic, so pretentious, by Liel Leibovitz, and it said,"MoMA has mistaken video games for art."Again."The **museum** is putting Pac-Man alongside Picasso."Again."That misses the point."Excuse me. You ' re missing the point. And here, look, the above question is put bluntly :"Are video games art? No. Video games aren ' t art because they are quite thoroughly something else

: code.”Oh, so Picasso is not art because it ’ s oil paint. Right? So it ’ s so fantastic to see how these feathers that were ruffled, and these reactions, were so vehement. And you know what? The International Cat Video Film Festival didn ’ t have that much of a reaction. I think this was truly fantastic. We were talking about dancing ponies, but I was really jealous of the Walker Arts Center for putting up this festival, because it ’ s very, very wonderful. And there ’ s this Flaubert quote that I love :”I have always tried to live in an ivory tower, but a tide of shit is beating at its walls, threatening to undermine it.”I consider myself the tide of shit. You know, we have to go through that. Even in the 1930s, my colleagues that were trying to put together an abstract art show had all of these works stopped by the customs officers that decided they were not art. So it ’ s happened before, and it will happen in the future, but right now I can tell you that I am so, so proud to be able to call Pac-Man part of the MoMA collection. And the same with, for instance, Tetris, original version, the Soviet one. And you know, the amount of work — yeah, Alexey Pajitnov was working for the Soviet government and that ’ s how he developed Tetris, and Alexey himself reconstructed the whole game and even gave us a simulation of the cathode ray tube that makes it look slightly bombed. And it ’ s fantastic. So behind these acquisitions is an enormous amount of work, because we ’ re still the Museum of Modern Art, so even when we tackle popular culture, we tackle it as a form of interaction design and as something that has to go into the collection at MoMA, therefore, has to be researched. So to get to choosing Eric Chahi ’ s wonderful Another World, amongst others, we put together a **panel** of experts, and we worked on this acquisition, and it ’ s mostly myself and Kate Carmody and Paul Galloway. We worked on it for a year and a half. So many people helped us — designers of games, you might know Jamin Warren and his collaborators at Kill Screen magazine, and you know, Kevin Slavin. You name it. We bugged everybody, because we knew that we were ignorant. We were not real gamers enough, so we had to really talk to them. And so we decided, of course, to have Sim City 2000, not the other Sim City, that one in particular, so the criteria that we developed along the way were really strong, and were not only criteria of selection. They were also criteria of exhibition and of preservation. That ’ s what makes this acquisition more than a little game or a little joke. It ’ s truly a way to think of how to preserve and show artifacts that will more and more become part of our lives in the future. We live today, as you know very well, not in the digital, not in the physical, but in the kind of minestrone that our mind makes of the two. And that ’ s really where interaction lies, and that ’ s the importance of interaction. And in order to explain interaction, we need to really bring people in and make them realize how interaction is part of their lives. So when I talk about it, I don ’ t talk only about video games, which are in a way the purest form of interaction, unadulterated by any kind of function or finality. I also talk about the MetroCard vending machine, which I consider a masterpiece of interaction. I mean, that interface is beautiful. It looks like a burly MTA guy coming out of the tunnel. You know, with your mitt you can actually paw the MetroCard, and I talk about how bad ATM machines usually are. So I let people understand that it ’ s up to them to know how to judge interaction so as to know when it ’ s good or when it ’ s bad. So when I show The Sims, I try to make people really feel what it meant to have an interaction with The Sims, not only the **fun** but also the responsibility that came with the Tamagotchi. You know, video games can be truly deep even when they ’ re completely mindless. I ’ m sure that all of you know Katamari Damacy. It ’ s about rolling a ball and picking up as many objects as you can in a finite amount of time and hopefully you ’ ll be able to make it into a planet. I ’ ve never made it into a planet, but that ’ s it. Or, you know, Vib-Ribbon was not distributed here in the United States. It was a PlayStation game, but mostly for Japan. And it was one of the first video games in which you could choose your own music. So you would put into the PlayStation, you would put your own CD, and then the game would change alongside your music. So really fantastic. Not to mention Eve Online. Eve Online is an artificial universe, if you wish, but one of the diplomats that was killed in Benghazi, not Ambassador Stevens, but one of his collaborators, was a really big shot in Eve Online, so here you have a diplomat in the real world that spends his time in Eve Online to kind of test, maybe, all of his ideas about diplomacy and about universe-building, and to the point that the first announcement of the bombing was actually given on Eve Online, and after his death, several parts of the universe were named after him. And I was just recently at the Eve Online fan festival in Reykjavk that was quite amazing. I mean, we ' re talking about an experience that of course can seem weird to many, but that is very educational. Of course, there are games that are even more educational. Dwarf Fortress is like the holy grail of this kind of massive multiplayer online game, and in fact the two Adams brothers were in Reykjavk, and they were greeted by a standing ovation by all the Eve Online fans. It was amazing to see. And it ' s a beautiful game. So you start seeing here that the aesthetics that are so important to a **museum** collection like MoMA ' s are kept alive also by the selection of these games. And you know, Valve — you know, Portal — is an example of a video game in which you have a certain type of violence which also leads me to talk about one of the biggest issues that we had to discuss when we acquired the video games, what to do with violence. Right? We had to make decisions. At MoMA, interestingly, there ' s a lot of violence depicted in the art part of the collection, but when I came to MoMA 19 years ago, and as an Italian, I said,"You know what, we need a Beretta."And I was told,"No. No guns in the design collection."And I was like,"Why?"Interestingly, I learned that it ' s considered that in design and in the design collection, what you see is what you get. So when you see a gun, it ' s an instrument for killing in the design collection. If it ' s in the art collection, it might be a critique of the killing instrument. So it ' s very interesting. But we are acquiring our critical dimension also in design, so maybe one day we ' ll be able to acquire also the guns. But here, in this particular case, we decided, you know, with Kate and Paul, that we would have no gratuitous violence. So we have Portal because you shoot walls in order to create new spaces. We have Street Fighter II, because martial arts are good. But we don ' t have GTA because, maybe it ' s my own reflection, I ' ve never been able to do anything but crashing cars and shooting prostitutes and pimps. So it was not very constructive. So, I ' m making **fun** of it, but we discussed this for so many days. You have no idea. And to this day, I am ambivalent, but when you have instead games like Flow, there ' s no doubt. It ' s like, it ' s about serenity and it ' s about sublime. It ' s about experiencing what it means to be a sea creature. Then we have a few also side-scrollers — classical ones. So it ' s quite a hefty collection. And right now, we started with the first 14, but we have several that are coming up, and the reason why we haven ' t acquired them yet is because you don ' t acquire just the game. You acquire the relationship with the company. What we want, what we aspire to, is the code. It ' s very hard to get, of course. But that ' s what would enable us to preserve the video games for a really long time, and that ' s what **museums** do. They also preserve artifacts for posterity. In absence of the code, because, you know, video game companies are not very forthcoming in some cases, in absence of that, we acquire the relationship with the company. We ' re going to stay with them forever. They ' re not going to get rid of us. And one day, we ' ll get that code. But I want to explain to you the criteria that we chose for interaction design. Aesthetics are really important. And I ' m showing you Core War here, which is an early game that takes advantage aesthetically of the limitations of the processor. So the kind of interferences that you see here that look like beautiful barriers in the game are actually a consequence of the processor ' s limitedness, which is fantastic. So aesthetics is always important. And so is space, the spatial aspect of games. You know, I feel that the best video games are the ones that have really savvy **architects** that are behind them, and if they ' re not **architects**, bona fide trained in architecture, they have that feeling. But the spatial evolution in video games is extremely important. Time. The way we experience time in video games, as in other forms of interaction design, is really quite amazing. It can be real time or it can be the time within the game, as is in Animal Crossing, where seasons follow each other at their own pace. So time, space, aesthetics, and then, most important, behavior. The real core issue of interaction design is behavior. Designers that deal with interaction design behaviors that go to influence the rest of our lives. They ' re not just limited to our interaction with the screen. In this case, I ' m showing you Marble Madness, which is a beautiful game in which the controller is a big sphere that vibrates with you, so you have a sphere that ' s moving in this landscape, and the sphere, the controller itself, gives you a sense of the movement. In a way, you can see how video games are the purest aspect of interaction design and are very useful to explain what interaction is. We don ' t want to show the video games with the paraphernalia. No arcade nostalgia. If anything, we want to show the code, and here you see Ben Fry ' s distellamap of Pac-Man, of the Pac-Man code. So the way we acquired the games is very interesting and very unorthodox. You see them here displayed alongside other examples of design, furniture and other parts, but there ' s no paraphernalia, no nostalagia, only the screen and a little shelf with the controllers. The controllers are, of course, part of the experience, so you cannot do away with it. But interestingly, this choice was not condemned too vehemently by gamers. I was afraid that they would kill us, and instead they understood, especially when I told them that I was trying to apply the same stratagem that Philip Johnson applied in 1934 when he wanted to make people understand the importance of design, and he took propeller blades and pieces of machinery and in the MoMA galleries he put them on white pedestals against white walls, as if they were Brancusi sculptures. He created this strange distance, this shock, that made people realize how gorgeous formally, and also important functionally, design pieces were. I would like to do the same with video games. By getting rid of the sticky carpets and the cigarette butts and everything else that we might remember from our childhood, I want people to understand that those are important forms of design. And in a way, the video games, the fonts and everything else lead us to make people understand a wider meaning for design. One of my dream acquisitions, which has been on hold for a few years but now will come back on the front burner, is a 747. I would like to acquire it, but without owning it. I don ' t want it to be at MoMA and possessed by MoMA. I want it to keep flying. So it ' s an acquisition where MoMA makes an arrangement with an airline and keeps the Boeing 747 flying. And the same with the"@"sign that we acquired a few years ago. It was the first example of an acquisition of something that is in the public domain. And what I say to people, it ' s almost as if a butterfly were flying by and we captured the shadow on the wall, and just we ' re showing the shadow. So in a way, we ' re showing a manifestation of something that is truly important and that is part of our identity but that nobody can have. And it ' s too long to explain the acquisition, but if you want to go on the MoMA blog, there ' s a long post where I explain why it ' s such a great example of design. Along the way, I ' ve had to burn a few chairs. You know? I ' ve had to do away with a few concepts of design past. But I see that people are coming along, that the audiences, paradoxically, are much more responsive and much more understanding of this expansion of design than some of my colleagues are. Design is truly everywhere, and design is as important as anything, and I ’ m so glad that, because of its diversity and because of its centrality to our lives, many more people are coming to it as a profession, as a passion, and as, very simply, part of their own culture. Thank you very much.

Announcer : 10 seconds. Five, four, three, two, one. Official top. Plus one, two, three, four, five six, seven, eight, nine, ten. Guillaume NĂŠry, France. Constant weight, 123 meters, three minutes and 25 seconds. National record attempt. 70 meters. [123 meters] Judge : White card. Guillaume NĂŠry! National record! Guillaume NĂŠry : Thank you. Thank you very much, thanks for the warm welcome. That dive you just watched is a journey â a journey between two breaths. A journey that takes place between two breaths â the last one before diving into the water, and the first one, coming back to the surface. That dive is a journey to the very limits of human possibility, a journey into the unknown. But it ’ s also, and above all, an inner journey, where a number of things happen, physiologically as well as mentally. And that ’ s why I ’ m here today, to share my journey with you and to take you along with me. So, we start with the last breath. As you noticed, that last breath in is slow, deep and intense. It ends with a special technique called the **carp**, which allows me to store one to two extra liters of air in my lungs by compressing it. When I leave the surface, I have about 10 liters of air in my lungs. As soon as I leave the surface the first mechanism kicks in : the diving reflex. The first thing the diving reflex does is make your heart rate drop. My heart beat will drop from about 60-70 per minute to about 30-40 beats per minute in a matter of seconds ; almost immediately. Next, the diving reflex causes peripheral vasoconstriction, which means that the blood flow will leave the body ’ s extremities to feed the most important organs : the lungs, the heart and the brain. This mechanism is innate. I cannot control it. If you go underwater, even if you ’ ve never done it before, you ’ ll experience the exact same effects. All human beings share this characteristic. And what ’ s extraordinary is that we share this instinct with marine mammals â all marine mammals : dolphins, whales, sea lions, etc. When they dive deep into the ocean, these mechanisms become activated, but to a greater extent. And, of course, it works much better for them. It ’ s absolutely fascinating. Right as I leave the surface, nature gives me a push in the right direction, allowing me to descend with confidence. So as I dive deeper into the blue, the pressure slowly starts to squeeze my lungs. And since it ’ s the amount of air in my lungs that makes me float, the farther down I go, the more pressure there is on my lungs, the less air they contain and the easier it is for my body to fall. And at one point, around 35 or 40 meters down, I don ’ t even need to swim. My body is dense and heavy enough to fall into the depths by itself, and I enter what ’ s called the free fall phase. The free fall phase is the best part of the dive. It ’ s the reason I still dive. Because it feels like you ’ re being pulled down and you don ’ t need to do anything. I can go from 35 meters to 123 meters without making a single movement. I let myself be pulled by the depths, and it feels like I ’ m flying underwater. It ’ s truly an amazing feeling â an extraordinary feeling of freedom. And so I slowly continue sliding to the **bottom**. 40 meters down, 50 meters down, and between 50 and 60 meters, a second physiological response kicks in. My lungs reach residual volume, below which they ’ re not supposed to be compressed, in theory. And this second

response is called blood shift, or"pulmonary erection"in French. I prefer"blood shift."So blood shift â how does it work? The capillaries in the lungs become engorged with blood â which is caused by the suction â so the lungs can harden and protect the whole chest cavity from being crushed. It prevents the two walls of the lungs from collapsing, from sticking together and caving in. Thanks to this phenomenon, which we also share with marine mammals, I ' m able to continue with my dive. 60, 70 meters down, I keep falling, faster and faster, because the pressure is crushing my body more and more. Below 80 meters, the pressure becomes a lot stronger, and I start to feel it physically. I really start to feel the suffocation. You can see what it looks like â not pretty at all. The diaphragm is completely collapsed, the rib cage is squeezed in, and mentally, there is something going on as well. You may be thinking,"This doesn ' t look enjoyable. How do you do it?"If I relied on my earthly reflexes â what do we do above water when there ' s a problem? We resist, we go against it. We fight. Underwater, that doesn ' t work. If you try that underwater, you might tear your lungs, spit up blood, develop an edema and you ' ll have to stop diving for a good amount of time. So what you need to do, mentally, is to tell yourself that nature and the elements are stronger than you. And so I let the water crush me. I accept the pressure and go with it. At this point, my body receives this information, and my lungs start relaxing. I relinquish all control, and relax completely. The pressure starts crushing me, and it doesn ' t feel bad at all. I even feel like I ' m in a cocoon, protected. And the dive continues. 80, 85 meters down, 90, 100. 100 meters â the magic number. In every sport, it ' s a magic number. For swimmers and athletes and also for us, free divers, it ' s a number everyone dreams of. Everyone wishes one day to be able to get to 100 meters. And it ' s a symbolic number for us, because in the 1970s, doctors and physiologists did their math, and predicted that the human body would not be able to go below 100 meters. Below that, they said, the human body would implode. And then the Frenchman, Jacques Mayol â you all know him as the hero in"The Big Blue"â came along and dived down to 100 meters. He even reached 105 meters. At that time, he was doing"no limits."He ' d use weights to descend faster and come back up with a balloon, just like in the movie. Today, we go down 200 meters in no limit free diving. I can do 123 meters by simply using muscle strength. And in a way, it ' s all thanks to him, because he challenged known facts, and with a sweep of his hand, got rid of the theoretical beliefs and all the mental limits that we like to impose on ourselves. He showed us that the human body has an infinite ability to adapt. So I carry on with my dive. 105, 110, 115. The **bottom** is getting closer. 120, 123 meters. I ' m at the **bottom**. And now, I ' d like to ask you to join me and put yourself in my place. Close your eyes. Imagine you get to 123 meters. The surface is far, far away. You ' re alone. There ' s hardly any light. It ' s cold â freezing cold. The pressure is crushing you completely â 13 times stronger than on the surface. And I know what you ' re thinking :"This is horrible. What the **hell** am I doing here? He ' s insane."But no. That ' s not what I think when I ' m down there. When I ' m at the **bottom**, I feel good. I get this extraordinary feeling of well-being. Maybe it ' s because I ' ve completely released all tensions and let myself go. I feel great, without the need to breathe. Although, you ' d agree, I should be worried. I feel like a tiny dot, a little drop of water, floating in the middle of the ocean. And each time, I **picture** the same image. [The Pale Blue Dot] It ' s that small dot the arrow is pointing to. Do you know what it is? It ' s planet Earth. Planet Earth, photographed by the Voyager probe, from 4 billion kilometers away. And it shows that our home is that small dot over there, floating in the middle of nothing. That ' s how I feel when I ' m at the **bottom**, at 123 meters. I feel like a small dot, a speck of dust, stardust, floating in the middle of the cosmos, in the middle of nothing, in the immensity of space. It ’ s a fascinating sensation, because when I look up, down, left, right, in front, behind, I see the same thing : the infinite deep blue. Nowhere else on Earth you can experience this â looking all around you, and seeing the same thing. It ’ s extraordinary. And at that moment, I still get that feeling each time, building up inside of me â the feeling of humility. Looking at this **picture**, I feel very humble â just like when I ’ m all the way down at the **bottom** â because I ’ m nothing, I ’ m a little speck of nothingness lost in all of time and space. And it still is absolutely fascinating. I decide to go back to the surface, because this is not where I belong. I belong up there, on the surface. So I start heading back up. I get something of a shock at the very moment when I decide to go up. First, because it takes a huge effort to tear yourself away from the **bottom**. It pulled you down on the way in, and will do the same on the way up. You have to swim twice as hard. Then, I ’ m hit with another phenomenon known as narcosis. I don ’ t know if you ’ ve heard of that. It ’ s called nitrogen narcosis. It ’ s something that happens to scuba divers, but it can happen to free divers. It ’ s caused by nitrogen dissolving in the blood, which causes confusion between the conscious and unconscious mind. A flurry of thoughts goes spinning through your head. You can ’ t control them, and you shouldn ’ t try to â you have to let it happen. The more you try to control it, the harder it is to manage. Then, a third thing happens : the desire to breathe. I ’ m not a fish, I ’ m a human being, and the desire to breathe reminds me of that fact. Around 60, 70 meters, you start to feel the need to breathe. And with everything else that ’ s going on, you can very easily lose your ground and start to panic. When that happens, you think,”Where ’ s the surface? I want to go up. I want to breathe now.”You should not do that. Never look up to the surface â not with your eyes, or your mind. You should never **picture** yourself up there. You have to stay in the present. I look at the rope right in front of me, leading me back to the surface. And I focus on that, on the present moment. Because if I think about the surface, I panic. And if I panic, it ’ s over. Time goes faster this way. And at 30 meters : deliverance. I ’ m not alone any more. The safety divers, my guardian angels, join me. They leave the surface, we meet at 30 meters, and they escort me for the final few meters, where potential problems could arise. Every time I see them, I think to myself,”It ’ s thanks to you.”It ’ s thanks to them, my team, that I ’ m here. It brings back the sense of humility. Without my team, without all the people around me, the adventure into the deep would be impossible. A journey into the deep is above all a group effort. So I ’ m happy to finish my journey with them, because I wouldn ’ t be here if it weren ’ t for them. 20 meters, 10 meters, my lungs slowly return to their normal volume. Buoyancy pushes me up to the surface. Five meters below the surface, I start to breathe out, so that as soon as I get to the surface all I do is breathe in. And so I arrive at the surface. Air floods into my lungs. It ’ s like being born again, a relief. It feels good. Though the journey was extraordinary, I do need to feel those small oxygen molecules fueling my body. It ’ s an extraordinary sensation, but at the same time it ’ s traumatizing. It ’ s a shock to the system, as you can you imagine. I go from complete darkness to the light of day, from the near-silence of the depths to the commotion up top. In terms of touch, I go from the soft, velvety feeling of the water, to air rubbing across my face. In terms of smell, there is air rushing into my lungs. And in return, my lungs open up. They were completely squashed just 90 seconds ago, and now, they ’ ve opened up again. So all of this affects quite a lot of things. I need a few seconds to come back, and to feel”all there”again. But that needs to happen quickly, because the judges are there to verify my performance ; I need to show them I ’ m in perfect physical condition.

You saw in the video, I was doing a so-called exit protocol. Once at the surface, I have 15 seconds to take off my nose clip, give this signal and say"I am OK."Plus, you need to be bilingual. On top of everything â that ' s not very nice. Once the protocol is completed, the judges show me a white card, and that ' s when the joy starts. I can finally celebrate what has just happened. So, the journey I ' ve just described to you is a more extreme version of free diving. Luckily, it ' s far from just that. For the past few years, I ' ve been trying to show another side of free diving, because the media mainly talks about competitions and records. But free diving is more than just that. It ' s about being at ease in the water. It ' s extremely beautiful, very poetic and artistic. So my wife and I decided to **film** it and try to show another side of it, mostly to make people want to go into the water. Let me show you some images to finish my story. It ' s a mix of beautiful underwater photos. I ' d like you to know that if one day you try to stop breathing, you ' ll realize that when you stop breathing, you stop thinking, too. It calms your mind. Today, in the 21st century, we ' re under so much pressure. Our minds are overworked, we think at a million miles an hour, we ' re always stressed. Being able to free dive lets you, just for a moment, relax your mind. Holding your breath underwater means giving yourself the chance to experience weightlessness. It means being underwater, floating, with your body completely relaxed, letting go of all your tensions. This is our plight in the 21st century : our backs hurt, our necks hurt, everything hurts, because we ' re stressed and tense all the time. But when you ' re in the water, you let yourself float, as if you were in space. You let yourself go completely. It ' s an extraordinary feeling. You can finally get in touch with your body, mind and spirit. Everything feels better, all at once. Learning how to free dive is also about learning to breathe correctly. We breathe with our first breath at birth, up until our last one. Breathing gives rhythm to our lives. Learning how to breathe better is learning how to live better. Holding your breath in the sea, not necessarily at 100 meters, but maybe at two or three, putting on your goggles, a pair of flippers, means you can go see another world, another universe, completely magical. You can see little fish, seaweed, the flora and fauna, you can watch it all discreetly, sliding underwater, looking around, and coming back to the surface, leaving no trace. It ' s an amazing feeling to become one with nature like that. And if I may say one more thing, holding your breath, being in the water, finding this underwater world â it ' s all about connecting with yourself. You heard me talk a lot about the body ' s memory that dates back millions of years, to our marine origins. The day you get back into the water, when you hold your breath for a few seconds, you will reconnect with those origins. And I guarantee it ' s absolute magic. I encourage you to try it out. Thank you.

Text Sample 706: POS Dim 5 – 2013 – Score 5.00 – 2013/t001925.txt

I would like to show you how architecture has helped to change the life of my community and has opened opportunities to hope. I am a native of Burkina Faso. According to the World Bank, Burkina Faso is one of the poorest countries in the world, but what does it look like to grow up in a place like that? I am an example of that. I was born in a little village called Gando. In Gando, there was no electricity, no access to **clean** drinking water, and no school. But my father wanted me to learn how to read and write. For this reason, I had to leave my family when I was seven and to stay in a city far away from my village with no contact with my family. In this place I sat in a class like that with more than 150 other kids, and for six years. In this time, it just happened to me to come to school to realize that my classmate died. Today, not so much has changed. There is still no electricity in my village. People still are dying in Burkina Faso, and access to **clean** drinking water is still a big problem. I had luck. I was lucky, because this is a fact of life when you grow up in a place like that. But I was lucky. I had a scholarship. I could go to Germany to study. So now, I suppose, I don ’ t need to explain to you how great a privilege it is for me to be standing before you today. From Gando, my home village in Burkina Faso, to Berlin in Germany to become an **architect** is a big, big step. But what to do with this privilege? Since I was a student, I wanted to open up better opportunities to other kids in Gando. I just wanted to use my skills and build a school. But how do you do it when you ’ re still a student and you don ’ t have money? Oh yes, I started to make **drawings** and asked for money. Fundraising was not an easy task. I even asked my classmates to spend less money on coffee and cigarettes, but to sponsor my school project. In real wonder, two years later, I was able to collect 50, 000 U. S. dollars. When I came home to Gando to bring the good news, my people were over the moon, but when they realized that I was planning to use clay, they were shocked.”A clay building is not able to stand a rainy season, and Francis wants us to use it and build a school. Is this the reason why he spent so much time in Europe studying instead of working in the field with us?”My people build all the time with clay, but they don ’ t see any innovation with mud. So I had to convince everybody. I started to speak with the community, and I could convince everybody, and we could start to work. And the women, the men, everybody from the village, was part of this building process. I was allowed to use even traditional techniques. So clay floor for example, the young men come and stand like that, beating, hours for hours, and then their mothers came, and they are beating in this position, for hours, giving water and beating. And then the polishers come. They start polishing it with a stone for hours. And then you have this result, very fine, like a baby **bottom**. It ’ s not photoshopped. This is the school, built with the community. The walls are totally made out of compressed clay blocks from Gando. The **roof** structure is made with cheap steel bars normally hiding inside concrete. And the classroom, the ceiling is made out of both of them used together. In this school, there was a simple idea : to create comfort in a classroom. Don ’ t forget, it can be 45 degrees in Burkina Faso, so with simple ventilation, I wanted to make the classroom good for teaching and learning. And this is the project today, 12 years old, still in best condition. And the kids, they love it. And for me and my community, this project was a huge success. It has opened up opportunities to do more projects in Gando. So I could do a lot of projects, and here I am going to share with you only three of them. The first one is the school extension, of course. How do you explain **drawings** and engineering to people who are neither able to read nor write? I started to build a prototype like that. The innovation was to build a clay vault. So then, I jumped on the top like that, with my team, and it works. The community is looking. It still works. So we can build. And we kept building, and that is the result. The kids are happy, and they love it. The community is very proud. We made it. And even animals, like these donkeys, love our buildings. The next project is the library in Gando. And see now, we tried to introduce different ideas in our buildings, but we often don ’ t have so much material. Something we have in Gando are clay pots. We wanted to use them to create openings. So we just bring them like you can see to the building site. we start cutting them, and then we place them on top of the **roof** before we pour the concrete, and you have this result. The openings are letting the hot air out and light in. Very simple. My most recent project in Gando is a high school project. I would like to share with you this. The innovation in this project is to cast mud like you cast concrete. How do you cast mud? We start making a lot of mortars, like you can see, and when everything is ready, when you know what is the best recipe and the best form, you start working with the community. And sometimes I can leave. They will do it themselves. I came to speak to you like that. Another factor in Gando is rain. When the rains come, we hurry up to protect our fragile walls against the rain. Don ’ t confound with Christo and Jeanne- Claude. It is simply how we protect our walls. The rain in Burkina comes very fast, and after that, you have floods everywhere in the country. But for us, the rain is good. It brings sand and gravel to the river we need to use to build. We just wait for the rain to go. We take the sand, we mix it with clay, and we keep building. That is it. The Gando project was always connected to training the people, because I just wanted, one day when I fall down and die, that at least one person from Gando keeps doing this work. But you will be surprised. I ’ m still alive. And my people now can use their skills to earn money themselves. Usually, for a young man from Gando to earn money, you have to leave the country to the city, sometimes leave the country and some never come back, making the community weaker. But now they can stay in the country and work on different building sites and earn money to feed their family. There ’ s a new quality in this work. Yes, you know it. I have won a lot of awards through this work. For sure, it has opened opportunities. I have become myself known. But the reason why I do what I do is my community. When I was a kid, I was going to school, I was coming back every holiday to Gando. By the end of every holidays, I had to say goodbye to the community, going from one compound to another one. All women in Gando will open their clothes like that and give me the last penny. In my culture, this is a symbol of deep affection. As a seven-year-old guy, I was impressed. I just asked my mother one day,”Why do all these women love me so much?”She just answered,”They are contributing to pay for your education hoping that you will be successful and one day come back and help improve the quality of life of the community.”I hope now that I was able to make my community proud through this work, and I hope I was able to prove you the power of community, and to show you that architecture can be inspiring for communities to shape their own future. Merci beaucoup. Thank you. Thank you. Thank you. Thank you. Thank you. Thank you.

Now, I ’ m an ethnobotanist. That ’ s a scientist who works in the rainforest to document how people use local plants. I ’ ve been doing this for a long time, and I want to tell you, these people know these forests and these medicinal treasures better than we do and better than we ever will. But also, these cultures, these indigenous cultures, are disappearing much faster than the forests themselves. And the greatest and most endangered species in the Amazon Rainforest is not the jaguar, it ’ s not the harpy eagle, it ’ s the isolated and uncontacted tribes. Now four years ago, I injured my **foot** in a climbing accident and I went to the doctor. She gave me heat, she gave me cold, aspirin, narcotic painkillers, anti-inflammatories, cortisone shots. It didn ’ t work. Several months later, I was in the northeast Amazon, walked into a village, and the shaman said,”You ’ re limping.”And I ’ ll never forget this as long as I live. He looked me in the face and he said,”Take off your shoe and give me your machete.”He walked over to a palm tree and carved off a fern, threw it in the fire, applied it to my **foot**, threw it in a pot of water, and had me drink the tea. The pain disappeared for seven months. When it came back, I went to see the shaman again. He gave me the same treatment, and I ’ ve been cured for three years now. Who would

you rather be treated by? Now, make no mistake — Western medicine is the most successful system of healing ever devised, but there ' s plenty of holes in it. Where ' s the cure for breast cancer? Where ' s the cure for schizophrenia? Where ' s the cure for acid reflux? Where ' s the cure for insomnia? The fact is that these people can sometimes, sometimes, sometimes cure things we cannot. Here you see a medicine man in the northeast Amazon treating leishmaniasis, a really nasty protozoal disease that afflicts 12 million people around the world. Western treatment are injections of antimony. They ' re painful, they ' re expensive, and they ' re probably not good for your heart ; it ' s a heavy **metal**. This man cures it with three plants from the Amazon Rainforest. This is the magic frog. My colleague, the late great Loren McIntyre, discoverer of the source lake of the Amazon, Laguna McIntyre in the Peruvian Andes, was lost on the Peru-Brazil border about 30 years ago. He was rescued by a group of isolated Indians called the Matss. They beckoned for him to follow them into the forest, which he did. There, they took out palm leaf baskets. There, they took out these green monkey frogs — these are big suckers, they ' re like this — and they began licking them. It turns out, they ' re highly hallucinogenic. McIntyre wrote about this and it was read by the editor of High Times magazine. You see that ethnobotanists have friends in all sorts of strange cultures. This guy decided he would go down to the Amazon and give it a whirl, or give it a lick, and he did, and he wrote,"My blood pressure went through the **roof**, I lost full control of my bodily functions, I passed out in a heap, I woke up in a hammock six hours later, felt like God for two days."An Italian chemist read this and said,"I ' m not really interested in the theological aspects of the green monkey frog. What ' s this about the change in blood pressure?"Now, this is an Italian chemist who ' s working on a new treatment for high blood pressure based on peptides in the skin of the green monkey frog, and other scientists are looking at a cure for drug-resistant Staph aureus. How ironic if these isolated Indians and their magic frog prove to be one of the cures. Here ' s an ayahuasca shaman in the northwest Amazon, in the middle of a yage ceremony. I took him to Los Angeles to meet a foundation officer looking for support for monies to protect their culture. This fellow looked at the medicine man, and he said,"You didn ' t go to medical school, did you?"The shaman said,"No, I did not."He said,"Well, then what can you know about healing?"The shaman looked at him and he said,"You know what? If you have an infection, go to a doctor. But many human afflictions are diseases of the heart, the mind and the spirit. Western medicine can ' t touch those. I cure them."But all is not rosy in learning from nature about new medicines. This is a viper from Brazil, the venom of which was studied at the Universidade de So Paulo here. It was later developed into ACE inhibitors. This is a frontline treatment for hypertension. Hypertension causes over 10 percent of all deaths on the planet every day. This is a $4 billion industry based on venom from a Brazilian snake, and the Brazilians did not get a nickel. This is not an acceptable way of doing business. The rainforest has been called the greatest expression of life on Earth. There ' s a saying in Suriname that I dearly love :"The rainforests hold answers to questions we have yet to ask."But as you all know, it ' s rapidly disappearing. Here in Brazil, in the Amazon, around the world. I took this **picture** from a small plane flying over the eastern border of the Xingu indigenous reserve in the state of Mato Grosso to the northwest of here. The top half of the **picture**, you see where the Indians live. The line through the middle is the eastern border of the reserve. Top half Indians, **bottom** half white guys. Top half wonder drugs, **bottom** half just a bunch of skinny-ass cows. Top half carbon sequestered in the forest where it belongs, **bottom** half carbon in the atmosphere where it ' s driving climate change. In fact, the number two cause of carbon being released into the atmosphere is forest destruction. But in talking about destruction, it ' s important to keep in mind that the Amazon is the mightiest landscape of all. It ' s a place of beauty and wonder. The biggest anteater in the world lives in the rain forest, tips the scale at 90 pounds. The goliath bird-eating spider is the world ' s largest spider. It ' s found in the Amazon as well. The harpy eagle wingspan is over seven **feet**. And the black cayman — these monsters can tip the scale at over half a ton. They ' re known to be man-eaters. The anaconda, the largest snake, the capybara, the largest rodent. A specimen from here in Brazil tipped the scale at 201 pounds. Let ' s visit where these creatures live, the northeast Amazon, home to the Akuriyo tribe. Uncontacted peoples hold a mystical and iconic role in our imagination. These are the people who know nature best. These are the people who truly live in total harmony with nature. By our standards, some would dismiss these people as primitive."They don ' t know how to make fire, or they didn ' t when they were first contacted."But they know the forest far better than we do. The Akuriyos have 35 words for honey, and other Indians look up to them as being the true masters of the emerald realm. Here you see the face of my friend Pohnay. When I was a teenager rocking out to the Rolling Stones in my hometown of New Orleans, Pohnay was a forest nomad roaming the jungles of the northeast Amazon in a small band, looking for game, looking for medicinal plants, looking for a wife, in other small nomadic bands. But it ' s people like these that know things that we don ' t, and they have lots of lessons to teach us. However, if you go into most of the forests of the Amazon, there are no indigenous peoples. This is what you find : rock carvings which indigenous peoples, uncontacted peoples, used to sharpen the edge of the stone axe. These cultures that once danced, made love, sang to the gods, worshipped the forest, all that ' s left is an imprint in stone, as you see here. Let ' s move to the western Amazon, which is really the epicenter of isolated peoples. Each of these dots represents a small, uncontacted tribe, and the big reveal today is we believe there are 14 or 15 isolated groups in the Colombian Amazon alone. Why are these people isolated? They know we exist, they know there ' s an outside world. This is a form of resistance. They have chosen to remain isolated, and I think it is their human right to remain so. Why are these the tribes that hide from man? Here ' s why. Obviously, some of this was set off in 1492. But at the turn of the last century was the rubber trade. The demand for natural rubber, which came from the Amazon, set off the botanical equivalent of a gold rush. Rubber for bicycle tires, rubber for automobile tires, rubber for zeppelins. It was a mad race to get that rubber, and the man on the left, Julio Arana, is one of the true thugs of the story. His people, his company, and other companies like them killed, massacred, tortured, butchered Indians like the Witotos you see on the right hand side of the slide. Even today, when people come out of the forest, the story seldom has a happy ending. These are Nukaks. They were contacted in the ' 80s. Within a year, everybody over 40 was dead. And remember, these are preliterate societies. The elders are the libraries. Every time a shaman dies, it ' s as if a library has burned down. They have been forced off their lands. The drug traffickers have taken over the Nukak lands, and the Nukaks live as beggars in public **parks** in eastern Colombia. From the Nukak lands, I want to take you to the southwest, to the most spectacular landscape in the world : Chiribiquete National Park. It was surrounded by three isolated tribes and thanks to the Colombian government and Colombian colleagues, it has now expanded. It ' s bigger than the state of Maryland. It is a treasure trove of botanical diversity. It was first explored botanically in 1943 by my mentor, Richard Schultes, seen here atop the Bell Mountain, the sacred mountains of the Karijonas. And let me show you what it looks like today. Flying over Chiribiquete, realize that these lost world mountains are still lost. No scientist has been atop them. In fact, nobody has been atop the Bell Mountain since Schultes in ' 43. And we ' ll end up here with the Bell Mountain just to the east of the **picture**. Let me show you what it looks like today. Not only is this a treasure trove of botanical diversity, not only is it home to three isolated tribes, but it ' s the greatest treasure trove of pre-Colombian art in the world : over 200, 000 paintings. The Dutch scientist Thomas van der Hammen described this as the Sistine Chapel of the Amazon Rainforest. But move from Chiribiquete down to the southeast, again in the Colombian Amazon. Remember, the Colombian Amazon is bigger than New England. The Amazon ' s a big forest, and Brazil ' s got a big part of it, but not all of it. Moving down to these two national **parks**, Cahuinari and Pur in the Colombian Amazon — that ' s the Brazilian border to the right — it ' s home to several groups of isolated and uncontacted peoples. To the trained eye, you can look at the **roofs** of these malocas, these longhouses, and see that there ' s cultural diversity. These are, in fact, different tribes. As isolated as these areas are, let me show you how the outside world is crowding in. Here we see trade and transport increased in Putumayo. With the diminishment of the Civil War in Colombia, the outside world is showing up. To the north, we have illegal gold mining, also from the east, from Brazil. There ' s increased hunting and fishing for commercial purposes. We see illegal logging coming from the south, and drug runners are trying to move through the **park** and get into Brazil. This, in the past, is why you didn ' t mess with isolated Indians. And if it looks like this **picture** is out of focus because it was taken in a hurry, here ' s why. This looks like — This looks like a hangar from the Brazilian Amazon. This is an art exhibit in Havana, Cuba. A group called Los Carpinteros. This is their perception of why you shouldn ' t mess with uncontacted Indians. But the world is changing. These are Mashco-Piros on the Brazil-Peru border who stumbled out of the jungle because they were essentially chased out by drug runners and timber people. And in Peru, there ' s a very nasty business. It ' s called human safaris. They will take you in to isolated groups to take their **picture**. Of course, when you give them clothes, when you give them tools, you also give them diseases. We call these"inhuman safaris."These are Indians again on the Peru border, who were overflown by flights sponsored by missionaries. They want to get in there and turn them into Christians. We know how that turns out. What ' s to be done? Introduce technology to the contacted tribes, not the uncontacted tribes, in a culturally sensitive way. This is the perfect marriage of ancient shamanic wisdom and 21st century technology. We ' ve done this now with over 30 tribes, mapped, managed and increased protection of over 70 million acres of ancestral rainforest. So this allows the Indians to take control of their environmental and cultural destiny. They also then set up guard houses to keep outsiders out. These are Indians, trained as indigenous **park** rangers, patrolling the borders and keeping the outside world at bay. This is a **picture** of actual contact. These are Chitonahua Indians on the Brazil-Peru border. They ' ve come out of the jungle asking for help. They were shot at, their malocas, their longhouses, were burned. Some of them were massacred. Using automatic weapons to slaughter uncontacted peoples is the single most despicable and disgusting human rights abuse on our planet today, and it has to stop. But let me conclude by saying, this work can be spiritually rewarding, but it ' s difficult and it can be dangerous. Two colleagues of mine passed away recently in the crash of a small plane. They were serving the forest to protect those uncontacted tribes. So the question is, in conclusion, is what the future holds. These are the Uray people in Brazil. What does the future hold for them, and what does the future hold for us? Let ' s think differently. Let ' s make a better world. If the climate ' s going to change, let ' s have a climate that changes for the better rather than the worse. Let ' s live on a planet full of luxuriant vegetation, in which isolated peoples can remain in isolation, can maintain that mystery and that knowledge if they so choose. Let ' s live in a world where the shamans live in these forests and heal themselves and us with their mystical plants and their sacred frogs. Thanks again.

Text Sample 708: POS Dim 5 – 2014 – Score 7.00 – 2014/t000045.txt

Hello, Manchester. I ' m so happy to be here. My name is Sophia Wallace. I ' m an artist. And I ' m here today to share with you a project that I hope will empower you personally, and by extension those that you love, especially if they have a clitoris. To make this work, I have to talk about independent female desire. I have to speak about a universal taboo - female genitals. This is not easy. It taints the speaker. I want to thank TEDxSalford for having me here and hosting this conversation. All bodies are entitled to experience the pleasure that they are capable of. This is a core pillar of cliteracy. In making this work, I had to say that the clitoris, first, as an organ, has a right to being, and that this right is not just about not being cut off. Sadly, to this day, over a 140 million women have had their external clitorises cut off. This doesn ' t make it into the news very often, and this doesn ' t come up in foreign policy discussion. So number one, the clitoris has a right to exist, free of harm, like any other organ. But secondly, I argue with cliteracy that the clitoris has a right to pleasure, and this is part of its primary right of being. How is it possible that we landed on the Moon and walked around 29 years before we discovered the anatomy of the clitoris? We actually cloned sheep, identified the Higgs boson particle, and only discovered the clitoris 29 years ago. Unfortunately, this discovery has not been adopted, so most people don ' t know the actual anatomy of the clitoris. The clitoris is not a button. It is an iceberg. Like many in the room who are hearing this for the first time, I was shocked to find out that I didn ' t know the actual anatomy of half of the population, that I didn ' t know my own anatomy. In fact, the clitoris is not a button, it is like an iceberg. Most of the organ is internal. This slide is an anatomical example of the penis and the clitoris side by side. Now, we ' ve all been taught that male bodies and female bodies are opposites : the male body sort of sticks out, the female body is solely internal. Well, in fact, there ' re so many similarities between the penis and the clitoris. So, if you ' ll see, both the glans and - The glans of the penis and the glans of the clitoris - both organs have a glans. There are 3000 nerves in the glans of the penis. There are 8000 nerves in the glans of the clitoris. Both organs have a corpus cavernosum. Both organs have crura, like two little legs or wings. Both organs have bulbs of erectile tissue. Both organs get erect. The penis is outside of the body mostly, and the clitoris is inside the body mostly. That ' s the biggest difference. In fact, they ' re very similar. Actually, fetuses have the same tissue, and in boys it develops as a penis, in girls it develops as a clitoris. Some people have small penises, some people have very large clitorises. If one has a clitoris and takes testosterone, their clitoris can expand. What I ' m saying is that these organs are actually quite similar. And, while we are different, while we are unique as men and women, our differences are not a sign of opposition. In fact, we ' re related to each other, we ' re connected. And that ' s an exciting fact. With Cliteracy, I started with language. Language has been a place that so much of sort of the division of men and women and the subjugation of women has been entrenched with the language itself. ' Vagina ' - the single most misused word in the English language. This is one of the laws of Cliteracy. It ' s intentionally hyperbolic. But unfortunately, it ' s more true than I wish it was. ’ Vagina ’ is a Latin word. It means ’ sword holder ’. Vagina, medically, technically, only includes the opening. This term is used almost universally in doctor ’ s offices. It ’ s also used in feminism to sort of advocate. But it ’ s a term that ignores the clitoris, which is the female sexual organ. And secondly, it reduces the female body to being a receptacle, a sword holder. If you want to use a term that addresses all the female genitals, both the reproductive and the sexual parts of it, the word is ’ vulva ’. This is a word that almost no one uses, but this is the word if you want to talk about female genitals - vulva. If you want to talk about pleasure, ’ clitoris ’ is the term. The clitoris is both internal and external. So, when the clitoris is engaged, internal stimulation feels great. If the clitoris is not engaged, it can feel not great, or it can feel painful. It ’ s all about what ’ s happening with the clitoris. If it was about the vagina, there would be so many nerves that childbirth would be impossible. There ’ re very few nerves in the vagina. All of the nerves inside are from the internal clitoris, which gets stimulated both from external and internal portions. With Cliteracy I felt that - Yes, language has been this way of restricting and confining the female body, but if language can do these thing, it can also liberate, it can also be expansive. It ’ s also an opportunity to come together. And so I sought to use language as a way to shift the discourse and create new space and more alignment. With Cliteracy, I first began with the term, and then a definition of the term, and then an eye chart. The aesthetics of this project were also extremely important and intentional. I avoided any kind of pink and purple ; I didn ’ t use flowers ; I didn ’ t use any fabric or yarn, anything soft and fluffy. I also didn ’ t make any small works that you could hold in your hand or eat off of like plates. I also intentionally avoided any kind of sexual imagery, any kind of graphic, close-up, literal depictions. I think that everywhere we see the exposed female body, and yet we don ’ t know the actual female sexual organ, the clitoris. So showing it is not the point, right? Understanding it is the point. Literacy of it, knowledge of it is the point. [The hole is not the whole] The hole is not the whole. With Cliteracy I had a lot of **fun** with word-play. There was just so much material to work with and so much to talk about. I also am making the radical claim with Cliteracy that we can ’ t truly be free if our bodies are assailed. We can ’ t truly be fully enjoying our democracy when half of the population can ’ t speak about their own body, is censored when they say the words because these words are taboo, or are regularly having sex without orgasms. And we don ’ t talk about this. I ’ m making the radical claim that freedom in society can also be measured by the distribution of orgasms. This could be one indicator that we use when we look at education, access to health care, economics. We could also say : How are orgasms being distributed? That tells us something about a society. There is no lack. Truly. Freud invented the paradigm of the phallus versus the lack. He said that men have the phallus, they have the penis, they have agency ; women have a lack, they have a vagina, they have a void. In fact, Freud was wrong, the vagina is not the female sexual organ, it is the clitoris. There is no lack, none of us have lack, none of us are lacking, we ’ re all whole. And none of us need to be depicted in terms solely of a void. [Girls are taught it ’ s normal for sex to hurt. Phallusy.] In many ways, all of us have had a psychological clitoridectomy because the clitoris is never taught. In sex education it is taught that boys are both sexual and reproductive, boys have erections, boys have wet dreams, boys ejaculate, and then the semen fertilizes the egg. Girls, we ’ re taught, have reproductive organs, they menstruate, menstruation is painful. Girls should not get pregnant if they don ’ t mean to. Girls should not get sexually transmitted diseases. We never learn about the clitoris. We never learn that girls have desire, that this is natural, that girls have sexual dreams, that girls have fantasies. So already, as a culture, I would say we all have clitoridectomies. ’ Clitoris, say my name, say my name. ’ I really enjoyed using word-play and putting the clitoris into popular culture and song lyrics. So much of popular culture, music - the female genitals are kind of riffed on but almost always in a negative way. If you want to humiliate a man, call him a word for female genitals, right? But this is also an opportunity, you can just pop in the clit, and suddenly the whole song changes ; it ’ s very powerful. So, this is a Destiny ’ s Child song, there ’ re many more in the Laws of Cliteracy like ’ **Ain** ’ t no half-stepping to the clit, ’ ’ Sleeping on the clit? That shit cray ’, which it is. Here ’ s an example from looking below at the 100 Laws of Cliteracy. So this work spans 13 **feet** long by 10 **feet** tall. It dwarfs anyone ’ s body. When I first showed this work, I had no idea what the response would be. Of course, I was hoping it would be positive, but I didn ’ t know. And I have to say, I was overwhelmed with the way audiences responded. They really wanted to have this conversation. They would stay with the work for 15 minutes. I would come back, they would still be there, they would have friends with them. And I felt like this work was needed. I was invited to speak about it a lot, and I was also contacted privately. People shared secrets with me, people told me for the first time they didn ’ t feel ashamed about their body, or they went home with this knowledge and are having a great time with their girlfriend, and wanted to thank me for that. So this was extremely gratifying. I think for me, what made me feel like I was onto something was that such a diverse group of people supported this project : men and women, young and old, religious and secular, queer and straight. So many people came together to support this project. And I was contacted by people from as far as New Zealand, Egypt, Brazil, saying : ’ How can we help you with this project? Can you translate this project into Arabic or into Portuguese, like, we need this here in our country. ’ I wanted Cliteracy to go everywhere, but I didn ’ t know how to do that yet, and I ’ m still figuring that out. But I know that it ’ s needed. And I know that it can ’ t just stay within the walls of the art world. I don ’ t consider myself a street artist, but I began making work on the street for the same reason that I think a lot of artist do - I wanted to communicate more broadly. This is an example from a documentary of just me putting up some pieces. These are prints that I made on a news print, then I ’ m putting them up with wheat paste just like old posters were put up. I ’ m just doing this in Brooklyn. Some people like to do street art at the night time, I do it in the day because I feel like it ’ s a little safer, the anonymity of the crowd in New York. So far so good. And one of the cool things about doing street art is that people will comment on your work. Sometimes they cross it out or destroy it, but other times they put their art on top of it. And in this case that happened. Again, like when I showed the work in the gallery, on the street there was a big response, people would photograph it, they would post it on Twitter and Instagram. And it felt like I was talking about something that needed to be talked about, that the project was needed and people were grateful to find it and to keep pushing it out there more. Doing the street work emboldened me to take on even crazier ideas that I never thought I would find myself doing. And I actually, together with an artist named Clit Eastwood, or Ken Thomas, held the world ’ s first-ever clit rodeo last summer. We created a rideable golden clit. And we held the first clit rodeo. And, you know, there were two rules to the rodeo. Basically, one : respect the clit. Respect it. Two : have **fun**. Those were the rules. We had so many riders who wanted to ride, more than we could host for our event. But the riders were judged on three categories : dexterity, style and generosity. And they were really good riders, I have to say. I was worried that it might get a little boring because as you saw on the previous slide, it was just a spring. But people were reading erotica to the clit, someone did a striptease for the clit, someone surfed the clit, someone offered a cigarette to the clit, and then, like - There was a couple where the woman was nine-months-pregnant ; she was riding, and her husband was in the background as her backup dancer, dancing around... So, it was way better than I ever expected. I just was thrilled because the clit was the star of the show. Finally! I ’ ve always wanted Cliteracy to be in the public space, to be at large scale, to be seen over time, not to have to be hidden away or be a secret. And I had the opportunity last fall. Together with Center and Santa Fe we put up a 35 **feet** billboard of Cliteracy, or 11 metre billboard. The text says : ’ Democracy without cliteracy - phallusy ’. And I was thrilled to do this, especially because where it was on this highway is travelled by such a broad range of people, from long-haul truck drivers to art collectors and everyone in between. The billboard company was a little bit less psyched about how much feedback they got about the billboard, but I thought this was great. A lot of people were like : ’ What are you selling? I don ’ t understand. ’ I actually got a call that I ’ ll never forget from a mom, saying : ’ I have to drive this route with my son every day, and I don ’ t know what to tell him. ’ But I was thrilled because she ’ s going to talk to him about cliteracy, and this is something that he needs to know about. Cliteracy needs more than text though, and I always knew that I wanted to explore the form as well. None of us know this form, right? I didn ’ t know this form. So I set about making the world ’ s first anatomically correct sculpture of the clitoris. And this was something that was actually quite hard to do because there are so few accurate representations of the anatomy. And when you find these very few **drawings** or **scans**, they contradict each other, they don ’ t make sense. So, it was actually not that easy to do, but I set about making this form. With the form I wanted to not only explore the anatomy and get it accurate, but I also wanted to show the gesture of beauty of this organ and the gracefulness of it. Here is the first sculpture that I know of of the anatomically correct clitoris. It ’ s six **feet** tall and five **feet** wide. And I wanted to create an iconic form of this unseen organ half of us have, all of us were born through the body of someone that has a clitoris. Everyone in this room was born through the body of someone that has a clitoris. So all of us have been touched by the clitoris. This is universal and yet we don ’ t know about it. So I wanted to create an iconic form that ’ s memorable, that puts this into our consciousness. And I hope that finally this form would be treated with honour and respect and not be treated as obscene. I think it ’ s a beautiful form, and I didn ’ t know it, but once I saw it, it started to feel familiar in this way. And I started to see it around in the natural world, in plants. I also saw it in engravings, on architectural sites. I saw it in weavings of oriental tapestries. I started to see it around. And that was very exciting. And the form is interesting not strictly as a sculpture, but in patterns. There ’ s something very exciting about looking into the power of the small, the power of multiplicity. Instead of creating just this singular superior object, what about putting all these tiny beautiful forms that together form a baby-clit army. The one on the right, I call it ’ Fleur-de-clits ’, and the one on the left was later used in the intervention at the Whitney Museum. So here ’ s a sort of subversive clit army coming together to make the ’ Fleur-de-clit ’, which is this beautiful pattern. But unfortunately, if some people knew what it was, it wouldn ’ t be allowed to be. And that ’ s sort of the rub of it. Here is an example of more clit forms and patterns that I created. This is a clit damask pattern with clit forms burnished onto wood. On the left is a new sculpture. So, this is the first sketch of an invisible clit sculpture. It ’ s the same digital form that I used to make the gold sculpture I just showed to you. But this exists in the negative space. So I used the **laser** to actually cut out the form from clear plexiglass. And so this invisible sculpture addresses the fact that this is omnipresent, and yet it ’ s negated, it ’ s invisible, it ’ s not allowed to be spoken of. I also continued with this idea of negation and using the **laser** to burn away with laser-cut works on paper. And I developed a brand new technology. You might not have heard about it, but it ’ s very cutting edge. I ’ ll try to explain. It ’ s called ’ clitglass ’, and the way that it works - anyone can wear it ; anyone who wants neutral vision can wear a clitglass. So you put on the clitglass, and you look through the perspective of the clit. And the clit refracts any kind of phallocentricacy that ’ s coming back at you. And so you obtain neutral vision, or what I like to call ’ normal ’ vision. Now, you can use clitglass at the Whitney Museum, or you can use it at work, in front of the TV, even at a family reunion. This is an example of looking through this cutting edge technology. So those forms that I showed earlier, I also played a game at my intervention at the Whitney Museum, called ’ put a clit on it ’, or - ’ clit-dazzle the Whitney ’. So basically I handed out these unknown clit forms, and I said : ’ Put the clit wherever you think it needs to go - put it as a subject in art history, put into the designs, put it on the American flag. Whole country has a problem with illcliteracy. Help America out. Just take the clit where it needs to go. ’ So you can see on the lower left, that ’ s a Clitchtenstein. On the lower right, Clitsper Johns. This is the family at the Whitney Museum during the intervention, and the boy on the left who looks to be about 11 years old, at one point asks his mom - they ’ d been wearing the clitglasses for about 15 minutes, having a great time. He was like, ’ Mom, what ’ s a clit? ’ And she said : ’ Oh, it ’ s a really sensitive part of the woman ’ s body. ’ And he was like, ’ Okay, cool. ’ And I was thrilled because one : he felt comfortable asking the question ; two : his mom was supportive and answered the question. And it was totally normal - nothing obscene, nothing secret, no one had to be dragged out of the room, no one had to be ashamed. And that ’ s what I ’ m hoping that Cliteracy can continue to do. Overwhelmingly, the response to Cliteracy has been positive. So many people have supported the project and wanted to help with it. And there ’ ve been a few institutions who have courageously started showing it. But there ’ s so much more that needs to be done. My dream is to radically change the way that we think about bodies so that everyone ’ s body is respected. I want to do this by creating large scale permanent public sculptures that exist for thousands of years. I want to work with **metals** and stone so that these forms don ’ t disappear in future generations, and we don ’ t have to have this conversation again and again. Democracy without cliteracy is a phallusy. I want cliteracy to be taught in schools so that no child has an unnameable part of their body. The clit should be a starring role in any bedroom that it ’ s in. And it shouldn ’ t be censored in the Parliament. So, in closing, I want to ask you to see the clit. See it everywhere. Don ’ t stop seeing it. And if you need help, you can borrow this pair of glasses from me. And don ’ t just stop with seeing it. Say it. Say its name. Thank you.

Text Sample 709: POS Dim 5 – 2014 – Score 6.00 – 2014/t001635.txt

Today I ’ m going to speak to you about the last 30 years of architectural history. That ’ s a lot to pack into 18 minutes. It ’ s a complex topic, so we ’ re just going to dive right in at a complex place : New Jersey. Because 30 years ago, I ’ m from Jersey, and I was six, and I lived there in my parents ’ house in a town called Livingston, and this was my childhood bedroom. Around the corner from my bedroom was the bathroom that I used to share with my sister. And in between my bedroom and the bathroom was a balcony that overlooked the family room. And that ’ s where everyone would hang out and watch TV, so that every time that I walked from my bedroom to the bathroom, everyone would see me, and every time I took a shower and would come back in a towel, everyone would see me. And I looked like this. I was awkward, insecure, and I hated it. I hated that walk, I hated that balcony, I hated that room, and I hated that house. And that ' s architecture. Done. That feeling, those emotions that I felt, that ' s the power of architecture, because architecture is not about math and it ' s not about zoning, it ' s about those visceral, emotional connections that we feel to the places that we occupy. And it ' s no surprise that we feel that way, because according to the EPA, Americans spend 90 percent of their time indoors. That ' s 90 percent of our time surrounded by architecture. That ' s huge. That means that architecture is shaping us in ways that we didn ' t even realize. That makes us a little bit gullible and very, very predictable. It means that when I show you a building like this, I know what you think : You think"power"and"stability"and"democracy."And I know you think that because it ' s based on a building that was build 2, 500 years ago by the Greeks. This is a trick. This is a trigger that **architects** use to get you to create an emotional connection to the forms that we build our buildings out of. It ' s a predictable emotional connection, and we ' ve been using this trick for a long, long time. We used it [200] years ago to build banks. We used it in the 19th century to build art **museums**. And in the 20th century in America, we used it to build houses. And look at these solid, stable little soldiers facing the ocean and keeping away the elements. This is really, really useful, because building things is terrifying. It ' s expensive, it takes a long time, and it ' s very complicated. And the people that build things — developers and governments — they ' re naturally afraid of innovation, and they ' d rather just use those forms that they know you ' ll respond to. That ' s how we end up with buildings like this. This is a nice building. This is the Livingston Public Library that was completed in 2004 in my hometown, and, you know, it ' s got a dome and it ' s got this round thing and columns, red brick, and you can kind of guess what Livingston is trying to say with this building : children, property values and history. But it doesn ' t have much to do with what a library actually does today. That same year, in 2004, on the other side of the country, another library was completed, and it looks like this. It ' s in Seattle. This library is about how we consume media in a digital age. It ' s about a new kind of public amenity for the city, a place to gather and read and share. So how is it possible that in the same year, in the same country, two buildings, both called libraries, look so completely different? And the answer is that architecture works on the principle of a pendulum. On the one side is innovation, and **architects** are constantly pushing, pushing for new technologies, new typologies, new solutions for the way that we live today. And we push and we push and we push until we completely alienate all of you. We wear all black, we get very depressed, you think we ' re adorable, we ' re dead inside because we ' ve got no choice. We have to go to the other side and reengage those symbols that we know you love. So we do that, and you ' re happy, we feel like sellouts, so we start experimenting again and we push the pendulum back and back and forth and back and forth we ' ve gone for the last 300 years, and certainly for the last 30 years. Okay, 30 years ago we were coming out of the ' 70s. **Architects** had been busy experimenting with something called brutalism. It ' s about concrete. You can guess this. Small windows, dehumanizing scale. This is really tough stuff. So as we get closer to the ' 80s, we start to reengage those symbols. We push the pendulum back into the other direction. We take these forms that we know you love and we update them. We add neon and we add pastels and we use new materials. And you love it. And we can ' t give you enough of it. We take Chippendale armoires and we turned those into skyscrapers, and skyscrapers can be medieval castles made out of glass. Forms got big, forms got bold and colorful. Dwarves became columns. Swans grew to the size of buildings. It was crazy. But it ’ s the ’ 80s, it ’ s cool. We ’ re all hanging out in malls and we ’ re all moving to the suburbs, and out there, out in the suburbs, we can create our own architectural fantasies. And those fantasies, they can be Mediterranean or French or Italian. Possibly with endless breadsticks. This is the thing about **postmodernism**. This is the thing about symbols. They ’ re easy, they ’ re cheap, because instead of making places, we ’ re making memories of places. Because I know, and I know all of you know, this isn ’ t Tuscany. This is Ohio. So **architects** get frustrated, and we start pushing the pendulum back into the other direction. In the late ’ 80s and early ’ 90s, we start experimenting with something called deconstructivism. We throw out historical symbols, we rely on new, computer-aided design techniques, and we come up with new compositions, forms crashing into forms. This is academic and heady stuff, it ’ s super unpopular, we totally alienate you. Ordinarily, the pendulum would just swing back into the other direction. And then, something amazing happened. In 1997, this building opened. This is the Guggenheim Bilbao, by Frank Gehry. And this building fundamentally changes the world ’ s relationship to architecture. Paul Goldberger said that Bilbao was one of those rare moments when critics, academics, and the general public were completely united around a building. The New York Times called this building a miracle. Tourism in Bilbao increased 2, 500 percent after this building was completed. So all of a sudden, everybody wants one of these buildings : L. A., Seattle, Chicago, New York, Cleveland, Springfield. Everybody wants one, and Gehry is everywhere. He is our very first starchitect. Now, how is it possible that these forms — they ’ re wild and radical — how is it possible that they become so ubiquitous throughout the world? And it happened because media so successfully galvanized around them that they quickly taught us that these forms mean culture and tourism. We created an emotional reaction to these forms. So did every mayor in the world. So every mayor knew that if they had these forms, they had culture and tourism. This phenomenon at the turn of the new millennium happened to a few other starchitects. It happened to Zaha and it happened to Libeskind, and what happened to these elite few **architects** at the turn of the new millennium could actually start to happen to the entire field of architecture, as digital media starts to increase the speed with which we consume information. Because think about how you consume architecture. A thousand years ago, you would have had to have walked to the village next door to see a building. Transportation speeds up : You can take a boat, you can take a plane, you can be a tourist. Technology speeds up : You can see it in a newspaper, on TV, until finally, we are all architectural photographers, and the building has become disembodied from the site. Architecture is everywhere now, and that means that the speed of communication has finally caught up to the speed of architecture. Because architecture actually moves quite quickly. It doesn ’ t take long to think about a building. It takes a long time to build a building, three or four years, and in the interim, an **architect** will design two or eight or a hundred other buildings before they know if that building that they designed four years ago was a success or not. That ’ s because there ’ s never been a good feedback loop in architecture. That ’ s how we end up with buildings like this. Brutalism wasn ’ t a two-year movement, it was a 20-year movement. For 20 years, we were producing buildings like this because we had no idea how much you hated it. It ’ s never going to happen again, I think, because we are living on the verge of the greatest revolution in architecture since the invention of concrete, of steel, or of the elevator, and it ’ s a media revolution. So my theory is that when you apply media to this pendulum, it starts swinging faster and faster, until it ’ s at both extremes nearly simultaneously, and that effectively blurs the difference between innovation and symbol, between us, the **architects**, and you, the public. Now we can make nearly instantaneous, emotionally charged symbols out of something that ' s brand new. Let me show you how this plays out in a project that my firm recently completed. We were hired to replace this building, which burned down. This is the center of a town called the Pines in Fire Island in New York State. It ' s a vacation community. We proposed a building that was audacious, that was different than any of the forms that the community was used to, and we were scared and our client was scared and the community was scared, so we created a series of photorealistic renderings that we put onto Facebook and we put onto Instagram, and we let people start to do what they do : share it, comment, like it, hate it. But that meant that two years before the building was complete, it was already a part of the community, so that when the renderings looked exactly like the finished product, there were no surprises. This building was already a part of this community, and then that first summer, when people started arriving and sharing the building on social media, the building ceased to be just an edifice and it became media, because these, these are not just **pictures** of a building, they ' re your **pictures** of a building. And as you use them to tell your story, they become part of your personal narrative, and what you ' re doing is you ' re short-circuiting all of our collective memory, and you ' re making these charged symbols for us to understand. That means we don ' t need the Greeks anymore to tell us what to think about architecture. We can tell each other what we think about architecture, because digital media hasn ' t just changed the relationship between all of us, it ' s changed the relationship between us and buildings. Think for a second about those librarians back in Livingston. If that building was going to be built today, the first thing they would do is go online and search"new libraries."They would be bombarded by examples of experimentation, of innovation, of pushing at the envelope of what a library can be. That ' s ammunition. That ' s ammunition that they can take with them to the mayor of Livingston, to the people of Livingston, and say, there ' s no one answer to what a library is today. Let ' s be a part of this. This abundance of experimentation gives them the freedom to run their own experiment. Everything is different now. **Architects** are no longer these mysterious creatures that use big words and complicated **drawings**, and you aren ' t the hapless public, the consumer that won ' t accept anything that they haven ' t seen anymore. **Architects** can hear you, and you ' re not intimidated by architecture. That means that that pendulum swinging back and forth from style to style, from movement to movement, is irrelevant. We can actually move forward and find relevant solutions to the problems that our society faces. This is the end of architectural history, and it means that the buildings of tomorrow are going to look a lot different than the buildings of today. It means that a public space in the ancient city of Seville can be unique and tailored to the way that a modern city works. It means that a stadium in Brooklyn can be a stadium in Brooklyn, not some red-brick historical pastiche of what we think a stadium ought to be. It means that robots are going to build our buildings, because we ' re finally ready for the forms that they ' re going to produce. And it means that buildings will twist to the whims of nature instead of the other way around. It means that a parking garage in Miami Beach, Florida, can also be a place for sports and for yoga and you can even get married there late at night. It means that three **architects** can dream about swimming in the East River of New York, and then raise nearly half a million dollars from a community that gathered around their cause, no one client anymore. It means that no building is too small for innovation, like this little reindeer pavilion that ' s as muscly and sinewy as the animals it ' s designed to observe. And it means that a building doesn ' t have to be beautiful to be lovable, like this ugly little building in Spain, where the **architects** dug a hole, packed it with hay, and then poured concrete around it, and when the concrete dried, they invited someone to come and **clean** that hay out so that all that ’ s left when it ’ s done is this hideous little room that ’ s filled with the imprints and scratches of how that place was made, and that becomes the most sublime place to watch a Spanish sunset. Because it doesn ’ t matter if a cow builds our buildings or a robot builds our buildings. It doesn ’ t matter how we build, it matters what we build. **Architects** already know how to make buildings that are greener and smarter and friendlier. We ’ ve just been waiting for all of you to want them. And finally, we ’ re not on opposite sides anymore. Find an **architect**, hire an **architect**, work with us to design better buildings, better cities, and a better world, because the stakes are high. Buildings don ’ t just reflect our society, they shape our society down to the smallest spaces : the local libraries, the homes where we raise our children, and the walk that they take from the bedroom to the bathroom. Thank you.

Welcome to the gates of **hell**. Now depending on your frame of mind, that is either a bizarrely morbid or entirely appropriate way to start a talk about climate action in the year 2022. Behind me is a **picture** from the **Hell** ’ s Gate National Park in the town of Naivasha, in the Great Rift Valley in my home country, Kenya. Now its name may not scream”tourist trap,”but believe me, it is a beautiful part of the world and you should all try and visit sometime. But more importantly, it could play – It has the potential to play a **crucial** role in the fight against global climate catastrophe. The most recent IPCC reports are clear. Humanity has left cutting emissions too late. Any realistic path to avoiding unacceptable levels of warming now requires us to not only drastically cut emissions, at least halving them by 2030, but also undertake an equally massive effort to remove greenhouse **gases** from the atmosphere at an accelerating rate. Now, let ’ s be clear. Greenhouse **gas** removal is not and cannot be an excuse for continuing to emit. Just as installing seat belts and airbags is not an excuse for deliberately ramming your car into a wall. Indeed, current estimates suggest that even with drastic emissions reductions, the world will need to be removing between five and 16 billion tons of carbon dioxide from the atmosphere every single year by 2050. Now to give you a sense of the scale of that, the low end of that range, five billion tons, that ’ s bigger than the size of the global petroleum industry in 2020. So let ’ s not kid ourselves that carbon removal, at anywhere close to the scale that we will need in order to survive, is some sort of easy way out. It is going to be damn difficult to do. So how do we do it? Well, the first and most familiar measures would be interventions such as reforestation and landscape restoration. Essentially giving Mother Nature the time and space to heal herself. In addition, we can increase the amount of carbon held in our soils through the widespread application of biochar and enhanced weathering of chemically suitable rocks. We estimate that in Africa alone, something like 100 million to 680 million additional tons of carbon dioxide could be drawn from the atmosphere using these types of methods. However, they do require a lot of land, a lot of water and a lot of other natural resources that may limit the extent to which we can scale them. Moreover, they are subject to some of the feedback loops from the climate change that we are already experiencing, such as more frequent and intense wildfires. And all of that means we are going to need to supplement them with technologies that accelerate and amplify natural processes to remove carbon dioxide from the atmosphere. Enter the members of my new favorite boy band. DAC, BECCS and BiCRS. These are a set of engineered approaches that use physical, chemical and biological processes to gather and concentrate carbon dioxide from the atmosphere before safely sequestering it, usually underground. As more people run the climate math, you ' re seeing growing levels of interest and investment in these technologies, with billions of dollars already being committed to early pilots and installations in various parts of the world, particularly in Europe and North America. But the reality is they have a very long way to go. To date, engineered removals around the world have accounted for something like 100, 000 tons of carbon dioxide removed total. To get to the multi-billion-ton scale we ' re going to need by 2050 is going to take a truly epic process of exponential scaling. Probably means we need to get to something – If we want to have a realistic shot at it, we need to get to something like 100 million tons per year by 2030. For those of you running the calculators, that ' s a thousand-fold increase in less than a decade. And guess what? We will have to continue that insane rate of growth for another two decades after that. And here ' s the really bad news. Anything close to that level of scaling of this industry in the places where it ' s currently being piloted presents some really difficult climate action trade offs. For that, let me take the example of DAC or direct air capture. The best known DAC facility in the world is in Iceland. It ' s the Orca plant in Iceland, it was inaugurated last year, 2021. It uses plentiful green geothermal energy to capture carbon dioxide, dissolve it in water and inject it into porous basalt deep underground, where it chemically reacts to create a stable solid that can stay there for centuries. It takes the equivalent of between two and three megawatt hours of energy to take a single ton of carbon dioxide today and render it in that way. To get to the hundred million number in 2030, on that track, would entail something like 200 to 300 terawatt hours of electricity. Again, that ' s about half the electricity usage of Germany. And all of that power would need to be renewable, otherwise, we would be taking two steps forward and one and a half steps back. Now it ' s reasonable to expect and assume that we are going to see substantial improvements in energy efficiency of these technologies as we deploy them and learn to use them better. However, keep in mind that probably the most urgent thing we can do to slow climate change right now is stop current emissions. And so scaling these technologies in places where we do have fossil fuel energy emissions that we could be curtailing does not make sense. Essentially, every unit of renewable energy that we are bringing on stream in places like North America and Europe should be going towards displacing and retiring existing fossil fuel capacity. And so the world is kind of stuck. Right? We need to scale this technology. We need to get DAC down the cost **curve** and up the efficiency **curve** urgently. Our lives literally depend on it. But at the same time, we cannot do it except at the expense of other equally urgent climate imperatives. So we need places in the world that somehow have three characteristics. A, they need to have the right geophysical conditions. You know, plenty of porous basalt rock in a geothermally active zone is one such example. Two, they need to have plenty of renewable energy potential. And three, they need to have no current proximate emissions that that renewable energy could be used to displace. And that brings us back to **Hell** ' s Gate National Park. Here ' s another view of the **park** from an angle that may explain its potential. That is one of the power plants that together constitute the Olkaria Geothermal Energy Plant, which provides about a third of Kenya ' s electricity. That ' s right. My home country not only has 92 percent renewable electricity being dispatched on its grids today, but its largest single-energy installation is seamlessly integrated into an honest-to-goodness national **park**. Literally, between the different plants you can see herds of zebra peacefully grazing all times of the day. It ' s amazing. Now at just under 1, 000 megawatts, Olkaria is nothing to sneeze at. It ' s one of the largest geothermal electricity installations in the world. But it ' s barely scratching the surface of the potential in Kenya. There ' s 10 gigawatts of proven, high-quality geothermal resource in the country, widely recognized, ready to be tapped. And in addition, Kenya is endowed with excellent wind and solar resources that have also barely been exploited. We are on the equator, after all. We estimate conservatively that there ' s about 50 gigawatts of potential deployable renewable energy in Kenya that can be readily accessed with the right level of investment. And yet, Kenya remains an energy-poor country where, despite a lot of progress in recent years, more than a quarter of the population still does not have access to basic electricity. And those that do often pay prices that are almost three times as much as much as their counterparts in countries like India and China. Now you might be sitting there wondering,"Well, all right, James, if this is true, if Kenya has all of this renewable energy potential and all of these people in need of energy, well, before we have this whole conversation about fancy climate tech, shouldn ' t we first have a TED Talk about affordable energy access?"And you would be right. Were it not for a particularly cruel paradox of energy economics in countries like Kenya. You see, part of the reason why energy is so expensive in the country is those consumers who are on the grid have to pay for capacity that is not currently being used. There ' s something like 1, 000 megawatt hours every day that goes begging because there isn ' t sufficient industrial demand. At the same time, those very same high energy prices make the country unattractive and uncompetitive for manufacturers and other users of energy looking for places to site their industries. So to get this straight, the reason why the average Kenyan cannot get affordable access to **clean**, renewable energy despite all of this natural bounty, is this tremendously frustrating feedback loop where firstly, we would have all of that energy if someone invested in renewable power plants. People would invest in those power plants if there was a lot of available industry to use the energy. Available industry would come if energy costs weren ' t so high. And energy costs wouldn ' t be so high if there was enough demand. It ' s enough to drive you crazy. But it also points the way to a potential huge triple opportunity. Firstly, introducing DAC and other energy-hungry climate technology into places like the Rift Valley would give them the space and capacity they need to really scale to planetary levels. With no competition, with none of the trade-offs they would face in other parts of the world. At the same time, having that energy-hungry anchor industry available suddenly creates the basis on which people are willing to invest in expanding the country ' s renewable energy potential. Actually creating the business case for providing tens of millions of people with the productive energy they need to improve the quality of their lives. And thirdly, introducing these new and exciting technologies on the continent with the world ' s youngest and fastest-growing workforce could potentially activate their imaginations and their energies towards becoming climate innovators and solution builders themselves, basically building an army from the world ' s largest workforce to solve the world ' s biggest problem. I call it the"Great Carbon Valley."And it ' s just one of the ways in which Africa, as the continent, which, per capita, is the closest to net-zero and has contributed the least to climate change, can play a role in helping the planet avert climate disaster. But in addition, it can do more and be the first continent to go substantially net-negative. We ' re used to thinking about the continent in terms of its forests, its peatlands, its grasslands, its wetlands that need to be preserved. And we should definitely continue to invest in the Indigenous communities, the smallholder farmers and the local innovators who are protecting and expanding natural carbon sinks. But that should not blind us to the fact that Africa also provides an **ideal** potential home for scaling the latest and most ambitious of climate technologies. Whichever of these narratives most speaks to you, one thing should be clear. We need to shake the old, tired idea that Africa is a poor, hapless, helpless climate change victim. Instead, Africa and its people have the potential. They can, and they should, be the world ’ s climate vanguard. Thank you.

Recently, I spent several days exploring Kashgar, a city in Xinjiang, northwest China. I got to wander the streets of the old town and visit the bazaar and several mosques and take in the sights. I ’ ve never been to Kashgar personally, but through the YouTube videos and Instagram posts of tourists, I was able to experience the city at a key moment in time : October 2017, just as the mass detention campaign in the region was gathering pace. These videos could help us investigate the visual signs of the crackdown. The checkpoints at each intersection with their **metal** detectors, ID checks and iris **scans**, the CCTV cameras which pervade the city and the riot police on every corner. Over the past decade, online and open-source investigations have taken off in the fields of journalism and human rights monitoring, using photographs, videos and the digital traces we leave behind as we use the internet to conduct investigations. Social media data is combined with tools like satellite imagery and 3D modelling, as well as more traditional journalistic techniques like interviews and searches of government documents. It ’ s also brought new kinds of people to journalism. Software developers, animators, archaeologists, or, like me, an **architect**. I got involved in investigating Xinjiang in the summer of 2018 when I met Megha Rajagopalan, an American journalist who had been working in China for several years. Over the past few years, China has been carrying out a campaign of oppression in Xinjiang against Turkic Muslims, including the largest group, the Uyghurs. It ’ s part of a campaign of forcible assimilation, and several nations have described it as a genocide. It ’ s estimated that over a million people have been disappeared into detention camps. And while the Chinese government claims that these are part of a benign program of reeducation, dozens of former detainees describe being tortured and abused and women being forcibly sterilized. And yet, for a long time, we lacked information about what was happening in Xinjiang, because the Chinese government controls the internet tightly and restricts journalists ’ work in the region. Journalists would be followed or detained, and the authorities occasionally even went so far as to set up fake roadworks or stage car crashes to prevent access to certain roads. Local people who did speak to journalists face the risk of being sent to a detention camp for doing so. Megha had been the first journalist to visit one of the camps. But shortly after publishing her article, the Chinese authorities declined to renew her visa, and she had to leave. Other journalists had managed to visit a handful of the camps, but this still represented a fraction of what we believed was out there, and no one knew where the others were. But Megha was keen to find the rest. She just needed to find a way to work effectively from outside China. Another challenge was that Xinjiang is huge. It ’ s four times the size of California, and that made it difficult to look for a network of camps that was spread across the region. Satellite imagery could help to solve both of those problems. But more importantly, satellite imagery was a source of information that the Chinese government couldn ’ t control because the satellites and the imagery they produce was owned by US and European organizations. But that still left us with the question of where in that

huge amount of satellite imagery to look. And then I heard about something strange that was happening in Baidu Total View, which is the Chinese equivalent of Google Street View. Photographer Jonathan Browning had discovered that buildings and facilities like industrial estates were being photoshopped out of ground level imagery, often very clumsily. Yeah, it ' s bizarre, right? At the time, it wasn ' t clear why this was happening, but I realized that if industrial estates in eastern China were being obscured, then probably the same thing was happening with detention camps in Xinjiang. And I went to look at the imagery there to see what I could find. There were a handful of camps which had been visited by journalists. And so I went to those locations in Baidu to see what the platform showed. There was no street level imagery. But as I zoomed in on the satellite images, this weird thing happened. A light gray square suddenly appeared above the location of the camp and then disappeared just as quickly as I zoomed in further. It was a bit like the map wasn ' t loading properly, but then I zoomed out and in again only for the same thing to happen. I realized it couldn ' t be a problem with the map loading because the tiles would have been in the browser ' s cache. And when I found the same thing happening at the other locations we knew to be camps, I realized that we had a technique we could use to find the rest of the network. It ' s quite rare for maps and satellite images to have these blank spots because blank areas tend to draw attention to themselves. But here we got lucky. Obscuring the camps had inadvertently revealed all of their locations. We worked with developer Christo Buschek, who specializes in documenting human rights issues and building tools for open-source researchers to map the masked-tile locations. We had to work quickly and secretively to map the masked tiles before anyone found out what we were doing and removed them because our investigation relied on access to that information. The idea was that we could go and look at the masked-tile locations and then look at that same location in other unaltered satellite imagery and see what was there. And this is what we saw. This is a former high school that became Kashgar Vocational Skills Education and Training Center. Zooming in on the satellite imagery, we can see the barbed wire in the courtyards that creates exercise pens for the detainees adjacent to the buildings. In other images, we can even see people, all wearing red uniforms, lined up in the courtyard. These features could help us decide whether a location was a camp or not. As we investigated further, we realized that the camp ' s program had evolved away from the early days of makeshift camps in former schools and hospitals, and had become more permanent, that the camps were now larger, higher-security and purpose-built. This is the largest camp that we know of. It ' s in Dabancheng. The complex is two miles long, and it would cover a quarter of New York ' s Central Park. In the satellite images, we can see the thick perimeter walls, the guard towers and these blueish buildings, which we believe to be factories. We estimate that this complex can hold over 40, 000 people without overcrowding. We corroborated these locations using government documents, many of which mention the camps address, the few media reports which did exist on the camps and our own interviews with former detainees who had managed to leave Xinjiang and are now living in Kazakhstan, Turkey or Europe. In total, we found 348 locations bearing the hallmarks of camps and prisons. And we believe that this is close to being the full network. We estimate that these facilities have been built to hold more than a million people. That ' s enough space to detain one in every 25 of Xinjiang ' s residents. And that doesn ' t take into account the overcrowding that so many former detainees have described. So that number could be even higher. And then one morning, a few months after we had published our map, I woke up to a series of messages about a YouTube video that was doing the rounds on Chinese social media. A Chinese vlogger, who goes by the name Guanguan, had taken our map and traveled to Xinjiang. In his video, we see him driving down a main road past a compound with barbed wire on top of the perimeter wall and bars on the windows. Next, he pretends to take a wrong turn down a side street so that he can **film** the facility at the end. The sign on the gate says"13th Division Detention Center."And then he hurriedly turns his car and drives away. Later, he hangs his camera from his backpack as he walks past this huge prison complex in Ürümqi. From Ürümqi he drove to the Dabancheng, that small town with the enormous detention facility that I showed earlier. He turned off the main road and drove up a gravel track, then got out of his car and climbed up on an earth berm overlooking the new compound. This was a recklessly brave thing to do because, as he notes in the video, tourists don ' t go to that place. He had no plausible deniability for being there. But this is the view from the top, and it ' s the first image that I ' m aware of of the new camp at Dabancheng. This video showed us places from ground level that previously we had only seen from above, indicating that our interpretations were correct. Seeing the signs at the gates of the facility, which told us the name and the type of facility, added further evidence that these places were camps. This video helped us to corroborate a series of locations where previously all we had had was satellite imagery. In Xinjiang, open sources have allowed us to examine and counter the Chinese government ' s claims about what ' s happening in the region. But this isn ' t the only time that open-source data has led to a government losing control of their narrative. At the time, the civil war in Syria was probably the most documented conflict ever, as people **filmed** bombings and their aftermath and uploaded the videos to social media. Researchers like Bellingcat then used that material to investigate allegations of war crimes, such as the use of chlorine **gas** against civilians. Open-source data has allowed journalistic work that previously would have been really difficult, either because it happened in a place that you can ' t safely go to or because often there previously wouldn ' t have been adequate evidence to examine. Now researchers are using these same tools and techniques to monitor the most recent Russian invasion of Ukraine. One of the first signs of the invasion came in Google Maps with a traffic jam created by Russian artillery moving across the border that blocked the roads for civilian traffic. TikTok videos have given away Russian troop movements. Researchers are investigating potential war crimes and aiming to fact-check claims about the war in close to real time. To do this work, satellite imagery is essential. In Xinjiang, we were lucky enough to have satellite imagery, high-resolution, up-to-date, often taken every month or so and available to us for free. This allowed us to verify potential camp locations and to follow the progress of the camp ' s construction closely. But this isn ' t true of everywhere that journalists would want to investigate, and we need affordable access to imagery of those places as well. We also rely on access to other forms of data. We not only need people to take photos and videos, we need them to upload them to a platform where researchers can access them. And then we need that material to be preserved. Often social media platforms have removed material showing violence, even when it ' s providing key evidence of human rights violations. Civil society actors such as the Syrian Archive have stepped in to download and preserve that material. With social media data and satellite imagery, we can provide evidence of human rights abuses in a way that wasn ' t possible before. We can move beyond looking at individual instances of human rights violations to show the scale of what ' s happened. We can corroborate the testimony of eyewitnesses and provide further proof of their stories. We can build a more detailed **picture** of what ' s happening to inform policymakers or to provide evidence that can be presented in court. With open-source data, we can provide the evidence needed for accountability and then, hopefully, action.

Thank you.

Hi. It ’ s about as intimidating as I thought it would be. And yet you ’ d think or I ’ d think that I ’ d be accustomed to more stressful situations. You see, I work in international security and in conflict resolution. And today, I ’ m here to talk about some of our blind spots related to decarbonization. Now, what does one have to do with the other, you may ask. Good question. We often hear that a climate-safe future is a necessary condition for peace. That ’ s true. We also often hear that renewables could be the energy of peace. Less true. To understand, I need to tell you about the materials that we need in order to decarbonize. They ’ re pretty. And they can be deadly. Looking into their story tells us that confronting conflict and building new forms of international peace are going to be critical foundations to build a climate-safe future. So let me tell you about them, starting with where we stand now. When we talk about a decarbonized future, we generally have in mind the possibility of decoupling economic growth from greenhouse **gas** emissions. That ’ s what we call”green growth.”What we tend to think about less often is that to get there we need to recouple economic growth with intensive mineral extraction. To harness renewables or renewable energy like the sun and the wind, we obviously need to build technologies such as solar **panels**, windmills, batteries, right? And to build those, we need to mine huge quantities of non-renewable materials such as these. Knowing that it takes mines as big as these to produce that much amount of usable material. Our ticket to green growth, in other words, is digging deep in the environment. Now we know that mining can have grave impacts for local ecosystems and populations. I ’ ve seen it myself, and it really isn ’ t pretty. But what I want to talk about today is about how much and where we ’ re going to have to dig, and what that means for planetary security and for geopolitics. I ’ ll start from there. History tells us that when the dominant source of energy changes, power relations change as well. Countries that can transform energy to their own advantage, can gain the upper hand economically and politically, and then can put themselves at the center of the global order. Think of the United Kingdom and coal, for instance, or how oil determined the ascendance of the US to a global superpower. What that tells us is that the access to and processing of energy literally materializes into the ability to shape geopolitical power dynamics. And today, we ’ re facing the challenge of implementing the biggest energy transition in the history of humankind under a ticking climate clock. The race is on for a new generation of power. At the heart of which you have all of the critical materials that we need to decarbonize on the one hand and digitalize on the other. So what ’ s happening with them? On the demand side we ’ re at the beginning of an exponential demand **curve**. If you take lithium as a proxy, a key component for [batteries], global production already increased by just short of 300 percent between 2010 and 2020. I ’ m going to pause here for a sec. This is really good news. It means that decarbonization is in motion. The not so good news is that our”**clean**”future is going to be more materially intensive than before. If you take a simple measure for it, the International Energy Agency tells us that with the current level of innovation, an electric car requires six times more mineral inputs than a conventional car. And this is only the start. The World Bank tells us that with the current projections, global production for minerals such as graphite and cobalt will increase by 500 percent by 2050, only to meet the demand for **clean** energy technologies. Now let ’ s look on the supply side. That ’

s where a lot of really interesting things are happening. Who currently exploits and processes minerals and where deposits to meet future demand are located tell us exactly how the transition is going to change geopolitics. So if you look at a material such as lithium, countries like Chile and Australia tend to dominate extraction while China dominates processing. For cobalt, the Democratic Republic of Congo dominates extraction while China dominates processing. For nickel, countries like Indonesia and the Philippines tend to dominate extraction, while China, you guessed it, thank you, dominates processing. And for rare earths, China dominates extraction while China dominates processing. I ' ve just said China a lot, didn ' t I? Well, that ' s because China skillfully leveraged its geo-economic rise to power over the last two decades on the back of integrating supply chains for rare earths from extraction to processing to export. We tend to point fingers at China today for not going fast enough on its own domestic energy transition, but the truth is that China understood already long ago that it would play a central role in other countries ' transitions. And it is. The European Union, for instance, is 98 percent dependent on China for rare earths. Needless to say, this puts China in a prime position to redesign the global balance of power. Now, you may argue that this is a good thing because the global balance of power needs a rehaul anyway. And you know what? I can totally roll with that. But – and this applies to China, the United States, and any other big player – we need to make sure that the redesigning process doesn ' t compromise on human rights or open societies. And that it doesn ' t lead to the weaponization of supply chains at a time of international instability, and more importantly, at a time of complete climate breakdown. Unfortunately, we ' re already seeing signs of this happening. China is currently trying to gain access to more mineral resources through its Belt and Road Initiative. The United States and Europe are both thinking of reshoring critical mining and processing and orienting some of their international partnerships to facilitate access to more mineral resources. Japan is exploring some of its oceanic marine reserves to build strategic reserves. I ' m also speaking in the shadow of a war on the European continent. Now at first sight, Russia ' s invasion of Ukraine has nothing to do with what I ' ve been talking about. But Ukraine happens to be mineral rich. It also happens to be one of only two countries that had struck a partnership with the European Union to diversify and develop supply chains for critical raw materials. That partnership was specifically designed to help the EU decarbonize and in the process to better integrate with Ukraine from a political and economic perspective. Eight months after the partnership was struck, the invasion took place. Now, mineral resources may not explain everything about the war. But they certainly can ' t be ignored in analyzing the events. Because when it comes to the race for critical raw materials, what ' s actually happening is that we ' re headed right back into a new scramble for resources, at the heart of which you find all of the big players eyeing countries with vast mineral deposits. And yet it ' s so obvious many of these countries that are located, for the most part, in Africa, in Latin America, in Central Asia and in the Indo-Pacific. Economists will tell you that this is a great thing, because these countries, or at least a lot of them, need economic resources and many, to accelerate their development pathway and climate adaptation. But. Many of these countries also have very real overlapping risk profiles. The International Institute for Sustainable Development first produced this map back in 2018. Can you see the green dots on the map? They represent all of the different materials that we need in order to decarbonize, their geographic location and their deposit size. As it so happens, a lot of the deposits are located in countries that rank fairly high on corruption indices. They are represented essentially by the shades of brown and red on the map. And as it so happens, a lot of the materials are also located in countries that are fragile, such as Sri Lanka, or downright conflict affected, like Myanmar and the Central African Republic. That ’ s not all. The Notre Dame Institute tells us, with this map, in which you see, again, some red and orange, that countries that are climate vulnerable are also the ones that are resource endowed. And one final thing. You know those big ecosystems that we need to protect and regenerate in order to stabilize the global climate regime? To reboot the hydrological cycle and to protect biodiversity? They ’ re also represented in orange and red on this map. Many of these big ecosystems are located in the same fragile countries that I was mentioning before. They also happen to sit on vast mineral deposits. Changing or eliminating these ecosystems through mining, through deforestation or anything else would undermine planetary security. Not just international security. Planetary security. It ’ s essentially like a perfect storm in the making. Corruption, institutional and socioeconomic fragility, climate disruptions and environmental plundering, all acting as a backdrop to a competition to gain access to the minerals that we need in order to decarbonize. All of these factors will be magnified if we don ’ t rein in the scramble for resources. All of them will reinforce one another. And I want to make something very clear here. The countries at the heart of the resource scrambling may suffer the most direct consequences in terms of their ability to develop, to adapt to climate change and to avoid violence. But their fate is not isolated. Their problems are not geographically distant. Our big blind spot here is that we ’ re headed towards a decarbonization trajectory that may end up undermining ecological integrity and heighten the risks of conflict and insecurity whose consequences would reverberate worldwide. I know that this is not a particularly encouraging **picture**. And that it comes on top of layers of **pictures** that are not particularly encouraging. Our modern economies have advanced and grown for two centuries through the gigantic blind spot of fossil fuel exploitation and its unintended consequences. The big lesson here is that we can ’ t afford to just shift to a different set of energies, technologies and materials without paying attention to the unintended consequences. The stakes are too high. They involve our future. That we know. But they also involve our humanity. And they involve our nature, by which I mean the nature that we choose for ourselves. Decarbonization is the way forward. There ’ s not one single doubt allowedd about this. But the way forward also demands of us that we start imagining our future beyond decarbonization already. Remember what I said at the beginning? A climate-safe future is a necessary condition for peace. But we won ’ t achieve a climate-safe future without peace. And to build peace, we need to shake things up in international politics and in the way that we do business and economics. So where do we start? I ’ d like to offer the scaffolding of a plan in four different baskets. First, science. Science can tell us exactly where it is safe to mine and where it isn ’ t, from an ecological perspective. Where it is not safe to mine, we need to act as though these minerals did not exist and establish protected areas under which no mining licensing can take place. Where mining does take place, we can integrate socioeconomic and ecological regeneration within business models. Second, a global public good regime. If decarbonization is a matter of human survival, then the materials that we need in order to decarbonize should be managed collectively under a global public good regime. The alternative is conflict and planetary breakdown. So while we figure out exactly how to design this regime, the countries at the heart of the scramble for resources should receive adequate support, competent and coherent support to face off the joint challenges of geopolitical competition and climate disruptions on the other hand. In other words, investing into conflict resolution, into the fight against corruption and into context-specific **resilience**, should be top priorities of our global energy transition. Third, changing the way that we do business and economics. We can ’ t just switch from one energy system to another. I ’ ve made that pretty clear, right? What we need instead is to reduce our need for energy and for materials. And that starts with massive public and private investments into circular economic models that favor recyclability and material substitution. Now, here ’ s the thing. We know that this is a necessary step, but not a sufficient one. So what we also need to do is to develop ecological assessments for supply chains that account for greenhouse **gas** emissions, but also for water, soil, biodiversity, material and energy footprint all at once. Only on this all-encompassing basis will we understand how supply and distribution chains need to change and therefore how globalization needs to transform. Fourth, innovation. All of this can only happen if we start shifting our thinking about innovation. Innovation in our times is about bringing back economic footprint within planetary boundaries. Anything else, even the coolest of new products, if it isn ’ t aligned with that goal, it ’ s not innovation, it ’ s business as usual. In our little corner of the world, my team and I at Carnegie Europe have been working really hard to identify what regenerative foreign policy looks like and what it aims for. There are two things that we know by now. One is obvious, we need to tackle fundamental issues around economic redistribution on a global scale. The other thing is that we need a geopolitical de-escalation around decarbonisation and regeneration. We ’ ve translated that into a concept we ’ ve called ecological diplomacy. And we ’ re pushing really hard for the European Union to adopt this framework within their foreign policy. Because if there is one thing that we ’ ve understood, it ’ s that ecological integrity is the foundation for all types of security. Which makes it the one common denominator that we can work on rebuilding collectively. And we can manage. Truly, I believe that we can. As long as we shed light on our transition blind spots and take them as our guiding companions to identify what truly systemic, truly peaceful and truly safe solution pathways look like for the age of climate-disrupted futures. Thank you so much.

So I understand that this meeting was planned, and the slogan was From Was to Still. And I am illustrating Still. Which, of course, I am not agreeing with because, although I am 94, I am not still working. And anybody who asks me,”Are you still doing this or that?”I don ’ t answer because I ’ m not doing things still, I ’ m doing it like I always did. I still have — or did I use the word still? I didn ’ t mean that. I have my file which is called To Do. I have my plans. I have my clients. I am doing my work like I always did. So this takes care of my age. I want to show you my work so you know what I am doing and why I am here. This was about 1925. All of these things were made during the last 75 years. But, of course, I ’ m working since 25, doing more or less what you see here. This is Castleton China. This was an exhibition at the Museum of Modern Art. This is now for sale at the Metropolitan Museum. This is still at the Metropolitan Museum now for sale. This is a portrait of my daughter and myself. These were just some of the things I ’ ve made. I made hundreds of them for the last 75 years. I call myself a maker of things. I don ’ t call myself an industrial designer because I ’ m other things. Industrial designers want to make novel things. Novelty is a concept of commerce, not an aesthetic concept. The industrial design magazine, I believe, is called”Innovation.”Innovation is not part of the aim of my work. Well, makers of things : they make things more beautiful, more elegant, more comfortable than just the craftsmen do. I have so much to say. I have to think what I am going to say. Well, to describe our profession otherwise, we are actually concerned with the playful search for beauty. That means the playful search for beauty was called the first activity of Man. Sarah Smith, who was a mathematics professor at MIT, wrote,"The playful search for beauty was Man ' s first activity — that all useful qualities and all material qualities were developed from the playful search for beauty."These are tiles. The word,"playful"is a necessary aspect of our work because, actually, one of our problems is that we have to make, produce, lovely things throughout all of life, and this for me is now 75 years. So how can you, without drying up, make things with the same pleasure, as a gift to others, for so long? The playful is therefore an important part of our quality as designer. Let me tell you some about my life. As I said, I started to do these things 75 years ago. My first exhibition in the United States was at the Sesquicentennial exhibition in 1926 — that the Hungarian government sent one of my hand-drawn pieces as part of the exhibit. My work actually took me through many countries, and showed me a great part of the world. This is not that they took me — the work didn ' t take me — I made the things particularly because I wanted to use them to see the world. I was incredibly curious to see the world, and I made all these things, which then finally did take me to see many countries and many cultures. I started as an apprentice to a Hungarian craftsman, and this taught me what the guild system was in Middle Ages. The guild system : that means when I was an apprentice, I had to apprentice myself in order to become a pottery master. In my shop where I studied, or learned, there was a traditional hierarchy of master, journeyman and learned worker, and apprentice, and I worked as the apprentice. The work as an apprentice was very primitive. That means I had to actually learn every aspect of making pottery by hand. We mashed the clay with our **feet** when it came from the hillside. After that, it had to be kneaded. It had to then go in, kind of, a mangle. And then finally it was prepared for the throwing. And there I really worked as an apprentice. My master took me to set ovens because this was part of oven-making, oven-setting, in the time. And finally, I had received a document that I had accomplished my apprenticeship successfully, that I had behaved morally, and this document was given to me by the Guild of Roof- Coverers, Rail-Diggers, Oven-Setters, Chimney Sweeps and Potters. I also got at the time a workbook which explained my rights and my working conditions, and I still have that workbook. First I set up a shop in my own garden, and made pottery which I sold on the marketplace in Budapest. And there I was sitting, and my then-boyfriend — I didn ' t mean it was a boyfriend like it is meant today — but my boyfriend and I sat at the market and sold the pots. My mother thought that this was not very proper, so she sat with us to add propriety to this activity. However, after a while there was a new factory being built in Budapest, a pottery factory, a large one. And I visited it with several ladies, and asked all sorts of questions of the director. Then the director asked me, why do you ask all these questions? I said, I also have a pottery. So he asked me, could he please visit me, and then finally he did, and explained to me that what I did now in my shop was an anachronism, that the industrial revolution had broken out, and that I rather should join the factory. There he made an art department for me where I worked for several months. However, everybody in the factory spent his time at the art department. The director there said there were several women casting and producing my designs now in molds, and this was sold also to America. I remember that it was quite successful. However, the director, the chemist, model maker — everybody — concerned himself much more with the art department — that means, with my work — than making toilets, so finally they got a letter from the center, from the bank who owned the factory, saying, make toilet-setting behind the art department, and that was my end. So this gave me the possibility because now I was a journeyman, and journeymen also take their satchel and go to see the world. So as a journeyman, I put an ad into the paper that I had studied, that I was a down-to-earth potter ’ s journeyman and I was looking for a job as a journeyman. And I got several answers, and I accepted the one which was farthest from home and practically, I thought, halfway to America. And that was in Hamburg. Then I first took this job in Hamburg, at an art pottery where everything was done on the wheel, and so I worked in a shop where there were several potters. And the first day, I was coming to take my place at the turntable — there were three or four turntables — and one of them, behind where I was sitting, was a hunchback, a deaf-mute hunchback, who smelled very bad. So I doused him in cologne every day, which he thought was very nice, and therefore he brought bread and butter every day, which I had to eat out of courtesy. The first day I came to work in this shop there was on my wheel a surprise for me. My colleagues had thoughtfully put on the wheel where I was supposed to work a very nicely modeled natural man ’ s organs. After I brushed them off with a hand motion, they were very — I finally was now accepted, and worked there for some six months. This was my first job. If I go on like this, you will be here till midnight. So I will try speed it up a little Moderator : Eva, we have about five minutes. Eva Zeisel : Are you sure? Moderator : Yes, I am sure. EZ : Well, if you are sure, I have to tell you that within five minutes I will talk very fast. And actually, my work took me to many countries because I used my work to fill my curiosity. And among other things, other countries I worked, was in the Soviet Union, where I worked from ’ 32 to ’ 37 — actually, to ’ 36. I was finally there, although I had nothing to do — I was a foreign expert. I became art director of the china and glass industry, and eventually under Stalin ’ s purges — at the beginning of Stalin ’ s purges, I didn ’ t know that hundreds of thousands of innocent people were arrested. So I was arrested quite early in Stalin ’ s purges, and spent 16 months in a Russian prison. The accusation was that I had successfully prepared an Attentat on Stalin ’ s life. This was a very dangerous accusation. And if this is the end of my five minutes, I want to tell you that I actually did survive, which was a surprise. But since I survived and I ’ m here, and since this is the end of the five minutes, I will — Moderator : Tell me when your last trip to Russia was. Weren ’ t you there recently? EZ : Oh, this summer, in fact, the Lomonosov factory was bought by an American company, invited me. They found out that I had worked in ’ 33 at this factory, and they came to my studio in Rockland County, and brought the 15 of their artists to visit me here. And they invited myself to come to the Russian factory last summer, in July, to make some dishes, design some dishes. And since I don ’ t like to travel alone, they also invited my daughter, son-in-law and granddaughter, so we had a lovely trip to see Russia today, which is not a very pleasant and happy view. Here I am now, if this is the end? Thank you.

Text Sample 714: POS Dim 5 – 2001 – Score 2.00 – 2001/t000367.txt

I ’ d like to do pretty much what I did the first time, which is to choose a lighthearted theme. Last time, I talked about death and dying. This time, I ’ m going to talk about mental illness. But it has to be technological, so I ’ ll talk about electroshock therapy. You know, ever since man had any notion that some of his other people, his colleagues, could be different, could be strange, could be severely depressed or what we now recognize as schizophrenia, he was certain that this kind of illness had to come from evil spirits getting into the body. So, the way of treating these diseases in early times was to, in some way or other, exorcise those evil spirits, and this is still going on, as you know. But it wasn ’ t enough to use the priests. When medicine became somewhat scientific, in about 450 BC, with Hippocrates and those boys, they tried to look for herbs, plants that would literally shake the bad spirits out. So, they found certain plants that could cause convulsions. And the herbals, the botanical books of up to the late Middle Ages, the Renaissance are filled with prescriptions for causing convulsions to shake the evil spirits out. Finally, in about the sixteenth century, a physician whose name was Theophrastus Bombastus Aureolus von Hohenheim, called Paracelsus, a name probably familiar to some people here — — good, old Paracelsus found that he could predict the degree of convulsion by using a measured amount of camphor to produce the convulsion. Can you imagine going to your closet, pulling out a mothball, and chewing on it if you ’ re feeling depressed? It ’ s better than Prozac, but I wouldn ’ t recommend it. So what we see in the seventeenth, eighteenth century is the continued search for medications other than camphor that ’ ll do the trick. Well, along comes Benjamin Franklin, and he comes close to convulsing himself with a bolt of electricity off the end of his kite. And so people begin thinking in terms of electricity to produce convulsions. And then, we fast-forward to about 1932, when three Italian psychiatrists, who were largely treating depression, began to notice among their patients, who were also epileptics, that if they had an epileptic — a series of epileptic fits, a lot of them in a row — the depression would very frequently lift. Not only would it lift, but it might never return. So they got very interested in producing convulsions, measured types of convulsions. And they thought,"Well, we ’ ve got electricity, we ’ ll plug somebody into the wall. That always makes hair stand up and people shake a lot."So, they tried it on a few pigs, and none of the pigs were killed. So, they went to the police and they said,"We know that at the Rome **railroad** station, there are all these lost souls wandering around, muttering gibberish. Can you bring one of them to us?"Someone who is, as the Italians say,"cagoots."So they found this"cagoots"guy, a 39-year-old man who was really hopelessly schizophrenic, who was known, had been known for months, to be literally defecating on himself, talking nothing that made any sense, and they brought him into the hospital. So these three psychiatrists, after about two or three weeks of observation, laid him down on a table, connected his temples to a very small source of current. They thought,"Well, we ’ ll try 55 volts, two-tenths of a second. That ’ s not going to do anything terrible to him."So they did that. Well, I have the following from a firsthand observer, who told me this about 35 years ago, when I was thinking about these things for some research project of mine. He said,"This fellow"— remember, he wasn ’ t even put to sleep —"after this major grand mal convulsion, sat right up, looked at these three fellas and said, ’ What the fuck are you assholes trying to do? ’"If I could only say that in Italian. Well, they were happy as could be, because he hadn ’ t said a rational word in the weeks of observation. So they plugged him in again, and this time they used 110 volts for half a second. And to their amazement, after it was over, he began speaking like he was perfectly well. He relapsed a little bit, they gave him a series of treatments, and he was essentially cured. But of course, having schizophrenia, within a few months, it returned. But they wrote a paper about this, and everybody in the Western world began using electricity to convulse people who were either schizophrenic or severely depressed. It didn ’ t work very well on the schizophrenics, but it was pretty clear in the ’ 30s and by the middle of the ’ 40s that electroconvulsive therapy was very, very effective in the treatment of depression. And of course, in those days, there were no antidepressant drugs, and it became very, very popular. They would anesthetize people, convulse them, but the real difficulty was that there was no way to paralyze muscles. So people would have a real grand mal seizure. Bones were broken. Especially in old, fragile people, you couldn ’ t use it. And then in the 1950s, late 1950s, the so-called muscle relaxants were developed by pharmacologists, and it got so that you could induce a complete convulsion, an electroencephalographic convulsion — you could see it on the brain waves — without causing any convulsion in the body except a little bit of twitching of the toes. So again, it was very, very popular and very, very useful. Well, you know, in the middle ’ 60s, the first antidepressants came out. Tofranil was the first. In the late ’ 70s, early ’ 80s, there were others, and they were very effective. And patients ’ rights groups seemed to get very upset about the kinds of things that they would witness. And so the whole idea of electroconvulsive, electroshock therapy disappeared, but has had a renaissance in the last 10 years. And the reason that it has had a renaissance is that probably about 10 percent of the people, severe depressives, do not respond, regardless of what is done for them. Now, why am I telling you this story at this meeting? I ’ m telling you this story, because actually ever since Richard called me and asked me to talk about — as he asked all of his speakers — to talk about something that would be new to this audience, that we had never talked about, never written about, I ’ ve been planning this moment. This reason really is that I am a man who, almost 30 years ago, had his life saved by two long courses of electroshock therapy. And let me tell you this story. I was, in the 1960s, in a marriage. To use the word bad would be perhaps the understatement of the year. It was dreadful. There are, I ’ m sure, enough divorced people in this room to know about the hostility, the anger, who knows what. Being someone who had had a very difficult childhood, a very difficult adolescence — it had to do with not quite poverty but close. It had to do with being brought up in a family where no one spoke English, no one could read or write English. It had to do with death and disease and lots of other things. I was a little prone to depression. So, as things got worse, as we really began to hate each other, I became progressively depressed over a period of a couple of years, trying to save this marriage, which was inevitably not to be saved. Finally, I would schedule — all my major surgical cases, I was scheduling them for 12, one o ’ clock in the afternoon, because I couldn ’ t get out of bed before about 11 o ’ clock. And anybody who ’ s been depressed here knows what that ’ s like. I couldn ’ t even pull the covers off myself. Well, you ’ re in a university medical center, where everybody knows everybody, and it ’ s perfectly clear to my colleagues, so my referrals began to decrease. As my referrals began to decrease, I clearly became increasingly depressed until I thought, my God, I can ’ t work anymore. And, in fact, it didn ’ t make any difference because I didn ’ t have any patients anymore. So, with the advice of my physician, I had myself admitted to the acute care psychiatric unit of our university hospital. And my colleagues, who had known me since medical school in that place, said,”Don ’ t worry, chap. Six weeks, you ’ re back in the operating room. Everything ’ s going to be great.”Well, you know what bovine stercus is? That proved to be a lot of bovine stercus. I know some people who got tenure in that place with lies like that. So I was one of their failures. But it wasn ’ t that simple. Because by the time I got out of that unit, I was not functional at all. I could hardly see five **feet** in front of myself. I shuffled when I walked. I was bowed over. I rarely bathed. I sometimes didn ’ t shave. It was dreadful. And it was clear — not to me, because nothing was clear to me at that time anymore — that I would need long-term hospitalization in that awful place called a mental hospital. So I was admitted, in 1973, in the spring of 1973, to the Institute of Living, which used to be called the Hartford Retreat. It was founded in the eighteenth century, the largest psychiatric hospital in the state of Connecticut, other than the huge public hospitals that existed at that time. And they tried everything they had.

They tried the usual psychotherapy. They tried every medication available in those days. And they did have Tofranil and other things — Mellaril, who knows what. Nothing happened except that I got jaundiced from one of these things. And finally, because I was well known in Connecticut, they decided they better have a meeting of the senior staff. All the senior staff got together, and I later found out what happened. They put all their heads together and they decided that there was nothing that could be done for this surgeon who had essentially separated himself from the world, who by that time had become so overwhelmed, not just with depression and feelings of worthlessness and inadequacy, but with obsessional thinking, obsessional thinking about coincidences. And there were particular numbers that every time I saw them, just got me dreadfully upset — all kinds of ritualistic observances, just awful, awful stuff. Remember when you were a kid, and you had to step on every line? Well, I was a grown man who had all of these rituals, and it got so there was a throbbing, there was a ferocious fear in my head. You ' ve seen this painting by Edvard Munch, The Scream. Every moment was a scream. It was impossible. So they decided there was no therapy, there was no treatment. But there was one treatment, which actually had been pioneered at the Hartford hospital in the early 1940s, and you can imagine what it was. It was pre-frontal lobotomy. So they decided — I didn ' t know this, again, I found this out later — that the only thing that could be done was for this 43-year-old man to have a pre-frontal lobotomy. Well, as in all hospitals, there was a resident assigned to my case. He was 27 years old, and he would meet with me two or three times a week. And of course, I had been there, what, three or four months at the time. And he asked to meet with the senior staff, and they agreed to meet with him because he was very well thought of in that place. They thought he had a really extraordinary future. And he dug in his heels and said,"No. I know this man better than any of you. I have met with him over and over again. You ' ve just seen him from time to time. You ' ve read reports and so forth. I really honestly believe that the basic problem here is pure depression, and all of the obsessional thinking comes out of it. And you know, of course, what ' ll happen if you do a pre- frontal lobotomy. Any of the results along the spectrum, from pretty bad to terrible, terrible, terrible is going to happen. If he does the best he can, he will have no further obsessions, probably no depression, but his affect will be dulled, he will never go back to surgery, he will never be the loving father that he was to his two children, his life will be changed. If he has the usual result, he will end up like ' One Flew Over the Cuckoo ' s Nest. ' And you know about that, just essentially in a stupor the rest of his life."Well, he said,"Can ' t we try a course of electroshock therapy?"And you know why they agreed? They agreed to humor him. They just thought,"Well, we ' ll give a course of 10. And so we ' ll lose a little time. Big deal. It doesn ' t make any difference."So they gave the course of 10, and the first — the usual course, incidentally, was six to eight and still is six to eight. Plugged me into the wires, put me to sleep, gave me the muscle relaxant. Six didn ' t work. Seven didn ' t work. Eight didn ' t work. At nine, I noticed — and it ' s wonderful that I could notice anything — I noticed a change. And at 10, I noticed a real change. And he went back to them, and they agreed to do another 10. Again, not a single one of them — I think there are about seven or eight of them — thought this would do any good. They thought this was a temporary change. But, lo and behold, by 16, by 17, there were demonstrable differences in the way I felt. By 18 and 19, I was sleeping through the night. And by 20, I had the sense, I really had the sense that I could overcome this, that I was now strong enough that by an act of will, I could blow the obsessional thinking away. I could blow the depression away. And I ' ve never forgotten — I never will forget — standing in the kitchen of the unit, it was a Sunday morning in January of 1974, standing in the kitchen by myself and thinking,"I ' ve got the strength now to do this."It was as though those tightly coiled wires in my head had been disconnected and I could think clearly. But I need a formula. I need some thing to say to myself when I begin thinking obsessionally, obsessively. Well, the Gilbert and Sullivan fans in this room will remember"Ruddigore,"and they will remember Mad Margaret, and they will remember that she was married to a fellow named Sir Despard Murgatroyd. And she used to go nuts, every five minutes or so in the play, and he said to her,"We must have a word to bring you back to reality, and the word, my dear, will be ' Basingstoke. '"So every time she got a little nuts, he would say,"Basingstoke!"And she would say,"Basingstoke, it is."And she would be fine for a little while. Well, you know, I ' m from the Bronx. I can ' t say"Basingstoke."But I had something better. And it was very simple. It was,"Ah, fuck it!"Much better than"Basingstoke,"at least for me. And it worked — my God, it worked. Every time I would begin thinking obsessionally — again, once more, after 20 shock treatments — I would say,"Ah, fuck it."And things got better and better, and within three or four months, I was discharged from that hospital, and I joined a group of surgeons where I could work with other people in the community, not in New Haven, but fairly close by. I stayed there for three years. At the end of three years, I went back to New Haven, had remarried by that time. I brought my wife with me, actually, to make sure I could get through this. My children came back to live with us. We had two more children after that. Resuscitated the career, even better than it had been before. Went right back into the university and began to write books. Well, you know, it ' s been a wonderful life. It ' s been, as I said, close to 30 years. I stopped doing surgery about six years ago and became a full-time writer, as many people know. But it ' s been very exciting. It ' s been very happy. Every once in a while, I have to say,"Ah, fuck it."Every once in a while, I get somewhat depressed and a little obsessional. So, I ' m not free of all of this. But it ' s worked. It ' s always worked. Why have I chosen, after never, ever talking about this, to talk about it now? Well, those of you who know some of these books know that one is about death and dying, one is about the human body and the human spirit, one is about the way mystical thoughts are constantly in our minds, and they have always to do with my own personal experiences. One might think reading these books — and I ' ve gotten thousands of letters about them by people who do think this — that based on my life ' s history as I ' ve portrayed in the books, my early life ' s history, I am someone who has overcome adversity. That I am someone who has drunk, drank, drunk of the bitter dregs of near-disaster in childhood and emerged not just unscathed but strengthened. I really have it figured out, so that I can advise people about death and dying, so that I can talk about mysticism and the human spirit. And I ' ve always felt guilty about that. I ' ve always felt that somehow I was an impostor because my readers don ' t know what I have just told you. It ' s known by some people in New Haven, obviously, but it is not generally known. So one of the reasons that I have come here to talk about this today is to — frankly, selfishly — unburden myself and let it be known that this is not an untroubled mind that has written all of these books. But more importantly, I think, is the fact that a very significant proportion of people in this audience are under 30, and there are many, of course, who are well over 30. For people under 30, and it looks to me like almost all of you — I would say all of you — are either on the cusp of a magnificent and exciting career or right into a magnificent and exciting career : anything can happen to you. Things change. Accidents happen. Something from childhood comes back to haunt you. You can be thrown off the track. I hope it happens to none of you, but it will probably happen to a small percentage of you. To those to whom it doesn ’ t happen, there will be adversities. If I, with the bleakness of spirit, with no spirit, that I had in the 1970s and no possibility of recovery, as far as that group of very experienced psychiatrists thought, if I can find my way back from this, believe me, anybody can find their way back from any adversity that exists in their lives. And for those who are older, who have lived through perhaps not something as bad as this, but who have lived through difficult times, perhaps where they lost everything, as I did, and started out all over again, some of these things will seem very familiar. There is recovery. There is redemption. And there is resurrection. There are resurrection themes in every society that has ever been studied, and it is because not just only do we fantasize about the possibility of resurrection and recovery, but it actually happens. And it happens a lot. Perhaps the most popular resurrection theme, outside of specifically religious ones, is the one about the phoenix, the ancient story of the phoenix, who, every 500 years, resurrects itself from its own ashes to go on to live a life that is even more beautiful than it was before. Richard, thanks very much.

I coined my own definition of success in 1934, when I was teaching at a high school in South Bend, Indiana, being a little bit disappointed, and [disillusioned] perhaps, by the way parents of the youngsters in my English classes expected their youngsters to get an A or a B. They thought a C was all right for the neighbors ’ children, because they were all average. But they weren ’ t satisfied when their own — it would make the teacher feel that they had failed, or the youngster had failed. And that ’ s not right. The good Lord in his infinite wisdom didn ’ t create us all equal as far as intelligence is concerned, any more than we ’ re equal for size, appearance. Not everybody could earn an A or a B, and I didn ’ t like that way of judging, and I did know how the alumni of various schools back in the ’ 30s judged coaches and athletic teams. If you won them all, you were considered to be reasonably successful — not completely. Because I found out — we had a number of years at UCLA where we didn ’ t lose a game. But it seemed that we didn ’ t win each individual game by the margin that some of our alumni had predicted — And quite frequently I really felt that they had backed up their predictions in a more materialistic manner. But that was true back in the 30s, so I understood that. But I didn ’ t like it, I didn ’ t agree with it. I wanted to come up with something I hoped could make me a better teacher, and give the youngsters under my supervision, be it in athletics or the English classroom, something to which to aspire, other than just a higher mark in the classroom, or more points in some athletic contest. I thought about that for quite a spell, and I wanted to come up with my own definition. I thought that might help. And I knew how Mr. Webster defined it, as the accumulation of material possessions or the attainment of a position of power or prestige, or something of that sort, worthy accomplishments perhaps, but in my opinion, not necessarily indicative of success. So I wanted to come up with something of my own. And I recalled — I was raised on a small farm in Southern Indiana, and Dad tried to teach me and my brothers that you should never try to be better than someone else. I ’ m sure at the time he did that, I didn ’ t — it didn ’ t — well, somewhere, I guess in the hidden recesses of the mind, it popped out years later. Never try to be better than someone else, always learn from others. Never cease trying to be the best you can be — that ’ s under your control. If you get too engrossed and involved and concerned in regard to the things over which you have no control, it will adversely affect the things over which you have control. Then I ran across this simple verse that said,”At God ’ s footstool to confess, a poor soul knelt, and bowed his head. ’ I failed! ’ he cried. The Master said, ’ Thou didst thy best, that is success. ’”From those things, and one other perhaps, I coined my own definition of success, which is : Peace of mind attained only through self-satisfaction in knowing you made the effort to do the best of which you ’ re capable. I believe that ’ s true. If you make the effort to do the best of which you ’ re capable, trying to improve the situation that exists for you, I think that ’ s success, and I don ’ t think others can judge that ; it ’ s like character and reputation — your reputation is what you ’ re perceived to be ; your character is what you really are. And I think that character is much more important than what you are perceived to be. You ’ d hope they ’ d both be good, but they won ’ t necessarily be the same. Well, that was my idea that I was going to try to get across to the youngsters. I ran across other things. I love to teach, and it was mentioned by the previous speaker that I enjoy poetry, and I dabble in it a bit, and love it. There are some things that helped me, I think, be better than I would have been. I know I ’ m not what I ought to be, what I should be, but I think I ’ m better than I would have been if I hadn ’ t run across certain things. One was just a little verse that said,”No written word, no spoken plea can teach our youth what they should be ; nor all the books on all the shelves — it ’ s what the teachers are themselves.”That made an impression on me in the 1930s. And I tried to use that more or less in my teaching, whether it be in sports, or whether it be in the English classroom. I love poetry and always had an interest in that somehow. Maybe it ’ s because Dad used to read to us at night, by coal oil lamp — we didn ’ t have electricity in our farm home. And Dad would read poetry to us. So I always liked it. And about the same time I ran across this one verse, I ran across another one. Someone asked a lady teacher why she taught, and after some time, she said she wanted to think about that. Then she came up and said,”They ask me why I teach, and I reply, ’ Where could I find such splendid company? ’ There sits a statesman, strong, unbiased, wise ; another Daniel Webster, silver-tongued. A doctor sits beside him, whose quick, steady hand may mend a bone, or stem the life-blood ’ s flow. And there a builder ; upward rise the arch of a church he builds, wherein that minister may speak the word of God, and lead a stumbling soul to touch the Christ. And all about, a gathering of teachers, farmers, merchants, laborers — those who work and vote and build and plan and pray into a great tomorrow. And I may say, I may not see the church, or hear the word, or eat the food their hands may grow, but yet again I may ; And later I may say, I knew him once, and he was weak, or strong, or bold or proud or gay. I knew him once, but then he was a boy. They ask me why I teach and I reply, ’ Where could I find such splendid company? ’”And I believe the teaching profession — it ’ s true, you have so many youngsters, and I ’ ve got to think of my youngsters at UCLA — 30-some attorneys, 11 dentists and doctors, many, many teachers and other professions. And that gives you a great deal of pleasure, to see them go on. I always tried to make the youngsters feel that they ’ re there to get an education, number one ; basketball was second, because it was paying their way, and they do need a little time for social activities, but you let social activities take a little precedence over the other two, and you ’ re not going to have any very long. So that was the idea that I tried to get across to the youngsters under my supervision. I had three rules, pretty much, that I stuck with practically all the time. I ’ d learned these prior to coming to UCLA, and I decided they were very important. One was”Never be late.”Later on I said certain things — the players, if we were leaving for somewhere, had to be neat and **clean**. There was a time when I made them wear jackets and shirts and ties. Then I saw our chancellor coming to school in denims and turtlenecks, and thought, it ’ s not right for me to keep this other [rule] so I let them just — they had to be neat and **clean**. I had one of my greatest players that you probably heard of, Bill Walton. He came to catch the bus ; we were leaving for somewhere to play. And he wasn ’ t **clean** and neat, so I wouldn ’ t let him go. He couldn ’ t get on the bus, he had to go home and get **cleaned** up to get to the airport. So I was a stickler for that. I believed in that. I believe in time ; very important. I believe you should be on time, but I felt at practice, for example — we start on time, we close on time. The youngsters didn ’ t have to feel that we were going to keep them over. When I speak at coaching clinics, I often tell young coaches — and at coaching clinics, more or less, they ’ ll be the younger coaches getting in the profession. Most of them are young, you know, and probably newly-married. And I tell them,”Don ’ t run practices late, because you ’ ll go home in a bad mood, and that ’ s not good, for a young married man to go home in a bad mood. When you get older, it doesn ’ t make any difference, but —”So I did believe : on time. I believe starting on time, and I believe closing on time. And another one I had was, not one word of profanity. One word of profanity, and you are out of here for the day. If I see it in a game, you ’ re going to come out and sit on the bench. And the third one was, never criticize a teammate. I didn ’ t want that. I used to tell them I was paid to do that. That ’ s my job. I ’ m paid to do it. Pitifully poor, but I am paid to do it. Not like the coaches today, for gracious sakes, no. It ’ s a little different than it was in my day. Those were three things that I stuck with pretty closely all the time. And those actually came from my dad. That ’ s what he tried to teach me and my brothers at one time. I came up with a pyramid eventually, that I don ’ t have the time to go on that. But that helped me, I think, become a better teacher. It ’ s something like this : And I had blocks in the pyramid, and the cornerstones being industriousness and enthusiasm, working hard and enjoying what you ’ re doing, coming up to the apex, according to my definition of success. And right at the top, faith and patience. And I say to you, in whatever you ’ re doing, you must be patient. You have to have patience to — we want things to happen. We talk about our youth being impatient a lot, and they are. They want to change everything. They think all change is progress. And we get a little older — we sort of let things go. And we forget there is no progress without change. So you must have patience, and I believe that we must have faith. I believe that we must believe, truly believe. Not just give it word service, believe that things will work out as they should, providing we do what we should. I think our tendency is to hope things will turn out the way we want them to much of the time, but we don ’ t do the things that are necessary to make those things become reality. I worked on this for some 14 years, and I think it helped me become a better teacher. But it all revolved around that original definition of success. You know, a number of years ago, there was a Major League Baseball umpire by the name of George Moriarty. He spelled Moriarty with only one ’ i ’. I ’ d never seen that before, but he did. Big league baseball players — they ’ re very perceptive about those things, and they noticed he had only one ’ i ’ in his name. You ’ d be surprised how many also told him that that was one more than he had in his head at various times. But he wrote something where I think he did what I tried to do in this pyramid. He called it”The Road Ahead, or the Road Behind.”He said,”Sometimes I think the Fates must grin as we denounce them and insist the only reason we can ’ t win, is the Fates themselves have missed. Yet there lives on the ancient claim : we win or lose within ourselves. The shining trophies on our shelves can never win tomorrow ’ s game. You and I know deeper down, there ’ s always a chance to win the crown. But when we fail to give our best, we simply haven ’ t met the test, of giving all and saving none until the game is really won ; of showing what is meant by grit ; of playing through when others quit ; of playing through, not letting up. It ' s bearing down that wins the cup. Of dreaming there ' s a goal ahead ; of hoping when our dreams are dead ; of praying when our hopes have fled ; yet losing, not afraid to fall, if, bravely, we have given all. For who can ask more of a man than giving all within his span. Giving all, it seems to me, is not so far from victory. And so the Fates are seldom wrong, no matter how they twist and wind. It ' s you and I who make our fates — we open up or close the gates on the road ahead or the road behind."Reminds me of another set of threes that my dad tried to get across to us : Don ' t whine. Don ' t complain. Don ' t make excuses. Just get out there, and whatever you ' re doing, do it to the best of your ability. And no one can do more than that. I tried to get across, too, that — my opponents will tell you — you never heard me mention winning. Never mention winning. My idea is that you can lose when you outscore somebody in a game, and you can win when you ' re outscored. I ' ve felt that way on certain occasions, at various times. And I just wanted them to be able to hold their head up after a game. I used to say that when a game is over, and you see somebody that didn ' t know the outcome, I hope they couldn ' t tell by your actions whether you outscored an opponent or the opponent outscored you. That ' s what really matters : if you make an effort to do the best you can regularly, the results will be about what they should be. Not necessarily what you ' d want them to be but they ' ll be about what they should ; only you will know whether you can do that. And that ' s what I wanted from them more than anything else. And as time went by, and I learned more about other things, I think it worked a little better, as far as the results. But I wanted the score of a game to be the byproduct of these other things, and not the end itself. I believe it was one great philosopher who said — no, no — Cervantes. Cervantes said,"The journey is better than the end."And I like that. I think that it is — it ' s getting there. Sometimes when you get there, there ' s almost a let down. But it ' s the getting there that ' s the **fun**. As a basketball coach at UCLA, I liked our practices to be the journey, and the game would be the end, the end result. I liked to go up and sit in the stands and watch the players play, and see whether I ' d done a decent job during the week. There again, it ' s getting the players to get that self-satisfaction, in knowing that they ' d made the effort to do the best of which they are capable. Sometimes I ' m asked who was the best player I had, or the best teams. I can never answer that. As far as the individuals are concerned — I was asked one time about that, and they said,"Suppose that you, in some way, could make the perfect player. What would you want?"And I said,"Well, I ' d want one that knew why he was at UCLA : to get an education, he was a good student, really knew why he was there in the first place. But I ' d want one that could play, too. I ' d want one to realize that defense usually wins championships, and who would work hard on defense. But I ' d want one who would play offense, too. I ' d want him to be unselfish, and look for the pass first and not shoot all the time. And I ' d want one that could pass and would pass. I ' ve had some that could and wouldn ' t, and I ' ve had some that would and could. So, yeah, I ' d want that. And I wanted them to be able to shoot from the outside. I wanted them to be good inside too. I ' d want them to be able to rebound well at both ends, too. Why not just take someone like Keith Wilkes and let it go at that. He had the qualifications. Not the only one, but he was one that I used in that particular category, because I think he made the effort to become the best. There was a couple. I mention in my book,"They Call Me Coach,"two players that gave me great satisfaction, that came as close as I think anyone I ever had to reach their full potential : one was Conrad Burke, and one was Doug McIntosh. When I saw them as freshmen, on our freshmen team — freshmen couldn ' t play varsity when I taught. I thought,"Oh gracious, if these two players, either one of them"—

they were different years, but I thought about each one at the time he was there —"Oh, if he ever makes the varsity, our varsity must be pretty miserable, if he ' s good enough to make it."And you know, one of them was a starting player for a season and a half. The other one, his next year, played 32 minutes in a national championship game, Did a tremendous job for us. The next year, he was a starting player on the national championship team, and here I thought he ' d never play a minute, when he was — so those are the things that give you great joy, and great satisfaction to see. Neither one of those youngsters could shoot very well. But they had outstanding shooting percentages, because they didn ' t force it. And neither one could jump very well, but they kept good position, and so they did well rebounding. They remembered that every shot that ' s taken, they assumed would be missed. I ' ve had too many stand around and wait to see if it ' s missed, then they go and it ' s too late, somebody else is in there ahead of them. They weren ' t very quick, but they played good position, kept in good balance. And so they played pretty good defense for us. So they had qualities that — they came close to — as close to reaching possibly their full potential as any players I ever had. So I consider them to be as successful as Lewis Alcindor or Bill Walton, or many of the others that we had ; there were some outstanding players. Have I rambled enough? I was told that when he makes his appearance, I was supposed to shut up.

I ' d like to take you on the epic quest of the Rosetta spacecraft. To escort and land the probe on a comet, this has been my passion for the past two years. In order to do that, I need to explain to you something about the origin of the solar system. When we go back four and a half billion years, there was a cloud of **gas** and dust. In the center of this cloud, our sun formed and ignited. Along with that, what we now know as planets, comets and asteroids formed. What then happened, according to theory, is that when the Earth had cooled down a bit after its formation, comets massively impacted the Earth and delivered water to Earth. They probably also delivered complex organic material to Earth, and that may have bootstrapped the emergence of life. You can compare this to having to solve a 250-piece puzzle and not a 2, 000-piece puzzle. Afterwards, the big planets like Jupiter and Saturn, they were not in their place where they are now, and they interacted gravitationally, and they swept the whole interior of the solar system **clean**, and what we now know as comets ended up in something called the Kuiper Belt, which is a belt of objects beyond the orbit of Neptune. And sometimes these objects run into each other, and they gravitationally deflect, and then the gravity of Jupiter pulls them back into the solar system. And they then become the comets as we see them in the sky. The important thing here to note is that in the meantime, the four and a half billion years, these comets have been sitting on the outside of the solar system, and haven ' t changed — deep, frozen versions of our solar system. In the sky, they look like this. We know them for their tails. There are actually two tails. One is a dust tail, which is blown away by the solar wind. The other one is an ion tail, which is charged particles, and they follow the magnetic field in the solar system. There ' s the coma, and then there is the nucleus, which here is too small to see, and you have to remember that in the case of Rosetta, the spacecraft is in that center pixel. We are only 20, 30, 40 kilometers away from the comet. So what ' s important to remember? Comets contain the original material from which our solar system was formed, so they ' re **ideal** to study the components that were present at the time when Earth, and life, started. Comets are also suspected of having brought the elements which may have bootstrapped life. In 1983, ESA set up its long-term Horizon 2000 program, which contained one cornerstone, which would be a mission to a comet. In parallel, a small mission to a comet, what you see here, Giotto, was launched, and in 1986, flew by the comet of Halley with an armada of other spacecraft. From the results of that mission, it became immediately clear that comets were **ideal** bodies to study to understand our solar system. And thus, the Rosetta mission was approved in 1993, and originally it was supposed to be launched in 2003, but a problem arose with an Ariane rocket. However, our P. R. department, in its enthusiasm, had already made 1, 000 Delft Blue plates with the name of the wrong comets. So I ’ ve never had to buy any china since. That ’ s the positive part. Once the whole problem was solved, we left Earth in 2004 to the newly selected comet, Churyumov-Gerasimenko. This comet had to be specially selected because A, you have to be able to get to it, and B, it shouldn ’ t have been in the solar system too long. This particular comet has been in the solar system since 1959. That ’ s the first time when it was deflected by Jupiter, and it got close enough to the sun to start changing. So it ’ s a very fresh comet. Rosetta made a few historic firsts. It ’ s the first satellite to orbit a comet, and to escort it throughout its whole tour through the solar system — closest approach to the sun, as we will see in August, and then away again to the exterior. It ’ s the first ever landing on a comet. We actually orbit the comet using something which is not normally done with spacecraft. Normally, you look at the sky and you know where you point and where you are. In this case, that ’ s not enough. We navigated by looking at landmarks on the comet. We recognized features — boulders, craters — and that ’ s how we know where we are respective to the comet. And, of course, it ’ s the first satellite to go beyond the orbit of Jupiter on solar cells. Now, this sounds more heroic than it actually is, because the technology to use radio isotope thermal generators wasn ’ t available in Europe at that time, so there was no choice. But these solar arrays are big. This is one wing, and these are not specially selected small people. They ’ re just like you and me. We have two of these wings, 65 square meters. Now later on, of course, when we got to the comet, you find out that 65 square meters of sail close to a body which is outgassing is not always a very handy choice. Now, how did we get to the comet? Because we had to go there for the Rosetta scientific objectives very far away — four times the distance of the Earth to the sun — and also at a much higher velocity than we could achieve with fuel, because we ’ d have to take six times as much fuel as the whole spacecraft weighed. So what do you do? You use gravitational flybys, slingshots, where you pass by a planet at very low altitude, a few thousand kilometers, and then you get the velocity of that planet around the sun for free. We did that a few times. We did Earth, we did Mars, we did twice Earth again, and we also flew by two asteroids, Lutetia and Steins. Then in 2011, we got so far from the sun that if the spacecraft got into trouble, we couldn ’ t actually save the spacecraft anymore, so we went into hibernation. Everything was switched off except for one clock. Here you see in white the trajectory, and the way this works. You see that from the circle where we started, the white line, actually you get more and more and more elliptical, and then finally we approached the comet in May 2014, and we had to start doing the rendezvous maneuvers. On the way there, we flew by Earth and we took a few **pictures** to test our cameras. This is the moon rising over Earth, and this is what we now call a selfie, which at that time, by the way, that word didn ’ t exist. It ’ s at Mars. It was taken by the CIVA camera. That ’ s one of the cameras on the lander, and it just looks under the solar arrays, and you see the planet Mars and the solar array in the distance. Now, when we got out of hibernation in January 2014, we started arriving at a distance of two million kilometers from the comet in May. However, the velocity the spacecraft had was much too fast. We were going 2, 800 kilometers an hour faster than the comet, so we had to brake. We had to do eight maneuvers, and you see here, some of them were really big. We had to brake the first one by a few hundred kilometers per hour, and actually, the duration of that was seven hours, and it used 218 kilos of fuel, and those were seven nerve-wracking hours, because in 2007, there was a leak in the system of the propulsion of Rosetta, and we had to close off a branch, so the system was actually operating at a pressure which it was never designed or qualified for. Then we got in the vicinity of the comet, and these were the first **pictures** we saw. The true comet rotation period is 12 and a half hours, so this is accelerated, but you will understand that our flight dynamics engineers thought, this is not going to be an easy thing to land on. We had hoped for some kind of spud-like thing where you could easily land. But we had one hope : maybe it was smooth. No. That didn ’ t work either. So at that point in time, it was clearly unavoidable : we had to map this body in all the detail you could get, because we had to find an area which is 500 meters in diameter and flat. Why 500 meters? That ’ s the error we have on landing the probe. So we went through this process, and we mapped the comet. We used a technique called photoclinometry. You use shadows thrown by the sun. What you see here is a rock sitting on the surface of the comet, and the sun shines from above. From the shadow, we, with our brain, can immediately determine roughly what the shape of that rock is. You can program that in a computer, you then cover the whole comet, and you can map the comet. For that, we flew special trajectories starting in August. First, a triangle of 100 kilometers on a side at 100 kilometers ’ distance, and we repeated the whole thing at 50 kilometers. At that time, we had seen the comet at all kinds of angles, and we could use this technique to map the whole thing. Now, this led to a selection of landing sites. This whole process we had to do, to go from the mapping of the comet to actually finding the final landing site, was 60 days. We didn ’ t have more. To give you an idea, the average Mars mission takes hundreds of scientists for years to meet about where shall we go? We had 60 days, and that was it. We finally selected the final landing site and the commands were prepared for Rosetta to launch Philae. The way this works is that Rosetta has to be at the right point in space, and aiming towards the comet, because the lander is passive. The lander is then pushed out and moves towards the comet. Rosetta had to turn around to get its cameras to actually look at Philae while it was departing and to be able to communicate with it. Now, the landing duration of the whole trajectory was seven hours. Now do a simple calculation : if the velocity of Rosetta is off by one centimeter per second, seven hours is 25, 000 seconds. That means 252 meters wrong on the comet. So we had to know the velocity of Rosetta much better than one centimeter per second, and its location in space better than 100 meters at 500 million kilometers from Earth. That ’ s no mean feat. Let me quickly take you through some of the science and the instruments. I won ’ t bore you with all the details of all the instruments, but it ’ s got everything. We can sniff **gas**, we can measure dust particles, the shape of them, the composition, there are magnetometers, everything. This is one of the results from an instrument which measures **gas** density at the position of Rosetta, so it ’ s **gas** which has left the comet. The **bottom** graph is September of last year. There is a long-term variation, which in itself is not surprising, but you see the sharp peaks. This is a comet day. You can see the effect of the sun on the evaporation of **gas** and the fact that the comet is rotating. So there is one spot, apparently, where there is a lot of stuff coming from, it gets heated in the Sun, and then cools down on the back side. And we can see the density variations of this. These are the **gases** and the organic compounds that we already have measured. You will see it ’ s an impressive list, and there is much, much, much more to come, because there are more measurements. Actually, there is a conference going on in Houston at the moment where many of these results are presented. Also, we measured dust particles. Now, for you, this will not look very impressive, but the scientists were thrilled when they saw this. Two dust particles : the right one they call Boris, and they shot it with tantalum in order to be able to analyze it. Now, we found sodium and magnesium. What this tells you is this is the concentration of these two materials at the time the solar system was formed, so we learned things about which materials were there when the planet was made. Of course, one of the important elements is the imaging. This is one of the cameras of Rosetta, the OSIRIS camera, and this actually was the cover of Science magazine on January 23 of this year. Nobody had expected this body to look like this. Boulders, rocks — if anything, it looks more like the Half Dome in Yosemite than anything else. We also saw things like this : dunes, and what look to be, on the righthand side, wind-blown shadows. Now we know these from Mars, but this comet doesn ’ t have an atmosphere, so it ’ s a bit difficult to create a wind-blown shadow. It may be local outgassing, stuff which goes up and comes back. We don ’ t know, so there is a lot to investigate. Here, you see the same image twice. On the **left-hand** side, you see in the middle a pit. On the right-hand side, if you carefully look, there are three jets coming out of the **bottom** of that pit. So this is the activity of the comet. Apparently, at the **bottom** of these pits is where the active regions are, and where the material evaporates into space. There is a very intriguing crack in the neck of the comet. You see it on the right-hand side. It ’ s a kilometer long, and it ’ s two and a half meters wide. Some people suggest that actually, when we get close to the sun, the comet may split in two, and then we ’ ll have to choose, which comet do we go for? The lander — again, lots of instruments, mostly comparable except for the things which hammer in the ground and drill, etc. But much the same as Rosetta, and that is because you want to compare what you find in space with what you find on the comet. These are called ground truth measurements. These are the landing descent images that were taken by the OSIRIS camera. You see the lander getting further and further away from Rosetta. On the top right, you see an image taken at 60 meters by the lander, 60 meters above the surface of the comet. The boulder there is some 10 meters. So this is one of the last images we took before we landed on the comet. Here, you see the whole sequence again, but from a different perspective, and you see three blown-ups from the bottom-left to the middle of the lander traveling over the surface of the comet. Then, at the top, there is a before and an after image of the landing. The only problem with the after image is, there is no lander. But if you carefully look at the right-hand side of this image, we saw the lander still there, but it had bounced. It had departed again. Now, on a bit of a comical note here is that originally Rosetta was designed to have a lander which would bounce. That was discarded because it was way too expensive. Now, we forgot, but the lander knew. During the first bounce, in the magnetometers, you see here the data from them, from the three axes, x, y and z. Halfway through, you see a red line. At that red line, there is a change. What happened, apparently, is during the first bounce, somewhere, we hit the edge of a crater with one of the legs of the lander, and the rotation velocity of the lander changed. So we ’ ve been rather lucky that we are where we are. This is one of the iconic images of Rosetta. It ’ s a man-made object, a leg of the lander, standing on a comet. This, for me, is one of the very best images of space science I have ever seen. One of the things we still have to do is to actually find the lander. The blue area here is where we know it must be. We haven ’ t been able to find it yet, but the search is continuing, as are our efforts to start getting the lander to work again. We listen every day, and we hope that between now and somewhere in April, the lander will wake up again. The findings of what we found on the comet : This thing would float in water. It ’ s half the density of water. So it looks like a very big rock, but it ’ s not. The activity increase we saw in June, July, August last year was a four-fold activity increase. By the time we will be at the sun, there will be 100 kilos a second leaving this comet : **gas**, dust, whatever. That ’ s 100 million kilos a day. Then, finally, the landing day. I will never forget — absolute madness, 250 TV crews in Germany. The BBC was interviewing me, and another TV crew who was following me all day were **filming** me being interviewed, and it went on like that for the whole day. The Discovery Channel crew actually caught me when leaving the control room, and they asked the right question, and man, I got into tears, and I still feel this. For a month and a half, I couldn ’ t think about landing day without crying, and I still have the emotion in me. With this image of the comet, I would like to leave you. Thank you.

So I ’ ve had the great privilege of traveling to some incredible places, photographing these distant landscapes and remote cultures all over the world. I love my job. But people think it ’ s this string of epiphanies and sunrises and rainbows, when in reality, it looks more something like this. This is my office. We can ’ t afford the fanciest places to stay at night, so we tend to sleep a lot outdoors. As long as we can stay dry, that ’ s a bonus. We also can ’ t afford the fanciest restaurants. So we tend to eat whatever ’ s on the local menu. And if you ’ re in the Ecuadorian Pramo, you ’ re going to eat a large rodent called a cuy. But what makes our experiences perhaps a little bit different and a little more unique than that of the average person is that we have this gnawing thing in the back of our mind that even in our darkest moments, and those times of despair, we think,”Hey, there might be an image to be made here, there might be a story to be told.”And why is storytelling important? Well, it helps us to connect with our cultural and our natural heritage. And in the Southeast, there ’ s an alarming disconnect between the public and the natural areas that allow us to be here in the first place. We ’ re visual creatures, so we use what we see to teach us what we know. Now the majority of us aren ’ t going to willingly go way down to a swamp. So how can we still expect those same people to then advocate on behalf of their protection? We can ’ t. So my job, then, is to use photography as a communication tool, to help bridge the gap between the science and the aesthetics, to get people talking, to get them thinking, and to hopefully, ultimately, get them caring. I started doing this 15 years ago right here in Gainesville, right here in my backyard. And I fell in love with adventure and discovery, going to explore all these different places that were just minutes from my front doorstep. There are a lot of beautiful places to find. Despite all these years that have passed, I still see the world through the eyes of a child and I try to incorporate that sense of wonderment and that sense of curiosity into my photography as often as I can. And we ’ re pretty lucky because here in the South, we ’ re still blessed with a relatively blank canvas that we can fill with the most fanciful adventures and incredible experiences. It ’ s just a matter of how far our imagination will take us. See, a lot of people look at this and they say,”Oh yeah, wow, that ’ s a pretty tree.”But I don ’ t just see a tree — I look at this and I see opportunity. I see an entire weekend. Because when I was a kid, these were the types of images that got me off the sofa and dared me to explore, dared me to go find the woods and put my head underwater and see what we have. And folks, I ’ ve been photographing all over the world and I promise you, what we have here in the South, what we have in the Sunshine State, rivals anything else that I ’ ve seen. But yet our tourism industry is busy promoting all the wrong things. Before most kids are 12, they ’ ll have been to Disney World more times than they ’ ve been in a canoe or camping under a starry sky. And I have nothing against Disney or Mickey ; I used to go there, too. But they ’ re missing out on those fundamental connections that create a real sense of pride and ownership for the place that they call home. And this is compounded by the issue that the landscapes that define our natural heritage and fuel our aquifer for our drinking water have been deemed as scary and dangerous and spooky. When our ancestors first came here, they warned,”Stay out of these areas, they ’ re haunted. They ’ re full of evil spirits and ghosts.”I don ’ t know where they came up with that idea. But it ’ s actually led to a very real disconnect, a very real negative mentality that has kept the public disinterested, silent, and ultimately, our environment at risk. We ’ re a state that ’ s surrounded and defined by water, and yet for centuries, swamps and wetlands have been regarded as these obstacles to overcome. And so we ’ ve treated them as these second-class ecosystems, because they have very little monetary value and of course, they ’ re known to harbor alligators and snakes — which, I ’ ll admit, these aren ’ t the most cuddly of ambassadors. So it became assumed, then, that the only good swamp was a drained swamp. And in fact, draining a swamp to make way for agriculture and development was considered the very essence of conservation not too long ago. But now we ’ re backpedaling, because the more we come to learn about these sodden landscapes, the more secrets we ’ re starting to unlock about interspecies relationships and the connectivity of habitats, watersheds and flyways. Take this bird, for example : this is the prothonotary warbler. I love this bird because it ’ s a swamp bird, through and through, a swamp bird. They nest and they mate and they breed in these old-growth swamps in these flooded forests. And so after the spring, after they raise their young, they then fly thousand of miles over the Gulf of Mexico into Central and South America. And then after the winter, the spring rolls around and they come back. They fly thousands of miles over the Gulf of Mexico. And where do they go? Where do they land? Right back in the same tree. That ’ s nuts. This is a bird the size of a tennis ball — I mean, that ’ s crazy! I used a GPS to get here today, and this is my hometown. It ’ s crazy. So what happens, then, when this bird flies over the Gulf of Mexico into Central America for the winter and then the spring rolls around and it flies back, and it comes back to this : a freshly sodded golf course? This is a narrative that ’ s all too commonly unraveling here in this state. And this is a natural process that ’ s occurred for thousands of years and we ’ re just now learning about it. So you can imagine all else we have to learn about these landscapes if we just preserve them first. Now despite all this rich life that abounds in these swamps, they still have a bad name. Many people feel uncomfortable with the idea of wading into Florida ’ s blackwater. I can understand that. But what I loved about growing up in the Sunshine State is that for so many of us, we live with this latent but very palpable fear that when we put our toes into the water, there might be something much more ancient and much more adapted than we are. Knowing that you ’ re not top dog is a welcomed discomfort, I think. How often in this modern and urban and digital age do you actually get the chance to feel vulnerable, or consider that the world may not have been made for just us? So for the last decade, I began seeking out these areas where the concrete yields to forest and the pines turn to cypress, and I viewed all these mosquitoes and reptiles, all these discomforts, as affirmations that I ’ d found true wilderness, and I embrace them wholly. Now as a conservation photographer obsessed with blackwater, it ’ s only fitting that I ’ d eventually end up in the most famous swamp of all : the Everglades. Growing up here in North Central Florida, it always had these enchanted names, places like Loxahatchee and Fakahatchee, Corkscrew, Big Cypress. I started what turned into a five-year project to hopefully reintroduce the Everglades in a new light, in a more inspired light. But I knew this would be a tall order, because here you have an area that ’ s roughly a third the size the state of Florida, it ’ s huge. And when I say Everglades, most people are like,”Oh, yeah, the national **park**.”But the Everglades is not just a **park** ; it ’ s an entire watershed, starting with the Kissimmee chain of lakes in the north, and then as the rains would fall in the summer, these downpours would flow into Lake Okeechobee, and Lake Okeechobee would fill up and it would overflow its banks and spill southward, ever slowly, with the topography, and get into the river of grass, the Sawgrass Prairies, before meting into the cypress slews, until going further south into the mangrove swamps, and then finally — finally — reaching Florida Bay, the emerald gem of the Everglades, the great estuary, the 850 square-mile estuary. So sure, the national **park** is the southern end of this system, but all the things that make it unique are these inputs that come in, the fresh water that starts 100 miles north. So no manner of these political or invisible boundaries protect the **park** from polluted water or insufficient water. And unfortunately, that ’ s precisely what we ’ ve done. Over the last 60 years, we have drained, we have dammed, we have dredged the Everglades to where now only one third of the water that used to reach the bay now reaches the bay today. So this story is not all sunshine and rainbows, unfortunately. For better or for worse, the story of the Everglades is intrinsically tied to the peaks and the **valleys** of mankind ’ s relationship with the natural world. But I ’ ll show you these beautiful **pictures**, because it gets you on board. And while I have your attention, I can tell you the real story. It ’ s that we ’ re taking this, and we ’ re trading it for this, at an alarming rate. And what ’ s lost on so many people is the sheer scale of which we ’ re discussing. Because the Everglades is not just responsible for the drinking water for 7 million Floridians ; today it also provides the agricultural fields for the year-round tomatoes and oranges for over 300 million Americans. And it ’ s that same seasonal pulse of water in the summer that built the river of grass 6, 000 years ago. Ironically, today, it ’ s also responsible for the over half a million acres of the endless river of sugarcane. These are the same fields that are responsible for dumping exceedingly high levels of fertilizers into the watershed, forever changing the system. But in order for you to not just understand how this system works, but to also get personally connected to it, I decided to break the story down into several different narratives. And I wanted that story to start in Lake Okeechobee, the beating heart of the Everglade system. And to do that, I picked an ambassador, an iconic species. This is the Everglade snail kite. It ’ s a great bird, and they used to nest in the thousands, thousands in the northern Everglades. And then they ’ ve gone down to about 400 nesting pairs today. And why is that? Well, it ’ s because they eat one source of food, an apple snail, about the size of a ping-pong ball, an aquatic gastropod. So as we started damming up the Everglades, as we started diking Lake Okeechobee and draining the wetlands, we lost the habitat for the snail. And thus, the population of the kites declined. And so, I wanted a photo that would not only communicate this relationship between wetland, snail and bird, but I also wanted a photo that would communicate how incredible this relationship was, and how very important it is that they ’ ve come to depend on each other, this healthy wetland and this bird. And to do that, I brainstormed this idea. I started sketching out these plans to make a photo, and I sent it to the wildlife biologist down in Okeechobee — this is an endangered bird, so it takes special permission to do. So I built this submerged platform that would hold snails just right under the water. And I spent months planning this crazy idea. And I took this platform down to Lake Okeechobee and I spent over a week in the water, wading waist-deep, 9-hour shifts from dawn until dusk, to get one image that I thought might communicate this. And here ' s the day that it finally worked : [Video : After setting up the platform, I look off and I see a kite coming over the cattails. And I see him **scanning** and searching. And he gets right over the trap, and I see that he ' s seen it. And he beelines, he goes straight for the trap. And in that moment, all those months of planning, waiting, all the sunburn, mosquito bites — suddenly, they ' re all worth it. Oh my gosh, I can ' t believe it!] You can believe how excited I was when that happened. But what the idea was, is that for someone who ' s never seen this bird and has no reason to care about it, these photos, these new perspectives, will help shed a little new light on just one species that makes this watershed so incredible, so valuable, so important. Now, I know I can ' t come here to Gainesville and talk to you about animals in the Everglades without talking about gators. I love gators, I grew up loving gators. My parents always said I had an unhealthy relationship with gators. But what I like about them is, they ' re like the freshwater equivalent of sharks. They ' re feared, they ' re hated, and they are tragically misunderstood. Because these are a unique species, they ' re not just apex predators. In the Everglades, they are the very **architects** of the Everglades, because as the water drops down in the winter during the dry season, they start excavating these holes called gator holes. And they do this because as the water drops down, they ' ll be able to stay wet and they ' ll be able to forage. And now this isn ' t just affecting them, other animals also depend on this relationship, so they become a keystone species as well. So how do you make an apex predator, an ancient reptile, at once look like it dominates the system, but at the same time, look vulnerable? Well, you wade into a pit of about 120 of them, then you hope that you ' ve made the right decision. I still have all my fingers, it ' s cool. But I understand, I know I ' m not going to rally you guys, I ' m not going to rally the troops to"Save the Everglades for the gators!"It won ' t happen because they ' re so ubiquitous, we see them now, they ' re one of the great conservation success stories of the US. But there is one species in the Everglades that no matter who you are, you can ' t help but love, too, and that ' s the roseate spoonbill. These birds are great, but they ' ve had a really tough time in the Everglades, because they started out with thousands of nesting pairs in Florida Bay, and at the turn of the 20th century, they got down to two — two nesting pairs. And why? That ' s because women thought they looked better on their hats then they did flying in the sky. Then we banned the plume trade, and their numbers started rebounding. And as their numbers started rebounding, scientists began to pay attention, they started studying these birds. And what they found out is that these birds ' behavior is intrinsically tied to the annual draw-down cycle of water in the Everglades, the thing that defines the Everglades watershed. What they found out is that these birds started nesting in the winter as the water drew down, because they ' re tactile feeders, so they have to touch whatever they eat. And so they wait for these concentrated pools of fish to be able to feed enough to feed their young. So these birds became the very icon of the Everglades — an indicator species of the overall health of the system. And just as their numbers were rebounding in the mid-20th century — shooting up to 900, 1, 000, 1, 100, 1, 200 — just as that started happening, we started draining the southern Everglades. And we stopped two-thirds of that water from moving south. And it had drastic consequences. And just as those numbers started reaching their peak, unfortunately, today, the real spoonbill story, the real photo of what it looks like is more something like this. And we ' re down to less than 70 nesting pairs in Florida Bay today, because we ' ve disrupted the system so much. So all these different organizations are shouting, they ' re screaming,"The Everglades is fragile! It ' s fragile!"It is not. It is resilient. Because despite all we ' ve taken, despite all we ' ve done and we ' ve drained and we ' ve dammed and we ' ve dredged it, pieces of it are still here, waiting to be put back together. And this is what I ' ve loved about South Florida, that in one place, you have this unstoppable force of mankind meeting the immovable object of tropical nature. And it ' s at this new frontier that we are forced with a new appraisal. What is wilderness worth? What is the value of biodiversity, or our drinking water? And fortunately, after decades of debate, we ' re finally starting to act on those questions. We ' re slowly undertaking these projects to bring more freshwater back to the bay. But it ' s up to us as citizens, as residents, as stewards to hold our elected officials to their promises. What can you do to help? It ' s so easy. Just get outside, get out there. Take your friends out, take your kids out, take your family out. Hire a fishing guide. Show the state that protecting wilderness not only makes ecological sense, but economic sense as well. It ' s a lot of **fun**, just do it — put your **feet** in the water. The swamp will change you, I promise. Over the years, we ' ve been so generous with these other landscapes around the country, cloaking them with this American pride, places that we now consider to define us : Grand Canyon, Yosemite, Yellowstone. And we use these **parks** and these natural areas as beacons and as cultural compasses. And sadly, the Everglades is very commonly left out of that conversation. But I believe it ' s every bit as iconic and emblematic of who we are as a country as any of these other wildernesses. It ' s just a different kind of wild. But I ' m encouraged, because maybe we ' re finally starting to come around, because what was once deemed this swampy wasteland, today is a World Heritage site. It ' s a wetland of international importance. And we ' ve come a long way in the last 60 years. And as the world ' s largest and most ambitious wetland restoration project, the international spotlight is on us in the Sunshine State. Because if we can heal this system, it ' s going to become an icon for wetland restoration all over the world. But it ' s up to us to decide which legacy we want to attach our flag to. They say that the Everglades is our greatest test. If we pass it, we get to keep the planet. I love that quote, because it ' s a challenge, it ' s a prod. Can we do it? Will we do it? We have to, we must. But the Everglades is not just a test. It ' s also a gift, and ultimately, our responsibility. Thank you.

Blah blah blah blah blah. Blah blah blah blah, blah blah, blah blah blah blah blah blah. Blah blah blah, blah. So what the **hell** was that? Well, you don ' t know because you couldn ' t understand it. It wasn ' t clear. But hopefully, it was said with enough conviction that it was at least alluringly mysterious. Clarity or mystery? I ' m balancing these two things in my daily work as a graphic designer, as well as my daily life as a New Yorker every day, and there are two elements that absolutely **fascinate** me. Here ' s an example. Now, how many people know what this is? Okay. Now how many people know what this is? Okay. Thanks to two more deft strokes by the genius Charles M. Schulz, we now have seven deft strokes that in and of themselves create an entire emotional life, one that has enthralled hundreds of millions of fans for over 50 years. This is actually a cover of a book that I designed about the work of Schulz and his art, which will be coming out this fall, and that is the entire cover. There is no other typographic information or visual information on the front, and the name of the book is”Only What ’ s Necessary.”So this is sort of symbolic about the decisions I have to make every day about the design that I ’ m perceiving, and the design I ’ m creating. So clarity. Clarity gets to the point. It ’ s blunt. It ’ s honest. It ’ s sincere. We ask ourselves this. [”When should you be clear?”] Now, something like this, whether we can read it or not, needs to be really, really clear. Is it? This is a rather recent example of urban clarity that I just love, mainly because I ’ m always late and I am always in a hurry. So when these meters started showing up a couple of years ago on street corners, I was thrilled, because now I finally knew how many seconds I had to get across the street before I got run over by a car. Six? I can do that. So let ’ s look at the yin to the clarity yang, and that is mystery. Mystery is a lot more complicated by its very definition. Mystery demands to be decoded, and when it ’ s done right, we really, really want to. [”When should you be mysterious?”] In World War II, the Germans really, really wanted to decode this, and they couldn ’ t. Here ’ s an example of a design that I ’ ve done recently for a novel by Haruki Murakami, who I ’ ve done design work for for over 20 years now, and this is a novel about a young man who has four dear friends who all of a sudden, after their freshman year of college, completely cut him off with no explanation, and he is devastated. And the friends ’ names each have a connotation in Japanese to a color. So there ’ s Mr. Red, there ’ s Mr. Blue, there ’ s Ms. White, and Ms. Black. Tsukuru Tazaki, his name does not correspond to a color, so his nickname is Colorless, and as he ’ s looking back on their friendship, he recalls that they were like five fingers on a hand. So I created this sort of abstract representation of this, but there ’ s a lot more going on underneath the surface of the story, and there ’ s more going on underneath the surface of the jacket. The four fingers are now four train lines in the Tokyo subway system, which has significance within the story. And then you have the colorless subway line intersecting with each of the other colors, which basically he does later on in the story. He catches up with each of these people to find out why they treated him the way they did. And so this is the three-dimensional finished product sitting on my desk in my office, and what I was hoping for here is that you ’ ll simply be allured by the mystery of what this looks like, and will want to read it to decode and find out and make more clear why it looks the way it does. [”The Visual Vernacular.”] This is a way to use a more familiar kind of mystery. What does this mean? This is what it means. [”Make it look like something else.”] The visual vernacular is the way we are used to seeing a certain thing applied to something else so that we see it in a different way. This is an approach I wanted to take to a book of essays by David Sedaris that had this title at the time. [”All the Beauty You Will Ever Need”] Now, the challenge here was that this title actually means nothing. It ’ s not connected to any of the essays in the book. It came to the author ’ s boyfriend in a dream. Thank you very much, so — — so usually, I am creating a design that is in some way based on the text, but this is all the text there is. So you ’ ve got this mysterious title that really doesn ’ t mean anything, so I was trying to think : Where might I see a bit of mysterious text that seems to mean something but doesn ’ t? And sure enough, not long after, one evening after a Chinese meal, this arrived, and I thought,”Ah, bing, ideagasm!”I ’ ve always loved the hilariously mysterious tropes of fortune cookies that seem to mean something extremely deep but when you think about them — if you think about them — they really don ’ t. This says,”Hardly anyone knows how much is gained by ignoring the future.”Thank you. But we can take this visual vernacular and apply it to Mr. Sedaris, and we are so familiar with how fortune cookie fortunes look that we don ’ t even need the bits of the cookie anymore. We ’ re just seeing this strange thing and we know we love David Sedaris, and so we ’ re hoping that we ’ re in for a good time. [”’ Fraud ’ Essays by David Rakoff”] David

Rakoff was a wonderful writer and he called his first book”Fraud”because he was getting sent on assignments by magazines to do things that he was not equipped to do. So he was this skinny little urban guy and GQ magazine would send him down the Colorado River whitewater rafting to see if he would survive. And then he would write about it, and he felt that he was a fraud and that he was misrepresenting himself. And so I wanted the cover of this book to also misrepresent itself and then somehow show a reader reacting to it. This led me to graffiti. I ’ m **fascinated** by graffiti. I think anybody who lives in an urban environment encounters graffiti all the time, and there ’ s all different sorts of it. This is a **picture** I took on the Lower East Side of just a transformer box on the sidewalk and it ’ s been tagged like crazy. Now whether you look at this and think,”Oh, that ’ s a charming urban affectation,”or you look at it and say,”That ’ s illegal abuse of property,”the one thing I think we can all agree on is that you cannot read it. Right? There is no clear message here. There is another kind of graffiti that I find far more interesting, which I call editorial graffiti. This is a **picture** I took recently in the subway, and sometimes you see lots of prurient, stupid stuff, but I thought this was interesting, and this is a poster that is saying rah-rah Airbnb, and someone has taken a Magic Marker and has editorialized about what they think about it. And it got my attention. So I was thinking, how do we apply this to this book? So I get the book by this person, and I start reading it, and I ’ m thinking, this guy is not who he says he is ; he ’ s a fraud. And I get out a red Magic Marker, and out of frustration just scribble this across the front. Design done. And they went for it! Author liked it, publisher liked it, and that is how the book went out into the world, and it was really **fun** to see people reading this on the subway and walking around with it and what have you, and they all sort of looked like they were crazy. [”’ Perfidia ’ a novel by James Ellroy”] Okay, James Ellroy, amazing crime writer, a good friend, I ’ ve worked with him for many years. He is probably best known as the author of”The Black Dahlia”and”L. A. Confidential.”His most recent novel was called this, which is a very mysterious name that I ’ m sure a lot of people know what it means, but a lot of people don ’ t. And it ’ s a story about a Japanese-American detective in Los Angeles in 1941 investigating a murder. And then Pearl Harbor happens, and as if his life wasn ’ t difficult enough, now the race relations have really ratcheted up, and then the Japanese- American internment camps are quickly created, and there ’ s lots of tension and horrible stuff as he ’ s still trying to solve this murder. And so I did at first think very literally about this in terms of all right, we ’ ll take Pearl Harbor and we ’ ll add it to Los Angeles and we ’ ll make this apocalyptic dawn on the horizon of the city. And so that ’ s a **picture** from Pearl Harbor just grafted onto Los Angeles. My editor in chief said,”You know, it ’ s interesting but I think you can do better and I think you can make it simpler.”And so I went back to the **drawing** board, as I often do. But also, being alive to my surroundings, I work in a high-rise in Midtown, and every night, before I leave the office, I have to push this button to get out, and the big heavy glass doors open and I can get onto the elevator. And one night, all of a sudden, I looked at this and I saw it in a way that I hadn ’ t really noticed it before. Big red circle, danger. And I thought this was so obvious that it had to have been done a zillion times, and so I did a Google image search, and I couldn ’ t find another book cover that looked quite like this, and so this is really what solved the problem, and graphically it ’ s more interesting and creates a bigger tension between the idea of a certain kind of sunrise coming up over L. A. and America. [”’ Gulp ’ A tour of the human digestive system by Mary Roach.”] Mary Roach is an amazing writer who takes potentially mundane scientific subjects and makes them not mundane at all ; she makes them really **fun**. So in this particular case, it ’ s about the human digestive system. So I

’ m trying to figure out what is the cover of this book going to be. This is a self-portrait. Every morning I look at myself in the medicine cabinet mirror to see if my tongue is black. And if it ’ s not, I ’ m good to go. I recommend you all do this. But I also started thinking, here ’ s our introduction. Right? Into the human digestive system. But I think what we can all agree on is that actual photographs of human mouths, at least based on this, are off-putting. So for the cover, then, I had this illustration done which is literally more palatable and reminds us that it ’ s best to approach the digestive system from this end. I don ’ t even have to complete the sentence. All right. [”Unuseful mystery”] What happens when clarity and mystery get mixed up? And we see this all the time. This is what I call unuseful mystery. I go down into the subway — I take the subway a lot — and this piece of paper is **taped** to a girder. Right? And now I ’ m thinking, uh-oh, and the train ’ s about to come and I ’ m trying to figure out what this means, and thanks a lot. Part of the problem here is that they ’ ve compartmentalized the information in a way they think is helpful, and frankly, I don ’ t think it is at all. So this is mystery we do not need. What we need is useful clarity, so just for **fun**, I redesigned this. This is using all the same elements. Thank you. I am still waiting for a call from the MTA. You know, I ’ m actually not even using more colors than they use. They just didn ’ t even bother to make the 4 and the 5 green, those idiots. So the first thing we see is that there is a service change, and then, in two complete sentences with a beginning, a middle and an end, it tells us what the change is and what ’ s going to be happening. Call me crazy! [”Useful mystery”] All right. Now, here is a piece of mystery that I love : packaging. This redesign of the Diet Coke can by Turner Duckworth is to me truly a piece of art. It ’ s a work of art. It ’ s beautiful. But part of what makes it so heartening to me as a designer is that he ’ s taken the visual vernacular of Diet Coke — the typefaces, the colors, the silver background — and he ’ s reduced them to their most essential parts, so it ’ s like going back to the Charlie Brown face. It ’ s like, how can you give them just enough information so they know what it is but giving them the credit for the knowledge that they already have about this thing? It looks great, and you would go into a delicatessen and all of a sudden see that on the shelf, and it ’ s wonderful. Which makes the next thing — [”Unuseful clarity”] — all the more disheartening, at least to me. So okay, again, going back down into the subway, after this came out, these are **pictures** that I took. Times Square subway station : Coca-Cola has bought out the entire thing for advertising. Okay? And maybe some of you know where this is going. Ahem.”You moved to New York with the clothes on your back, the cash in your pocket, and your eyes on the prize. You ’ re on Coke.””You moved to New York with an MBA, one **clean** suit, and an extremely firm handshake. You ’ re on Coke.”These are real! Not even the support beams were spared, except they switched into Yoda mode.”Coke you ’ re on.”[”Excuse me, I ’ m on WHAT??”] This campaign was a huge misstep. It was pulled almost instantly due to consumer backlash and all sorts of unflattering parodies on the web — — and also that dot next to”You ’ re on,”that ’ s not a period, that ’ s a trademark. So thanks a lot. So to me, this was just so bizarre about how they could get the packaging so mysteriously beautiful and perfect and the message so unbearably, clearly wrong. It was just incredible to me. So I just hope that I ’ ve been able to share with you some of my insights on the uses of clarity and mystery in my work, and maybe how you might decide to be more clear in your life, or maybe to be a bit more mysterious and not so over- sharing. And if there ’ s just one thing that I leave you with from this talk, I hope it ’ s this : Blih blih blih blah. Blah blah blih blih. [”’ Judge This, ’ Chip Kidd”] Blih blih blah blah blah. Blah blah blah. Blah blah.

Text Sample 719: POS Dim 5 – 2016 – Score 8.00 – 2016/t001286.txt

There ’ s this fact that I love that I read somewhere once, that one of the things that ’ s contributed to homo sapiens ’ success as a species is our lack of body hair â that our hairlessness, our nakedness combined with our invention of clothing, gives us the ability to modulate our body temperature and thus be able to survive in any climate we choose. And now we ’ ve evolved to the point where we can ’ t survive without clothing. And it ’ s more than just utility, now it ’ s a communication. Everything that we choose to put on is a narrative, a story about where we ’ ve been, what we ’ re doing, who we want to be. I was a lonely kid. I didn ’ t have an easy time finding friends to play with, and I ended up making a lot of my own play. I made a lot of my own toys. It began with ice cream. There was a Baskin-Robbins in my hometown, and they served ice cream from behind the counter in these giant, five-gallon, cardboard tubs. And someone told me â I was eight years old â someone told me that when they were done with those tubs, they washed them out and kept them in the back, and if you asked they would give you one. It took me a couple of weeks to work up the courage, but I did, and they did. They gave me one â I went home with this beautiful cardboard tub. I was trying to figure out what I could do with this exotic material â **metal** ring, top and **bottom**. I started turning it over in my head, and I realized,”Wait a minute â my head actually fits inside this thing.”Yeah, I cut a hole out, I put some acetate in there and I made myself a space helmet. I needed a place to wear the space helmet, so I found a refrigerator box a couple blocks from home. I pushed it home, and in my parents ’ **guest** room closet, I turned it into a spaceship. I started with a control **panel** out of cardboard. I cut a hole for a radar screen and put a flashlight underneath it to light it. I put a view screen up, which I offset off the back wall â and this is where I thought I was being really clever â without permission, I painted the back wall of the closet black and put a star field, which I lit up with some Christmas lights I found in the attic, and I went on some space missions. A couple years later, the movie”Jaws”came out. I was way too young to see it, but I was caught up in”Jaws”fever, like everyone else in America at the time. There was a store in my town that had a”Jaws”costume in their window, and my mom must have overheard me talking to someone about how awesome I thought this costume was, because a couple days before Halloween, she blew my freaking mind by giving me this”Jaws”costume. Now, I recognize it ’ s a bit of a trope for people of a certain age to complain that kids these days have no idea how good they have it, but let me just show you a random sampling of entry-level kids ’ costumes you can buy online right now...... and this is the”Jaws”costume my mom bought for me. This is a paper-thin shark face and a vinyl bib with the poster of”Jaws”on it. And I loved it. A couple years later, my dad took me to a **film** called”Excalibur.”I actually got him to take me to it twice, which is no small thing, because it is a hard, R-rated **film**. But it wasn ’ t the blood and guts or the boobs that made me want to go see it again. They helped â It was the armor. The armor in”Excalibur”was intoxicatingly beautiful to me. These were literally knights in shining, mirror-polished armor. And moreover, the knights in”Excalibur”wear their armor everywhere. All the time â they wear it at dinner, they wear it to bed. I was like,”Are they reading my mind? I want to wear armor all the time!”So I went back to my favorite material, the gateway drug for making, corrugated cardboard, and I made myself a suit of armor, replete with the neck shields and a white horse. Now that I ’ ve oversold it, here ’ s a **picture** of the armor that I made. Now, this is only the first suit of armor I made inspired by”Excalibur.”A couple of years later, I convinced my dad to embark on making me a proper suit of armor. Over about a month, he graduated me from cardboard to roofing aluminum called flashing and still, one of my all-time favorite attachment materials, POP rivets. We carefully, over that month, constructed an articulated suit of aluminum armor with compound **curves**. We drilled holes in the helmet so that I could breathe, and I finished just in time for Halloween and wore it to school. Now, this is the one thing in this talk that I don ’ t have a slide to show you, because no photo exists of this armor. I did wear it to school, there was a yearbook photographer patrolling the halls, but he never found me, for reasons that are about to become clear. There were things I didn ’ t anticipate about wearing a complete suit of aluminum armor to school. In third period math, I was standing in the back of class, and I ’ m standing in the back of class because the armor did not allow me to sit down. This is the first thing I didn ’ t anticipate. And then my teacher looks at me sort of concerned about halfway through the class and says,”Are you feeling OK?”I ’ m thinking,”Are you kidding? Am I feeling OK? I ’ m wearing a suit of armor! I am having the time of my â”And I ’ m just about to tell her how great I feel, when the classroom starts to list to the left and disappear down this long tunnel, and then I woke up in the nurse ’ s office. I had passed out from heat exhaustion, wearing the armor. And when I woke up, I wasn ’ t embarrassed about having passed out in front of my class, I was wondering,”Who took my armor? Where ’ s my armor?”OK, fast-forward a whole bunch of years, some colleagues and I get hired to make a show for Discovery Channel, called”MythBusters.”And over 14 years, I learn on the job how to build experimental methodologies and how to tell stories about them for television. I also learn early on that costuming can play a key role in this storytelling. I use costumes to add humor, comedy, color and narrative clarity to the stories we ’ re telling. And then we do an episode called”Dumpster Diving,”and I learn a little bit more about the deeper implications of what costuming means to me. In the episode”Dumpster Diving,”the question we were trying to answer is : Is jumping into a dumpster as safe as the movies would lead you to believe? The episode was going to have two distinct parts to it. One was where we get trained to jump off buildings by a stuntman into an air bag. And the second was the graduation to the experiment : we ’ d fill a dumpster full of material and we ’ d jump into it. I wanted to visually separate these two elements, and I thought,”Well, for the first part we ’ re training, so we should wear sweatsuits â Oh! Let ’ s put ’ Stunt Trainee ’ on the back of the sweatsuits. That ’ s for the training.”But for the second part, I wanted something really visually striking â”I know! I ’ ll dress as Neo from ’ The Matrix. ’”So I went to Haight Street. I bought some beautiful knee-high, buckle boots. I found a long, flowing coat on eBay. I got sunglasses, which I had to wear contact lenses in order to wear. The day of the experiment shoot comes up, and I step out of my car in this costume, and my crew takes a look at me... and start suppressing their church giggles. They ’ re like,”.”And I feel two distinct things at this moment. I feel total embarrassment over the fact that it ’ s so nakedly clear to my crew that I ’ m completely into wearing this costume. But the producer in my mind reminds myself that in the high-speed shot in slow- mo, that flowing coat is going to look beautiful behind me. Five years into the”MythBusters”run, we got invited to appear at San Diego Comic-Con. I ’ d known about Comic-Con for years and never had time to go. This was the big leagues â this was costuming mecca. People fly in from all over the world to show their amazing creations on the floor in San Diego. And I wanted to participate. I decided that I would put together an elaborate costume that covered me completely, and I would walk the floor of San Diego Comic-Con anonymously. The costume I chose? Hellboy. That ’ s not my costume, that ’ s actually Hellboy. But I spent months assembling the most screen-accurate Hellboy costume I could, from the boots to the belt to the pants to the right hand of doom. I found a guy who made a prosthetic Hellboy head and chest and I put them on. I even had contact lenses made in my prescription. I wore it onto the floor at Comic-Con and I can ' t even tell you how balls hot it was in that costume. Sweating! I should ' ve remembered this. I ' m sweating buckets and the contact lenses hurt my eyes, and none of it matters because I ' m totally in love. Not just with the process of putting on this costume and walking the floor, but also with the community of other costumers. It ' s not called costuming at Cons, it ' s called"cosplay."Now ostensibly, cosplay means people who dress up as their favorite characters from **film** and television and especially anime, but it is so much more than that. These aren ' t just people who find a costume and put it on â they mash them up. They bend them to their will. They change them to be the characters they want to be in those productions. They ' re super clever and genius. They let their freak flag fly and it ' s beautiful. But more than that, they rehearse their costumes. At Comic-Con or any other Con, you don ' t just take **pictures** of people walking around. You go up and say,"Hey, I like your costume, can I take your **picture**?"And then you give them time to get into their pose. They ' ve worked hard on their pose to make their costume look great for your camera. And it ' s so beautiful to watch. And I take this to heart. At subsequent Cons, I learn Heath Ledger ' s shambling walk as the Joker from"The Dark Knight."I learn how to be a scary Ringwraith from"Lord of the Rings,"and I actually frighten some children. I learned that"hrr hrr hrr"â that head laugh that Chewbacca does. And then I dressed up as No-Face from"Spirited Away."If you don ' t know about"Spirited Away"and its director, Hayao Miyazaki, first of all, you ' re welcome. This is a masterpiece, and one of my all-time favorite **films**. It ' s about a young girl named Chihiro who gets lost in the spirit world in an abandoned Japanese theme **park**. And she finds her way back out again with the help of a couple of friends she makes â a captured dragon named Haku and a lonely demon named No-Face. No-Face is lonely and he wants to make friends, and he thinks the way to do it is by luring them to him and producing gold in his hand. But this doesn ' t go very well, and so he ends up going on kind of a rampage until Chihiro saves him, rescues him. So I put together a No-Face costume, and I wore it on the floor at Comic-Con. And I very carefully practiced No-Face ' s gestures. I resolved I would not speak in this costume at all. When people asked to take my **picture**, I would nod and I would shyly stand next to them. They would take the **picture** and then I would secret out from behind my robe a chocolate gold coin. And at the end of the photo process, I ' d make it appear for them. Ah, ah ah! â like that. And people were freaking out."Holy crap! Gold from No-Face! Oh my god, this is so cool!"And I ' m feeling and I ' m walking the floor and it ' s fantastic. And about 15 minutes in something happens. Somebody grabs my hand, and they put a coin back into it. And I think maybe they ' re giving me a coin as a return gift, but no, this is one of the coins that I ' d given away. I don ' t know why. And I keep on going, I take some more **pictures**. And then it happens again. Understand, I can ' t see anything inside this costume. I can see through the mouth â I can see people ' s shoes. I can hear what they ' re saying and I can see their **feet**. But the third time someone gives me back a coin, I want to know what ' s going on. So I sort of tilt my head back to get a better view, and what I see is someone walking away from me going like this. And then it hits me : it ' s bad luck to take gold from No-Face. In the **film**"Spirited Away,"bad luck befalls those who take gold from No-Face. This isn ' t a performer-audience relationship ; this is cosplay. We are, all of us on that floor, injecting ourselves into a narrative that meant something to us. And we ' re making it our own. We ' re connecting with something important inside of us. And the costumes are how we reveal ourselves to each other. Thank you.

I ’ m driven by pure passion to create photographs that tell stories. Photography can be described as the recording of a single moment frozen within a fraction of time. Each moment or photograph represents a tangible piece of our memories as time passes. But what if you could capture more than one moment in a photograph? What if a photograph could actually collapse time, compressing the best moments of the day and the night seamlessly into one single image? I ’ ve created a concept called”Day to Night”and I believe it ’ s going to change the way you look at the world. I know it has for me. My process begins by photographing iconic locations, places that are part of what I call our collective memory. I photograph from a fixed vantage point, and I never move. I capture the fleeting moments of humanity and light as time passes. Photographing for anywhere from 15 to 30 hours and shooting over 1, 500 images, I then choose the best moments of the day and night. Using time as a guide, I seamlessly blend those best moments into one single photograph, visualizing our conscious journey with time. I can take you to Paris for a view from the Tournelle Bridge. And I can show you the early morning rowers along the River Seine. And simultaneously, I can show you Notre Dame aglow at night. And in between, I can show you the romance of the City of Light. I am essentially a street photographer from 50 **feet** in the air, and every single thing you see in this photograph actually happened on this day. Day to Night is a global project, and my work has always been about history. I ’ m **fascinated** by the concept of going to a place like Venice and actually seeing it during a specific event. And I decided I wanted to see the historical Regata, an event that ’ s actually been taking place since 1498. The boats and the costumes look exactly as they did then. And an important element that I really want you guys to understand is : this is not a timelapse, this is me photographing throughout the day and the night. I am a relentless collector of magical moments. And the thing that drives me is the fear of just missing one of them. The entire concept came about in 1996. LIFE Magazine commissioned me to create a panoramic photograph of the cast and crew of Baz Luhrmann ’ s **film** Romeo + Juliet. I got to the set and realized : it ’ s a square. So the only way I could actually create a panoramic was to shoot a collage of 250 single images. So I had DiCaprio and Claire Danes embracing. And as I pan my camera to the right, I noticed there was a mirror on the wall and I saw they were actually reflecting in it. And for that one moment, that one image I asked them,”Would you guys just kiss for this one **picture**?”And then I came back to my studio in New York, and I hand-glued these 250 images together and stood back and went,”Wow, this is so cool! I ’ m changing time in a photograph.”And that concept actually stayed with me for 13 years until technology finally has caught up to my dreams. This is an image I created of the Santa Monica Pier, Day to Night. And I ’ m going to show you a little video that gives you an idea of what it ’ s like being with me when I do these **pictures**. To start with, you have to understand that to get views like this, most of my time is spent up high, and I ’ m usually in a cherry picker or a crane. So this is a typical day, 12-18 hours, non-stop capturing the entire day unfold. One of the things that ’ s great is I love to people-watch. And trust me when I tell you, this is the greatest seat in the house to have. But this is really how I go about creating these photographs. So once I decide on my view and the location, I have to decide where day begins and night ends. And that ’ s what I call the time vector. Einstein described time as a fabric. Think of the surface of a trampoline : it warps and stretches with gravity. I see time as a fabric as well, except I take that fabric and flatten it, compress it into single plane. One of the unique aspects of this work is also, if you look at all my **pictures**, the time vector changes : sometimes I ' ll go left to right, sometimes front to back, up or down, even diagonally. I am exploring the space-time continuum within a two-dimensional still photograph. Now when I do these **pictures**, it ' s literally like a real-time puzzle going on in my mind. I build a photograph based on time, and this is what I call the master plate. This can take us several months to complete. The **fun** thing about this work is I have absolutely zero control when I get up there on any given day and capture photographs. So I never know who ' s going to be in the **picture**, if it ' s going to be a great sunrise or sunset — no control. It ' s at the end of the process, if I ' ve had a really great day and everything remained the same, that I then decide who ' s in and who ' s out, and it ' s all based on time. I ' ll take those best moments that I pick over a month of editing and they get seamlessly blended into the master plate. I ' m compressing the day and night as I saw it, creating a unique harmony between these two very discordant worlds. Painting has always been a really important influence in all my work and I ' ve always been a huge fan of Albert Bierstadt, the great Hudson River School painter. He inspired a recent series that I did on the National Parks. This is Bierstadt ' s Yosemite Valley. So this is the photograph I created of Yosemite. This is actually the cover story of the 2016 January issue of National Geographic. I photographed for over 30 hours in this **picture**. I was literally on the side of a cliff, capturing the stars and the moonlight as it transitions, the moonlight lighting El Capitan. And I also captured this transition of time throughout the landscape. The best part is obviously seeing the magical moments of humanity as time changed — from day into night. And on a personal note, I actually had a photocopy of Bierstadt ' s painting in my pocket. And when that sun started to rise in the **valley**, I started to literally shake with excitement because I looked at the painting and I go,"Oh my god, I ' m getting Bierstadt ' s exact same lighting 100 years earlier."Day to Night is about all the things, it ' s like a compilation of all the things I love about the medium of photography. It ' s about landscape, it ' s about street photography, it ' s about color, it ' s about architecture, perspective, scale — and, especially, history. This is one of the most historical moments I ' ve been able to photograph, the 2013 Presidential Inauguration of Barack Obama. And if you look closely in this **picture**, you can actually see time changing in those large television sets. You can see Michelle waiting with the children, the president now greets the crowd, he takes his oath, and now he ' s speaking to the people. There ' s so many challenging aspects when I create photographs like this. For this particular photograph, I was in a 50-foot scissor lift up in the air and it was not very stable. So every time my assistant and I shifted our weight, our horizon line shifted. So for every **picture** you see, and there were about 1, 800 in this **picture**, we both had to **tape** our **feet** into position every time I clicked the shutter. I ' ve learned so many extraordinary things doing this work. I think the two most important are patience and the power of observation. When you photograph a city like New York from above, I discovered that those people in cars that I sort of live with everyday, they don ' t look like people in cars anymore. They feel like a giant school of fish, it was a form of emergent behavior. And when people describe the energy of New York, I think this photograph begins to really capture that. When you look closer in my work, you can see there ' s stories going on. You realize that Times Square is a canyon, it ' s shadow and it ' s sunlight. So I decided, in this photograph, I would checkerboard time. So wherever the shadows are, it ' s night and wherever the sun is, it ' s actually day. Time is this extraordinary thing that we never can really wrap our heads around. But in a very unique and special way, I believe these photographs begin to put a face on time. They embody a new metaphysical visual reality. When you spend 15 hours looking at a place, you ’ re going to see things a little differently than if you or I walked up with our camera, took a **picture**, and then walked away. This was a perfect example. I call it”Sacr-Coeur Selfie.”I watched over 15 hours all these people not even look at Sacr-Coeur. They were more interested in using it as a backdrop. They would walk up, take a **picture**, and then walk away. And I found this to be an absolutely extraordinary example, a powerful disconnect between what we think the human experience is versus what the human experience is evolving into. The act of sharing has suddenly become more important than the experience itself. And finally, my most recent image, which has such a special meaning for me personally : this is the Serengeti National Park in Tanzania. And this is photographed in the middle of the Seronera, this is not a reserve. I went specifically during the peak migration to hopefully capture the most diverse range of animals. Unfortunately, when we got there, there was a drought going on during the peak migration, a five-week drought. So all the animals were drawn to the water. I found this one watering hole, and felt if everything remained the same way it was behaving, I had a real opportunity to capture something unique. We spent three days studying it, and nothing could have prepared me for what I witnessed during our shoot day. I photographed for 26 hours in a sealed crocodile blind, 18 **feet** in the air. What I witnessed was unimaginable. Frankly, it was Biblical. We saw, for 26 hours, all these competitive species share a single resource called water. The same resource that humanity is supposed to have wars over during the next 50 years. The animals never even grunted at each other. They seem to understand something that we humans don ’ t. That this precious resource called water is something we all have to share. When I created this **picture**, I realized that Day to Night is really a new way of seeing, compressing time, exploring the space-time continuum within a photograph. As technology evolves along with photography, photographs will not only communicate a deeper meaning of time and memory, but they will compose a new narrative of untold stories, creating a timeless window into our world. Thank you.

I was excited to be a part of the”Dream”theme, and then I found out I ’ m leading off the”Nightmare?”section of it. And certainly there are things about the climate crisis that qualify. And I have some bad news, but I have a lot more good news. I ’ m going to propose three questions and the answer to the first one necessarily involves a little bad news. But — hang on, because the answers to the second and third questions really are very positive. So the first question is,”Do we really have to change?”And of course, the Apollo Mission, among other things changed the environmental movement, really launched the modern environmental movement. 18 months after this Earthrise **picture** was first seen on earth, the first Earth Day was organized. And we learned a lot about ourselves looking back at our planet from space. And one of the things that we learned confirmed what the scientists have long told us. One of the most essential facts about the climate crisis has to do with the sky. As this **picture** illustrates, the sky is not the vast and limitless expanse that appears when we look up from the ground. It is a very thin shell of atmosphere surrounding the planet. That right now is the open sewer for our industrial civilization as it ’ s currently organized. We are spewing 110 million tons of heat-trapping global warming pollution into it every 24 hours, free of charge, go ahead. And there are many sources of the greenhouse **gases**, I ’ m certainly not going to go through them all. I ’ m going to focus on the main one, but agriculture is involved, diet is involved, population is involved. Management of forests, transportation, the oceans, the melting of the permafrost. But I ’ m going to focus on the heart of the problem, which is the fact that we still rely on dirty, carbon-based fuels for 85 percent of all the energy that our world burns every year. And you can see from this image that after World War II, the emission rates started really accelerating. And the accumulated amount of man- made, global warming pollution that is up in the atmosphere now traps as much extra heat energy as would be released by 400, 000 Hiroshima-class atomic bombs exploding every 24 hours, 365 days a year. Fact-checked over and over again, conservative, it ’ s the truth. Now it ’ s a big planet, but — that is a lot of energy, particularly when you multiply it 400, 000 times per day. And all that extra heat energy is heating up the atmosphere, the whole earth system. Let ’ s look at the atmosphere. This is a depiction of what we used to think of as the normal distribution of temperatures. The white represents normal temperature days ; 1951-1980 are arbitrarily chosen. The blue are cooler than average days, the red are warmer than average days. But the entire **curve** has moved to the right in the 1980s. And you ’ ll see in the lower right-hand corner the appearance of statistically significant numbers of extremely hot days. In the 90s, the **curve** shifted further. And in the last 10 years, you see the extremely hot days are now more numerous than the cooler than average days. In fact, they are 150 times more common on the surface of the earth than they were just 30 years ago. So we ’ re having record-breaking temperatures. Fourteen of the 15 of the hottest years ever measured with instruments have been in this young century. The hottest of all was last year. Last month was the 371st month in a row warmer than the 20th-century average. And for the first time, not only the warmest January, but for the first time, it was more than two degrees Fahrenheit warmer than the average. These higher temperatures are having an effect on animals, plants, people, ecosystems. But on a global basis, 93 percent of all the extra heat energy is trapped in the oceans. And the scientists can measure the heat buildup much more precisely now at all depths : deep, mid-ocean, the first few hundred meters. And this, too, is accelerating. It goes back more than a century. And more than half of the increase has been in the last 19 years. This has consequences. The first order of consequence : the ocean-based storms get stronger. Super Typhoon Haiyan went over areas of the Pacific five and a half degrees Fahrenheit warmer than normal before it slammed into Tacloban, as the most destructive storm ever to make landfall. Pope Francis, who has made such a difference to this whole issue, visited Tacloban right after that. Superstorm Sandy went over areas of the Atlantic nine degrees warmer than normal before slamming into New York and New Jersey. The second order of consequences are affecting all of us right now. The warmer oceans are evaporating much more water vapor into the skies. Average humidity worldwide has gone up four percent. And it creates these atmospheric rivers. The Brazilian scientists call them”flying rivers.”And they funnel all of that extra water vapor over the land where storm conditions trigger these massive record-breaking downpours. This is from Montana. Take a look at this storm last August. As it moves over Tucson, Arizona. It literally splashes off the city. These downpours are really unusual. Last July in Houston, Texas, it rained for two days, 162 billion gallons. That represents more than two days of the full flow of Niagara Falls in the middle of the city, which was, of course, paralyzed. These record downpours are creating historic floods and mudslides. This one is from Chile last year. And you ’ ll see that warehouse going by. There are oil tankers cars going by. This is from Spain last September, you could call this the running of the cars and trucks, I guess. Every night on the TV news now is like a nature hike through the Book of Revelation. I mean, really. The insurance industry has certainly noticed, the losses have been mounting up. They ' re not under any illusions about what ' s happening. And the causality requires a moment of discussion. We ' re used to thinking of linear cause and linear effect — one cause, one effect. This is systemic causation. As the great Kevin Trenberth says,"All storms are different now. There ' s so much extra energy in the atmosphere, there ' s so much extra water vapor. Every storm is different now."So, the same extra heat pulls the soil moisture out of the ground and causes these deeper, longer, more pervasive droughts and many of them are underway right now. It dries out the vegetation and causes more fires in the western part of North America. There ' s certainly been evidence of that, a lot of them. More lightning, as the heat energy builds up, there ' s a considerable amount of additional lightning also. These climate-related disasters also have geopolitical consequences and create instability. The climate-related historic drought that started in Syria in 2006 destroyed 60 percent of the farms in Syria, killed 80 percent of the livestock, and drove 1. 5 million climate refugees into the cities of Syria, where they collided with another 1. 5 million refugees from the Iraq War. And along with other factors, that opened the gates of **Hell** that people are trying to close now. The US Defense Department has long warned of consequences from the climate crisis, including refugees, food and water shortages and pandemic disease. Right now we ' re seeing microbial diseases from the tropics spread to the higher latitudes ; the transportation revolution has had a lot to do with this. But the changing conditions change the latitudes and the areas where these microbial diseases can become endemic and change the range of the vectors, like mosquitoes and ticks that carry them. The Zika epidemic now — we ' re better positioned in North America because it ' s still a little too cool and we have a better public health system. But when women in some regions of South and Central America are advised not to get pregnant for two years — that ' s something new, that ought to get our attention. The Lancet, one of the two greatest medical journals in the world, last summer labeled this a medical emergency now. And there are many factors because of it. This is also connected to the extinction crisis. We ' re in danger of losing 50 percent of all the living species on earth by the end of this century. And already, land-based plants and animals are now moving towards the poles at an average rate of 15 **feet** per day. Speaking of the North Pole, last December 29, the same storm that caused historic flooding in the American Midwest, raised temperatures at the North Pole 50 degrees Fahrenheit warmer than normal, causing the thawing of the North Pole in the middle of the long, dark, winter, polar night. And when the land- based ice of the Arctic melts, it raises sea level. Paul Nicklen ' s beautiful photograph from Svalbard illustrates this. It ' s more dangerous coming off Greenland and particularly, Antarctica. The 10 largest risk cities for sea-level rise by population are mostly in South and Southeast Asia. When you measure it by assets at risk, number one is Miami : three and a half trillion dollars at risk. Number three : New York and Newark. I was in Miami last fall during the supermoon, one of the highest high-tide days. And there were fish from the ocean swimming in some of the streets of Miami Beach and Fort Lauderdale and Del Rey. And this happens regularly during the highest-tide tides now. Not with rain — they call it"sunny-day flooding."It comes up through the storm sewers. And the Mayor of Miami speaks for many when he says it is long past time this can be viewed through a partisan lens. This is a crisis that ' s getting worse day by day. We have to move beyond partisanship. And I want to take a moment to honor these House Republicans — who had the courage last fall to step out and take a political risk, by telling the truth about the climate crisis. So the cost of the climate crisis is mounting up, there are many of these aspects I haven ’ t even mentioned. It ’ s an enormous burden. I ’ ll mention just one more, because the World Economic Forum last month in Davos, after their annual survey of 750 economists, said the climate crisis is now the number one risk to the global economy. So you get central bankers like Mark Carney, the head of the UK Central Bank, saying the vast majority of the carbon reserves are unburnable. Subprime carbon. I ’ m not going to remind you what happened with subprime mortgages, but it ’ s the same thing. If you look at all of the carbon fuels that were burned since the beginning of the industrial revolution, this is the quantity burned in the last 16 years. Here are all the ones that are proven and left on the books, 28 trillion dollars. The International Energy Agency says only this amount can be burned. So the rest, 22 trillion dollars — unburnable. Risk to the global economy. That ’ s why divestment movement makes practical sense and is not just a moral imperative. So the answer to the first question,”Must we change?”is yes, we have to change. Second question,”Can we change?”This is the exciting news! The best projections in the world 16 years ago were that by 2010, the world would be able to install 30 gigawatts of wind capacity. We beat that mark by 14 and a half times over. We see an exponential **curve** for wind installations now. We see the cost coming down dramatically. Some countries — take Germany, an industrial powerhouse with a climate not that different from Vancouver ’ s, by the way — one day last December, got 81 percent of all its energy from renewable resources, mainly solar and wind. A lot of countries are getting more than half on an average basis. More good news : energy storage, from batteries particularly, is now beginning to take off because the cost has been coming down very dramatically to solve the intermittency problem. With solar, the news is even more exciting! The best projections 14 years ago were that we would install one gigawatt per year by 2010. When 2010 came around, we beat that mark by 17 times over. Last year, we beat it by 58 times over. This year, we ’ re on track to beat it 68 times over. We ’ re going to win this. We are going to prevail. The exponential **curve** on solar is even steeper and more dramatic. When I came to this stage 10 years ago, this is where it was. We have seen a revolutionary breakthrough in the emergence of these exponential **curves**. And the cost has come down 10 percent per year for 30 years. And it ’ s continuing to come down. Now, the business community has certainly noticed this, because it ’ s crossing the grid parity point. Cheaper solar penetration rates are beginning to rise. Grid parity is understood as that line, that threshold, below which renewable electricity is cheaper than electricity from burning fossil fuels. That threshold is a little bit like the difference between 32 degrees Fahrenheit and 33 degrees Fahrenheit, or zero and one Celsius. It ’ s a difference of more than one degree, it ’ s the difference between ice and water. And it ’ s the difference between markets that are frozen up, and liquid flows of capital into new opportunities for investment. This is the biggest new business opportunity in the history of the world, and two-thirds of it is in the private sector. We are seeing an explosion of new investment. Starting in 2010, investments globally in renewable electricity generation surpassed fossils. The gap has been growing ever since. The projections for the future are even more dramatic, even though fossil energy is now still subsidized at a rate 40 times larger than renewables. And by the way, if you add the projections for nuclear on here, particularly if you assume that the work many are doing to try to break through to safer and more acceptable, more affordable forms of nuclear, this could change even more dramatically. So is there any precedent for such a rapid adoption of a new technology? Well, there are many, but let ’ s look at cell phones. In 1980, AT&T, then Ma Bell, commissioned McKinsey to do a global market survey of those clunky new mobile phones that appeared then.”How many can we sell by the year 2000?”they asked. McKinsey came back and said,”900, 000.”And sure enough, when the year 2000 arrived, they did sell 900, 000 — in the first three days. And for the balance of the year, they sold 120 times more. And now there are more cell connections than there are people in the world. So, why were they not only wrong, but way wrong? I ’ ve asked that question myself,”Why?”And I think the answer is in three parts. First, the cost came down much faster than anybody expected, even as the quality went up. And low-income countries, places that did not have a landline grid — they leap-frogged to the new technology. The big expansion has been in the developing counties. So what about the electricity grids in the developing world? Well, not so hot. And in many areas, they don ’ t exist. There are more people without any electricity at all in India than the entire population of the United States of America. So now we ’ re getting this : solar **panels** on grass huts and new business models that make it affordable. Muhammad Yunus financed this one in Bangladesh with micro- credit. This is a village market. Bangladesh is now the fastest-deploying country in the world : two systems per minute on average, night and day. And we have all we need : enough energy from the Sun comes to the earth every hour to supply the full world ’ s energy needs for an entire year. It ’ s actually a little bit less than an hour. So the answer to the second question,”Can we change?”is clearly”Yes.”And it ’ s an ever-firmer”yes.”Last question,”Will we change?”Paris really was a breakthrough, some of the provisions are binding and the regular reviews will matter a lot. But nations aren ’ t waiting, they ’ re going ahead. China has already announced that starting next year, they ’ re adopting a nationwide cap and trade system. They will likely link up with the European Union. The United States has already been changing. All of these coal plants were proposed in the next 10 years and canceled. All of these existing coal plants were retired. All of these coal plants have had their retirement announced. All of them — canceled. We are moving forward. Last year — if you look at all of the investment in new electricity generation in the United States, almost three-quarters was from renewable energy, mostly wind and solar. We are solving this crisis. The only question is : how long will it take to get there? So, it matters that a lot of people are organizing to insist on this change. Almost 400, 000 people marched in New York City before the UN special session on this. Many thousands, tens of thousands, marched in cities around the world. And so, I am extremely optimistic. As I said before, we are going to win this. I ’ ll finish with this story. When I was 13 years old, I heard that proposal by President Kennedy to land a person on the Moon and bring him back safely in 10 years. And I heard adults of that day and time say,”That ’ s reckless, expensive, may well fail.”But eight years and two months later, in the moment that Neil Armstrong set **foot** on the Moon, there was great cheer that went up in NASA ’ s mission control in Houston. Here ’ s a little-known fact about that : the average age of the systems engineers, the controllers in the room that day, was 26, which means, among other things, their age, when they heard that challenge, was 18. We now have a moral challenge that is in the tradition of others that we have faced. One of the greatest poets of the last century in the US, Wallace Stevens, wrote a line that has stayed with me :”After the final ’ no, ’ there comes a ’ yes, ’ and on that ’ yes ’, the future world depends.”When the abolitionists started their movement, they met with no after no after no. And then came a yes. The Women ’ s Suffrage and Women ’ s Rights Movement met endless no ’ s, until finally, there was a yes. The Civil Rights Movement, the movement against apartheid, and more recently, the movement for gay and lesbian rights here in the United States and elsewhere. After the final”no”comes a”yes.”When any great moral challenge is ultimately resolved into a binary choice between what is right and what is wrong, the outcome is fore-ordained because of who we are as human beings. Ninety-nine percent of us, that is where we are now and it is why we ’ re going to win this. We have everything we need. Some still doubt that we have the will to act, but I say the will to act is itself a renewable resource. Thank you very much. Chris Anderson : You ’ ve got this incredible combination of skills. You ’ ve got this scientist mind that can understand the full range of issues, and the ability to turn it into the most vivid language. No one else can do that, that ’ s why you led this thing. It was amazing to see it 10 years ago, it was amazing to see it now. Al Gore : Well, you ’ re nice to say that, Chris. But honestly, I have a lot of really good friends in the scientific community who are incredibly patient and who will sit there and explain this stuff to me over and over and over again until I can get it into simple enough language that I can understand it. And that ’ s the key to trying to communicate. CA : So, your talk. First part : terrifying, second part : incredibly hopeful. How do we know that all those graphs, all that progress, is enough to solve what you showed in the first part? AG : I think that the crossing — you know, I ’ ve only been in the business world for 15 years. But one of the things I ’ ve learned is that apparently it matters if a new product or service is more expensive than the incumbent, or cheaper than. Turns out, it makes a difference if it ’ s cheaper than. And when it crosses that line, then a lot of things really change. We are regularly surprised by these developments. The late Rudi Dornbusch, the great economist said,”Things take longer to happen then you think they will, and then they happen much faster than you thought they could.”I really think that ’ s where we are. Some people are using the phrase”The Solar Singularity”now, meaning when it gets below the grid parity, unsubsidized in most places, then it ’ s the default choice. Now, in one of the presentations yesterday, the jitney thing, there is an effort to use regulations to slow this down. And I just don ’ t think it ’ s going to work. There ’ s a woman in Atlanta, Debbie Dooley, who ’ s the Chairman of the Atlanta Tea Party. They enlisted her in this effort to put a tax on solar **panels** and regulations. And she had just put solar **panels** on her **roof** and she didn ’ t understand the request. And so she went and formed an alliance with the Sierra Club and they formed a new organization called the Green Tea Party. And they defeated the proposal. So, finally, the answer to your question is, this sounds a little corny and maybe it ’ s a clich, but 10 years ago — and Christiana referred to this — there are people in this audience who played an incredibly significant role in generating those exponential **curves**. And it didn ’ t work out economically for some of them, but it kick-started this global revolution. And what people in this audience do now with the knowledge that we are going to win this. But it matters a lot how fast we win it. CA : Al Gore, that was incredibly powerful. If this turns out to be the year, that the partisan thing changes, as you said, it ’ s no longer a partisan issue, but you bring along people from the other side together, backed by science, backed by these kinds of investment opportunities, backed by reason that you win the day — boy, that ’ s really exciting. Thank you so much. AG : Thank you so much for bringing me back to TED. Thank you!

Text Sample 722: POS Dim 5 – 2017 – Score 9.00 – 2017/t001061.txt

Imagine that when you walked in here this evening, you discovered that everybody in the room looked almost exactly the same : ageless, raceless, generically good-looking. That person sitting right next to you might have the most idiosyncratic inner life, but you don ’ t have a clue because we ’ re all wearing the same blank expression all the time. That is the kind of creepy transformation that is taking over cities, only it applies to buildings, not people. Cities are full of roughness and shadow, texture and color. You can still find architectural surfaces of great individuality and character in apartment buildings in Riga and Yemen, social housing in Vienna, Hopi villages in Arizona, brownstones in New York, wooden houses in San Francisco. These aren ' t palaces or cathedrals. These are just ordinary residences expressing the ordinary splendor of cities. And the reason they ' re like that is that the need for shelter is so bound up with the human desire for beauty. Their rough surfaces give us a touchable city. Right? Streets that you can read by running your fingers over brick and stone. But that ' s getting harder to do, because cities are becoming smooth. New downtowns sprout towers that are almost always made of concrete and steel and covered in glass. You can look at skylines all over the world — Houston, Guangzhou, Frankfurt — and you see the same army of high-gloss robots marching over the horizon. Now, just think of everything we lose when **architects** stop using the full range of available materials. When we reject granite and limestone and sandstone and wood and copper and terra-cotta and brick and wattle and plaster, we simplify architecture and we impoverish cities. It ' s as if you reduced all of the world ' s cuisines down to airline food. Chicken or pasta? But worse still, assemblies of glass towers like this one in Moscow suggest a disdain for the civic and communal aspects of urban living. Right? Buildings like these are intended to enrich their owners and tenants, but not necessarily the lives of the rest of us, those of us who navigate the spaces between the buildings. And we expect to do so for free. Shiny towers are an invasive species and they are choking our cities and killing off public space. We tend to think of a facade as being like makeup, a decorative layer applied at the end to a building that ' s effectively complete. But just because a facade is superficial doesn ' t mean it ' s not also deep. Let me give you an example of how a city ' s surfaces affect the way we live in it. When I visited Salamanca in Spain, I gravitated to the Plaza Mayor at all hours of the day. Early in the morning, sunlight rakes the facades, sharpening shadows, and at night, lamplight segments the buildings into hundreds of distinct areas, balconies and windows and arcades, each one a separate pocket of visual activity. That detail and depth, that glamour gives the plaza a theatrical quality. It becomes a stage where the generations can meet. You have teenagers sprawling on the pavers, seniors monopolizing the benches, and real life starts to look like an opera set. The curtain goes up on Salamanca. So just because I ' m talking about the exteriors of buildings, not form, not function, not structure, even so those surfaces give texture to our lives, because buildings create the spaces around them, and those spaces can draw people in or push them away. And the difference often has to do with the quality of those exteriors. So one contemporary equivalent of the Plaza Mayor in Salamanca is the Place de la Dfense in Paris, a windswept, glass-walled open space that office workers hurry through on the way from the metro to their cubicles but otherwise spend as little time in as possible. In the early 1980s, the **architect** Philip Johnson tried to recreate a gracious European plaza in Pittsburgh. This is PPG Place, a half acre of open space encircled by commercial buildings made of mirrored glass. And he ornamented those buildings with **metal** trim and bays and Gothic turrets which really pop on the skyline. But at ground level, the plaza feels like a black glass cage. I mean, sure, in summertime kids are running back and forth through the fountain and there ' s ice-skating in the winter, but it lacks the informality of a leisurely hangout. It ' s just not the sort of place you really want to just hang out and chat. Public spaces thrive or fail for many different reasons. Architecture is only one, but it ' s an important one. Some recent plazas like Federation Square in Melbourne or Superkilen in Copenhagen succeed because they combine old and new, rough and smooth, neutral and bright colors, and because they don ’ t rely excessively on glass. Now, I ’ m not against glass. It ’ s an ancient and versatile material. It ’ s easy to manufacture and transport and install and replace and **clean**. It comes in everything from enormous, ultraclear sheets to translucent bricks. New coatings make it change mood in the shifting light. In expensive cities like New York, it has the magical power of being able to multiply real estate values by allowing views, which is really the only commodity that developers have to offer to justify those surreal prices. In the middle of the 19th century, with the construction of the Crystal Palace in London, glass leapt to the top of the list of quintessentially modern substances. By the mid-20th century, it had come to dominate the downtowns of some American cities, largely through some really spectacular office buildings like Lever House in midtown Manhattan, designed by Skidmore, Owings and Merrill. Eventually, the technology advanced to the point where **architects** could design structures so transparent they practically disappear. And along the way, glass became the default material of the high-rise city, and there ’ s a very powerful reason for that. Because as the world ’ s populations converge on cities, the least fortunate pack into jerry-built shantytowns. But hundreds of millions of people need apartments and places to work in ever-larger buildings, so it makes economic sense to put up towers and wrap them in cheap and practical curtain walls. But glass has a limited ability to be expressive. This is a section of wall framing a plaza in the pre-Hispanic city of Mitla, in southern Mexico. Those 2, 000-year-old carvings make it clear that this was a place of high ritual significance. Today we look at those and we can see a historical and textural continuity between those carvings, the mountains all around and that church which is built on top of the ruins using stone plundered from the site. In nearby Oaxaca, even ordinary plaster buildings become canvasses for bright colors, political murals and sophisticated graphic arts. It ’ s an intricate, communicative language that an epidemic of glass would simply wipe out. The good news is that **architects** and developers have begun to rediscover the joys of texture without backing away from modernity. Some find innovative uses for old materials like brick and terra-cotta. Others invent new products like the molded **panels** that Snhetta used to give the San Francisco Museum of Modern Art that crinkly, sculptural quality. The **architect** Stefano Boeri even created living facades. This is his Vertical Forest, a pair of apartment towers in Milan, whose most visible feature is greenery. And Boeri is designing a version of this for Nanjing in China. And imagine if green facades were as ubiquitous as glass ones how much **cleaner** the air in Chinese cities would become. But the truth is that these are mostly one-offs, boutique projects, not easily reproduced at a global scale. And that is the point. When you use materials that have a local significance, you prevent cities from all looking the same. Copper has a long history in New York — the Statue of Liberty, the crown of the Woolworth Building — but it fell out of fashion for a long time until SHoP **Architects** used it to cover the American Copper Building, a pair of twisting towers on the East River. It ’ s not even finished and you can see the way sunset lights up that metallic facade, which will weather to green as it ages. Buildings can be like people. Their faces broadcast their experience. And that ’ s an important point, because when glass ages, you just replace it, and the building looks pretty much the same way it did before until eventually it ’ s demolished. Almost all other materials have the ability to absorb infusions of history and memory, and project it into the present. The firm Ennead clad the Utah Natural History Museum in Salt Lake City in copper and zinc, ores that have been mined in the area for 150 years and that also camouflage the building against the ochre hills so that you have a natural history

museum that reflects the region ’ s natural history. And when the Chinese Pritzker Prize winner Wang Shu was building a history **museum** in Ningbo, he didn ’ t just create a wrapper for the past, he built memory right into the walls by using brick and stones and shingles salvaged from villages that had been demolished. Now, **architects** can use glass in equally lyrical and inventive ways. Here in New York, two buildings, one by Jean Nouvel and this one by Frank Gehry face off across West 19th Street, and the play of reflections that they toss back and forth is like a symphony in light. But when a city defaults to glass as it grows, it becomes a hall of mirrors, disquieting and cold. After all, cities are places of concentrated variety where the world ’ s cultures and languages and lifestyles come together and mingle. So rather than encase all that variety and diversity in buildings of crushing sameness, we should have an architecture that honors the full range of the urban experience. Thank you.

Text Sample 723: POS Dim 5 – 2017 – Score 7.00 – 2017/t001083.txt

Chris Anderson : Elon, hey, welcome back to TED. It ’ s great to have you here. Elon Musk : Thanks for having me. CA : So, in the next half hour or so, we ’ re going to spend some time exploring your vision for what an exciting future might look like, which I guess makes the first question a little ironic : Why are you boring? EM : Yeah. I ask myself that frequently. We ’ re trying to dig a hole under LA, and this is to create the beginning of what will hopefully be a 3D network of tunnels to alleviate congestion. So right now, one of the most soul-destroying things is traffic. It affects people in every part of the world. It takes away so much of your life. It ’ s horrible. It ’ s particularly horrible in LA. CA : I think you ’ ve brought with you the first visualization that ’ s been shown of this. Can I show this? EM : Yeah, absolutely. So this is the first time — Just to show what we ’ re talking about. So a couple of key things that are important in having a 3D tunnel network. First of all, you have to be able to integrate the entrance and exit of the tunnel seamlessly into the fabric of the city. So by having an elevator, sort of a car skate, that ’ s on an elevator, you can integrate the entrance and exits to the tunnel network just by using two parking spaces. And then the car gets on a skate. There ’ s no speed limit here, so we ’ re designing this to be able to operate at 200 kilometers an hour. CA : How much? EM : 200 kilometers an hour, or about 130 miles per hour. So you should be able to get from, say, Westwood to LAX in six minutes — five, six minutes. CA : So possibly, initially done, it ’ s like on a sort of toll road-type basis. EM : Yeah. CA : Which, I guess, alleviates some traffic from the surface streets as well. EM : So, I don ’ t know if people noticed it in the video, but there ’ s no real limit to how many levels of tunnel you can have. You can go much further deep than you can go up. The deepest mines are much deeper than the tallest buildings are tall, so you can alleviate any arbitrary level of urban congestion with a 3D tunnel network. This is a very important point. So a key rebuttal to the tunnels is that if you add one layer of tunnels, that will simply alleviate congestion, it will get used up, and then you ’ ll be back where you started, back with congestion. But you can go to any arbitrary number of tunnels, any number of levels. CA : But people — seen traditionally, it ’ s incredibly expensive to dig, and that would block this idea. EM : Yeah. Well, they ’ re right. To give you an example, the LA subway extension, which is — I think it ’ s a two-and-a-half mile extension that was just completed for two billion dollars. So it ’ s roughly a billion dollars a mile to do the subway extension in LA. And this is not the highest utility subway in the world. So yeah, it ’ s quite difficult to dig tunnels normally. I think we need to have at least a tenfold improvement in the cost per mile of tunneling. CA :

And how could you achieve that? EM : Actually, if you just do two things, you can get to approximately an order of magnitude improvement, and I think you can go beyond that. So the first thing to do is to cut the tunnel diameter by a factor of two or more. So a single road lane tunnel according to regulations has to be 26 **feet**, maybe 28 **feet** in diameter to allow for crashes and emergency vehicles and sufficient ventilation for combustion engine cars. But if you shrink that diameter to what we ' re attempting, which is 12 **feet**, which is plenty to get an electric skate through, you drop the diameter by a factor of two and the cross-sectional area by a factor of four, and the tunneling cost scales with the cross-sectional area. So that ' s roughly a half-order of magnitude improvement right there. Then tunneling machines currently tunnel for half the time, then they stop, and then the rest of the time is putting in reinforcements for the tunnel wall. So if you design the machine instead to do continuous tunneling and reinforcing, that will give you a factor of two improvement. Combine that and that ' s a factor of eight. Also these machines are far from being at their power or thermal limits, so you can jack up the power to the machine substantially. I think you can get at least a factor of two, maybe a factor of four or five improvement on top of that. So I think there ' s a fairly straightforward series of steps to get somewhere in excess of an order of magnitude improvement in the cost per mile, and our target actually is — we ' ve got a pet snail called Gary, this is from Gary the snail from"South Park,"I mean, sorry,"SpongeBob SquarePants."So Gary is capable of — currently he ' s capable of going 14 times faster than a tunnel-boring machine. CA : You want to beat Gary. EM : We want to beat Gary. He ' s not a patient little fellow, and that will be victory. Victory is beating the snail. CA : But a lot of people imagining, dreaming about future cities, they imagine that actually the solution is flying cars, drones, etc. You go aboveground. Why isn ' t that a better solution? You save all that tunneling cost. EM : Right. I ' m in favor of flying things. Obviously, I do rockets, so I like things that fly. This is not some inherent bias against flying things, but there is a challenge with flying cars in that they ' ll be quite noisy, the wind force generated will be very high. Let ' s just say that if something ' s flying over your head, a whole bunch of flying cars going all over the place, that is not an anxiety-reducing situation. You don ' t think to yourself,"Well, I feel better about today."You ' re thinking,"Did they service their hubcap, or is it going to come off and guillotine me?"Things like that. CA : So you ' ve got this vision of future cities with these rich, 3D networks of tunnels underneath. Is there a tie-in here with Hyperloop? Could you apply these tunnels to use for this Hyperloop idea you released a few years ago. EM : Yeah, so we ' ve been sort of puttering around with the Hyperloop stuff for a while. We built a Hyperloop test track adjacent to SpaceX, just for a student competition, to encourage innovative ideas in transport. And it actually ends up being the biggest vacuum chamber in the world after the Large Hadron Collider, by volume. So it was quite **fun** to do that, but it was kind of a hobby thing, and then we think we might — so we ' ve built a little pusher car to push the student pods, but we ' re going to try seeing how fast we can make the pusher go if it ' s not pushing something. So we ' re cautiously optimistic we ' ll be able to be faster than the world ' s fastest bullet train even in a. 8-mile stretch. CA : Whoa. Good brakes. EM : Yeah, I mean, it ' s — yeah. It ' s either going to smash into tiny pieces or go quite fast. CA : But you can **picture**, then, a Hyperloop in a tunnel running quite long distances. EM : Exactly. And looking at tunneling technology, it turns out that in order to make a tunnel, you have to — In order to seal against the water table, you ' ve got to typically design a tunnel wall to be good to about five or six atmospheres. So to go to vacuum is only one atmosphere, or near-vacuum. So actually, it sort of turns out that automatically, if you build a tunnel that is good enough to resist the water table, it is automatically capable of holding vacuum. CA : Huh. EM : So, yeah. CA : And so you could actually **picture**, what kind of length tunnel is in Elon ' s future to running Hyperloop? EM : I think there ' s no real length limit. You could dig as much as you want. I think if you were to do something like a DC-to-New York Hyperloop, I think you ' d probably want to go underground the entire way because it ' s a high- density area. You ' re going under a lot of buildings and houses, and if you go deep enough, you cannot detect the tunnel. Sometimes people think, well, it ' s going to be pretty annoying to have a tunnel dug under my house. Like, if that tunnel is dug more than about three or four tunnel diameters beneath your house, you will not be able to detect it being dug at all. In fact, if you ' re able to detect the tunnel being dug, whatever device you are using, you can get a lot of money for that device from the Israeli military, who is trying to detect tunnels from Hamas, and from the US Customs and Border patrol that try and detect drug tunnels. So the reality is that earth is incredibly good at absorbing vibrations, and once the tunnel depth is below a certain level, it is undetectable. Maybe if you have a very sensitive seismic instrument, you might be able to detect it. CA : So you ' ve started a new company to do this called The Boring Company. Very nice. Very funny. EM : What ' s funny about that? CA : How much of your time is this? EM : It ' s maybe... two or three percent. CA : You ' ve called it a hobby. This is what an Elon Musk hobby looks like. EM : I mean, it really is, like — This is basically interns and people doing it part time. We bought some second-hand machinery. It ' s kind of puttering along, but it ' s making good progress, so — CA : So an even bigger part of your time is being spent on electrifying cars and transport through Tesla. Is one of the motivations for the tunneling project the realization that actually, in a world where cars are electric and where they ' re self-driving, there may end up being more cars on the roads on any given hour than there are now? EM : Yeah, exactly. A lot of people think that when you make cars autonomous, they ' ll be able to go faster and that will alleviate congestion. And to some degree that will be true, but once you have shared autonomy where it ' s much cheaper to go by car and you can go point to point, the affordability of going in a car will be better than that of a bus. Like, it will cost less than a bus ticket. So the amount of driving that will occur will be much greater with shared autonomy, and actually traffic will get far worse. CA : You started Tesla with the goal of persuading the world that electrification was the future of cars, and a few years ago, people were laughing at you. Now, not so much. EM : OK. I don ' t know. I don ' t know. CA : But isn ' t it true that pretty much every auto manufacturer has announced serious electrification plans for the short- to medium-term future? EM : Yeah. Yeah. I think almost every automaker has some electric vehicle program. They vary in seriousness. Some are very serious about transitioning entirely to electric, and some are just dabbling in it. And some, amazingly, are still pursuing fuel cells, but I think that won ' t last much longer. CA : But isn ' t there a sense, though, Elon, where you can now just declare victory and say, you know,"We did it."Let the world electrify, and you go on and focus on other stuff? EM : Yeah. I intend to stay with Tesla as far into the future as I can imagine, and there are a lot of exciting things that we have coming. Obviously the Model 3 is coming soon. We ' ll be unveiling the Tesla Semi truck. CA : OK, we ' re going to come to this. So Model 3, it ' s supposed to be coming in July-ish. EM : Yeah, it ' s looking quite good for starting production in July. CA : Wow. One of the things that people are so excited about is the fact that it ' s got autopilot. And you put out this video a while back showing what that technology would look like. EM : Yeah. CA : There ' s obviously autopilot in Model S right now. What are we seeing here? EM : Yeah, so this is using only cameras and GPS. So there ' s no

LIDAR or radar being used here. This is just using passive optical, which is essentially what a person uses. The whole road system is meant to be navigated with passive optical, or cameras, and so once you solve cameras or vision, then autonomy is solved. If you don ’ t solve vision, it ’ s not solved. So that ’ s why our focus is so heavily on having a vision neural net that ’ s very effective for road conditions. CA : Right. Many other people are going the LIDAR route. You want cameras plus radar is most of it. EM : You can absolutely be superhuman with just cameras. Like, you can probably do it ten times better than humans would, just cameras. CA : So the new cars being sold right now have eight cameras in them. They can ’ t yet do what that showed. When will they be able to? EM : I think we ’ re still on track for being able to go cross-country from LA to New York by the end of the year, fully autonomous. CA : OK, so by the end of the year, you ’ re saying, someone ’ s going to sit in a Tesla without touching the steering wheel, tap in”New York,”off it goes. EM : Yeah. CA : Won ’ t ever have to touch the wheel — by the end of 2017. EM : Yeah. Essentially, November or December of this year, we should be able to go all the way from a parking lot in California to a parking lot in New York, no controls touched at any point during the entire journey. CA : Amazing. But part of that is possible because you ’ ve already got a fleet of Teslas driving all these roads. You ’ re accumulating a huge amount of data of that national road system. EM : Yes, but the thing that will be interesting is that I ’ m actually fairly confident it will be able to do that route even if you change the route dynamically. So, it ’ s fairly easy — If you say I ’ m going to be really good at one specific route, that ’ s one thing, but it should be able to go, really be very good, certainly once you enter a highway, to go anywhere on the highway system in a given country. So it ’ s not sort of limited to LA to New York. We could change it and make it Seattle-Florida, that day, in real time. So you were going from LA to New York. Now go from LA to Toronto. CA : So leaving aside regulation for a second, in terms of the technology alone, the time when someone will be able to buy one of your cars and literally just take the hands off the wheel and go to sleep and wake up and find that they ’ ve arrived, how far away is that, to do that safely? EM : I think that ’ s about two years. So the real trick of it is not how do you make it work say 99. 9 percent of the time, because, like, if a car crashes one in a thousand times, then you ’ re probably still not going to be comfortable falling asleep. You shouldn ’ t be, certainly. It ’ s never going to be perfect. No system is going to be perfect, but if you say it ’ s perhaps — the car is unlikely to crash in a hundred lifetimes, or a thousand lifetimes, then people are like, OK, wow, if I were to live a thousand lives, I would still most likely never experience a crash, then that ’ s probably OK. CA : To sleep. I guess the big concern of yours is that people may actually get seduced too early to think that this is safe, and that you ’ ll have some horrible incident happen that puts things back. EM : Well, I think that the autonomy system is likely to at least mitigate the crash, except in rare circumstances. The thing to appreciate about vehicle safety is this is probabilistic. I mean, there ’ s some chance that any time a human driver gets in a car, that they will have an accident that is their fault. It ’ s never zero. So really the key threshold for autonomy is how much better does autonomy need to be than a person before you can rely on it? CA : But once you get literally safe hands-off driving, the power to disrupt the whole industry seems massive, because at that point you ’ ve spoken of people being able to buy a car, drops you off at work, and then you let it go and provide a sort of Uber-like service to other people, earn you money, maybe even cover the cost of your lease of that car, so you can kind of get a car for free. Is that really likely? EM : Yeah. Absolutely this is what will happen. So there will be a shared autonomy fleet where you buy your car and you can choose to use that car exclusively, you could choose to have it be used only by friends and family, only by other drivers who are rated five star, you can choose to share it sometimes but not other times. That ’ s 100 percent what will occur. It ’ s just a question of when. CA : Wow. So you mentioned the Semi and I think you ’ re planning to announce this in September, but I ’ m curious whether there ’ s anything you could show us today? EM : I will show you a teaser shot of the truck. It ’ s alive. CA : OK. EM : That ’ s definitely a case where we want to be cautious about the autonomy features. Yeah. CA : We can ’ t see that much of it, but it doesn ’ t look like just a little friendly neighborhood truck. It looks kind of badass. What sort of semi is this? EM : So this is a heavy duty, long-range semitruck. So it ’ s the highest weight capability and with long range. So essentially it ’ s meant to alleviate the heavy-duty trucking loads. And this is something which people do not today think is possible. They think the truck doesn ’ t have enough power or it doesn ’ t have enough range, and then with the Tesla Semi we want to show that no, an electric truck actually can out-torque any diesel semi. And if you had a tug-of-war competition, the Tesla Semi will tug the diesel semi uphill. CA : That ’ s pretty cool. And short term, these aren ’ t driverless. These are going to be trucks that truck drivers want to drive. EM : Yes. So what will be really **fun** about this is you have a flat torque RPM **curve** with an electric motor, whereas with a diesel motor or any kind of internal combustion engine car, you ’ ve got a torque RPM **curve** that looks like a hill. So this will be a very spry truck. You can drive this around like a sports car. There ’ s no gears. It ’ s, like, single speed. CA : There ’ s a great movie to be made here somewhere. I don ’ t know what it is and I don ’ t know that it ends well, but it ’ s a great movie. EM : It ’ s quite bizarre test-driving. When I was driving the test prototype for the first truck. It ’ s really weird, because you ’ re driving around and you ’ re just so nimble, and you ’ re in this giant truck. CA : Wait, you ’ ve already driven a prototype? EM : Yeah, I drove it around the parking lot, and I was like, this is crazy. CA : Wow. This is no vaporware. EM : It ’ s just like, driving this giant truck and making these mad maneuvers. CA : This is cool. OK, from a really badass **picture** to a kind of less badass **picture**. This is just a cute house from”Desperate Housewives”or something. What on earth is going on here? EM : Well, this illustrates the **picture** of the future that I think is how things will evolve. You ’ ve got an electric car in the driveway. If you look in between the electric car and the house, there are actually three Powerwalls stacked up against the side of the house, and then that house **roof** is a solar **roof**. So that ’ s an actual solar glass **roof**. CA : OK. EM : That ’ s a **picture** of a real — well, admittedly, it ’ s a real fake house. That ’ s a real fake house. CA : So these **roof** tiles, some of them have in them basically solar power, the ability to — EM : Yeah. Solar glass tiles where you can adjust the texture and the color to a very fine-grained level, and then there ’ s sort of microlouvers in the glass, such that when you ’ re looking at the **roof** from street level or close to street level, all the tiles look the same whether there is a solar cell behind it or not. So you have an even color from the ground level. If you were to look at it from a helicopter, you would be actually able to look through and see that some of the glass tiles have a solar cell behind them and some do not. You can ’ t tell from street level. CA : You put them in the ones that are likely to see a lot of sun, and that makes these **roofs** super affordable, right? They ’ re not that much more expensive than just tiling the **roof**. EM : Yeah. We ’ re very confident that the cost of the **roof** plus the cost of electricity — A solar glass **roof** will be less than the cost of a normal **roof** plus the cost of electricity. So in other words, this will be economically a no-brainer, we think it will look great, and it will last — We thought about having the warranty be infinity, but then people thought, well, that might sound like were just talking rubbish, but actually this is toughened glass. Well after the house has collapsed and there ' s nothing there, the glass tiles will still be there. CA : I mean, this is cool. So you ' re rolling this out in a couple week ' s time, I think, with four different roofing types. EM : Yeah, we ' re starting off with two, two initially, and the second two will be introduced early next year. CA : And what ' s the scale of ambition here? How many houses do you believe could end up having this type of roofing? EM : I think eventually almost all houses will have a solar **roof**. The thing is to consider the time scale here to be probably on the order of 40 or 50 years. So on average, a **roof** is replaced every 20 to 25 years. But you don ' t start replacing all **roofs** immediately. But eventually, if you say were to fast- forward to say 15 years from now, it will be unusual to have a **roof** that does not have solar. CA : Is there a mental model thing that people don ' t get here that because of the shift in the cost, the economics of solar power, most houses actually have enough sunlight on their **roof** pretty much to power all of their needs. If you could capture the power, it could pretty much power all their needs. You could go off-grid, kind of. EM : It depends on where you are and what the house size is relative to the **roof** area, but it ' s a fair statement to say that most houses in the US have enough **roof** area to power all the needs of the house. CA : So the key to the economics of the cars, the Semi, of these houses is the falling price of lithium-ion batteries, which you ' ve made a huge bet on as Tesla. In many ways, that ' s almost the core competency. And you ' ve decided that to really, like, own that competency, you just have to build the world ' s largest manufacturing plant to double the world ' s supply of lithium-ion batteries, with this guy. What is this? EM : Yeah, so that ' s the Gigafactory, progress so far on the Gigafactory. Eventually, you can sort of roughly see that there ' s sort of a diamond shape overall, and when it ' s fully done, it ' ll look like a giant diamond, or that ' s the idea behind it, and it ' s aligned on true north. It ' s a small detail. CA : And capable of producing, eventually, like a hundred gigawatt hours of batteries a year. EM : A hundred gigawatt hours. We think probably more, but yeah. CA : And they ' re actually being produced right now. EM : They ' re in production already. CA : You guys put out this video. I mean, is that speeded up? EM : That ' s the slowed down version. CA : How fast does it actually go? EM : Well, when it ' s running at full speed, you can ' t actually see the cells without a strobe light. It ' s just blur. CA : One of your core ideas, Elon, about what makes an exciting future is a future where we no longer feel guilty about energy. Help us **picture** this. How many Gigafactories, if you like, does it take to get us there? EM : It ' s about a hundred, roughly. It ' s not 10, it ' s not a thousand. Most likely a hundred. CA : See, I find this amazing. You can **picture** what it would take to move the world off this vast fossil fuel thing. It ' s like you ' re building one, it costs five billion dollars, or whatever, five to 10 billion dollars. Like, it ' s kind of cool that you can **picture** that project. And you ' re planning to do, at Tesla — announce another two this year. EM : I think we ' ll announce locations for somewhere between two and four Gigafactories later this year. Yeah, probably four. CA : Whoa. No more teasing from you for here? Like — where, continent? You can say no. EM : We need to address a global market. CA : OK. This is cool. I think we should talk for — Actually, global market. I ' m going to ask you one question about politics, only one. I ' m kind of sick of politics, but I do want to ask you this. You ' re on a body now giving advice to a guy — EM : Who? CA : Who has said he doesn ' t really believe in climate change, and there ' s a lot of people out there who think you shouldn ' t be doing that. They ' d like you to walk away from that. What would you say to them? EM : Well, I think that first of all, I ' m just on two advisory councils where the format consists of going around the room and asking people ' s opinion on things, and so there ' s like a meeting every month or two. That ' s the sum total of my contribution.

But I think to the degree that there are people in the room who are arguing in favor of doing something about climate change, or social issues, I ’ ve used the meetings I ’ ve had thus far to argue in favor of immigration and in favor of climate change. And if I hadn ’ t done that, that wasn ’ t on the agenda before. So maybe nothing will happen, but at least the words were said. CA : OK. So let ’ s talk SpaceX and Mars. Last time you were here, you spoke about what seemed like a kind of incredibly ambitious dream to develop rockets that were actually reusable. And you ’ ve only gone and done it. EM : Finally. It took a long time. CA : Talk us through this. What are we looking at here? EM : So this is one of our rocket boosters coming back from very high and fast in space. So just delivered the upper stage at high velocity. I think this might have been at sort of Mach 7 or so, delivery of the upper stage. CA : So that was a sped-up — EM : That was the slowed down version. CA : I thought that was the sped-up version. But I mean, that ’ s amazing, and several of these failed before you finally figured out how to do it, but now you ’ ve done this, what, five or six times? EM : We ’ re at eight or nine. CA : And for the first time, you ’ ve actually reflown one of the rockets that landed. EM : Yeah, so we landed the rocket booster and then prepped it for flight again and flew it again, so it ’ s the first reflight of an orbital booster where that reflight is relevant. So it ’ s important to appreciate that reusability is only relevant if it is rapid and complete. So like an aircraft or a car, the reusability is rapid and complete. You do not send your aircraft to Boeing in- between flights. CA : Right. So this is allowing you to dream of this really ambitious idea of sending many, many, many people to Mars in, what, 10 or 20 years time, I guess. EM : Yeah. CA : And you ’ ve designed this outrageous rocket to do it. Help us understand the scale of this thing. EM : Well, visually you can see that ’ s a person. Yeah, and that ’ s the vehicle. CA : So if that was a skyscraper, that ’ s like, did I read that, a 40-story skyscraper? EM : Probably a little more, yeah. The thrust level of this is really — This configuration is about four times the thrust of the Saturn V moon rocket. CA : Four times the thrust of the biggest rocket humanity ever created before. EM : Yeah. Yeah. CA : As one does. EM : Yeah. In units of 747, a 747 is only about a quarter of a million pounds of thrust, so for every 10 million pounds of thrust, there ’ s 40 747s. So this would be the thrust equivalent of 120 747s, with all engines blazing. CA : And so even with a machine designed to escape Earth ’ s gravity, I think you told me last time this thing could actually take a fully loaded 747, people, cargo, everything, into orbit. EM : Exactly. This can take a fully loaded 747 with maximum fuel, maximum passengers, maximum cargo on the 747 — this can take it as cargo. CA : So based on this, you presented recently this Interplanetary Transport System which is visualized this way. This is a scene you **picture** in, what, 30 years time? 20 years time? People walking into this rocket. EM : I ’ m hopeful it ’ s sort of an eight- to 10-year time frame. Aspirationally, that ’ s our target. Our internal targets are more aggressive, but I think — CA : OK. EM : While vehicle seems quite large and is large by comparison with other rockets, I think the future spacecraft will make this look like a rowboat. The future spaceships will be truly enormous. CA : Why, Elon? Why do we need to build a city on Mars with a million people on it in your lifetime, which I think is kind of what you ’ ve said you ’ d love to do? EM : I think it ’ s important to have a future that is inspiring and appealing. I just think there have to be reasons that you get up in the morning and you want to live. Like, why do you want to live? What ’ s the point? What inspires you? What do you love about the future? And if we ’ re not out there, if the future does not include being out there among the stars and being a multiplanet species, I find that it ’ s incredibly depressing if that ’ s not the future that we ’ re going to have. CA : People want to position this as an either or, that there are so many desperate things happening on the planet now from climate to poverty to, you know, you pick your issue. And this feels like a distraction. You shouldn ’ t be thinking about this. You should be solving what ’ s here and now. And to be fair, you ’ ve done a fair old bit to actually do that with your work on sustainable energy. But why not just do that? EM : I think there ’ s — I look at the future from the standpoint of probabilities. It ’ s like a branching stream of probabilities, and there are actions that we can take that affect those probabilities or that accelerate one thing or slow down another thing. I may introduce something new to the probability stream. Sustainable energy will happen no matter what. If there was no Tesla, if Tesla never existed, it would have to happen out of necessity. It ’ s tautological. If you don ’ t have sustainable energy, it means you have unsustainable energy. Eventually you will run out, and the laws of economics will drive civilization towards sustainable energy, inevitably. The fundamental value of a company like Tesla is the degree to which it accelerates the advent of sustainable energy, faster than it would otherwise occur. So when I think, like, what is the fundamental good of a company like Tesla, I would say, hopefully, if it accelerated that by a decade, potentially more than a decade, that would be quite a good thing to occur. That ’ s what I consider to be the fundamental aspirational good of Tesla. Then there ’ s becoming a multiplanet species and space-faring civilization. This is not inevitable. It ’ s very important to appreciate this is not inevitable. The sustainable energy future I think is largely inevitable, but being a space- faring civilization is definitely not inevitable. If you look at the progress in space, in 1969 you were able to send somebody to the moon. 1969. Then we had the Space Shuttle. The Space Shuttle could only take people to low Earth orbit. Then the Space Shuttle retired, and the United States could take no one to orbit. So that ’ s the trend. The trend is like down to nothing. People are mistaken when they think that technology just automatically improves. It does not automatically improve. It only improves if a lot of people work very hard to make it better, and actually it will, I think, by itself degrade, actually. You look at great civilizations like Ancient Egypt, and they were able to make the pyramids, and they forgot how to do that. And then the Romans, they built these incredible aqueducts. They forgot how to do it. CA : Elon, it almost seems, listening to you and looking at the different things you ’ ve done, that you ’ ve got this unique double motivation on everything that I find so interesting. One is this desire to work for humanity ’ s long-term good. The other is the desire to do something exciting. And often it feels like you feel like you need the one to drive the other. With Tesla, you want to have sustainable energy, so you made these super sexy, exciting cars to do it. Solar energy, we need to get there, so we need to make these beautiful **roofs**. We haven ’ t even spoken about your newest thing, which we don ’ t have time to do, but you want to save humanity from bad AI, and so you ’ re going to create this really cool brain-machine interface to give us all infinite memory and telepathy and so forth. And on Mars, it feels like what you ’ re saying is, yeah, we need to save humanity and have a backup plan, but also we need to inspire humanity, and this is a way to inspire. EM : I think the value of beauty and inspiration is very much underrated, no question. But I want to be clear. I ’ m not trying to be anyone ’ s savior. That is not the — I ’ m just trying to think about the future and not be sad. CA : Beautiful statement. I think everyone here would agree that it is not — None of this is going to happen inevitably. The fact that in your mind, you dream this stuff, you dream stuff that no one else would dare dream, or no one else would be capable of dreaming at the level of complexity that you do. The fact that you do that, Elon Musk, is a really remarkable thing. Thank you for helping us all to dream a bit bigger. EM : But you ’ ll tell me if it ever starts getting genuinely insane, right? CA : Thank you, Elon Musk. That was really, really fantastic. That was really fantastic.

You may have noticed that I ’ m wearing two different shoes. It probably looks funny â it definitely feels funny â but I wanted to make a point. Let ’ s say my left shoe corresponds to a sustainable footprint, meaning we humans consume less natural resources than our planet can regenerate, and emit less carbon dioxide than our forests and oceans can reabsorb. That ’ s a stable and healthy condition. Today ’ s situation is more like my other shoe. It ’ s way oversized. At the second of August in 2017, we had already consumed all resources our planet can regenerate this year. This is like spending all your money until the 18th of a month and then needing a credit from the bank for the rest of the time. For sure, you can do this for some months in a row, but if you don ’ t change your behavior, sooner or later, you will run into big problems. We all know the devastating effects of this excessive exploitation : global warming, rising of the sea levels, melting of the glaciers and polar ice, increasingly extreme climate patterns and more. The enormity of this problem really frustrates me. What frustrates me even more is that there are solutions to this, but we keep doing things like we always did. Today I want to share with you how a new solar technology can contribute to a sustainable future of buildings. Buildings consume about 40 percent of our total energy demand, so tackling this consumption would significantly reduce our climate emissions. A building designed along sustainable principles can produce all the power it needs by itself. To achieve this, you first have to reduce the consumption as much as possible, by using well-insulated walls or windows, for instance. These technologies are commercially available. Then you need energy for warm water and heating. You can get this in a renewable way from the sun through solar-thermal installations or from the ground and air, with heat pumps. All of these technologies are available. Then you are left with the need for electricity. In principle, there are several ways to get renewable electricity, but how many buildings do you know which have a windmill on the **roof** or a water power plant in the garden? Probably not so many, because usually, it doesn ’ t make sense. But the sun provides abundant energy to our **roofs** and facades. The potential to harvest this energy at our buildings ’ surfaces is enormous. Let ’ s take Europe as an example. If you would utilize all areas which have a nice orientation to the sun and they ’ re not overly shaded, the power generated by photovoltaics would correspond to about 30 percent of our total energy demand. But today ’ s photovoltaics have some issues. They do offer a good cost-performance ratio, but they aren ’ t really flexible in terms of their design, and this makes aesthetics a challenge. People often imagine **pictures** like this when thinking about solar cells on buildings. This may work for solar farms, but when you think of buildings, of streets, of architecture, aesthetics does matter. This is the reason why we don ’ t see many solar cells on buildings today. They just don ’ t match. Our team is working on a totally different solar-cell technology, which is called organic photovoltaics or OPV. The term organic describes that the material used for light absorption and charge transport are mainly based on the element carbon, and not on **metals**. We utilize the mixture of a polymer which is set up by different repeating units, like the pearls in a pearl chain, and a small molecule which has the shape of a football and is called fullerene. These two compounds are mixed and dissolved to become an ink. And like ink, they can be printed with simple printing techniques like slot-die coating in a continuous roll-to-roll process on flexible substrates. The resulting thin layer is the active layer, absorbing the energy of the sun. This active layer is extremely effective. You only need a layer thickness of 0. 2 micrometers to absorb the energy of the sun. This is 100 times thinner than a human hair. To give you another example, take one kilogram of the basic polymer and use it to formulate the active ink. With this amount of ink, you can print a solar cell the size of a complete football field. So OPV is extremely material efficient, which I think is a **crucial** thing when talking about sustainability. After the printing process, you can have a solar module which could look like this... It looks a bit like a plastic foil and actually has many of its features. It ’ s lightweight... it ’ s bendable... and it ’ s semi-transparent. But it can harvest the energy of the sun outdoors and also of this indoor light, as you can see with this small, illuminated LED. You can use it in its plastic form and take advantage of its low weight and its bendability. The first is important when thinking about buildings in warmer regions. Here, the **roofs** are not designed to bear additionally heavy loads. They aren ’ t designed for snow in winter, for instance, so heavy silicon solar cells cannot be used for light harvesting, but these lightweight solar foils are very well suited. The bendability is important if you want to combine the solar cell with membrane architecture. Imagine the sails of the Sydney Opera as power plants. Alternatively, you can combine the solar foils with conventional construction materials like glass. Many glass facade elements contain a foil anyway, to create laminated safety glass. It ’ s not a big deal to add a second foil in the production process, but then the facade element contains the solar cell and can produce electricity. Besides looking nice, these integrated solar cells come along with two more important benefits. Do you remember the solar cell attached to a **roof** I showed before? In this case, we install the **roof** first, and as a second layer, the solar cell. This is adding on the installation costs. In the case of integrated solar cells, at the site of construction, only one element is installed, being at the same time the envelope of the building and the solar cell. Besides saving on the installation costs, this also saves resources, because the two functions are combined into one element. Earlier, I ’ ve talked about optics. I really like this solar **panel** â maybe you have different taste or different design needs... No problem. With the printing process, the solar cell can change its shape and design very easily. This will give the flexibility to **architects**, to planners and building owners, to integrate this electricity-producing technology as they wish. I want to stress that this is not just happening in the labs. It will take several more years to get to mass adoption, but we are at the edge of commercialization, meaning there are several companies out there with production lines. They are scaling up their capacities, and so are we, with the inks. This smaller footprint is much more comfortable. It is the right size, the right scale. We have to come back to the right scale when it comes to energy consumption. And making buildings carbon-neutral is an important part here. In Europe, we have the goal to decarbonize our building stock [by] 2050. I hope organic photovoltaics will be a big part of this. Here are a couple of examples. This is the first commercial installation of fully printed organic solar cells.”Commercial”means that the solar cells were printed on industrial equipment. The so-called”solar trees”were part of the German pavilion at the World Expo in Milan in 2015. They provided shading during the day and electricity for the lighting in the evening. You may wonder why this hexagonal shape was chosen for the solar cells. Easy answer : the **architects** wanted to have a specific shading pattern on the floor and asked for it, and then it was printed as requested. Being far from a real product, this free-form installation hooked the imagination of the visiting **architects** much more than we expected. This other application is closer to the projects and applications we are targeting. In an office building in SĂŁo Paulo, Brazil, semitransparent OPV **panels** are integrated into the glass facade, serving different needs. First, they provided shading for the meeting rooms behind. Second, the logo of the company is displayed in an innovative way. And of course, electricity is produced, reducing the energy footprint of the building. This is pointing towards a future where buildings are no longer energy consumers, but energy providers. I want to see solar cells seamlessly integrated into our building shells to be both resource-efficient and a pleasure to look at. For **roofs**, silicon solar cells will often continue to be a good solution. But to exploit the potential of all facades and other areas, such as semitransparent areas, **curved** surfaces and shadings, I believe organic photovoltaics can offer a significant contribution, and they can be made in any form **architects** and planners will want them to. Thank you.

Text Sample 725: POS Dim 5 – 2020 – Score 11.00 – 2020/t004276.txt
Arthur Brooks : Starting when I was eight or nine years old, I literally wanted to be the greatest French horn player in the world. That was what I always wanted to do. That was my whole life dream. Adam Grant : What was behind that? AB : I was ambitious. I wanted to play for a lot of people. And I guess that was just simply expressed in the only thing that I really knew how to do, the only thing I really cared about, which was music. AG : Arthur Brooks was a natural. He could read music before he could actually read. He played in youth orchestras as a kid, prestigious ones. Eventually he dropped out of college to go on tour. AB : I went on the road playing classical music. I did that for six years. I saw all 50 states from the back of a van. AG : Arthur recorded an album that played on classical radio stations across the country. But then something started to change. AB : I realized, about age 21, that things were starting to go south, and I couldn ’ t explain it. Ordinarily, classical musicians, they will see their skills increase through their 20s, and sometimes even their 30s. So whereas if I were a baseball pitcher, it would be totally normal that I would be losing heat off my fastball by my early 20s. As a French horn player, I shouldn ’ t have been seeing that, but I was. AG : To turn things around he practiced his heart out. Finally, he got his big break, his debut at Carnegie Hall. AB : So I got ready for this concert, and the first half of the concert, I have to say, was phenomenal. It was really one of the best concerts I ’ d ever given. And in the second half, I had this experience where I had to actually talk to the audience and I walked toward the front of the stage to address the crowd, and I wasn ’ t watching my **feet** and I slipped, or something collapsed, I still don ’ t know, and I fell five **feet** into the audience. AG : You literally fell off the stage? AB : I literally fell off the stage. It was just ridiculous. It was... I wrecked my instrument, I fell on my instrument, I hurt my arm. And, of course, I did what you would do when you ’ re 22 years old. I jumped up and said,”I ’ m okay, folks.”And I obviously was not okay. AG : Oh, no. AB : It was just so terrible, Adam. It was so terrible. AG : Arthur tried to shake off the feeling that falling off the stage was a bad omen. He spent the next decade practicing. He studied with the best tutors in Europe. He got a job at a symphony in Barcelona, but – AB : It was a wreck. It was a slow-moving wreck in my career itself. I was in decline. Finally had to pack it in. I had to admit it to myself that I wasn ’ t the horn player I had always dreamed of being. And right now, I ’ m talking about it with you and, you know, we ’ re laughing and all that, but I ’ ve got to tell you, it kills me, I still hate it. AG : Arthur didn ’ t plan to quit music so early. He simply stopped being great at his job. And in the years since, it ’ s made him wonder, does career decline happened to all of us eventually? And is there anything we can do about it? I ’ m Adam Grant, and this is WorkLife, my podcast with TED. I ’ m an

organizational psychologist. I study how to make work not suck. In this show, I ’ m inviting myself inside the minds of some truly unusual people, because they mastered something I wish everyone knew about work. Today, career staying power. It ’ s more about the choices you make than the age you reach. Thanks to Accenture for sponsoring this episode. Let ’ s be honest, we all have peaks and **valleys** in our careers, times when we hit our stride and do our best work, and times when we ’ re in a slump. Most of us are worried that as we age, our physical and mental skills will decline and we might enter into a permanent slump. And that fear is compounded by the fact that age is seldom seen as an asset in the modern workplace. Far too often, our older colleagues don ’ t get the respect they deserve. Arthur ’ s slump happened at a particularly early age, so he changed careers and became a public policy expert. AB : Basically I ’ m just an old fashioned, number-crunching, quantitative social scientist. AG : Given what he ’ s gone through, it ’ s not entirely surprising that his big area of focus now is career decline. AB : Career decline is a very personal and personalized phenomenon in which your skills are not what they once were. So you might be making as much, or more, money than you ever have before, but you know that you are not at the same level of technical adeptness that you had once attained, and / or you ’ re not on the trajectory to attain what you had hoped. AG : Maybe you felt your stomach lurch when someone younger than you has a smashing success in your field or your workplace. Or maybe you ’ ve been humming along feeling good about your work, until one day you noticed your skills don ’ t seem quite as sharp as they used to. In 2019, Arthur wrote a major story about this phenomenon in”The Atlantic.”The headline was”Your Professional Decline Is Coming Sooner Than You Think.”As in, long before you even start to see retirement on the horizon. AB : I mean the number one myth is that, you know, particularly in certain professions, like, let ’ s just say yours and mine, which is coming up with big ideas and sharing them, that that ’ ll never go into decline. Why? Because it doesn ’ t require, you know, strong biceps, and yet there ’ s overwhelming evidence that in idea professions people experience decline as well. They just don ’ t expect it. AG : What happens to our cognitive abilities as we age is not straightforward. It actually depends on what kind of mental skills we ’ re talking about. Psychologists have long distinguished between two kinds of intelligence : fluid and crystallized. Fluid intelligence is your raw processing power. It ’ s basically your IQ, your innate capacity for learning and problem solving. AB : That ’ s a big part of the modern idea economy. I ’ m going to come in here, I ’ m going to be a whizzbang person who comes up with brand new ideas. That ’ s actually what ’ s rewarded for young people because young people have high levels of fluid intelligence. It increases through your teens and 20s, and maybe through your 30s, although it tends to start declining for most people in their 30s and 40s, and it makes this original idea generation harder. Now that doesn ’ t mean that you ’ re going to be unsuccessful, but it means if you ’ re relying entirely on this fluid intelligence, you ’ re going to struggle. AG : A common refrain in Silicon Valley is that young people are just smarter. When it comes to fluid intelligence, that ’ s generally true. But the story changes with crystallized intelligence, your acquired ability to solve problems by applying your knowledge and experience. AB : Your ability to synthesize things that you didn ’ t necessarily invent, that ’ s crystallized intelligence and that tends to happen later. AG : Think about how crystallized intelligence comes in handy in your job. If you ’ re in sales, you ’ ve used it to tailor your pitches to different clients based on what you ’ ve learned about them in the past. If you ’ re in government, you ’ ve relied on it to get around red **tape**. If you ’ re in finance, maybe you ’ ve applied it to predict how markets are affected by crises. Crystallized intelligence peaks much later than fluid intelligence, in large part because our body of knowledge keeps growing. AB : Think of it like a library. Think of the brain as basically filling up with a lot of volumes. And that means you have a lot of crystallized intelligence. AG : Depth and breadth of knowledge aren ’ t the only benefits of aging. Evidence suggests that self-control and socio-emotional skills often keep climbing, too. Many of us continue gaining willpower and emotional intelligence well into our 40s and 50s. We ’ re still getting better at delaying gratification, reading other people ’ s emotions and regulating our own moods. Even into our 70s and 80s, we ’ re still improving at ignoring sunk costs, all of which can enhance our job performance. But Arthur doesn ’ t think that ’ s enough to keep us from declining. AB : Everybody falls in their game at some particular point. AG : At what age do you think the average person is going to start to face significant career decline? AB : I ’ ve got to give you the social scientist answer – it depends but if I were to guess, I ’ ve got to say that in your mid-40s is when you ’ re likely to see the peak of your originality and creativity, and you should be making plans in your 40s to how you can be the best creator with your crystallized intelligence, how you can be the best instructor, the best synthesizer, you can possibly be. AG : OK, so this is where I want to start disagreeing with you. So my read of the evidence is that people don ’ t inherently become less creative. One of the things that happens as people ’ s careers advance is they tend to produce less, just, you know, in terms of overall volume. I think it ’ s not ability. I think it ’ s motivation that ’ s dropping. I think, you know, a lot of people become complacent and they feel like they ’ ve achieved enough success, and so they may scale back a little bit. It may be that priorities outside of work become more important to them. And if we can maintain that motivation, there ’ s no inherent reason why the quality of creative output would decline. What do you think? AB : Hmm, I ’ m willing to entertain your hypothesis. AG : OK, cool. So there ’ s a study I really like of scientists, filmmakers and artists, showing that as they advance from their 20s and 30s toward their 50s and 60s, they do less work. The scientists run fewer experiments, the filmmakers don ’ t make as many movies and the artists produce fewer paintings. But those who stay productive, their hit rate was every bit as high in their 50s and 60s as it was in their 20s and 30s. So, you know, I think about Frank Lloyd Wright designing Fallingwater at 68 years old, his crowning architectural achievement. Or I ’ m sure you ’ ve come across Raymond Davis Jr, the scientists who measured neutrinos from the sun. He didn ’ t build the key detector until he was 51 and kept running his experiments until he was 88, the year he won the Nobel Prize. I ’ d be willing to bet that we would either uncover, or even create more Frank Lloyd Wrights and more Raymond Davises if we had ways of keeping more people motivated to produce into and past mid career. Agree or disagree? AB : I think that if there is a natural cadence to the average person ’ s life, and you ’ re saying it doesn ’ t have to be this way, then the societal goal will be one in which everybody is above average. And you know, that becomes an exercise in frustration. AG : In other words, that ’ s a nice theory about encouraging everyone to keep producing at maximum capacity for decades, but it might not be realistic if you ’ re not a superstar in your field. The rest of us are going to do what people naturally do. And Arthur wants there to be space for that path, too. He wants people to be excellent in their own way, which made me wonder if he thinks career decline is more inevitable for people who achieve excellence. AB : What goes up must come down ultimately, and the higher up you go, the more obvious it is that you ’ re not there anymore. That ’ s what I call the Law of Psychoprofessional Gravitation. You notice a lot when you were great and you ’ re not as great as you once were. And if you can do something to get on your crystallized intelligence **curve**, you get a different kind of productivity, and you can be successful in a different way. That ' s the knowledge I want to get across. AG : He ' s arguing that regardless of what field you ' re in, as your fluid intelligence declines, you should make a change. Stop trying to innovate. Take what you ' ve learned and accomplished and shift into a mode where you can transmit your knowledge and skills to other people. Become a teacher or a mentor. AB : And frankly, the world needs those people. And we don ' t have enough of them. When I ' m at a certain point in my career, and I see that I ' m not on the top of my game, I need to start thinking, is what got me here, whether it ' s the insight or the innovation or whatever it happens to be that got me here, is it something that I can sustain? If it ' s not, start looking for something else. Specifically, start looking for a way that you can move into instruction mode. AG : In Arthur ' s case, after giving up on music, he spent years running a conservative think tank. And then having learned the lessons of his fall at Carnegie Hall, he took his own advice. AB : And I had somebody I really respect, and he said,"You know, when you are a chief executive and you have to be on the razor ' s edge every single day, you have two choices on how to step out of your chief executive job."And I said,"Well, good, two choices. I like two choices. You know, it ' s like the Monty Hall game. You know, door number one and door number two. So what ' s behind door number one?"And he said,"Leave before you ' re ready."And I said,"Oh, I don ' t like that. What ' s behind door number two?"And he says,"Leave on someone else ' s terms."I said,"Ooh, I really hate that one."AG : What did Arthur decide to do then? Exactly what he ' s suggesting you do. He went into teaching. AB : The **bottom** line is, when the stakes are high, it ' s worth leaving things before you ' re ready. AG : Arthur is content with how his career choices worked out. He wants you to walk off the stage before you fall off of it. I understand where he ' s coming from, but I ' d rather see you find your balance, or get on a different stage altogether. You do have choices beyond aging out and opting out. More on those after the break. OK, this is going to be a different kind of ad. I played a personal role in selecting the sponsors for this podcast, because they all have interesting cultures of their own. Today, we ' re going inside the workplace at Accenture. Gonzalo Adriazola : I ' m from Arequipa, which is the second largest city in Peru. We have the coast, we have the Andes and we have a bit of jungle. AG : This is Gonzalo Adriazola. When he was 19, he and his mother left Peru and moved to rural Ohio. GA : I don ' t think I fully processed that I was leaving a whole life behind. I think I was just excited for the future. AG : As a young immigrant to a new country, Gonzalo didn ' t know exactly what the future held, but his mother became a tremendous source of inspiration. From early on, she taught him about the importance of education. GA : She would always tell me,"I might not leave you anything, but I ' m going to leave you a good education."AG : Gonzalo got a job at a local restaurant while he applied to colleges. GA : When I got the acceptance letter, my mom and I were just, like, jumping and dancing and just so happy. AG : He headed to the Ohio State University, and it didn ' t take him long to fit in. He was crowned homecoming king, started working full time at a bank and found a community within the Hispanic Business Student Association. They sponsored a trip to a conference in Washington. GA : It ' s the largest gathering of professional Latinos in the US. I saw this one speaker and he was so good. He was so passionate, energetic. Besides being phenomenal, he looked like me, and this was the first time I had seen someone in person that looked like me that was a total boss. AG : At the end of the talk, Gonzalo went up to the speaker and asked for advice. GA : I asked him like,"I want to be a CEO one day. How do I get to be like you?"And he laughed and looked at me and told me that professional services firms, all they have is people. So they ' re going to do their best to make the best of you. And that ' s how I found out about consulting. AG : Research shows that role models can elevate our aspirations. When we see someone similar to us do something inspiring, it builds our confidence that we can follow in their footsteps. When Gonzalo graduated from college, he followed his role model ’ s advice and went to work as a consultant at Accenture. GA : I was really happy to join the firm. And I mean, it has only been great experiences. AG : Gonzalo had accomplished a big goal, and for four years, he helped companies grow and perform better. But he had a nagging feeling that something was missing from his life. GA : As soon as I got to Accenture, I wanted to give back to Latin America. That was kind of, like, my life objective. I saw that we had worked with this microlending institution called Caja Arequipa, and I ’ m like,”What are the odds?”AG : He reached out to the leadership team running the project. GA : They told me about, like, everything we were doing in regards to financial inclusion in Latin America. I was really excited to know that I was from that same city. Very welcoming to my help. AG : Alongside his consulting work, Gonzalo has been a leader in the Hispanic Employee Resource Group and volunteered his extra time to help the team in Latin America. His dedication paid off. Earlier this year, Accenture development partnerships moved him to Colombia where he joined the project team full time. GA : It was a dream come true. I called my mom. We laughed, we smiled, we danced. AG : This isn ’ t the only way Gonzalo gives back. Every year he ’ s gone back to the conference where he was first inspired by someone he felt he could relate to. GA : It feels like I ’ m doing my mission. I was in their shoes one day and now I ’ m the person lifting up, just as others lift me up. And there ’ s people lifting me up right now. There ’ s going to be a brighter future for my community. AG : Accenture is working to become one of the most truly human companies in the digital age. Learn more at Accenture. com / careers. Lyn Slater : I ’ m not a Pollyanna about aging. There ’ s certainly changes in my body. You know, I have my wrinkles, I have my white hair, but I think that I could generate content as much as someone who ’ s younger than me. In fact, most of the peers who are at my level are all younger than me. AG : Lyn Slater is 65. She recently quit her career as a professor to become a full-time social media influencer. Lots of people call themselves influencers, but Lyn ’ s version is a real job. LS : I ’ m also known as The Accidental Icon. AG : The Accidental Icon has more than 700, 000 followers on Instagram, and she gets paid to run ads on her account for brands like Kate Spade, Visa and Teva. Her feed is filled with stylized photos of herself posing around New York City in designer clothes and large sunglasses. She ’ s been featured in magazines like”Cosmo”and”In Style.”And she ’ s walked the runway at New York Fashion Week. Actually, she ’ s walked more than one runway. LS : I have no background in the fashion industry, but I was in the runway show last spring with Kate Spade. I ’ ve worked with them quite a bit. AG : Some people will tell you that most of us do our best work when we ’ re younger, that when we approach retirement age, we should slow down, take up a hobby, play with the grandkids. But excellence later in your career is possible, and there are a few ways you can get there. Lyn is living proof that you don ’ t have to avoid career decline by shifting from doing into teaching. You can actually reinvigorate your career by experimenting, by doing something new. In Lyn ’ s case, she did something completely new. We saw her in action one Saturday near her home in Manhattan. LS : We ’ re on Fifth Avenue in New York City. It ’ s called Museum Mile because everywhere is a **museum**. I ’ m going to be shooting my outfit outside. AG : She ’ s with her partner who doubles as her photographer. Calvin : Your bangs are good. LS : Thank you. AG : Lyn is petite with a short white bob and bangs that stop just above her huge sunglasses. She takes off a long velvet coat and **scans** the brick facades of the Museum of the City of New York for her next spot of inspiration.

LS : And right now, that little nook over there is really calling to me because it does look like a place... AG : Before becoming a social media influencer, she had an entirely different decades-long career in social work. She was an expert for New York City family courts on child abuse issues. She wrote a seminal book on social work and law, and she spent the last 20 years as a professor of social work at Fordham University. She was quite an authority in her field, but she told me she ’ d become frustrated with the glacial pace of academia. Like, how long it takes to write and publish journal articles. LS : The whole process could take almost two years and maybe a handful of people would read it. And so, as I began to get more followers on Instagram and I began to do more things, you know, for example, I did a short **film** and within a couple of weeks, that was in front of, you know, millions of people. AG : Lyn went about as far from her original field of work as she could go. So what leads to a spectacular pivot like that? A dose of novelty. Research shows that curiosity is a key factor that can help you find creative peaks as you age, rather than decline. This is one way to stay productive and maintain motivation later in your career. Find something new to explore. For you, novelty might mean switching to a new team or a new market, getting certified in a fresh skill set, or mastering a hobby completely outside your experience. For Lyn, that hobby was fashion. LS : I ’ ve always had, sort of, what I call a very performative relationship with my clothes. I resist like crazy social categories or constructions of who I should be. AG : In this case, she was resisting the idea that a long time professor of social work wouldn ’ t also be interested in high fashion. She ’ d been toying with the idea of starting a fashion blog. And one day, unexpectedly, the name came to her. LS : It was the first week of school, and I always used to dress up for that. And I was meeting a friend for lunch and I had on a Yohji Yamamoto suit, and a couple of photographers started taking my **picture** and then a bunch of other photographers saw them do it so they came over, and my friend was making a joke like,”You ’ re an accidental icon.”AG : If you ’ re going to experiment with something new, it helps to fully immerse yourself in that world. Lyn was creative in where she looked for her mentors. LS : I found out that I could get a press pass to what is called the market shows, and I would spend hours talking with these young designers. They taught me a great deal about how clothing is made, what the processes are. That ’ s how I really began to understand fashion. AG : Instead of being intimidated by new technology and seeing it as something only young people can master, she went straight to the experts she knew. LS : My students helped me to figure out Instagram and Snapchat, and I started to take classes in social media and fashion and just random things, like, how to start your own vintage store. AG : In a study in the fashion industry, the more time designers and directors spend abroad, the more creative they became over their careers, but it wasn ’ t traveling or even living abroad that mattered. It was the amount of time they spent working abroad. They couldn ’ t just observe it from the sidelines. They had to be in the arena. That ’ s how they really internalize the novel elements of a foreign culture. For Lyn, seeking out new perspectives included small steps, too. LS : I do things that I don ’ t normally do. And so that could be very simple things, like taking a different route to work. It ’ s really, put yourself into different experiences that are creative and see where that takes you. AG : You may not aspire to quit your job and become an Instagram star, or to switch fields at all. And you don ’ t have to. There are ways to reach new heights while staying within your career path. Think about whether you ’ re a sprinter or a marathoner, not in terms of running, but how you go about generating creative ideas. Economists call the sprinters conceptual innovators. They typically start with a big idea and they tend to peak early, because they have eureka moments when they ’ re relatively new to a domain. Like Einstein at 16 imagining himself chasing a beam of light, or Mary Shelley at 18 starting to write"Frankenstein."But as they accumulate knowledge, they ' re more likely to get stuck in their ways and stop gaining new perspectives. There ' s a term for that : cognitive entrenchment. The longer they stay in a field, the more likely they are to take for granted assumptions that need to be questioned. Marathoners, on the other hand, are experimental innovators. They usually discover their ideas through trial and error. They often peak later because it takes time to test out different approaches, like Darwin, spending decades tracing the origins of species, or da Vinci experimenting for years with different ways of modeling light in his paintings. But those habits allow them to sustain their peaks longer and peak again later as they explore new areas. That kind of experimentation is familiar to Lynda Weinman. Lynda Weinman : I ' m an autodidactic person. I always love learning new things. AG : She got her start in the 1980s as an animator at a **film** studio. She often compared herself to her higher achieving peers who were sprinting ahead. LW : I remember when I was in my 20s watching some of my friends who were uber successful and I, you know, at my 30th birthday was in tears that I hadn ' t accomplished what I wanted to accomplish yet with my life. AG : But she didn ' t rush it. Instead, for the next 10 years, she kept chugging along, testing out different ways to build and use her skills. Finally, the year of her next big birthday, she created a website. Lynda called her site Lynda. com. LW : Well, when we started Lynda. com I was 40 and when we sold it I was 60. AG : She sold it in 2015 to LinkedIn, for, oh, 1. 5 billion dollars. Lynda. com was one of the first companies to offer professional learning online. Maybe you ' ve heard of their courses in animation, design and software. Maybe you ' ve even taken classes there that advanced your career. Many founders who are trying to grow a unicorn company, think they need to generate one brilliant idea and scale it rapidly. They think they need to be sprinters, but Lynda approached her career more like a marathoner. Her online learning company didn ' t look anything like a success early on. Instead, she was constantly trying out new ideas and innovating over time. In some ways, Lynda was primed for this kind of scrappy test-and-learn approach. LW : I actually had a pretty troubled childhood. I moved in with my dad and my stepmom who weren ' t expecting to raise me and my siblings. And, you know, it was just this feeling of having to find my way because all the adults in my life were, you know, having their own problems. And I think what I probably am is a very resourceful person who realized at an early age that it was on me to figure out my life. AG : During her early days as an animator, Lynda encountered her first computer. She was unimpressed, at first. LW : It was a Apple II Plus clone that my boyfriend brought home, and so to please him, I turned it on and I started pecking at the keys and I caught the bug that so many people since have caught. And he eventually called himself a computer widow, because I liked the computer more than him. AG : LW : I mean, I was just amazed at what it could do. AG : What it could do was draw. So Lynda got her own Macintosh and brought it into work. People started asking her to do projects for them. LW : Somehow they thought I knew more than they did, which was, you know, basically I ' d had five minutes longer with something than they had. AG : Lynda was onto something. By experimenting with new tools and following her curiosities to uncharted places, she could carve out a niche and continue iterating instead of stagnating. LW : Oh, do I want to do what everybody else is doing, or I ' m being asked to do something that only I know how to do, and maybe that ' s more **fun**. AG : Lynda ran two more experiments. First, she started teaching in-person college classes in web design. Then when she saw a lack of good manuals for students, she wrote one herself. LW : Then it became a huge success, way bigger than any of us could have imagined. AG : Well, you ’ re being very modest, but can I get you to describe a little bit just how successful the book was? LW : I ’ m not sure how many millions it sold, but it was translated into many, many languages and it was the de facto web-design book for all colleges. It was the”it”book. AG : From there, Lynda continued to test out new methods of teaching. She started selling instructional videos on VHS **tapes**. Then, as technology changed, she switched to CDs, then DVDs. Then she launched the website Lynda. com. In the late ’ 90s, she and her business partner and husband tried launching memberships on Lynda. com. They weren ’ t exactly an instant hit. LW : In the beginning it was just an abject failure. It was cannibalizing some of our other work. AG : But they didn ’ t give up. Not every experiment succeeds, and they don ’ t all succeed right away. Memberships weren ’ t growing like crazy, but there was steady growth. Lynda paid attention to that. Eventually they hit an inflection point. While Lynda. com was quietly adding hours of material to their catalog, more people were using the internet for online learning. Their online audience doubled each year. And in time that grew into a big number. By 2012, they had over a million paying users and over a hundred million dollars in revenue. LW : It was literally a very organic growth process. AG : Lynda could ’ ve simply continued to develop her skills as an expert animator and would have had a nice career. She could ’ ve kept teaching, too, but her greatest success came when her experimentation led her into entrepreneurship, turning her various projects into a business. She didn ’ t listen to the narrative that as you get older, you should pull over into the slow lane. She saw some benefits of building something later in her career. LW : By the time you ’ re 40, you believe in yourself more. You ’ re a more seasoned human being that has better judgment and better experience and better confidence. AG : This might be one of the reasons why older founders are actually more successful than younger ones. In a study of several million entrepreneurs, 40-year-olds were more than twice as likely as 25-year-olds to launch a successful start-up. And they were also nearly a third more likely to be in the top 0. 1 percent of fastest-growing tech start-ups. Yes, sprinters sometimes get lucky right out of the gate, but marathoners know how to persevere. LW : I think everybody would probably like to be instantly successful and be revered and acknowledged and acclaimed and all those things, but when it happens to you too young, it actually can be very damaging. At least the people that I ’ ve seen, who, you know, they burned bright and they burned all the way out. They didn ’ t understand that it wasn ’ t going to last forever and that they had to keep reinventing and they had to earn it again. AG : If you ’ re worried that your career will decline, don ’ t let your output decline, and don ’ t let your curiosity stagnate either. It ’ s never too late to invent or to reinvent yourself. LW : I think the older you are, the more valuable you can be. AG : I love that because I don ’ t ever want to retire. Next time on”WorkLife.”Working remotely is full of challenges that have made our work lives harder. Lizet Ocampo : So we turn our cameras on and there I am as something else. At first, we didn ’ t realize it was a potato. We ’ re like,”What is going on?”I just essentially was a potato for the meeting. AG : But some of the solutions might be easier than you think.”WorkLife”is hosted by me, Adam Grant. The show is produced by TED with Transmitter Media. Our team includes Colin Helms, Gretta Cohn, Dan O ’ Donnell, Constanza Gallardo, Grace Rubenstein, Michelle Quint, Angela Cheng and Anna Phelin. This episode was produced by Jessica Glazer. Our show is mixed by Rick Kwan. Original music by Hahnsdale Hsu and Allison Layton-Brown. Ad stories produced by Pineapple Street Studios. Special thanks to our sponsors, Accenture, BetterUp, Hilton and SAP. For their research thanks to Dean Simonton on creative productivity, Lu Liu and colleagues on career hot streaks, Ben Jones and colleagues on the success of older entrepreneurs, David Galenson on conceptual and experimental innovators, Erik Dane on cognitive entrenchment and Will Maddux, Adam Galinsky and colleagues on working abroad. In some ways, Lynda was primed for this kind of crap... Excuse me. In some ways, Lynda was primed for this kind of crap... It ’ s not crappy, it ’ s scrappy. In some ways, Lynda was primed for this kind of crappy... Sorry.
