Text Sample 1: POS Dim 1 – 1994 – Score 15.00 – 1994/t002458.txt
Because I usually take **the** role of trying to explain to people how wonderful **the** new technologies that are coming along are going to be, and I thought that, since I was among friends here, I would tell you what I really think and try to look back and try to understand what is really going on here with these amazing jumps in technology that seem so fast that we can barely keep on top of it. So I ’ m going to start out by showing just one very boring technology **slide**. And then, so if you can just turn on **the slide** that ’ s on. This is just a random **slide** that I picked out of my file. What I want to show you is not so much **the** details of **the slide**, but **the** general form of it. This happens to be a **slide** of

some analysis that we were doing about **the** power of RISC microprocessors versus **the** power of local area networks. And **the** interesting thing about it is that this **slide**, like so many technology **slides** that we ' re used to, is a sort of a straight line on a semi-log curve. In other words, every step here represents an order of magnitude in performance scale. And this is a new thing that we talk about technology on semi-log curves. Something really weird is going on here. And that ' s basically what I ' m going to be talking about. So, if you could bring up **the** lights. If you could bring up **the** lights higher, because I ' m just going to use a piece of paper here. Now why do we draw technology curves in semi-log curves? Well **the** answer is, if I drew it on a normal curve where, let ' s say, this is years, this is time of some sort, and this is whatever measure of **the** technology that I ' m trying to graph, **the** graphs look sort of silly. They sort of go like this. And they don ' t tell us much. Now if I graph, for instance, some other technology, say **transportation** technology, on a semi-log curve, it would look very stupid, it would look like a flat line. But when something like this happens, things are qualitatively changing. So if **transportation** technology was moving along as fast as microprocessor technology, then **the** day after tomorrow, I would be able to get in a taxi cab and be in Tokyo in 30 seconds. It ' s not moving like that. And there ' s nothing precedented in **the** history of technology development of this kind of self- **feeding** growth where you go by orders of magnitude every few years. Now **the** question that I ' d like to ask is, if you look at these exponential curves, they don ' t go on forever. Things just can ' t possibly keep changing as fast as they are. One of two things is going to happen. Either it ' s going to turn into a sort of classical S-curve like this, until something totally different comes along, or maybe it ' s going to do this. That ' s about all it can do. Now I ' m an optimist, so I sort of think it ' s probably going to do something like that. If so, that means that what we ' re in **the** middle of right now is a transition. We ' re sort of on this line in a transition from **the** way **the** world used to be to some new way that **the** world is. And so what I ' m trying to ask, what I ' ve been asking myself, is what ' s this new way that **the** world is? What ' s that new state that **the** world is heading toward? Because **the** transition seems very, very confusing when we ' re right in **the** middle of it. Now when I was a kid growing up, **the** future was kind of **the** year 2000, and people used to talk about what would happen in **the** year 2000. Now here ' s a conference in which people talk about **the** future, and you notice that **the** future is still at about **the** year 2000. It ' s about as far as we go out. So in other words, **the** future has kind of been shrinking one year per year for my whole lifetime. Now I think that **the** reason is because we all feel that something ' s happening there. That transition is happening. We can all sense it. And we know that it just doesn ' t make too much sense to think out 30, 50 years because everything ' s going to be so different that a simple extrapolation of what we ' re doing just doesn ' t make any sense at all. So what I would like to talk about is what that could be, what that transition could be that we ' re going through. Now in order to do that I ' m going to have to talk about a bunch of stuff that really has nothing to do with technology and **computers**. Because I think **the** only way to understand this is to really step back and take a long time scale look at things. So **the** time scale that I would like to look at this on is **the** time scale of life on Earth. So I think this picture makes sense if you look at it a few billion years at a time. So if you go back about two and a half billion years, **the** Earth was this big, sterile hunk of **rock** with a lot of chemicals floating around on it. And if you look at **the** way that **the** chemicals got organized, we begin to get a pretty good idea of how they do it. And I think that there ' s theories that are beginning to understand about how it started with RNA, but I ' m going to tell a sort of simple story of it, which is that, at that time, there were little drops of **oil** floating around with all kinds of different recipes of chemicals in them. And some of those drops of **oil** had a particular combination of chemicals in them which caused them to incorporate chemicals from **the** outside and grow **the** drops of **oil**. And those that were like that started to split and divide. And those were **the** most primitive forms of cells in a sense, those little drops of **oil**. But now those drops of **oil** weren ’ t really alive, as we say it now, because every one of them was a little random recipe of chemicals. And every time it divided, they got sort of unequal division of **the** chemicals within them. And so every drop was a little bit different. In fact, **the** drops that were different in a way that caused them to be better at incorporating chemicals around them, grew more and incorporated more chemicals and divided more. So those tended to live longer, get expressed more. Now that ’ s sort of just a very simple chemical form of life, but when things got interesting was when these drops learned a trick about abstraction. Somehow by ways that we don ’ t quite understand, these little drops learned to write down information. They learned to record **the** information that was **the** recipe of **the** cell onto a particular kind of chemical called DNA. So in other words, they worked out, in this mindless sort of **evolutionary** way, a form of writing that let them write down what they were, so that that way of writing it down could get **copied**. **The** amazing thing is that that way of writing seems to have stayed steady since it **evolved** two and a half billion years ago. In fact **the** recipe for us, our genes, is exactly that same code and that same way of writing. In fact, every living creature is written in exactly **the** same set of letters and **the** same code. In fact, one of **the** things that I did just for amusement purposes is we can now write things in this code. And I ’ ve got here a little 100 micrograms of white **powder**, which I try not to let **the** security people see at airports. But this has in it — what I did is I took this code — **the** code has standard letters that we use for symbolizing it — and I wrote my business card onto a piece of DNA and amplified it 10 to **the** 22 times. So if anyone would like a hundred million **copies** of my business card, I have plenty for everyone in **the** room, and, in fact, everyone in **the** world, and it ’ s right here. If I had really been a egotist, I would have put it into a virus and released it in **the** room. So what was **the** next step? Writing down **the** DNA was an interesting step. And that caused these cells — that kept them happy for another billion years. But then there was another really interesting step where things became completely different, which is these cells started exchanging and communicating information, so that they began to get communities of cells. I don ’ t know if you know this, but bacteria can actually exchange DNA. Now that ’ s why, for instance, antibiotic resistance has **evolved**. Some bacteria figured out how to stay away from penicillin, and it went around sort of creating its little DNA information with other bacteria, and now we have a lot of bacteria that are resistant to penicillin, because bacteria communicate. Now what this communication allowed was communities to form that, in some sense, were in **the** same boat together ; they were synergistic. So they survived or they failed together, which means that if a community was very successful, all **the** individuals in that community were repeated more and they were favored by **evolution**. Now **the** transition point happened when these communities got so close that, in fact, they got together and decided to write down **the** whole recipe for **the** community together on one string of DNA. And so **the** next stage that ’ s interesting in life took about another billion years. And at that stage, we have multi-cellular communities, communities of lots of different types of cells, working together as a single organism. And in fact, we ’ re such a multi- cellular community. We have lots of cells that are not out for themselves anymore. Your skin cell is really useless without a heart cell, muscle cell, a brain cell and so on. So these communities began to **evolve** so that **the** interesting level on which **evolution** was taking place was no longer a cell, but a community which we call an organism. Now **the** next step that happened is within these communities. These communities of cells, again, began to **abstract** information. And they began building very special structures that did nothing but process information within **the** community. And those are **the** neural structures. So neurons are **the** information processing apparatus that those communities of cells built up. And in fact, they began to get specialists in **the** community and special structures that were responsible for recording, understanding, learning information. And that was **the** brains and **the** nervous system of those communities. And that gave them an **evolutionary** advantage. Because at that point, an individual — **learning** could happen within **the** time span of a single organism, instead of over this **evolutionary** time span. So an organism could, for instance, learn not to eat a certain kind of fruit because it tasted bad and it got sick last time it ate it. That could happen within **the** lifetime of a single organism, whereas before they ’ d built these special information processing structures, that would have had to be learned evolutionarily over hundreds of thousands of years by **the** individuals dying off that ate that kind of fruit. So that nervous system, **the** fact that they built these special information structures, tremendously sped up **the** whole process of **evolution**. Because **evolution** could now happen within an individual. It could happen in learning time scales. But then what happened was **the** individuals worked out, of course, tricks of communicating. And for example, **the** most sophisticated version that we ’ re aware of is human language. It ’ s really a pretty amazing invention if you think about it. Here I have a very complicated, messy, confused idea in my head. I ’ m sitting here making grunting sounds basically, and hopefully constructing a similar messy, confused idea in your head that bears some analogy to it. But we ’ re taking something very complicated, turning it into sound, sequences of sounds, and producing something very complicated in your brain. So this allows us now to begin to start functioning as a single organism. And so, in fact, what we ’ ve done is we, humanity, have started **abstracting** out. We ’ re going through **the** same levels that multi-cellular organisms have gone through — **abstracting** out our methods of recording, presenting, processing information. So for example, **the** invention of language was a tiny step in that direction. Telephony, **computers**, videotapes, CD-ROMs and so on are all our specialized mechanisms that we ’ ve now built within our society for handling that information. And it all connects us together into something that is much bigger and much faster and able to **evolve** than what we were before. So now, **evolution** can take place on a scale of microseconds. And you saw Ty ’ s little **evolutionary** example where he sort of did a little bit of **evolution** on **the** Convolution program right before your eyes. So now we ’ ve speeded up **the** time scales once again. So **the** first steps of **the** story that I told you about took a billion years a piece. And **the** next steps, like nervous systems and brains, took a few hundred million years. Then **the** next steps, like language and so on, took less than a million years. And these next steps, like electronics, seem to be taking only a few decades. **The** process is feeding on itself and becoming, I guess, autocatalytic is **the** word for it — when something reinforces its rate of change. **The** more it changes, **the** faster it changes. And I think that that ’ s what we ’ re seeing here in this **explosion** of curve. We ’ re seeing this process feeding back on itself. Now I design **computers** for a living, and I know that **the** mechanisms that I use to design **computers** would be impossible without recent advances in **computers**. So right now, what I do is I design **objects** at such complexity that it ’ s really impossible for me to design them in **the** traditional sense. I don ’ t know what every transistor in **the** connection machine does. There are billions of them. Instead, what I do and what **the** designers at Thinking Machines do is we think at some level of abstraction and then we hand it to **the** machine and **the** machine takes it beyond what we could ever do, much farther and faster than we could ever do. And in fact, sometimes it takes it by methods that we don ’ t quite even understand. One method that ’ s particularly interesting that I ’ ve been using a lot lately is **evolution** itself. So what we do is we put inside **the** machine a process of **evolution** that takes place on **the** microsecond time scale. So for example, in **the** most extreme cases, we can actually **evolve** a program by starting out with random sequences of instructions. Say,”Computer, would you please make a hundred million random sequences of instructions. Now would you please run all of those random sequences of instructions, run all of those programs, and pick out **the** ones that came closest to doing what I wanted.”So in other words, I define what I wanted. Let ’ s say I want to sort numbers, as a simple example I ’ ve done it with. So find **the** programs that come closest to sorting numbers. So of course, random sequences of instructions are very unlikely to sort numbers, so none of them will really do it. But one of them, by luck, may put two numbers in **the** right order. And I say,”Computer, would you please now take **the** 10 percent of those random sequences that did **the** best job. Save those. Kill off **the** rest. And now let ’ s reproduce **the** ones that sorted numbers **the** best. And let ’ s reproduce them by a process of recombination analogous to sex.”Take two programs and they produce children by exchanging their subroutines, and **the** children inherit **the** traits of **the** subroutines of **the** two programs. So I ’ ve got now a new generation of programs that are produced by combinations of **the** programs that did a little bit better job. Say,”Please repeat that process.”Score them again. Introduce some mutations perhaps. And try that again and do that for another generation. Well every one of those generations just takes a few milliseconds. So I can do **the** equivalent of millions of years of **evolution** on that within **the computer** in a few minutes, or in **the** complicated cases, in a few hours. At **the** end of that, I end up with programs that are absolutely perfect at sorting numbers. In fact, they are programs that are much more efficient than programs I could have ever written by hand. Now if I look at those programs, I can ’ t tell you how they work. I ’ ve tried looking at them and telling you how they work. They ’ re **obscure**, weird programs. But they do **the** job. And in fact, I know, I ’ m very confident that they do **the** job because they come from a line of hundreds of thousands of programs that did **the** job. In fact, their life depended on doing **the** job. I was riding in a 747 with Marvin Minsky once, and he pulls out this card and says,”Oh look. Look at this. It says, ’ This plane has hundreds of thousands of tiny parts working together to make you a safe flight. ’ Doesn ’ t that make you feel confident?”In fact, we know that **the** engineering process doesn ’ t work very well when it gets complicated. So we ’ re beginning to depend on **computers** to do a process that ’ s very different than engineering. And it lets us produce things of much more complexity than normal engineering lets us produce. And yet, we don ’ t quite understand **the** options of it. So in a sense, it ’ s getting ahead of us. We ’ re now using those programs to make much faster **computers** so that we ’ ll be able to run this process much faster. So it ’ s **feeding** back on itself. **The** thing is becoming faster and that ’ s why I think it seems so confusing. Because all of these technologies are feeding back on themselves. We ’ re taking off. And what we are is we ’ re at a point in time which is analogous to when single- celled organisms were turning into multi-celled organisms. So we ’ re **the** amoebas and we can ’ t quite figure out what **the** hell this thing is we ’ re creating. We ’ re right at that point of transition. But I think that there really is something coming along after us. I think it ’ s very haughty of us to think that we ’ re **the** end product of **evolution**. And

I think all of us here are a part of producing whatever that next thing is. So lunch is coming along, and I think I will stop at that point, before I get selected out.

Text Sample 2: POS Dim 1 – 2003 – Score 24.00 – 2003/t000436.txt

I ’ m supposed to scare you, because it ’ s about fear, right? And you should be really afraid, but not for **the** reasons why you think you should be. You should be really afraid that — if we stick up **the** first **slide** on this thing — there we go — that you ’ re missing out. Because if you spend this week thinking about Iraq and thinking about Bush and thinking about **the** stock market, you ’ re going to miss one of **the** greatest adventures that we ’ ve ever been on. And this is what this adventure ’ s really about. This is crystallized DNA. Every life form on this **planet** — every insect, every bacteria, every plant, every animal, every human, every politician — is coded in that stuff. And if you want to take a single crystal of DNA, it looks like that. And we ’ re just beginning to understand this stuff. And this is **the** single most exciting adventure that we have ever been on. It ’ s **the** single greatest mapping project we ’ ve ever been on. If you think that **the** mapping of America ’ s made a difference, or landing on **the** moon, or this other stuff, it ’ s **the** map of ourselves and **the** map of every plant and every insect and every bacteria that really makes a difference. And it ’ s beginning to tell us a lot about **evolution**. It turns out that what this stuff is — and Richard Dawkins has written about this — is, this is really a river out of Eden. So, **the** 3. 2 billion base pairs inside each of your cells is really a history of where you ’ ve been for **the** past billion years. And we could start dating things, and we could start changing medicine and archeology. It turns out that if you take **the** human species about 700 years ago, white Europeans diverged from black Africans in a very significant way. White Europeans were subject to **the** plague. And when they were subject to **the** plague, most people didn ’ t survive, but those who survived had a mutation on **the** CCR5 receptor. And that mutation was passed on to their kids because they ’ re **the** ones that survived, so there was a great deal of population pressure. In Africa, because you didn ’ t have these cities, you didn ’ t have that CCR5 population pressure mutation. We can date it to 700 years ago. That is one of **the** reasons why AIDS is raging across Africa as fast as it is, and not as fast across Europe. And we ’ re beginning to find these little things for **malaria**, for sickle cell, for cancers. And in **the** measure that we map ourselves, this is **the** single greatest adventure that we ’ ll ever be on. And this Friday, I want you to pull out a really good bottle of wine, and I want you to toast these two people. Because this Friday, 50 years ago, Watson and Crick found **the** structure of DNA, and that is almost as important a date as **the** 12th of February when we first mapped ourselves, but anyway, we ’ ll get to that. I thought we ’ d talk about **the** new zoo. So, all you guys have heard about DNA, all **the** stuff that DNA does, but some of **the** stuff we ’ re discovering is kind of nifty because this turns out to be **the** single most abundant species on **the planet**. If you think you ’ re successful or **cockroaches** are successful, it turns out that there ’ s ten trillion trillion Pleurococcus sitting out there. And we didn ’ t know that Pleurococcus was out there, which is part of **the** reason why this whole species-mapping project is so important. Because we ’ re just beginning to learn where we came from and what we are. And we ’ re finding amoebas like this. This is **the** amoeba dubia. And **the** amoeba dubia doesn ’ t look like much, except that each of you has about 3. 2 billion letters, which is what makes you you, as far as gene code inside each of your cells, and this little amoeba which, you know, sits in water in hundreds and millions and billions, turns out to have 620 billion base pairs of gene code inside. So, this little thingamajig has a **genome** that ’ s 200 times **the** size of yours. And if you ’ re thinking of efficient information storage mechanisms, it may not turn out to be chips. It may turn out to be something that looks a little like that amoeba. And, again, we ’ re learning from life and how life works. This funky little thing : people didn ’ t used to think that it was worth taking samples out of nuclear reactors because it was dangerous and, of course, nothing lived there. And then finally somebody picked up a microscope and looked at **the** water that was sitting next to **the** cores. And sitting next to that water in **the** cores was this little Deinococcus radiodurans, doing a backstroke, having its chromosomes blown apart every day, six, seven times, restitching them, living in about 200 times **the** radiation that would kill you. And by now you should be getting a hint as to how diverse and how important and how interesting this journey into life is, and how many different life forms there are, and how there can be different life forms living in very different places, maybe even outside of this **planet**. Because if you can live in radiation that looks like this, that brings up a whole series of interesting questions. This little thingamajig : we didn ’ t know this thingamajig existed. We should have known that this existed because this is **the** only bacteria that you can see to **the** naked eye. So, this thing is 0. 75 millimeters. It lives in a deep trench off **the** coast of Namibia. And what you ’ re looking at with this namibiensis is **the** biggest bacteria we ’ ve ever seen. So, it ’ s about **the** size of a little period on a sentence. Again, we didn ’ t know this thing was there three years ago. We ’ re just beginning this journey of life in **the** new zoo. This is a really odd one. This is Ferroplasma. **The** reason why Ferroplasma is interesting is because it eats **iron**, lives inside **the** equivalent of battery acid, and excretes sulfuric acid. So, when you think of odd life forms, when you think of what it takes to live, it turns out this is a very efficient life form, and they call it an archaea. Archaea means”**the** ancient ones.”And **the** reason why they ’ re ancient is because this thing came up when this **planet** was covered by things like sulfuric acid in batteries, and it was eating **iron** when **the** earth was part of a melted core. So, it ’ s not just dogs and cats and **whales** and dolphins that you should be aware of and interested in on this little journey. Your fear should be that you are not, that you ’ re paying attention to stuff which is temporal. I mean, George Bush — he ’ s going to be gone, alright? Life isn ’ t. Whether **the** humans survive or don ’ t survive, these things are going to be living on this **planet** or other **planets**. And it ’ s just beginning to understand this code of DNA that ’ s really **the** most exciting intellectual adventure that we ’ ve ever been on. And you can do strange things with this stuff. This is a baby gaur. Conservation group gets together, tries to figure out how to breed an animal that ’ s almost extinct. They can ’ t do it naturally, so what they do with this thing is they take a spoon, take some cells out of an adult gaur ’ s mouth, code, take **the** cells from that and insert it into a fertilized cow ’ s egg, reprogram cow ’ s egg — different gene code. When you do that, **the** cow gives birth to a gaur. We are now experimenting with bongos, pandas, elands, Sumatran **tigers**, and **the** Australians — bless their hearts — are playing with these things. Now, **the** last of these things died in September 1936. These are Tasmanian **tigers**. **The** last known one died at **the** Hobart Zoo. But it turns out that as we learn more about gene code and how to reprogram species, we may be able to close **the** gene gaps in deteriorate DNA. And when we learn how to close **the** gene gaps, then we can put a full string of DNA together. And if we do that, and insert this into a fertilized wolf ’ s egg, we may give birth to an animal that hasn ’ t walked **the** earth since 1936. And then you can start going back further, and you can start thinking about dodos, and you can think about other species. And in other places, like Maryland, they ’ re trying to figure out what **the** primordial ancestor is. Because each of us contains our entire gene code of where we ’ ve been for **the** past billion years, because we ’ ve **evolved** from that stuff, you can take that tree of life and collapse it back, and in **the** measure that you learn to reprogram, maybe we ’ ll give birth to something that is very close to **the** first primordial ooze. And it ’ s all coming out of things that look like this. These are companies that didn ’ t exist five years ago. Huge gene sequencing facilities **the** size of football fields. Some are public. Some are private. It takes about 5 billion dollars to sequence a human being **the** first time. Takes about 3 million dollars **the** second time. We will have a 1, 000-dollar **genome** within **the** next five to eight years. That means each of you will contain on a CD your entire gene code. And it will be really boring. It will read like this. **The** really neat thing about this stuff is that ’ s life. And Laurie ’ s going to talk about this one a little bit. Because if you happen to find this one inside your body, you ’ re in big trouble, because that ’ s **the** source code for Ebola. That ’ s one of **the** deadliest diseases known to humans. But plants work **the** same way and insects work **the** same way, and this apple works **the** same way. This apple is **the** same thing as this floppy **disk**. Because this thing codes ones and zeros, and this thing codes A, T, C, Gs, and it sits up there, absorbing energy on a tree, and one fine day it has enough energy to say, execute, and it goes [thump]. Right? And when it does that, pushes a. EXE, what it does is, it executes **the** first line of code, which reads just like that, AATCAGGGACCC, and that means : make a root. Next line of code : make a stem. Next line of code, TACGGGG : make a flower that ’ s white, that blooms in **the spring**, that smells like this. In **the** measure that you have **the** code and **the** measure that you read it — and, by **the** way, **the** first plant was read two years ago ; **the** first human was read two years ago ; **the** first insect was read two years ago. **The** first thing that we ever read was in 1995 : a little bacteria called Haemophilus influenzae. In **the** measure that you have **the** source code, as all of you know, you can change **the** source code, and you can reprogram life forms so that this little thingy becomes a vaccine, or this little thingy starts producing biomaterials, which is why DuPont is now growing a form of polyester that feels like silk in corn. This changes all rules. This is life, but we ’ re reprogramming it. This is what you look like. This is one of your chromosomes. And what you can do now is, you can outlay exactly what your chromosome is, and what **the** gene code on that chromosome is right here, and what those genes code for, and what animals they code against, and then you can tie it to **the** literature. And in **the** measure that you can do that, you can go home today, and get on **the** Internet, and access **the** world ’ s biggest public library, which is a library of life. And you can do some pretty strange things because in **the** same way as you can reprogram this apple, if you go to Cliff Tabin ’ s lab at **the** Harvard Medical School, he ’ s reprogramming chicken embryos to grow more **wings**. Why would Cliff be doing that? He doesn ’ t have a restaurant. **The** reason why he ’ s reprogramming that animal to have more **wings** is because when you used to play with lizards as a little child, and you picked up **the** lizard, sometimes **the** tail fell off, but it regrew. Not so in human beings : you cut off an arm, you cut off a leg — it doesn ’ t regrow. But because each of your cells contains your entire gene code, each cell can be reprogrammed, if we don ’ t stop stem cell research and if we don ’ t stop genomic research, to express different body functions. And in **the** measure that we learn how chickens grow **wings**, and what **the** program is for those cells to differentiate, one of **the** things we ’ re going to be able to do is to stop undifferentiated cells, which you know as cancer, and one of **the** things we ’ re going to learn how to do is how to reprogram cells like stem cells in such a way that they express bone, stomach, skin, pancreas. And you are likely to be wandering around — and your children — on regrown body parts in a reasonable period of time, in some places in **the** world where they don ’ t stop **the** research. How ’ s this stuff work? If each of you differs from **the** person next to you by one in a thousand, but only three percent codes, which means it ’ s only one in a thousand times three percent, very small differences in expression and punctuation can make a significant difference. Take a simple declarative sentence. Right? That ’ s perfectly clear. So, men read that sentence, and they look at that sentence, and they read this. **Okay**? Now, women look at that sentence and they say, uh-uh, wrong. This is **the** way it should be seen. That ’ s what your genes are doing. That ’ s why you differ from this person over here by one in a thousand. Right? But, you know, he ’ s reasonably good looking, but... I won ’ t go there. You can do this stuff even without changing **the** punctuation. You can look at this, right? And they look at **the** world a little differently. They look at **the** same world and they say... That ’ s how **the** same gene code — that ’ s why you have 30, 000 genes, mice have 30, 000 genes, husbands have 30, 000 genes. Mice and men are **the** same. Wives know that, but anyway. You can make very small changes in gene code and get really different outcomes, even with **the** same string of letters. That ’ s what your genes are doing every day. That ’ s why sometimes a person ’ s genes don ’ t have to change a lot to get cancer. These little chippies, these things are **the** size of a credit card. They will test any one of you for 60, 000 genetic conditions. That brings up questions of privacy and insurability and all kinds of stuff, but it also allows us to start going after diseases, because if you run a person who has leukemia through something like this, it turns out that three diseases with completely similar clinical syndromes are completely different diseases. Because in ALL leukemia, that set of genes over there over-expresses. In MLL, it ’ s **the** middle set of genes, and in AML, it ’ s **the** bottom set of genes. And if one of those particular things is expressing in your body, then you take Gleevec and you ’ re cured. If it is not expressing in your body, if you don ’ t have one of those types — a particular one of those types — don ’ t take Gleevec. It won ’ t do anything for you. Same thing with Receptin if you ’ ve got breast cancer. Don ’ t have an HER- 2 receptor? Don ’ t take Receptin. Changes **the** nature of medicine. Changes **the** predictions of medicine. Changes **the** way medicine works. **The** greatest repository of knowledge when most of us went to college was this thing, and it turns out that this is not so important any more. **The** U. S. Library of Congress, in terms of its printed volume of data, contains less data than is coming out of a good genomics company every month on a compound basis. Let me say that again : A single genomics company generates more data in a month, on a compound basis, than is in **the** printed **collections** of **the** Library of Congress. This is what ’ s been powering **the** U. S. economy. It ’ s Moore ’ s Law. So, all of you know that **the** price of **computers** halves every 18 months and **the** power doubles, right? Except that when you lay that side by side with **the** speed with which gene data ’ s being deposited in GenBank, Moore ’ s Law is right here : it ’ s **the** **blue** line. This is on a log scale, and that ’ s what superexponential growth means. This is going to push **computers** to have to grow faster than they ’ ve been growing, because so far, there haven ’ t been applications that have been required that need to go faster than Moore ’ s Law. This stuff does. And here ’ s an interesting map. This is a map which was finished at **the** Harvard Business School. One of **the** really interesting questions is, if all this data ’ s free, who ’ s using it? This is **the** greatest public library in **the** world. Well, it turns out that there ’ s about 27 trillion bits moving inside from **the** United States to **the** United States ; about 4. 6 trillion is going over to those European countries ; about 5. 5 ’ s going to Japan ; there ’ s almost no communication between Japan, and nobody else is literate in this stuff. It ’ s free. No one ’ s reading it. They ’ re focusing on **the** war ; they ’ re focusing on Bush ; they ’ re not interested in life. So, this is what a new map of **the** world looks like. That is **the** genomically literate world. And that is a problem. In fact, it ’ s not a genomically literate world. You can break this out by states. And you can watch states rise and fall depending on their ability to speak a language of life, and you can watch New York fall off a cliff, and you can watch New Jersey fall off a cliff, and you can watch **the** rise of **the** new empires of intelligence. And you can break it out by counties, because it ’ s specific counties. And if you want to get more specific, it ’ s actually specific zip codes. So, you want to know where life is happening? Well, in Southern California it ’ s happening in 92121. And that ’ s it. And that ’ s **the triangle** between Salk, Scripps, UCSD, and it ’ s called Torrey Pines Road. That means you don ’ t need to be a big nation to be successful ; it means you don ’ t need a lot of people to be successful ; and it means you can move most of **the** wealth of a country in about three or four carefully picked 747s. Same thing in Massachusetts. Looks more spread out but — oh, by **the** way, **the** ones that are **the** same color are contiguous. What ’ s **the** net effect of this? In an agricultural society, **the** difference between **the** richest and **the** poorest, **the** most productive and **the** least productive, was five to one. Why? Because in **agriculture**, if you had 10 kids and you grow up a little bit earlier and you work a little bit harder, you could produce about five times more wealth, on average, than your neighbor. In a knowledge society, that number is now 427 to 1. It really matters if you ’ re literate, not just in reading and writing in English and French and German, but in Microsoft and Linux and Apple. And very soon it ’ s going to matter if you ’ re literate in life code. So, if there is something you should fear, it ’ s that you ’ re not keeping your eye on **the** ball. Because it really matters who speaks life. That ’ s why nations rise and fall. And it turns out that if you went back to **the** 1870s, **the** most productive nation on earth was Australia, per person. And New Zealand was way up there. And then **the** U. S. came in about 1950, and then Switzerland about 1973, and then **the** U. S. got back on top — beat up their chocolates and cuckoo clocks. And today, of course, you all know that **the** most productive nation on earth is Luxembourg, producing about one third more wealth per person per year than America. Tiny landlocked state. No **oil**. No diamonds. No natural resources. Just smart people moving bits. Different rules. Here ’ s differential productivity rates. Here ’ s how many people it takes to produce a single U. S. **patent**. So, about 3, 000 Americans, 6, 000 Koreans, 14, 000 Brits, 790, 000 Argentines. You want to know why Argentina ’ s crashing? It ’ s got nothing to do with inflation. It ’ s got nothing to do with privatization. You can take a Harvard-educated Ivy League economist, stick him in charge of Argentina. He still crashes **the** country because he doesn ’ t understand how **the** rules have changed. Oh, yeah, and it takes about 5. 6 million Indians. Well, watch what happens to India. India and China used to be 40 percent of **the** global economy just at **the** Industrial Revolution, and they are now about 4. 8 percent. Two billion people. One third of **the** global population producing 5 percent of **the** wealth because they didn ’ t get this change, because they kept treating their people like serfs instead of like shareholders of a common project. They didn ’ t keep **the** people who were educated. They didn ’ t foment **the** businesses. They didn ’ t do **the** IPOs. Silicon Valley did. And that ’ s why they say that Silicon Valley has been powered by ICs. Not integrated circuits : Indians and Chinese. Here ’ s what ’ s happening in **the** world. It turns out that if you ’ d gone to **the** U. N. in 1950, when it was founded, there were 50 countries in this world. It turns out there ’ s now about 192. Country after country is splitting, seceding, succeeding, failing — and it ’ s all getting very fragmented. And this has not stopped. In **the** 1990s, these are sovereign states that did not exist before 1990. And this doesn ’ t include **fusions** or name changes or changes in flags. We ’ re generating about 3. 12 states per year. People are taking control of their own states, sometimes for **the** better and sometimes for **the** worse. And **the** really interesting thing is, you and your kids are empowered to build great empires, and you don ’ t need a lot to do it. And, given that **the** music is over, I was going to talk about how you can use this to generate a lot of wealth, and how code works. Moderator : Two minutes. Juan Enriquez : No, I ’ m going to stop there and we ’ ll do it next year because I don ’ t want to take any of Laurie ’ s time. But thank you very much.

Text Sample 3: POS Dim 1 – 2003 – Score 23.00 – 2003/t000259.txt
Last year, I told you **the** story, in seven minutes, of Project Orion, which was this very implausible technology that technically could have worked, but it had this one-year political window where it could have happened. So it didn ’ t happen. It was a dream that did not happen. This year I ’ m going to tell you **the** story of **the** birth of digital computing. This was a perfect introduction. And it ’ s a story that did work. It did happen, and **the** machines are all around us. And it was a technology that was inevitable. If **the** people I ’ m going to tell you **the** story about, if they hadn ’ t done it, somebody else would have. So, it was sort of **the** right idea at **the** right time. This is Barricelli ’ s **universe**. This is **the universe** we live in now. It ’ s **the universe** in which these machines are now doing all these things, including changing **biology**. I ’ m starting **the** story with **the** first atomic bomb at Trinity, which was **the** Manhattan Project. It was a little bit like TED : it brought a whole lot of very smart people together. And three of **the** smartest people were Stan Ulam, Richard Feynman and John von Neumann. And it was Von Neumann who said, after **the** bomb, he was working on something much more important than bombs : he ’ s thinking about **computers**. So, he wasn ’ t only thinking about them ; he built one. This is **the** machine he built. He built this machine, and we had a beautiful demonstration of how this thing really works, with these little bits. And it ’ s an idea that goes way back. **The** first person to really explain that was Thomas Hobbes, who, in 1651, explained how arithmetic and logic are **the** same thing, and if you want to do **artificial** thinking and **artificial** logic, you can do it all with arithmetic. He said you needed addition and subtraction. Leibniz, who came a little bit later — this is 1679 — showed that you didn ’ t even need subtraction. You could do **the** whole thing with addition. Here, we have all **the** binary arithmetic and logic that drove **the computer** revolution. And Leibniz was **the** first person to really talk about building such a machine. He talked about doing it with marbles, having gates and what we now call shift registers, where you shift **the** gates, drop **the** marbles down **the** tracks. And that ’ s what all these machines are doing, except, instead of doing it with marbles, they ’ re doing it with electrons. And then we jump to Von Neumann, 1945, when he sort of reinvents **the** whole same thing. And 1945, after **the** war, **the** electronics existed to actually try and build such a machine. So June 1945 — actually, **the** bomb hasn ’ t even been dropped yet — and Von Neumann is putting together all **the** theory to actually build this thing, which also goes back to Turing, who, before that, gave **the** idea that you could do all this with a very brainless, little, finite state machine, just reading a tape in and reading a tape out. **The** other sort of genesis of what Von Neumann did was **the** difficulty of how you would predict **the** weather. Lewis Richardson saw how you could do this with a cellular **array** of people, giving them each a little chunk, and putting it together. Here, we have an **electrical** model illustrating a mind having a will, but capable of only two ideas. And

that ’ s really **the** simplest **computer**. It ’ s basically why you need **the** qubit, because it only has two ideas. And you put lots of those together, you get **the** essentials of **the** modern **computer** : **the** arithmetic unit, **the** central control, **the** memory, **the** recording medium, **the** input and **the** output. But, there ’ s one catch. This is **the** fatal — you know, we saw it in starting these programs up. **The** instructions which govern this operation must be given in absolutely exhaustive detail. So, **the** programming has to be perfect, or it won ’ t work. If you look at **the** origins of this, **the** classic history sort of takes it all back to **the** ENIAC here. But actually, **the** machine I ’ m going to tell you about, **the** Institute for Advanced Study machine, which is way up there, really should be down there. So, I ’ m trying to revise history, and give some of these guys more credit than they ’ ve had. Such a **computer** would open up **universes**, which are, at **the** present, outside **the** range of any instruments. So it opens up a whole new world, and these people saw it. **The** guy who was supposed to build this machine was **the** guy in **the** middle, Vladimir Zworykin, from RCA. RCA, in probably one of **the** lousiest business decisions of all time, decided not to go into **computers**. But **the** first meetings, November 1945, were at RCA ’ s offices. RCA started this whole thing off, and said, you know, televisions are **the** future, not **computers**. **The** essentials were all there — all **the** things that make these machines run. Von Neumann, and a logician, and a mathematician from **the** army put this together. Then, they needed a place to build it. When RCA said no, that ’ s when they decided to build it in Princeton, where Freeman works at **the** Institute. That ’ s where I grew up as a kid. That ’ s me, that ’ s my sister Esther, who ’ s talked to you before, so we both go back to **the** birth of this thing. That ’ s Freeman, a long time ago, and that was me. And this is Von Neumann and Morgenstern, who wrote **the**”Theory of Games.”All these forces came together there, in Princeton. Oppenheimer, who had built **the** bomb. **The** machine was actually used mainly for doing bomb calculations. And Julian Bigelow, who took Zworkykin ’ s place as **the** engineer, to actually figure out, using electronics, how you would build this thing. **The** whole gang of people who came to work on this, and women in front, who actually did most of **the** coding, were **the** first programmers. These were **the** prototype **geeks**, **the** nerds. They didn ’ t fit in at **the** Institute. This is a letter from **the** director, concerned about —”especially unfair on **the** matter of sugar.”You can read **the** text. This is hackers getting in trouble for **the** first time.. These were not theoretical physicists. They were real soldering-gun type guys, and they actually built this thing. And we take it for granted now, that each of these machines has billions of transistors, doing billions of cycles per second without failing. They were using vacuum tubes, very narrow, sloppy **techniques** to get actually binary behavior out of these radio vacuum tubes. They actually used 6J6, **the** common radio tube, because they found they were more reliable than **the** more expensive tubes. And what they did at **the** Institute was publish every step of **the** way. Reports were issued, so that this machine was **cloned** at 15 other places around **the** world. And it really was. It was **the** original microprocessor. All **the computers** now are **copies** of that machine. **The** memory was in cathode ray tubes — a whole bunch of spots on **the** face of **the** tube — very, very sensitive to electromagnetic disturbances. So, there ’ s 40 of these tubes, like a V-40 engine running **the** memory. **The** input and **the** output was by teletype tape at first. This is a wire drive, using bicycle wheels. This is **the** archetype of **the** hard **disk** that ’ s in your machine now. Then they switched to a magnetic **drum**. This is modifying IBM equipment, which is **the** origins of **the** whole data-processing industry, later at IBM. And this is **the** beginning of **computer graphics**. **The**”Graph ’ g-Beam Turn On.”This next **slide**, that ’ s **the** — as far as I know — **the** first digital bitmap display, 1954. So, Von Neumann was already off in a theoretical cloud, doing **abstract** sorts of studies of how you could build reliable machines out of unreliable components. Those guys **drinking** all **the** tea with sugar in it were writing in their logbooks, trying to get this thing to work, with all these 2, 600 vacuum tubes that failed half **the** time. And that ’ s what I ’ ve been doing, this last six months, is going through **the** logs.”Running time : two minutes. Input, output : 90 minutes.”This includes a large amount of human error. So they are always trying to figure out, what ’ s machine error? What ’ s human error? What ’ s code, what ’ s hardware? That ’ s an engineer gazing at tube number 36, trying to figure out why **the** memory ’ s not in focus. He had to focus **the** memory — seems OK. So, he had to focus each tube just to get **the** memory up and running, let alone having, you know, software problems.”No use, went home.””Impossible to follow **the** damn thing, where ’ s a directory?”So, already, they ’ re complaining about **the** manuals :”before closing down in disgust...””**The** General Arithmetic : Operating Logs.”Burning lots of midnight **oil**.”MANIAC,”which became **the** acronym for **the** machine, Mathematical and Numerical Integrator and Calculator,”lost its memory.””MANIAC regained its memory, when **the** power went off.””Machine or human?””Aha!”So, they figured out it ’ s a code problem.”Found trouble in code, I hope.””Code error, machine not guilty.””Damn it, I can be just as stubborn as this thing.””And **the** dawn came.”So they ran all night. Twenty-four hours a day, this thing was running, mainly running bomb calculations.”Everything up to this point is wasted time.””What ’ s **the** use? Good night.””Master control off. **The** hell with it. Way off.””Something ’ s wrong with **the** air conditioner — smell of burning V-belts in **the** air.””A short — do not turn **the** machine on.””IBM machine putting a tar-like substance on **the** cards. **The** tar is from **the** roof.”So they really were working under tough conditions. Here,”A mouse has climbed into **the** blower behind **the** regulator rack, set blower to vibrating. Result : no more mouse.””Here lies mouse. Born :?. Died : 4:50 a. m., May 1953.”There ’ s an inside joke someone has penciled in :”Here lies Marston Mouse.”If you ’ re a mathematician, you get that, because Marston was a mathematician who **objected** to **the computer** being there.”Picked a lightning bug off **the drum**.””Running at two kilocycles.”That ’ s two thousand cycles per second —”yes, I ’ m chicken”— so two kilocycles was slow speed. **The** high speed was 16 kilocycles. I don ’ t know if you remember a Mac that was 16 Megahertz, that ’ s slow speed.”I have now duplicated both results. How will I know which is right, assuming one result is correct? This now is **the** third different output. I know when I ’ m licked.””We ’ ve duplicated errors before.””Machine run, fine. Code isn ’ t.””Only happens when **the** machine is running.”And sometimes things are **okay**.”Machine a thing of beauty, and a joy forever.””Perfect running.””Parting thought : when there ’ s bigger and better errors, we ’ ll have them.”So, nobody was supposed to know they were actually designing bombs. They ’ re designing hydrogen bombs. But someone in **the** logbook, late one night, finally drew a bomb. So, that was **the** result. It was Mike, **the** first thermonuclear bomb, in 1952. That was designed on that machine, in **the** woods behind **the** Institute. So Von Neumann invited a whole gang of weirdos from all over **the** world to work on all these problems. Barricelli, he came to do what we now call, really, **artificial** life, trying to see if, in this **artificial universe** — he was a viral-geneticist, way, way, way ahead of his time. He ’ s still ahead of some of **the** stuff that ’ s being done now. Trying to start an **artificial** genetic system running in **the computer**. Began — his **universe** started March 3, ’ 53. So it ’ s almost exactly — it ’ s 50 years ago next Tuesday, I guess. And he saw everything in terms of — he could read **the** binary code straight off **the** machine. He had a wonderful rapport. Other people couldn ’ t get **the** machine running. It always worked for him. Even errors were duplicated.”Dr. Barricelli claims machine is wrong, code is right."So he designed this **universe**, and ran it. When **the** bomb people went home, he was allowed in there. He would run that thing all night long, running these things, if anybody remembers Stephen Wolfram, who reinvented this stuff. And he published it. It wasn ' t locked up and **disappeared**. It was published in **the** literature."If it ' s that easy to create living organisms, why not create a few yourself?"So, he decided to give it a try, to start this **artificial biology** going in **the** machines. And he found all these, sort of — it was like a naturalist coming in and looking at this tiny, 5, 000-byte **universe**, and seeing all these things happening that we see in **the** outside world, in **biology**. This is some of **the** generations of his **universe**. But they ' re just going to stay numbers ; they ' re not going to become organisms. They have to have something. You have a genotype and you have to have a phenotype. They have to go out and do something. And he started doing that, started giving these little numerical organisms things they could play with — playing chess with other machines and so on. And they did start to **evolve**. And he went around **the** country after that. Every time there was a new, fast machine, he started using it, and saw exactly what ' s happening now. That **the** programs, instead of being turned off — when you quit **the** program, you ' d keep running and, basically, all **the** sorts of things like Windows is doing, running as a multicellular organism on many machines, he envisioned all that happening. And he saw that **evolution** itself was an intelligent process. It wasn ' t any sort of creator intelligence, but **the** thing itself was a giant parallel computation that would have some intelligence. And he went out of his way to say that he was not saying this was lifelike, or a new kind of life. It just was another version of **the** same thing happening. And there ' s really no difference between what he was doing in **the computer** and what nature did billions of years ago. And could you do it again now? So, when I went into these archives looking at this stuff, lo and behold, **the** archivist came up one day, saying,"I think we found another box that had been thrown out."And it was his **universe** on punch cards. So there it is, 50 years later, sitting there — sort of suspended animation. That ' s **the** instructions for running — this is actually **the** source code for one of those **universes**, with a note from **the** engineers saying they ' re having some problems."There must be something about this code that you haven ' t explained yet."And I think that ' s really **the** truth. We still don ' t understand how these very simple instructions can lead to increasing complexity. What ' s **the** dividing line between when that is lifelike and when it really is alive? These cards, now, thanks to me showing up, are being saved. And **the** question is, should we run them or not? You know, could we get them running? Do you want to let it loose on **the** Internet? These machines would think they — these organisms, if they came back to life now — whether they ' ve died and gone to heaven, there ' s a **universe**. My **laptop** is 10 thousand million times **the** size of **the universe** that they lived in when Barricelli quit **the** project. He was thinking far ahead, to how this would really grow into a new kind of life. And that ' s what ' s happening! When Juan Enriquez told us about these 12 trillion bits being transferred back and forth, of all this genomics data going to **the** proteomics lab, that ' s what Barricelli imagined : that this digital code in these machines is actually starting to code — it already is coding from nucleic acids. We ' ve been doing that since, you know, since we started PCR and synthesizing small strings of DNA. And real soon, we ' re actually going to be synthesizing **the** proteins, and, like Steve showed us, that just opens an entirely new world. It ' s a world that Von Neumann himself envisioned. This was published after he died : his sort of unfinished notes on self-reproducing machines, what it takes to get **the** machines sort of jump-started to where they begin to reproduce. It took really three people : Barricelli had **the** concept of **the** code as a living thing ; Von Neumann saw how you could build **the** machines — that now, last count, four million of these Von Neumann machines is built every 24 hours ; and Julian Bigelow, who died 10 days ago — this is John Markoff ' s obituary for him — he was **the** important missing link, **the** engineer who came in and knew how to put those vacuum tubes together and make it work. And all our **computers** have, inside them, **the copies** of **the** architecture that he had to just design one day, sort of on pencil and paper. And we owe a tremendous credit to that. And he explained, in a very generous way, **the** spirit that brought all these different people to **the** Institute for Advanced Study in **the** ' 40s to do this project, and make it freely available with no **patents**, no restrictions, no intellectual property disputes to **the** rest of **the** world. That ' s **the** last entry in **the** logbook when **the** machine was shut down, July 1958. And it ' s Julian Bigelow who was running it until midnight when **the** machine was officially turned off. And that ' s **the** end. Thank you very much.

Text Sample 4: POS Dim 1 – 2003 – Score 23.00 – 2003/t000117.txt

Right when I was 15 was when I first got interested in solar energy. My family had moved from Fort Lee, New Jersey to California, from **the** snow to lots of heat, and gas lines. There was gas rationing in 1973. **The** energy crisis was in full bore. I started reading"Popular Science"magazine, and I got really excited about **the** potential of solar energy to try and solve that crisis. I had just taken trigonometry in high school, I learned about **the** parabola and how it could concentrate rays of light to a single focus. That got me very excited. And I really felt that there would be potential to build some kind of thing that could concentrate light. So, I started this company called Solar Devices. And this was a company where I built parabolas, I took metal shop, and I remember walking into metal shop building parabolas and Stirling engines. And I was building a Stirling engine over on **the** lathe, and all **the** motorcycle guys said,"You ' re building a bong, aren ' t you?"And I said,"No, it ' s a Stirling engine."But they didn ' t believe me. I sold **the** plans for this engine and for this dish in **the** back of"Popular Science"magazine, for four dollars each. And I earned enough money to pay for my first year of Caltech. It was a really big excitement for me to get into Caltech. And at my first year at Caltech, I continued **the** business. But then, in **the** second year of Caltech, they started grading. **The** whole first year was pass / fail, but **the** second year was graded. I wasn ' t able to keep up with **the** business, and I ended up with a 25-year detour. My dream had been to convert solar energy at a very practical cost, but then I had this big detour. First, **the** coursework at Caltech. Then, when I graduated from Caltech, **the** IBM PC came out, and I got addicted to **the** IBM PC in 1981. And then in 1983, Lotus 1-2-3 came out, and I was completely blown away by Lotus 1-2-3. I began operating my business with 1-2-3, began writing add-ins for 1-2-3, wrote a natural language interface to 1-2-3. I started an educational software company after I joined Lotus, and then I started Idealab so I could have a roof under which I could build multiple companies in succession. Much later — in 2000, very recently — **the** new California energy crisis — what was purported to be a big energy crisis — was coming. And I was trying to figure out if we could build something that would capitalize on that and get people backup energy, in case **the** crisis really came. And I started looking at how we could build battery backup systems that could give people five hours, 10 hours, maybe even a full day, or three days ' worth of backup power. I ' m glad you heard earlier today, batteries are unbelievably — lack density compared to fuel. So much more energy can be stored with fuel than with batteries. You ' d have to fill your entire parking space of one garage space just to give yourself four hours of battery backup. And I **concluded**, after researching every other technology that we could deploy for storing energy — flywheels, different formulations of batteries — it just wasn ’ t practical to store energy. So what about making energy? Maybe we could make energy. I tried to figure out — maybe solar ’ s become attractive. It ’ s been 25 years since I was doing this, let me go back and look at what ’ s been happening with solar cells. And **the** price had gone down from 10 dollars a watt to about four or five dollars a watt, but it stabilized. And it needed to get much lower to be cost-effective. I studied all **the** new things that had happened in solar cells, and was looking for ways we could make solar cells more inexpensively. A lot of new things are happening to do that, but fundamentally, **the** process requires a tremendous amount of energy. Some people say it takes more energy to make a solar cell than it will give out in its entire life. If we reduce **the** amount of energy it takes to make **the** cells, that will become more practical. But right now, you pretty much have to take silicon, put it in an oven at 1600 F for 17 hours, to make **the** cells. A lot of people are working to try and reduce that, but I didn ’ t have anything to contribute. So I tried to figure out what other way could we try to make cost-effective solar electricity. What if we collect **the** sun with a large reflector — like I had been thinking about in high school, but maybe with modern technology we could make it cheaper — concentrate it to a small converter, and then **the** conversion **device** wouldn ’ t have to be as expensive, because it ’ s much smaller, rather than solar cells, which have to cover **the** entire **surface** that you want to gather sun from. This seemed practical now, because a lot of new technologies had come in **the** 25 years since I had last looked at it. There was a lot of new manufacturing **techniques**, not to mention really cheap miniature motors — brushless motors, servomotors, stepper motors, that are used in printers and scanners. So, that ’ s a breakthrough. Of course, inexpensive microprocessors and a very important breakthrough — genetic algorithms. I ’ ll be very short on genetic algorithms. It ’ s a powerful way of solving intractable problems using natural **selection**. You take a problem that you can ’ t solve with a pure mathematical answer, you build an **evolutionary** system to try multiple tries at guessing, you add sex — where you take half of one solution and half of another and then make new mutations — and you use natural **selection** to kill off not-as-good solutions. Usually, with a genetic algorithm on a **computer** today, with a three gigahertz processor, you can solve many formerly intractable problems in just a matter of minutes. So we tried to come up with a way to use genetic algorithms to create a new type of concentrator. And I ’ ll show you what we came up with. Traditionally, concentrators look like this. Those shapes are parabolas. They take all **the** parallel incoming rays and focus it to a single spot. They have to track **the** sun, because they have to point directly at **the** sun. They usually have a one degree acceptance angle — once they ’ re more than a degree off, none of **the** sunlight rays will hit **the** focus. So we tried to come up with a non-tracking collector that would gather much more than one degree of light, with no moving parts. So we created a genetic algorithm to try this out, we made a model in Excel of a multisurface reflector, and an amazing thing **evolved**, literally, from trying a billion cycles, a billion different attempts, with a fitness function that defined how can you collect **the** most light, from **the** most angles, over a day, from **the** sun. And this is **the** shape that **evolved**. It ’ s this non-tracking collector with these six tuba-like horns, and each of them collect light in **the** following way — if **the** sunlight strikes right here, it might bounce right to **the** center, **the** hot spot, directly, but if **the** sun is off axis and comes from **the** side, it might hit two places and take two bounces. So for direct light, it takes only one bounce, for off-axis light it might take two, and for extreme off-axis, it might take three. Your efficiency goes down with more bounces, because you lose about 10 percent with each bounce, but this allowed us to collect light from a plus or minus 25-degree angle. So, about two and a half hours of **the** day we could collect with a stationary component. Solar cells collect light for four and a half hours though. On an average adjusted day, a solar cell — because **the** sun ' s moving across **the** sky, **the** solar cell is going down with a sine wave function of performance at **the** off- axis angles. It collects about four and a half average hours of sunlight a day. So even this, although it was great with no moving parts — we could achieve high temperatures — wasn ' t enough. We needed to beat solar cells. So we took a look at another idea. We looked at a way to break up a parabola into individual petals that would track. So what you see here is 12 separate petals that each could be controlled with individual microprocessors that would only cost a dollar. You can buy a two- megahertz microprocessor for a dollar now. And you can buy stepper motors that pretty much never wear out because they have no brushes, for a dollar. So we can control all 12 of these petals for under 50 dollars and what this would allow us to do is not have to move **the** focus any more, but only move **the** petals. **The** whole system would have a much lower profile, but also we could gather sunlight for six and a half to seven hours a day. Now that we have concentrated sunlight, what are we going to put at **the** center to convert sunlight to electricity? So we tried to look at all **the** different heat engines that have been used in history to convert sunlight or heat to electricity, And one of **the** great ones of all time, James Watt ' s steam engine of 1788 was a major breakthrough. James Watt didn ' t actually invent **the** steam engine, he just refined it. But his refinements were incredible. He added new linear motion guides to **the** pistons, he added a condenser to cool **the** steam outside **the** cylinder, he made **the** engine double-acting, so it had double **the** power. Those were major breakthroughs. All of **the** improvements he made — and it ' s justifiable that our measure of energy, **the** watt, today is named after him. So we looked at this engine, and this had some potential. Steam engines are dangerous, and they had tremendous impact on **the** world — industrial revolution and ships and locomotives. But they ' re usually good to be large, so they ' re not good for distributed power generation. They ' re also very high- pressure, so they ' re dangerous. Another type of engine is **the** hot air engine. And **the** hot air engine also was not invented by Robert Stirling, but Robert Stirling came along in 1816 and radically improved it. This engine, because it was so interesting — it only worked on air, no steam — has led to hundreds of creative designs over **the** years that use **the** Stirling engine principle. But after **the** Stirling engine, Otto came along, and also, he didn ' t invent **the** internal combustion engine, he just refined it. He showed it in Paris in 1867, and it was a major achievement because it brought **the** power density of **the** engine way up. You could now get a lot more power in a lot smaller space, and that allowed **the** engine to be used for mobile applications. So, once you have mobility, you ' re making a lot of engines because you ' ve got lots of units, as opposed to steam ships or big factories, so this was **the** engine that ended up benefiting from mass production where all **the** other engines didn ' t. So, because it went into mass production, costs were reduced, 100 years of refinement, **emissions** were reduced, tremendous production value. There have been hundreds of millions of internal combustion engines built, compared to thousands of Stirling engines built. And not nearly as many small steam engines being built anymore, only large ones for big operations. So after looking at these three, and 47 others, we **concluded** that **the** Stirling engine would be **the** best one to use. I want to give you a brief explanation of how we looked at it and how it works. So we tried to look at **the** Stirling engine in a new way, because it was practical — weight no longer mattered for our application. **The** internal combustion engine took off because weight mattered, because you were moving around. But if you ’ re trying to generate solar energy in a static place **the** weight doesn ’ t matter so much. We also discovered that efficiency doesn ’ t matter so much if your energy source is free. Normally, efficiency is crucial because **the** fuel cost of your engine over its life **dwarfs the** cost of **the** engine. But if your fuel source is free, then **the** only thing that matters is **the** up-front capital cost of **the** engine. So you don ’ t want to optimize for efficiency, you want to optimize for power per dollar. So using that new twist, with **the** new criteria, we thought we could relook at **the** Stirling engine, and also bring genetic algorithms in. Basically, Robert Stirling didn ’ t have Gordon Moore before him to get us three gigahertz of processor power. So we took **the** same genetic algorithm that we used earlier to make that concentrator, which didn ’ t work out for us, to optimize **the** Stirling engine, and make its design sizes and all of its **dimensions the exact** optimum to get **the** most power per dollar, irrespective of weight, irrespective of size, just to get **the** most conversion of solar energy, because **the** sun is free. And that ’ s **the** process we took — let me show you how **the** engine works. **The** simplest heat engine, or hot air engine, of all time would be this — take a box, a steel canister, with a piston. Put a flame under it, **the** piston moves up. Take it off **the** flame and pour water on it, or let it cool down, **the** piston moves down. That ’ s a heat engine. That ’ s **the** most fundamental heat engine you could have. **The** problem is **the** efficiency is one hundredth of one percent, because you ’ re heating all **the** metal of **the** chamber and then cooling all **the** metal of **the** chamber each time. And you ’ re only getting power from **the** air that ’ s heating at **the** same time, but you ’ re wasting energy heating and cooling **the** metal. So someone came up with a very clever idea. Instead of heating and cooling **the** whole cylinder, what about if you put a displacer inside — a little thing that shuttles **the** air back and forth. You move that up and down with a little bit of energy but now you ’ re only shifting **the** air down to **the** hot end and up to **the** cold end. So, now you ’ re not alternately heating and cooling **the** metal, just **the** air. That allows you to get **the** efficiency up from a hundredth of a percent to about two percent. And then Robert Stirling came along with this genius idea, which was, well, I ’ m still not heating **the** metal now, with this kind of engine, but I ’ m still reheating all **the** air. I ’ m still heating **the** air every time and cooling **the** air every time. What about if I put a thermal sponge in **the** middle, in **the** passageway between where **the** air has to move between hot and cold? So he made fine wires, and cracked glass, and all different kinds of materials to be a heat sponge. So when **the** air pushes up to go from **the** hot end to **the** cold end, it puts some heat into **the** sponge. And then when **the** air comes back after it ’ s been cooled, it picks up that heat again. So you ’ re reusing your energy five or six times, and that brings **the** efficiency up to between 30 and 40 percent. It ’ s a little known, but brilliant, genius invention of Robert Stirling that takes **the** hot air engine from being somewhat impractical — like I found out when I made **the** real simple version in high school — to very potentially possible, once you get **the** efficiency up, if you can design this to be low enough cost. So we really set out on a path to try and make **the** lowest cost possible. We built a huge mathematical model of how a Stirling engine works. We applied **the** genetic algorithm. We got **the** results from that for **the** optimal engine. We built engines — so we built 100 different engines over **the** last two years. We measured each one, we readjusted **the** model to what we measured, and then we led that to **the** current prototype. It led to a very compact, inexpensive engine, and this is what **the** engine looks like. Let me show you what it looks like in real life. So this is **the** engine. It ’ s just a small cylinder down here, which holds **the** generator inside and all

the linkage, and it ’ s **the** hot cap — **the** hot cylinder on **the** top — this part gets hot, this part is cool, and electricity comes out. **The exact** converse is also true. If you put electricity in, this will get hot and this will get cold, you get refrigeration. So it ’ s a complete reversible cycle, a very efficient cycle, and quite a simple thing to make. So now you put **the** two things together. So you have **the** engine. What if you combine **the** petals and **the** engine in **the** center? **The** petals track and **the** engine gets **the** concentrated sunlight, takes that heat and turns it into electricity. This is what **the** first prototype of our system looked like with **the** petals and **the** engine in **the** center. This is being run out in **the** sun, and now I want to show you what **the** actual thing looks like. Thank you. So this is a unit with **the** 12 petals. These petals cost about a dollar each — they ’ re lightweight, injection-molded plastic, aluminized. **The** mechanism to control each petal is below there, with a microprocessor on each one. There are thermocouples on **the** engine — little sensors that **detect the** heat when **the** sunlight strikes them. Each petal adjusts itself separately to keep **the** highest temperature on it. When **the** sun comes out in **the** morning, **the** petals will seek **the** sun, find it by **searching** for **the** highest temperature. About a minute and a half or two minutes after **the** rays are striking **the** hot cap **the** engine will be warm enough to start and then **the** engine will generate electricity for about six and a half hours a day — six and a half to seven hours as **the** sun moves across **the** sky. A critical part that we can take advantage of is that we have these inexpensive microprocessors and each of these petals is autonomous, and each of these petals figures out where **the** sun is with no user setup. So you don ’ t have to tell what latitude, longitude you ’ re at, what your roof **slope** angle is, or what orientation. It doesn ’ t really care. What it does is it **searches** to find **the** hottest spot, it **searches** again a half an hour later, a day later, a month later. It basically figures out where on Earth you are by watching **the** direction **the** sun moves, so you don ’ t have to actually enter anything about that. **The** way **the** unit works is, when **the** sun comes out, **the** engine will start and you get power out here. We have AC and DC, get 12 volts DC, so that could be used for certain applications. We have an inverter in there, so you get 117 volts AC. And you also get hot water. **The** hot water ’ s optional. You don ’ t have to use it, it will cool itself. But you can use it to optionally heat hot water and that brings **the** efficiency up even higher because some of **the** heat that you ’ d normally be rejecting, you can now use as useful energy, whether it ’ s for a pool or hot water. Let me show you a quick movie of what this looks like running. This is **the** first test where we took it outside and each of **the** petals were individually seeking. And what they do is step, very coarsely at first, and very finely afterward. Once they get a temperature reading on **the** thermocouple indicating they found **the** sun, they slow down and do a fine **search**. Then **the** petals will move into position, and **the** engine will start. We ’ ve been working on this for **the** last two years. We ’ re very excited about **the** progress, we have a long way to go though. This is how we envision it would be in a residential installation : you ’ d probably have more than one unit on your roof. It could be on your roof, your backyard, or somewhere else. You don ’ t have to have enough units to power your entire house, you just save money with each incremental one you add. So you ’ re still using **the** grid potentially, in this type of application, to be your backup supply — of course, you can ’ t use these at night, and you can ’ t use these on cloudy days. But by reducing your energy use, pretty much at **the** peak times — usually when you have your air conditioning on, or other times like that — this generates **the** peak power at **the** peak usage time, so it ’ s very complementary in that sense. This is how we would envision a residential application. We also think there ’ s very big potential for energy farms, especially in remote land where there happens to be a lot of sun. It ’ s a really good combination of those two factors. It turns out there ’ s a lot of powerful sun all around **the** world, obviously, but in special places where it happens to be relatively inexpensive to place these and also in many more places where there is high wind power. So an example of that is, here ’ s **the** map of **the** United States. Pretty much everywhere that ’ s not green or **blue** is a really ideal place, but even **the** green or **blue** areas are good, just not as good as **the** places that are red, orange and **yellow**. But **the** hot spot right around Las Vegas and Death Valley is very good. And is only affects **the** payback period, it doesn ’ t mean that you couldn ’ t use solar energy ; you could use it anywhere on Earth. It just affects **the** payback period if you ’ re comparing to grid-supplied electricity. But if you don ’ t have grid-supplied electricity, then **the** question of payback is a different one entirely. It ’ s just how many watts do you get per dollar, and how could you benefit from that to change your life in some way. This is **the** map of **the** whole Earth, and you can see a huge swathe in **the** middle where a large part of **the** population is, there ’ s tremendous chances for solar energy. And of course, look at Africa. **The** potential to take advantage of solar energy there is unbelievable, and I ’ m really excited to talk more about finding ways we can help with that. So, in conclusion, I would say my journey has shown me that you can revisit old ideas in a new light, and sometimes ideas that have been **discarded** in **the** past can be practical now if you apply some new technology or new twists. We believe we ’ re getting very close to something practical and affordable. Our short-term goal for this is to be half **the** price of solar cells and our longer-term goal is to be less than a five-year payback. And at less than a five-year payback, this becomes very economic. So you don ’ t have to just have a feel-good attitude about energy to want to have one of these. It just makes economic sense. Right now, solar paybacks are between 30 and 50 years. If you get it down below five years, then it ’ s almost a no-brainer because **the** interest to own it — someone else will finance it for you and you can just make money from day one. So that ’ s our real powerful goal that we ’ re really shooting for in **the** company. Two other things that I learned that were very surprising to me — one was how casual we are about energy. I was walking from **the** elevator over here, and even just looking at **the** stage right now — so there ’ s probably 20, 500-watt lights right now. There ’ s 10, 000 watts of light pouring on **the** stage, one horsepower is 746 watts, at full power. So there ’ s basically 15 horses running at full speed just to keep **the** stage lit. Not to mention **the** 200 horses that are probably running right now to keep **the** air-conditioning going. And it ’ s just amazing, walk in **the** elevator, and there ’ s lights on in **the** elevator. Of course, now I ’ m very sensitive at home when we leave **the** lights on by mistake. But, everywhere around us we have insatiable use for energy because it ’ s so cheap. And it ’ s cheap because we ’ ve been subsidized by energy that ’ s been concentrated by **the** sun. Basically, **oil** is solar-energy concentrate. It ’ s been **pounded** for a billion years with a lot of energy to make it have all that energy contained in it. And we don ’ t have a birthright to just use that up as fast as we are, I think. And it would be great if we could make our energy usage **renewable**, where as we ’ re using **the** energy, we ’ re creating it at **the** same pace, and I really hope we can get there. Thank you very much, you ’ ve been a great audience.

Text Sample 5: POS Dim 1 – 2005 – Score 32.00 – 2005/t000435.txt
It is a thrill to be here at a conference that ’ s devoted to”Inspired by Nature”â
you can imagine. And I ’ m also thrilled to be in **the** foreplay section. Did you

notice this section is foreplay? Because I get to talk about one of my favorite critters, which is **the** Western Grebe. You haven ’ t lived until you ’ ve seen these guys do their courtship dance. I was on Bowman Lake in Glacier National Park, which is a long, skinny lake with sort of mountains upside down in it, and my partner and I have a rowing shell. And so we were rowing, and one of these Western Grebes came along. And what they do for their courtship dance is, they go together, **the** two of them, **the** two **mates**, and they begin to run **underwater**. They paddle faster, and faster, and faster, until they ’ re going so fast that they literally lift up out of **the** water, and they ’ re standing upright, sort of paddling **the** top of **the** water. And one of these Grebes came along while we were rowing. And so we ’ re in a skull, and we ’ re moving really, really quickly. And this Grebe, I think, sort of, mistaked us for a prospect, and started to run along **the** water next to us, in a courtship dance â for miles. It would stop, and then start, and then stop, and then start. Now that is foreplay. I came this close to changing species at that moment. Obviously, life can teach us something in **the** entertainment section. Life has a lot to teach us. But what I ’ d like to talk about today is what life might teach us in technology and in design. What ’ s happened since **the** book came out â **the** book was mainly about research in biomimicry â and what ’ s happened since then is architects, designers, engineers â people who make our world â have started to call and say, we want a biologist to sit at **the** design table to help us, in real time, become inspired. Or â and this is **the** fun part for me â we want you to take us out into **the** natural world. We ’ ll come with a design challenge and we find **the** champion adapters in **the** natural world, who might inspire us. So this is a picture from a Galapagos trip that we took with some wastewater treatment engineers ; they purify wastewater. And some of them were very resistant, actually, to being there. What they said to us at first was, you know, we already do biomimicry. We use bacteria to clean our water. And we said, well, that ’ s not exactly being inspired by nature. That ’ s bioprocessing, you know ; that ’ s bio-assisted technology : using an organism to do your wastewater treatment is an old, old technology called”domestication.”This is learning something, learning an idea, from an organism and then applying it. And so they still weren ’ t getting it. So we went for a walk on **the** beach and I said, well, give me one of your big problems. Give me a design challenge, **sustainability** speed bump, that ’ s keeping you from being sustainable. And they said scaling, which is **the** build-up of minerals inside of pipes. And they said, you know what happens is, mineral â just like at your house â mineral builds up. And then **the** aperture closes, and we have to flush **the** pipes with toxins, or we have to dig them up. So if we had some way to stop this scaling â and so I picked up some shells on **the** beach. And I asked them, what is scaling? What ’ s inside your pipes? And they said, calcium carbonate. And I said, that ’ s what this is ; this is calcium carbonate. And they didn ’ t know that. They didn ’ t know that what a seashell is, it ’ s templated by proteins, and then ions from **the** seawater crystallize in place to create a shell. So **the** same sort of a process, without **the** proteins, is happening on **the** inside of their pipes. They didn ’ t know. This is not for lack of information ; it ’ s a lack of integration. You know, it ’ s a silo, people in silos. They didn ’ t know that **the** same thing was happening. So one of them thought about it and said, OK, well, if this is just crystallization that happens automatically out of seawater â self-assembly â then why aren ’ t shells infinite in size? What stops **the** scaling? Why don ’ t they just keep on going? And I said, well, in **the** same way that they exude a protein and it starts **the** crystallization â and then they all sort of leaned in â they let go of a protein that stops **the** crystallization. It literally adheres to **the** growing face of **the** crystal. And, in fact, there is a product called TPA that ’ s mimicked that protein â that stop-protein â and it ’ s an environmentally **friendly** way to stop scaling in pipes. That changed everything. From then on, you could not get these engineers back in **the** boat. **The** first day they would take a hike, and it was, click, click, click, click. Five minutes later they were back in **the** boat. We ’ re done. You know, I ’ ve seen that **island**. After this, they were crawling all over. They would snorkel for as long as we would let them snorkel. What had happened was that they realized that there were organisms out there that had already solved **the** problems that they had spent their careers trying to solve. Learning about **the** natural world is one thing ; learning from **the** natural world â that ’ s **the** switch. That ’ s **the** profound switch. What they realized was that **the** answers to their questions are everywhere ; they just needed to change **the** lenses with which they saw **the** world. 3. 8 billion years of field-testing. 10 to 30 â Craig Venter will probably tell you ; I think there ’ s a lot more than 30 million â well-adapted solutions. **The** important thing for me is that these are solutions solved in context. And **the** context is **the** Earth â **the** same context that we ’ re trying to solve our problems in. So it ’ s **the** conscious emulation of life ’ s genius. It ’ s not slavishly mimicking â although Al is trying to get **the** hairdo going â it ’ s not a slavish mimicry ; it ’ s taking **the** design principles, **the** genius of **the** natural world, and learning something from it. Now, in a group with so many IT people, I do have to mention what I ’ m not going to talk about, and that is that your field is one that has learned an enormous amount from living things, on **the** software side. So there ’ s **computers** that protect themselves, like an immune system, and we ’ re learning from gene regulation and biological development. And we ’ re learning from neural nets, genetic algorithms, **evolutionary** computing. That ’ s on **the** software side. But what ’ s interesting to me is that we haven ’ t looked at this, as much. I mean, these machines are really not very high tech in my estimation in **the** sense that there ’ s dozens and dozens of carcinogens in **the** water in Silicon Valley. So **the** hardware is not at all up to snuff in terms of what life would call a success. So what can we learn about making â not just **computers**, but everything? **The** plane you came in, cars, **the** seats that you ’ re sitting on. How do we redesign **the** world that we make, **the** human-made world? More importantly, what should we ask in **the** next 10 years? And there ’ s a lot of cool technologies out there that life has. What ’ s **the** syllabus? Three questions, for me, are key. How does life make things? This is **the** opposite ; this is how we make things. It ’ s called heat, beat and treat â that ’ s what material scientists call it. And it ’ s carving things down from **the** top, with 96 percent waste left over and only 4 percent product. You heat it up ; you beat it with high pressures ; you use chemicals. OK. Heat, beat and treat. Life can ’ t afford to do that. How does life make things? How does life make **the** most of things? That ’ s a geranium pollen. And its shape is what gives it **the** function of being able to tumble through air so easily. Look at that shape. Life adds information to matter. In other words : structure. It gives it information. By adding information to matter, it gives it a function that ’ s different than without that structure. And thirdly, how does life make things **disappear** into systems? Because life doesn ’ t really deal in things ; there are no things in **the** natural world divorced from their systems. Really quick syllabus. As I ’ m reading more and more now, and following **the** story, there are some amazing things coming up in **the** biological sciences. And at **the** same time, I ’ m listening to a lot of businesses and finding what their sort of grand challenges are. **The** two groups are not talking to each other. At all. What in **the** world of **biology** might be helpful at this juncture, to get us through this sort of **evolutionary** knothole that we ’ re in? I ’ m going to try to go through 12, really quickly. One that ’ s exciting to me is self-assembly. Now, you ’ ve heard about this in terms of nanotechnology.

Back to that shell : **the** shell is a self-assembling material. On **the** lower **left** there is a picture of mother of pearl forming out of seawater. It ’ s a layered structure that ’ s mineral and then polymer, and it makes it very, very tough. It ’ s twice as tough as our high-tech ceramics. But what ’ s really interesting : unlike our ceramics that are in kilns, it happens in seawater. It happens near, in and near, **the** organism ’ s body. This is Sandia National Labs. A guy named Jeff Brinker has found a way to have a self- assembling coding process. Imagine being able to make ceramics at room temperature by simply dipping something into a liquid, lifting it out of **the** liquid, and having evaporation force **the** molecules in **the** liquid together, so that they jigsaw together in **the** same way as this crystallization works. Imagine making all of our hard materials that way. Imagine spraying **the** precursors to a PV cell, to a solar cell, onto a roof, and having it self- assemble into a layered structure that harvests light. Here ’ s an interesting one for **the** IT world : bio-silicon. This is a diatom, which is made of silicates. And so silicon, which we make right now â it ’ s part of our carcinogenic problem in **the** manufacture of our chips â this is a bio-mineralization process that ’ s now being mimicked. This is at UC Santa Barbara. Look at these diatoms. This is from Ernst Haeckel ’ s work. Imagine being able to â and, again, it ’ s a templated process, and it solidifies out of a liquid process â imagine being able to have that sort of structure coming out at room temperature. Imagine being able to make perfect lenses. On **the** **left**, this is a brittle star ; it ’ s covered with lenses that **the** people at Lucent Technologies have found have no distortion whatsoever. It ’ s one of **the** most distortion-free lenses we know of. And there ’ s many of them, all over its entire body. What ’ s interesting, again, is that it self-assembles. A woman named Joanna Aizenberg, at Lucent, is now learning to do this in a low- temperature process to create these sort of lenses. She ’ s also looking at fiber optics. That ’ s a **sea** sponge that has a fiber optic. Down at **the** very base of it, there ’ s fiber optics that work better than ours, actually, to move light, but you can tie them in a knot ; they ’ re incredibly flexible. Here ’ s another big idea : CO2 as a feedstock. A guy named Geoff Coates, at Cornell, said to himself, you know, plants do not see CO2 as **the** biggest poison of our time. We see it that way. Plants are busy making long chains of starches and glucose, right, out of CO2. He ’ s found a way â he ’ s found a catalyst â and he ’ s found a way to take CO2 and make it into polycarbonates. Biodegradable plastics out of CO2 â how plant-like. Solar transformations : **the** most exciting one. There are people who are mimicking **the** energy-harvesting **device** inside of purple bacterium, **the** people at ASU. Even more interesting, lately, in **the** last couple of weeks, people have seen that there ’ s an enzyme called hydrogenase that ’ s able to **evolve** hydrogen from proton and electrons, and is able to take hydrogen up â basically what ’ s happening in a fuel cell, in **the** anode of a fuel cell and in a reversible fuel cell. In our fuel cells, we do it with platinum ; life does it with a very, very common **iron**. And a team has now just been able to mimic that hydrogen-juggling hydrogenase. That ’ s very exciting for fuel cells â to be able to do that without platinum. Power of shape : here ’ s a **whale**. We ’ ve seen that **the fins** of this **whale** have tubercles on them. And those little bumps actually increase efficiency in, for instance, **the** edge of an **airplane** â increase efficiency by about 32 percent. Which is an amazing **fossil** fuel savings, if we were to just put that on **the** edge of a **wing**. Color without pigments : this peacock is creating color with shape. Light comes through, it bounces back off **the** layers ; it ’ s called thin- film interference. Imagine being able to self-assemble products with **the** last few layers playing with light to create color. Imagine being able to create a shape on **the** outside of a **surface**, so that it ’ s self-cleaning with just water. That ’ s what a leaf does. See that up-close picture? That ’ s a ball of water, and those are dirt particles. And that ’ s an up-close picture of a lotus leaf. There ’ s a company making a product called Lotusan, which mimics â when **the** building facade paint dries, it mimics **the** bumps in a self-cleaning leaf, and rainwater cleans **the** building. Water is going to be our big, grand challenge : quenching thirst. Here are two organisms that pull water. **The** one on **the left** is **the** Namibian beetle pulling water out of fog. **The** one on **the** right is a pill bug â pulls water out of air, does not **drink** fresh water. Pulling water out of Monterey fog and out of **the** sweaty air in Atlanta, before it gets into a building, are key technologies. Separation technologies are going to be extremely important. What if we were to say, no more hard **rock** mining? What if we were to separate out metals from waste streams, small amounts of metals in water? That ’ s what microbes do ; they chelate metals out of water. There ’ s a company here in San Francisco called MR3 that is embedding mimics of **the** microbes ’ molecules on filters to mine waste streams. Green **chemistry** is **chemistry** in water. We do **chemistry** in **organic** solvents. This is a picture of **the** spinnerets coming out of a **spider** and **the** silk being formed from a **spider**. Isn ’ t that beautiful? Green **chemistry** is replacing our industrial **chemistry** with nature ’ s recipe book. It ’ s not easy, because life uses only a subset of **the** elements in **the** periodic table. And we use all of them, even **the** toxic ones. To figure out **the** elegant recipes that would take **the** small subset of **the** periodic table, and create miracle materials like that cell, is **the** task of green **chemistry**. Timed degradation : packaging that is good until you don ’ t want it to be good anymore, and dissolves on cue. That ’ s a mussel you can find in **the** waters out here, and **the** threads holding it to a **rock** are timed ; at exactly two years, they begin to dissolve. Healing : this is a good one. That little guy over there is a tardigrade. There is a problem with vaccines around **the** world not getting to patients. And **the** reason is that **the** refrigeration somehow gets broken ; what ’ s called **the**”cold chain”gets broken. A guy named Bruce Rosner looked at **the** tardigrade â which dries out completely, and yet stays alive for months and months and months, and is able to regenerate itself. And he found a way to dry out vaccines â encase them in **the** same sort of sugar capsules as **the** tardigrade has within its cells â meaning that vaccines no longer need to be refrigerated. They can be put in a glove compartment, OK. Learning from organisms. This is a session about water â learning about organisms that can do without water, in order to create a vaccine that lasts and lasts and lasts without refrigeration. I ’ m not going to get to 12. But what I am going to do is tell you that **the** most important thing, besides all of these adaptations, is **the** fact that these organisms have figured out a way to do **the** amazing things they do while taking care of **the** place that ’ s going to take care of their offspring. When they ’ re involved in foreplay, they ’ re thinking about something very, very important â and that ’ s having their genetic material remain, 10, 000 generations from now. And that means finding a way to do what they do without destroying **the** place that ’ ll take care of their offspring. That ’ s **the** biggest design challenge. Luckily, there are millions and millions of geniuses willing to gift us with their best ideas. Good luck having a conversation with them. Thank you. Chris Anderson : Talk about foreplay, I â we need to get to 12, but really quickly. Janine Benyus : Oh really? CA : Yeah. Just like, you know, like **the** 10-second version of 10, 11 and 12. Because we just â your **slides** are so gorgeous, and **the** ideas are so big, I can ’ t stand to let you go down without seeing 10, 11 and 12. JB : OK, put this â OK, I ’ ll just hold this thing. OK, great. OK, so that ’ s **the** healing one. Sensing and responding : feedback is a huge thing. This is a locust. There can be 80 million of them in a square kilometer, and yet they don ’ t collide with one another. And yet we have 3. 6 million car collisions a year. Right. There ’ s a person at Newcastle who has figured out that it ’ s a very large neuron. And she ’ s actually figuring out how to make a collision-avoidance circuitry based on this very large neuron in **the** locust. This is a huge and important one, number 11. And that ’ s **the** growing fertility. That means, you know, net fertility farming. We should be growing fertility. And, oh yes â we get food, too. Because we have to grow **the** capacity of this **planet** to create more and more opportunities for life. And really, that ’ s what other organisms do as well. In ensemble, that ’ s what whole ecosystems do : they create more and more opportunities for life. Our farming has done **the** opposite. So, farming based on how a prairie builds soil, ranching based on how a native ungulate herd actually increases **the** health of **the** range, even wastewater treatment based on how a marsh not only cleans **the** water, but creates incredibly sparkling productivity. This is **the** simple design brief. I mean, it looks simple because **the** system, over 3. 8 billion years, has worked this out. That is, those organisms that have not been able to figure out how to enhance or sweeten their places, are not around to tell us about it. That ’ s **the** twelfth one. Life â and this is **the** secret trick ; this is **the** magic trick â life creates conditions conducive to life. It builds soil ; it cleans air ; it cleans water ; it mixes **the** cocktail of gases that you and I need to live. And it does that in **the** middle of having great foreplay and meeting their needs. So it ’ s not mutually exclusive. We have to find a way to meet our needs, while making of this place an Eden. CA : Janine, thank you so much.

Text Sample 6: POS Dim 1 – 2005 – Score 27.00 – 2005/t000476.txt

Well, it ’ s great to be here. We ’ ve heard a lot about **the** promise of technology, and **the** peril. I ’ ve been quite interested in both. If we could convert 0. 03 percent of **the** sunlight that falls on **the** earth into energy, we could meet all of our projected needs for 2030. We can ’ t do that today because solar panels are heavy, expensive and very inefficient. There are nano-engineered designs, which at least have been analyzed theoretically, that show **the** potential to be very lightweight, very inexpensive, very efficient, and we ’ d be able to actually provide all of our energy needs in this **renewable** way. Nano-engineered fuel cells could provide **the** energy where it ’ s needed. That ’ s a key trend, which is decentralization, moving from centralized nuclear power plants and liquid natural gas tankers to decentralized resources that are environmentally more **friendly**, a lot more efficient and capable and safe from disruption. Bono spoke very eloquently, that we have **the** tools, for **the** first time, to address age-old problems of disease and poverty. Most regions of **the** world are moving in that direction. In 1990, in East Asia and **the** Pacific region, there were 500 million people living in poverty — that number now is under 200 million. **The** World Bank projects by 2011, it will be under 20 million, which is a reduction of 95 percent. I did **enjoy** Bono ’ s comment linking Haight-Ashbury to Silicon Valley. Being from **the** Massachusetts high-tech community myself, I ’ d point out that we were hippies also in **the** 1960s, although we hung around Harvard Square. But we do have **the** potential to overcome disease and poverty, and I ’ m going to talk about those issues, if we have **the** will. Kevin Kelly talked about **the** acceleration of technology. That ’ s been a strong interest of mine, and a **theme** that I ’ ve developed for some 30 years. I realized that my technologies had to make sense when I finished a project. That invariably, **the** world was a different place when I would introduce a technology. And, I noticed that most inventions fail, not because **the** R&D department can ’ t get it to work — if you look at most business plans, they will actually succeed if given **the** opportunity to build what they say they ’ re going to build — and 90 percent of those projects or more will fail, because **the** timing is wrong — not all **the** enabling factors will be in place when they ’ re needed. So I began to be an ardent student of technology trends, and track where technology would be at different points in time, and began to build **the** mathematical models of that. It ’ s kind of taken on a life of its own. I ’ ve got a group of 10 people that work with me to gather data on key measures of technology in many different areas, and we build models. And you ’ ll hear people say, well, we can ’ t predict **the** future. And if you ask me, will **the** price of Google be higher or lower than it is today three years from now, that ’ s very hard to say. Will WiMax CDMA G3 be **the** wireless standard three years from now? That ’ s hard to say. But if you ask me, what will it cost for one MIPS of computing in 2010, or **the** cost to sequence a base pair of DNA in 2012, or **the** cost of sending a megabyte of data wirelessly in 2014, it turns out that those are very predictable. There are remarkably smooth exponential curves that govern price performance, capacity, bandwidth. And I ’ m going to show you a small sample of this, but there ’ s really a theoretical reason why technology develops in an exponential fashion. And a lot of people, when they think about **the** future, think about it linearly. They think they ’ re going to continue to develop a problem or address a problem using today ’ s tools, at today ’ s pace of progress, and fail to take into consideration this exponential growth. **The Genome** Project was a controversial project in 1990. We had our best Ph. D. students, our most advanced equipment around **the** world, we got 1 / 10, 000th of **the** project done, so how ’ re we going to get this done in 15 years? And 10 years into **the** project, **the** skeptics were still going strong — says,”You ’ re two- thirds through this project, and you ’ ve managed to only sequence a very tiny percentage of **the** whole **genome**.”But it ’ s **the** nature of exponential growth that once it reaches **the** knee of **the** curve, it explodes. Most of **the** project was done in **the** last few years of **the** project. It took us 15 years to sequence HIV — we sequenced SARS in 31 days. So we are gaining **the** potential to overcome these problems. I ’ m going to show you just a few examples of how pervasive this phenomena is. **The** actual paradigm-shift rate, **the** rate of adopting new ideas, is doubling every decade, according to our models. These are all logarithmic graphs, so as you go up **the** levels it represents, generally multiplying by factor of 10 or 100. It took us half a century to adopt **the** telephone, **the** first virtual- reality technology. Cell phones were adopted in about eight years. If you put different communication technologies on this logarithmic graph, television, radio, telephone were adopted in decades. Recent technologies — like **the** PC, **the web**, cell phones — were under a decade. Now this is an interesting chart, and this really gets at **the** fundamental reason why an **evolutionary** process — and both **biology** and technology are **evolutionary** processes — accelerate. They work through interaction — they create a capability, and then it uses that capability to bring on **the** next stage. So **the** first step in biological **evolution**, **the evolution** of DNA — actually it was RNA came first — took billions of years, but then **evolution** used that information-processing backbone to bring on **the** next stage. So **the** Cambrian **Explosion**, when all **the** body plans of **the** animals were **evolved**, took only 10 million years. It was 200 times faster. And then **evolution** used those body plans to **evolve** higher cognitive functions, and biological **evolution** kept accelerating. It ’ s an inherent nature of an **evolutionary** process. So Homo sapiens, **the** first technology-creating species, **the** species that combined a cognitive function with an opposable appendage — and by **the** way, chimpanzees don ’ t really have a very good opposable thumb — so we could actually **manipulate** our environment with a power grip and fine motor coordination, and use our mental models to actually change **the** world and bring on technology. But anyway, **the**

evolution of our species took hundreds of thousands of years, and then working through interaction, **evolution** used, essentially, **the** technology-creating species to bring on **the** next stage, which were **the** first steps in technological **evolution**. And **the** first step took tens of thousands of years — stone tools, fire, **the** wheel — kept accelerating. We always used then **the** latest generation of technology to create **the** next generation. Printing press took a century to be adopted ; **the** first **computers** were designed pen-on-paper — now we use **computers**. And we ' ve had a continual acceleration of this process. Now by **the** way, if you look at this on a linear graph, it looks like everything has just happened, but some observer says,"Well, Kurzweil just put points on this graph that fall on that straight line."So, I took 15 different lists from key thinkers, like **the** Encyclopedia Britannica, **the** Museum of Natural History, Carl Sagan ' s Cosmic Calendar on **the** same — and these people were not trying to make my point ; these were just lists in reference works, and I think that ' s what they thought **the** key events were in biological **evolution** and technological **evolution**. And again, it forms **the** same straight line. You have a little bit of thickening in **the** line because people do have disagreements, what **the** key points are, there ' s differences of opinion when **agriculture** started, or how long **the** Cambrian **Explosion** took. But you see a very clear trend. There ' s a basic, profound acceleration of this **evolutionary** process. Information technologies double their capacity, price performance, bandwidth, every year. And that ' s a very profound **explosion** of exponential growth. A personal experience, when I was at MIT — **computer** taking up about **the** size of this room, less powerful than **the computer** in your cell phone. But Moore ' s Law, which is very often identified with this exponential growth, is just one example of many, because it ' s basically a property of **the evolutionary** process of technology. I put 49 **famous computers** on this logarithmic graph — by **the** way, a straight line on a logarithmic graph is exponential growth — that ' s another exponential. It took us three years to double our price performance of computing in 1900, two years in **the** middle ; we ' re now doubling it every one year. And that ' s exponential growth through five different paradigms. Moore ' s Law was just **the** last part of that, where we were shrinking transistors on an integrated circuit, but we had electro-mechanical calculators, relay-based **computers** that cracked **the** German Enigma Code, vacuum tubes in **the** 1950s predicted **the** election of Eisenhower, discreet transistors used in **the** first space flights and then Moore ' s Law. Every time one paradigm ran out of steam, another paradigm came out of left field to continue **the** exponential growth. They were shrinking vacuum tubes, making them smaller and smaller. That hit a wall. They couldn ' t shrink them and keep **the** vacuum. Whole different paradigm — transistors came out of **the** woodwork. In fact, when we see **the** end of **the** line for a particular paradigm, it creates research pressure to create **the** next paradigm. And because we ' ve been predicting **the** end of Moore ' s Law for quite a long time — **the** first prediction said 2002, until now it says 2022. But by **the** teen years, **the** features of transistors will be a few atoms in **width**, and we won ' t be able to shrink them any more. That ' ll be **the** end of Moore ' s Law, but it won ' t be **the** end of **the** exponential growth of computing, because chips are flat. We live in a three-dimensional world ; we might as well use **the** third **dimension**. We will go into **the** third **dimension** and there ' s been tremendous progress, just in **the** last few years, of getting three-dimensional, self- organizing molecular circuits to work. We ' ll have those ready well before Moore ' s Law runs out of steam. Supercomputers — same thing. Processor performance on Intel chips, **the** average price of a transistor — 1968, you could buy one transistor for a dollar. You could buy 10 million in 2002. It ' s pretty remarkable how smooth an exponential process that is. I mean, you ' d think this is **the** result of some tabletop experiment, but this is **the** result of worldwide chaotic behavior — countries accusing each other of dumping products, IPOs, bankruptcies, marketing programs. You would think it would be a very erratic process, and you have a very smooth outcome of this chaotic process. Just as we can ' t predict what one molecule in a gas will do — it ' s hopeless to predict a single molecule — yet we can predict **the** properties of **the** whole gas, using thermodynamics, very accurately. It ' s **the** same thing here. We can ' t predict any particular project, but **the** result of this whole worldwide, chaotic, unpredictable activity of competition and **the evolutionary** process of technology is very predictable. And we can predict these trends far into **the** future. Unlike Gertrude Stein ' s roses, it ' s not **the** case that a transistor is a transistor. As we make them smaller and less expensive, **the** electrons have less distance to travel. They ' re faster, so you ' ve got exponential growth in **the** speed of transistors, so **the** cost of a cycle of one transistor has been coming down with a halving rate of 1. 1 years. You add other forms of innovation and processor design, you get a doubling of price performance of computing every one year. And that ' s basically deflation — 50 percent deflation. And it ' s not just **computers**. I mean, it ' s true of DNA sequencing ; it ' s true of brain scanning ; it ' s true of **the** World Wide Web. I mean, anything that we can quantify, we have hundreds of different measurements of different, information-related measurements — capacity, adoption rates — and they basically double every 12, 13, 15 months, depending on what you ' re looking at. In terms of price performance, that ' s a 40 to 50 percent deflation rate. And economists have actually started worrying about that. We had deflation during **the** Depression, but that was collapse of **the** money supply, collapse of consumer confidence, a completely different phenomena. This is due to greater productivity, but **the** economist says,"But there ' s no way you ' re going to be able to keep up with that. If you have 50 percent deflation, people may increase their volume 30, 40 percent, but they won ' t keep up with it."But what we ' re actually seeing is that we actually more than keep up with it. We ' ve had 28 percent per year compounded growth in dollars in information technology over **the** last 50 years. I mean, people didn ' t build iPods for 10, 000 dollars 10 years ago. As **the** price performance makes new applications feasible, new applications come to **the** market. And this is a very widespread phenomena. Magnetic data storage — that ' s not Moore ' s Law, it ' s shrinking magnetic spots, different engineers, different companies, same exponential process. A key revolution is that we ' re understanding our own **biology** in these information terms. We ' re understanding **the** software programs that make our body run. These were **evolved** in very different times — we ' d like to actually change those programs. One little software program, called **the fat** insulin receptor gene, basically says,"Hold onto every calorie, because **the** next hunting season may not work out so well."That was in **the** interests of **the** species tens of thousands of years ago. We ' d like to actually turn that program off. They tried that in animals, and these mice ate ravenously and remained slim and got **the** health benefits of being slim. They didn ' t get diabetes ; they didn ' t get heart disease ; they lived 20 percent longer ; they got **the** health benefits of caloric restriction without **the** restriction. Four or five pharmaceutical companies have noticed this, felt that would be interesting drug for **the** human market, and that ' s just one of **the** 30, 000 genes that affect our biochemistry. We were **evolved** in an era where it wasn ' t in **the** interests of people at **the** age of most people at this conference, like myself, to live much longer, because we were using up **the** precious resources which were better deployed towards **the** children and those caring for them. So, life — long lifespans — like, that is to say, much more than 30 — weren ' t selected for, but we are learning to actually **manipulate** and change these software programs through **the** biotechnology revolution. For example, we can inhibit genes now with RNA interference. There are exciting new forms of gene therapy that overcome **the** problem of placing **the** genetic material in **the** right place on **the** chromosome. There ' s actually a — for **the** first time now, something going to human trials, that actually cures pulmonary hypertension — a fatal disease — using gene therapy. So we ' ll have not just designer babies, but designer baby boomers. And this technology is also accelerating. It cost 10 dollars per base pair in 1990, then a penny in 2000. It ' s now under a 10th of a cent. **The** amount of genetic data — basically this shows that smooth exponential growth doubled every year, enabling **the genome** project to be completed. Another major revolution : **the** communications revolution. **The** price performance, bandwidth, capacity of communications measured many different ways ; wired, wireless is growing exponentially. **The** Internet has been doubling in power and continues to, measured many different ways. This is based on **the** number of hosts. Miniaturization — we ' re shrinking **the** size of technology at an exponential rate, both wired and wireless. These are some designs from Eric Drexler ' s book — which we ' re now showing are feasible with supercomputing simulations, where actually there are scientists building molecule-scale robots. One has one that actually walks with a surprisingly human-like gait, that ' s built out of molecules. There are little machines doing things in experimental bases. **The** most exciting opportunity is actually to go inside **the** human body and perform therapeutic and diagnostic functions. And this is less futuristic than it may sound. These things have already been done in animals. There ' s one nano-engineered **device** that cures type 1 diabetes. It ' s **blood** cell- sized. They put tens of thousands of these in **the blood** cell — they tried this in rats — it lets insulin out in a controlled fashion, and actually cures type 1 diabetes. What you ' re watching is a design of a robotic red **blood** cell, and it does bring up **the** issue that our **biology** is actually very sub- optimal, even though it ' s remarkable in its intricacy. Once we understand its principles of operation, and **the** pace with which we are reverse-engineering **biology** is accelerating, we can actually design these things to be thousands of times more capable. An analysis of this respirocyte, designed by Rob Freitas, indicates if you replace 10 percent of your red **blood** cells with these robotic versions, you could do an Olympic sprint for 15 minutes without taking a breath. You could sit at **the** bottom of your pool for four hours — so,"Honey, I ' m in **the** pool,"will take on a whole new meaning. It will be interesting to see what we do in our Olympic trials. Presumably we ' ll ban them, but then we ' ll have **the** specter of teenagers in their high schools gyms routinely out- performing **the** Olympic athletes. Freitas has a design for a robotic white **blood** cell. These are 2020-circa scenarios, but they ' re not as futuristic as it may sound. There are four major conferences on building **blood** cell-sized **devices** ; there are many experiments in animals. There ' s actually one going into human trial, so this is feasible technology. If we come back to our exponential growth of computing, 1, 000 dollars of computing is now somewhere between an insect and a mouse brain. It will intersect human intelligence in terms of capacity in **the** 2020s, but that ' ll be **the** hardware side of **the** equation. Where will we get **the** software? Well, it turns out we can see inside **the** human brain, and in fact not surprisingly, **the** spatial and temporal resolution of brain scanning is doubling every year. And with **the** new generation of scanning tools, for **the** first time we can actually see individual inter-neural fibers and see them processing and signaling in real time — but then **the** question is, OK, we can get this data now, but can we understand it? Doug Hofstadter wonders, well, maybe our intelligence just isn ' t great enough to understand our intelligence, and if we were smarter, well, then our brains would be that much more complicated, and we

’ d never catch up to it. It turns out that we can understand it. This is a block diagram of a model and simulation of **the** human auditory cortex that actually works quite well — in applying psychoacoustic tests, gets very similar results to human auditory perception. There ’ s another simulation of **the** cerebellum — that ’ s more than half **the** neurons in **the** brain — again, works very similarly to human skill formation. This is at an early stage, but you can show with **the** exponential growth of **the** amount of information about **the** brain and **the** exponential improvement in **the** resolution of brain scanning, we will succeed in reverse-engineering **the** human brain by **the** 2020s. We ’ ve already had very good models and simulation of about 15 regions out of **the** several hundred. All of this is driving exponentially growing economic progress. We ’ ve had productivity go from 30 dollars to 150 dollars per hour of labor in **the** last 50 years. E-commerce has been growing exponentially. It ’ s now a trillion dollars. You might wonder, well, wasn ’ t there a boom and a bust? That was strictly a capital-markets phenomena. Wall Street noticed that this was a revolutionary technology, which it was, but then six months later, when it hadn ’ t revolutionized all business models, they figured, well, that was wrong, and then we had this bust. All right, this is a technology that we put together using some of **the** technologies we ’ re involved in. This will be a routine feature in a cell phone. It would be able to translate from one language to another. So let me just end with a couple of scenarios. By 2010 **computers** will **disappear**. They ’ ll be so small, they ’ ll be embedded in our clothing, in our environment. Images will be written directly to our retina, providing full- immersion virtual reality, augmented real reality. We ’ ll be interacting with virtual personalities. But if we go to 2029, we really have **the** full maturity of these trends, and you have to appreciate how many turns of **the** screw in terms of generations of technology, which are getting faster and faster, we ’ ll have at that point. I mean, we will have two-to-the-25th-power greater price performance, capacity and bandwidth of these technologies, which is pretty phenomenal. It ’ ll be millions of times more powerful than it is today. We ’ ll have completed **the** reverse-engineering of **the** human brain, 1, 000 dollars of computing will be far more powerful than **the** human brain in terms of basic raw capacity. **Computers** will combine **the** subtle pan-recognition powers of human intelligence with ways in which machines are already superior, in terms of doing analytic thinking, remembering billions of facts accurately. Machines can share their knowledge very quickly. But it ’ s not just an alien invasion of intelligent machines. We are going to merge with our technology. These nano-bots I mentioned will first be used for medical and health applications : cleaning up **the** environment, providing powerful fuel cells and widely distributed decentralized solar panels and so on in **the** environment. But they ’ ll also go inside our brain, interact with our biological neurons. We ’ ve demonstrated **the** key principles of being able to do this. So, for example, full-immersion virtual reality from within **the** nervous system, **the** nano-bots shut down **the** signals coming from your real senses, replace them with **the** signals that your brain would be receiving if you were in **the** virtual environment, and then it ’ ll feel like you ’ re in that virtual environment. You can go there with other people, have any kind of experience with anyone involving all of **the** senses.”Experience beamers,”I call them, will put their whole flow of sensory experiences in **the** neurological correlates of their emotions out on **the** Internet. You can plug in and experience what it ’ s like to be someone else. But most importantly, it ’ ll be a tremendous expansion of human intelligence through this direct merger with our technology, which in some sense we ’ re doing already. We routinely do intellectual feats that would be impossible without our technology. Human life expectancy is expanding. It was 37 in 1800, and with this sort of biotechnology, nano-technology revolutions, this will move up very rapidly in **the** years ahead. My main message is that progress in technology is exponential, not linear. Many — even scientists — assume a linear model, so they ' ll say,"Oh, it ' ll be hundreds of years before we have self-replicating nano-technology assembly or **artificial** intelligence."If you really look at **the** power of exponential growth, you ' ll see that these things are pretty soon at hand. And information technology is increasingly encompassing all of our lives, from our music to our manufacturing to our **biology** to our energy to materials. We ' ll be able to manufacture almost anything we need in **the** 2020s, from information, in very inexpensive raw materials, using nano-technology. These are very powerful technologies. They both empower our promise and our peril. So we have to have **the** will to apply them to **the** right problems. Thank you very much.

Text Sample 7: POS Dim 1 – 2005 – Score 27.00 – 2005/t000437.txt

If you take 10, 000 people at random, 9, 999 have something in common : their interests in business lie on or near **the** Earth ' s **surface**. **The** odd one out is an astronomer, and I am one of that strange breed. My talk will be in two parts. I ' ll talk first as an astronomer, and then as a worried member of **the** human race. But let ' s start off by remembering that Darwin showed how we ' re **the** outcome of four billion years of **evolution**. And what we try to do in astronomy and cosmology is to go back before Darwin ' s simple beginning, to set our Earth in a cosmic context. And let me just run through a few **slides**. This was **the** impact that happened last week on a comet. If they ' d sent a nuke, it would have been rather more spectacular than what actually happened last Monday. So that ' s another project for NASA. That ' s Mars from **the** European Mars Express, and at New Year. This artist ' s impression turned into reality when a parachute landed on Titan, Saturn ' s giant moon. It landed on **the** **surface**. This is pictures taken on **the** way down. That looks like a coastline. It is indeed, but **the** ocean is liquid methane — **the** temperature minus 170 degrees centigrade. If we go beyond our solar system, we ' ve learned that **the** stars aren ' t twinkly points of light. Each one is like a sun with a retinue of **planets** orbiting around it. And we can see places where stars are forming, like **the** Eagle Nebula. We see stars dying. In six billion years, **the** sun will look like that. And some stars die spectacularly in a supernova **explosion**, leaving remnants like that. On a still bigger scale, we see entire galaxies of stars. We see entire ecosystems where gas is being recycled. And to **the** cosmologist, these galaxies are just **the** atoms, as it were, of **the** large-scale **universe**. This picture shows a patch of sky so small that it would take about 100 patches like it to cover **the** full moon in **the** sky. Through a small telescope, this would look quite blank, but you see here hundreds of little, faint smudges. Each is a galaxy, fully like ours or Andromeda, which looks so small and faint because its light has taken 10 billion light-years to get to us. **The** stars in those galaxies probably don ' t have **planets** around them. There ' s scant chance of life there — that ' s because there ' s been no time for **the** nuclear **fusion** in stars to make silicon and **carbon** and **iron**, **the** building blocks of **planets** and of life. We believe that all of this emerged from a Big Bang — a hot, dense state. So how did that amorphous Big Bang turn into our complex cosmos? I ' m going to show you a movie simulation 16 powers of 10 faster than real time, which shows a patch of **the universe** where **the** expansions have subtracted out. But you see, as time goes on in gigayears at **the** bottom, you will see structures **evolve** as gravity feeds on small, dense irregularities, and structures develop. And we ' ll end up after 13 billion years with something looking rather like our own **universe**. And we compare simulated **universes** like that — I ’ ll show you a better simulation at **the** end of my talk — with what we actually see in **the** sky. Well, we can trace things back to **the** earlier stages of **the** Big Bang, but we still don ’ t know what banged and why it banged. That ’ s a challenge for 21st-century science. If my research group had a logo, it would be this picture here : an ouroboros, where you see **the** micro-world on **the left** — **the** world of **the** quantum — and on **the** right **the** large-scale **universe** of **planets**, stars and galaxies. We know our **universes** are united though — links between **left** and right. **The** everyday world is determined by atoms, how they stick together to make molecules. Stars are fueled by how **the** nuclei in those atoms react together. And, as we ’ ve learned in **the** last few years, galaxies are held together by **the** gravitational pull of so-called dark matter : particles in huge swarms, far smaller even than atomic nuclei. But we ’ d like to know **the** synthesis symbolized at **the** very top. **The** micro-world of **the** quantum is understood. On **the** right hand side, gravity holds sway. Einstein explained that. But **the** unfinished business for 21st-century science is to link together cosmos and micro-world with a unified theory — symbolized, as it were, gastronomically at **the** top of that picture. And until we have that synthesis, we won ’ t be able to understand **the** very beginning of our **universe** because when our **universe** was itself **the** size of an atom, quantum effects could shake everything. And so we need a theory that unifies **the** very large and **the** very small, which we don ’ t yet have. One idea, incidentally — and I had this hazard sign to say I ’ m going to **speculate** from now on — is that our Big Bang was not **the** only one. One idea is that our three-dimensional **universe** may be embedded in a high- dimensional space, just as you can imagine on these sheets of paper. You can imagine ants on one of them thinking it ’ s a two-dimensional **universe**, not being aware of another population of ants on **the** other. So there could be another **universe** just a millimeter away from ours, but we ’ re not aware of it because that millimeter is measured in some fourth spatial **dimension**, and we ’ re imprisoned in our three. And so we believe that there may be a lot more to physical reality than what we ’ ve normally called our **universe — the** aftermath of our Big Bang. And here ’ s another picture. Bottom right depicts our **universe**, which on **the** horizon is not beyond that, but even that is just one bubble, as it were, in some vaster reality. Many people suspect that just as we ’ ve gone from believing in one solar system to zillions of solar systems, one galaxy to many galaxies, we have to go to many Big Bangs from one Big Bang, perhaps these many Big Bangs displaying an immense variety of properties. Well, let ’ s go back to this picture. There ’ s one challenge symbolized at **the** top, but there ’ s another challenge to science symbolized at **the** bottom. You want to not only synthesize **the** very large and **the** very small, but we want to understand **the** very complex. And **the** most complex things are ourselves, midway between atoms and stars. We depend on stars to make **the** atoms we ’ re made of. We depend on **chemistry** to determine our complex structure. We clearly have to be large, compared to atoms, to have layer upon layer of complex structure. We clearly have to be small, compared to stars and **planets** — otherwise we ’ d be crushed by gravity. And in fact, we are midway. It would take as many human bodies to make up **the** sun as there are atoms in each of us. **The** geometric mean of **the** mass of a proton and **the** mass of **the** sun is 50 kilograms, within a factor of two of **the** mass of each person here. Well, most of you anyway. **The** science of complexity is probably **the** greatest challenge of all, greater than that of **the** very small on **the left** and **the** very large on **the** right. And it ’ s this science, which is not only enlightening our understanding of **the** biological world, but also transforming our world faster than ever. And more than that, it ’ s engendering new kinds of change. And I now move on to

the second part of my talk, and **the** book"Our Final Century"was mentioned. If I was not a self-effacing Brit, I would mention **the** book myself, and I would add that it ' s available in paperback. And in America it was called"Our Final Hour"because Americans like instant gratification. But my **theme** is that in this century, not only has science changed **the** world faster than ever, but in new and different ways. Targeted drugs, genetic modification, **artificial** intelligence, perhaps even implants into our brains, may change human beings themselves. And human beings, their physique and character, has not changed for thousands of years. It may change this century. It ' s new in our history. And **the** human impact on **the** global environment — **greenhouse** warming, mass extinctions and so forth — is unprecedented, too. And so, this makes this coming century a challenge. Bio- and cybertechnologies are environmentally benign in that they offer marvelous prospects, while, nonetheless, reducing pressure on energy and resources. But they will have a dark side. In our interconnected world, novel technology could empower just one fanatic, or some weirdo with a mindset of those who now design **computer** viruses, to trigger some kind on disaster. Indeed, catastrophe could arise simply from technical misadventure — error rather than terror. And even a tiny **probability** of catastrophe is unacceptable when **the** downside could be of global consequence. In fact, some years ago, Bill Joy wrote an article expressing tremendous concern about robots taking us over, etc. I don ' t go along with all that, but it ' s interesting that he had a simple solution. It was what he called"fine- grained relinquishment."He wanted to give up **the** dangerous kind of science and keep **the** good bits. Now, that ' s absurdly naive for two reasons. First, any scientific discovery has benign consequences as well as dangerous ones. And also, when a scientist makes a discovery, he or she normally has no clue what **the** applications are going to be. And so what this means is that we have to accept **the** risks if we are going to **enjoy the** benefits of science. We have to accept that there will be hazards. And I think we have to go back to what happened in **the** post-War era, post-World War II, when **the** nuclear scientists who ' d been involved in making **the** atomic bomb, in many cases were concerned that they should do all they could to alert **the** world to **the** dangers. And they were inspired not by **the** young Einstein, who did **the** great work in relativity, but by **the** old Einstein, **the** icon of poster and t-shirt, who failed in his scientific efforts to unify **the** physical laws. He was premature. But he was a moral compass — an inspiration to scientists who were concerned with arms control. And perhaps **the** greatest living person is someone I ' m privileged to know, Joe Rothblatt. Equally untidy office there, as you can see. He ' s 96 years old, and he founded **the** Pugwash movement. He persuaded Einstein, as his last act, to sign **the famous** memorandum of Bertrand Russell. And he sets an example of **the** concerned scientist. And I think to harness science optimally, to choose which doors to open and which to leave closed, we need latter-day counterparts of people like Joseph Rothblatt. We need not just campaigning physicists, but we need biologists, **computer** experts and environmentalists as well. And I think academics and independent entrepreneurs have a special obligation because they have more freedom than those in government service, or company employees subject to commercial pressure. I wrote my book,"Our Final Century,"as a scientist, just a general scientist. But there ' s one respect, I think, in which being a cosmologist offered a special perspective, and that ' s that it offers an awareness of **the** immense future. **The** stupendous time spans of **the evolutionary** past are now part of common culture — outside **the** American Bible Belt, anyway — but most people, even those who are familiar with **evolution**, aren ' t mindful that even more time lies ahead. **The** sun has been shining for four and a half billion years, but it ' ll be another six billion years before its fuel runs out. On that schematic picture, a sort of time-lapse picture, we ’ re halfway. And it ’ ll be another six billion before that happens, and any remaining life on Earth is vaporized. There ’ s an unthinking tendency to imagine that humans will be there, experiencing **the** sun ’ s demise, but any life and intelligence that exists then will be as different from us as we are from bacteria. **The** unfolding of intelligence and complexity still has immensely far to go, here on Earth and probably far beyond. So we are still at **the** beginning of **the** emergence of complexity in our Earth and beyond. If you represent **the** Earth ’ s lifetime by a single year, say from January when it was made to December, **the** 21st-century would be a quarter of a second in June — a tiny **fraction** of **the** year. But even in this concertinaed cosmic perspective, our century is very, very special, **the** first when humans can change themselves and their home **planet**. As I should have shown this earlier, it will not be humans who witness **the** end point of **the** sun ; it will be creatures as different from us as we are from bacteria. When Einstein died in 1955, one striking tribute to his global status was this cartoon by Herblock in **the** Washington Post. **The** plaque reads,”Albert Einstein lived here.”And I ’ d like to end with a vignette, as it were, inspired by this image. We ’ ve been familiar for 40 years with this image : **the** fragile beauty of land, ocean and clouds, contrasted with **the** sterile moonscape on which **the** astronauts left their footprints. But let ’ s suppose some aliens had been watching our pale **blue** dot in **the** cosmos from afar, not just for 40 years, but for **the** entire 4. 5 billion-year history of our Earth. What would they have seen? Over nearly all that immense time, Earth ’ s appearance would have changed very gradually. **The** only abrupt worldwide change would have been major **asteroid** impacts or volcanic super-eruptions. Apart from those brief traumas, nothing happens suddenly. **The** continental landmasses drifted around. Ice cover waxed and waned. Successions of new species emerged, **evolved** and became extinct. But in just a tiny sliver of **the** Earth ’ s history, **the** last one-millionth part, a few thousand years, **the** patterns of vegetation altered much faster than before. This signaled **the** start of **agriculture**. Change has accelerated as human populations rose. Then other things happened even more abruptly. Within just 50 years — that ’ s one hundredth of one millionth of **the** Earth ’ s age — **the** amount of **carbon** dioxide in **the** atmosphere started to rise, and ominously fast. **The planet** became an intense emitter of radio waves — **the** total output from all TV and cell phones and radar transmissions. And something else happened. Metallic **objects** — albeit very small ones, a few tons at most — escaped into orbit around **the** Earth. Some journeyed to **the** moons and **planets**. A race of advanced extraterrestrials watching our solar system from afar could confidently predict Earth ’ s final doom in another six billion years. But could they have predicted this unprecedented spike less than halfway through **the** Earth ’ s life? These human-induced alterations occupying overall less than a millionth of **the** elapsed lifetime and seemingly **occurring** with runaway speed? If they continued their vigil, what might these hypothetical aliens witness in **the** next hundred years? Will some spasm foreclose Earth ’ s future? Or will **the** biosphere stabilize? Or will some of **the** metallic **objects** launched from **the** Earth spawn new oases, a post-human life elsewhere? **The** science done by **the** young Einstein will continue as long as our civilization, but for civilization to survive, we ’ ll need **the** wisdom of **the** old Einstein — humane, global and farseeing. And whatever happens in this uniquely crucial century will resonate into **the** remote future and perhaps far beyond **the** Earth, far beyond **the** Earth as depicted here. Thank you very much.

Text Sample 8: POS Dim 1 – 2008 – Score 24.00 – 2008/t000180.txt

I thought I ’ d start with telling you or showing you **the** people who started [Jet Propulsion Lab]. When they were a bunch of kids, they were kind of very imaginative, very adventurous, as they were trying at Caltech to mix chemicals and see which one blows up more. Well, I don ’ t recommend that you try to do that now. Naturally, they blew up a shack, and Caltech, well, then, hey, you go to **the** Arroyo and really do all your tests in there. So, that ’ s what we call our first five employees during **the** tea break, you know, in here. As I said, they were adventurous people. As a matter of fact, one of them, who was, kind of, part of a cult which was not too far from here on Orange Grove, and unfortunately he blew up himself because he kept mixing chemicals and trying to figure out which ones were **the** best chemicals. So, that gives you a kind of flavor of **the** kind of people we have there. We try to avoid blowing ourselves up. This one I thought I ’ d show you. Guess which one is a JPL employee in **the** heart of this crowd. I tried to come like him this morning, but as I walked out, then it was too cold, and I said, I ’ d better put my shirt back on. But more importantly, **the** reason I wanted to show this picture : look where **the** other people are looking, and look where he is looking. Wherever anybody else looks, look somewhere else, and go do something different, you know, and doing that. And that ’ s kind of what has been **the** spirit of what we are doing. And I want to tell you a quote from Ralph Emerson that one of my colleagues, you know, put on my wall in my office, and it says,”Do not go where **the** path may lead. Go instead where there is no path, and leave a trail.”And that ’ s my recommendation to all of you : look what everybody is doing, what they are doing ; go do something completely different. Don ’ t try to improve a little bit on what somebody else is doing, because that doesn ’ t get you very far. In our early days we used to work a lot on rockets, but we also used to have a lot of parties, you know. As you can see, one of our parties, you know, a few years ago. But then a big difference happened about 50 years ago, after Sputnik was launched. We launched **the** first American satellite, and that ’ s **the** one you see on **the left** in there. And here we made 180 degrees change : we changed from a rocket house to be an exploration house. And that was done over a period of a couple of years, and now we are **the** leading organization, you know, exploring space on all of your behalf. But even when we did that, we had to remind ourselves, sometimes there are setbacks. So you see, on **the** bottom, that rocket was supposed to go upward ; somehow it ended going sideways. So that ’ s what we call **the** misguided missile. But then also, just to celebrate that, we started an event at JPL for”Miss Guided Missile.”So, we used to have a celebration every year and select — there used to be competition and parades and so on. It ’ s not very appropriate to do it now. Some people tell me to do it ; I think, well, that ’ s not really proper, you know, these days. So, we do something a little bit more serious. And that ’ s what you see in **the** last Rose Bowl, you know, when we entered one of **the** floats. That ’ s more on **the** play side. And on **the** right side, that ’ s **the** Rover just before we finished its testing to take it to **the** Cape to launch it. These are **the** Rovers up here that you have on Mars now. So that kind of tells you about, kind of, **the** fun things, you know, and **the** serious things that we try to do. But I said I ’ m going to show you a short **clip** of one of our employees to kind of give you an idea about some of **the** talent that we have. Video : Morgan Hendry : Beware of Safety is an instrumental **rock** band. It branches on more **the** experimental side. There ’ s **the** improvisational side of jazz. There ’ s **the** heavy-hitting sound of **rock**. Being able to treat sound as an instrument, and be able to dig for more **abstract** sounds and things to play live, mixing electronics and acoustics. **The** music ’ s half of me, but **the** other half — I landed probably **the** best gig of all. I work for **the** Jet Propulsion Lab. I

’ m building **the** next Mars Rover. Some of **the** most brilliant engineers I know are **the** ones who have that sort of artistic quality about them. You ’ ve got to do what you want to do. And anyone who tells you you can ’ t, you don ’ t listen to them. Maybe they ’ re right - I doubt it. Tell them where to put it, and then just do what you want to do. I ’ m Morgan Hendry. I am NASA. Charles Elachi : Now, moving from **the** play stuff to **the** serious stuff, always people ask, why do we explore? Why are we doing all of these missions and why are we exploring them? Well, **the** way I think about it is fairly simple. Somehow, 13 billion years ago there was a Big Bang, and you ’ ve heard a little bit about, you know, **the** origin of **the universe**. But somehow what strikes everybody ’ s imagination — or lots of people ’ s imagination — somehow from that original Big Bang we have this beautiful world that we live in today. You look outside : you have all that beauty that you see, all that life that you see around you, and here we have intelligent people like you and I who are having a conversation here. All that started from that Big Bang. So, **the** question is : How did that happen? How did that **evolve**? How did **the universe** form? How did **the** galaxies form? How did **the planets** form? Why is there a **planet** on which there is life which have **evolved**? Is that very common? Is there life on every **planet** that you can see around **the** stars? So we literally are all made out of stardust. We started from those stars ; we are made of stardust. So, next time you are really depressed, look in **the** mirror and you can look and say, hi, I ’ m looking at a star here. You can skip **the** dust part. But literally, we are all made of stardust. So, what we are trying to do in our exploration is effectively write **the** book of how things have came about as they are today. And one of **the** first, or **the** easiest, places we can go and explore that is to go towards Mars. And **the** reason Mars takes particular attention : it ’ s not very far from us. You know, it ’ ll take us only six months to get there. Six to nine months at **the** right time of **the** year. It ’ s a **planet** somewhat similar to Earth. It ’ s a little bit smaller, but **the** land mass on Mars is about **the** same as **the** land mass on Earth, you know, if you don ’ t take **the** oceans into account. It has polar caps. It has an atmosphere somewhat thinner than ours, so it has weather. So, it ’ s very similar to some extent, and you can see some of **the** features on it, like **the** Grand Canyon on Mars, or what we call **the** Grand Canyon on Mars. It is like **the** Grand Canyon on Earth, except a hell of a lot larger. So it ’ s about **the** size, you know, of **the** United States. It has volcanoes on it. And that ’ s Mount Olympus on Mars, which is a kind of huge volcanic shield on that **planet**. And if you look at **the** height of it and you compare it to Mount Everest, you see, it ’ ll give you an idea of how large that Mount Olympus, you know, is, **relative** to Mount Everest. So, it basically **dwarfs**, you know, Mount Everest here on Earth. So, that gives you an idea of **the** tectonic events or volcanic events which have happened on that **planet**. Recently from one of our satellites, this shows that it ’ s Earth-like — we caught a landslide **occurring** as it was happening. So it is a dynamic **planet**, and activity is going on as we speak today. And these Rovers, people wonder now, what are they doing today, so I thought I would show you a little bit what they are doing. This is one very large crater. Geologists love craters, because craters are like digging a big hole in **the** ground without really working at it, and you can see what ’ s below **the surface**. So, this is called Victoria Crater, which is about a few football fields in size. And if you look at **the** top **left**, you see a little teeny dark dot. This picture was taken from an orbiting satellite. If I zoom on it, you can see : that ’ s **the** Rover on **the surface**. So, that was taken from orbit ; we had **the** camera zoom on **the surface**, and we actually saw **the** Rover on **the surface**. And we actually used **the** combination of **the** satellite images and **the** Rover to actually conduct science, because we can observe large areas and then you can get those Rovers to move around and basically go to a certain location. So, specifically what we are doing now is that Rover is going down in that crater. As I told you, geologists love craters. And **the** reason is, many of you went to **the** Grand Canyon, and you see in **the** wall of **the** Grand Canyon, you see these layers. And what these layers — that ’ s what **the surface** used to be a million years ago, 10 million years ago, 100 million years ago, and you get deposits on top of them. So if you can read **the** layers it ’ s like reading your book, and you can learn **the** history of what happened in **the** past in that location. So what you are seeing here are **the** layers on **the** wall of that crater, and **the** Rover is going down now, measuring, you know, **the** properties and analyzing **the rocks** as it ’ s going down, you know, that canyon. Now, it ’ s kind of a little bit of a challenge driving down a **slope** like this. If you were there you wouldn ’ t do it yourself. But we really made sure we tested those Rovers before we got them down — or that Rover — and made sure that it ’ s all working well. Now, when I came last time, shortly after **the** landing — I think it was, like, a hundred days after **the** landing — I told you I was surprised that those Rovers are lasting even a hundred days. Well, here we are four years later, and they ’ re still working. Now you say, Charles, you are really lying to us, and so on, but that ’ s not true. We really believed they were going to last 90 days or 100 days, because they are solar powered, and Mars is a dusty **planet**, so we expected **the** dust would start accumulating on **the surface**, and after a while we wouldn ’ t have enough power, you know, to keep them warm. Well, I always say it ’ s important that you are smart, but every once in a while it ’ s good to be lucky. And that ’ s what we found out. It turned out that every once in a while there are dust devils which come by on Mars, as you are seeing here, and when **the** dust devil comes over **the** Rover, it just cleans it up. It is like a brand new car that you have, and that ’ s literally why they have lasted so long. And now we designed them reasonably well, but that ’ s exactly why they are lasting that long and still providing all **the** science data. Now, **the** two Rovers, each one of them is, kind of, getting old. You know, one of them, one of **the** wheels is stuck, is not working, one of **the** front wheels, so what we are doing, we are driving it **backwards**. And **the** other one has arthritis of **the** shoulder joint, you know, it ’ s not working very well, so it ’ s walking like this, and we can move **the** arm, you know, that way. But still they are producing a lot of scientific data. Now, during that whole period, a number of people got excited, you know, outside **the** science community about these Rovers, so I thought I ’ d show you a video just to give you a reflection about how these Rovers are being viewed by people other than **the** science community. So let me go on **the** next short video. By **the** way, this video is pretty accurate of how **the** landing took place, you know, about four years ago. Video : **Okay**, we have parachute aligned. **Okay**, deploy **the** airbags. Open. Camera. We have a picture right now. Yeah! CE : That ’ s about what happened in **the** Houston operation room. It ’ s exactly like this. Video : Now, if there is life, **the** Dutch will find it. What is he doing? What is that? CE : Not too bad. So anyway, let me continue on showing you a little bit about **the** beauty of that **planet**. As I said earlier, it looked very much like Earth, so you see sand dunes. It looks like I could have told you these are pictures taken from **the** Sahara Desert or somewhere, and you ’ d have believed me, but these are pictures taken from Mars. But one area which is particularly intriguing for us is **the** northern region, you know, of Mars, close to **the** North Pole, because we see ice caps, and we see **the** ice caps shrinking and expanding, so it ’ s very much like you have in northern Canada. And we wanted to find out — and we see all kinds of glacial features on it. So, we wanted to find out, actually, what is that ice made of, and could that have embedded in it some **organic**, you know, material. So we have a spacecraft which is heading towards Mars, called Phoenix, and that spacecraft will land

17 days, seven hours and 20 seconds from now, so you can adjust your watch. So it ’ s on May 25 around just before five o ’ clock our time here on **the** West Coast, actually we will be landing on another **planet**. And as you can see, this is a picture of **the** spacecraft put on Mars, but I thought that just in case you ’ re going to miss that show, you know, in 17 days, I ’ ll show you, kind of, a little bit of what ’ s going to happen. Video : That ’ s what we call **the** seven minutes of terror. So **the** plan is to dig in **the** soil and take samples that we put them in an oven and actually heat them and look what gases will come from it. So this was launched about nine months ago. We ’ ll be coming in at 12, 000 miles per hour, and in seven minutes we have to stop and touch **the surface** very softly so we don ’ t break that lander. Ben Cichy : Phoenix is **the** first Mars Scout mission. It ’ s **the** first mission that ’ s going to try to land near **the** North Pole of Mars, and it ’ s **the** first mission that ’ s actually going to try and reach out and touch water on **the surface** of another **planet**. Lynn Craig : Where there tends to be water, at least on Earth, there tends to be life, and so it ’ s potentially a place where life could have existed on **the planet** in **the** past. Erik Bailey : **The** main purpose of EDL is to take a spacecraft that is traveling at 12, 500 miles an hour and bring it to a screeching halt in a soft way in a very short amount of time. BC : We enter **the** Martian atmosphere. We ’ re 70 miles above **the surface** of Mars. And our lander is safely tucked inside what we call an aeroshell. EB : Looks kind of like an ice cream cone, more or less. BC : And on **the** front of it is this heat shield, this saucer-looking thing that has about a half-inch of essentially what ’ s cork on **the** front of it, which is our heat shield. Now, this is really special cork, and this cork is what ’ s going to protect us from **the** violent atmospheric entry that we ’ re about to experience. Rob Grover : Friction really starts to build up on **the** spacecraft, and we use **the** friction when it ’ s flying through **the** atmosphere to our advantage to slow us down. BC : From this point, we ’ re going to decelerate from 12, 500 miles an hour down to 900 miles an hour. EB : **The** outside can get almost as hot as **the surface** of **the** Sun. RG : **The** temperature of **the** heat shield can reach 2, 600 degrees Fahrenheit. EB : **The** inside doesn ’ t get very hot. It probably gets about room temperature. Richard Kornfeld : There is this window of opportunity within which we can deploy **the** parachute. EB : If you fire **the** ’ chute too early, **the** parachute itself could fail. **The** fabric and **the** stitching could just pull apart. And that would be bad. BC : In **the** first 15 seconds after we deploy **the** parachute, we ’ ll decelerate from 900 miles an hour to a relatively slow 250 miles an hour. We no longer need **the** heat shield to protect us from **the** force of atmospheric entry, so we jettison **the** heat shield, exposing for **the** first time our lander to **the** atmosphere of Mars. LC : After **the** heat shield has been jettisoned and **the** legs are deployed, **the** next step is to have **the** radar system begin to **detect** how far Phoenix really is from **the** ground. BC : We ’ ve lost 99 percent of our entry velocity. So, we ’ re 99 percent of **the** way to where we want to be. But that last one percent, as it always seems to be, is **the** tricky part. EB : Now **the** spacecraft actually has to decide when it ’ s going to get rid of its parachute. BC : We separate from **the** lander going 125 miles an hour at roughly a kilometer above **the surface** of Mars : 3, 200 feet. That ’ s like taking two Empire State Buildings and **stacking** them on top of one another. EB : That ’ s when we separate from **the** back shell, and we ’ re now in free-fall. It ’ s a very scary moment ; a lot has to happen in a very short amount of time. LC : So it ’ s in a free-fall, but it ’ s also trying to use all of its actuators to make sure that it ’ s in **the** right position to land. EB : And then it has to light up its engines, right itself, and then slowly slow itself down and touch down on **the** ground safely. BC : Earth and Mars are so far apart that it takes over ten minutes for a signal from Mars to get to Earth. And EDL itself is all over in a matter of seven minutes. So by **the** time

you even hear from **the** lander that EDL has started it ’ ll already be over. EB : We have to build large amounts of autonomy into **the** spacecraft so that it can land itself safely. BC : EDL is this immense, technically challenging problem. It ’ s about getting a spacecraft that ’ s hurtling through deep space and using all this bag of tricks to somehow figure out how to get it down to **the surface** of Mars at zero miles an hour. It ’ s this immensely exciting and challenging problem. CE : Hopefully it all will happen **the** way you saw it in here. So it will be a very tense moment, you know, as we are watching that spacecraft landing on another **planet**. So now let me talk about **the** next things that we are doing. So we are in **the** process, as we speak, of actually designing **the** next Rover that we are going to be sending to Mars. So I thought I would go a little bit and tell you, kind of, **the** steps we go through. It ’ s very similar to what you do when you design your product. As you saw a little bit earlier, when we were doing **the** Phoenix one, we have to take into account **the** heat that we are going to be facing. So we have to study all kinds of different materials, **the** shape that we want to do. In general we don ’ t try to please **the** customer here. What we want to do is to make sure we have an effective, you know, an efficient kind of machine. First we start by we want to have our employees to be as imaginative as they can. And we really love being close to **the** art center, because we have, as a matter of fact, one of **the** alumni from **the** art center, Eric Nyquist, had put a series of displays, far-out displays, you know, in our what we call mission design or spacecraft design room, just to get people to think wildly about things. We have a bunch of Legos. So, as I said, this is a playground for adults, where they sit down and try to play with different shapes and different designs. Then we get a little bit more serious, so we have what we call our CAD / CAMs and all **the** engineers who are involved, or scientists who are involved, who know about thermal properties, know about design, know about atmospheric interaction, parachutes, all of these things, which they work in a team effort and actually design a spacecraft in a **computer** to some extent, so to see, does that meet **the** requirement that we need. On **the** right, also, we have to take into account **the** environment of **the planet** where we are going. If you are going to Jupiter, you have a very high-radiation, you know, environment. It ’ s about **the** same radiation environment close by Jupiter as inside a nuclear reactor. So just imagine : you take your P. C. and throw it into a nuclear reactor and it still has to work. So these are kind of some of **the** little challenges, you know, that we have to face. If we are doing entry, we have to do tests of parachutes. You saw in **the** video a parachute breaking. That would be a bad day, you know, if that happened, so we have to test, because we are deploying this parachute at supersonic speeds. We are coming at extremely high speeds, and we are deploying them to slow us down. So we have to do all kinds of tests. To give you an idea of **the** size, you know, of that parachute **relative** to **the** people standing there. Next step, we go and actually build some kind of test models and actually test them, you know, in **the** lab at JPL, in what we call our Mars Yard. We kick them, we hit them, we drop them, just to make sure we understand how, where would they break. And then we back off, you know, from that point. And then we actually do **the** actual building and **the** flight. And this next Rover that we ’ re flying is about **the** size of a car. That big shield that you see outside, that ’ s a heat shield which is going to protect it. And that will be basically built over **the** next year, and it will be launched June a year from now. Now, in that case, because it was a very big Rover, we couldn ’ t use airbags. And I know many of you, kind of, last time afterwards said well, that was a cool thing to have — those airbags. Unfortunately this Rover is, like, ten times **the** size of **the**, you know, mass-wise, of **the** other Rover, or three times **the** mass. So we can ’ t use airbags. So we have to come up with another ingenious idea of how do we land it. And we didn ’ t want to take it propulsively all **the** way to **the surface** because we didn ’ t want to contaminate **the surface** ; we wanted **the** Rover to immediately land on its legs. So we came up with this ingenious idea, which is used here on Earth for helicopters. Actually, **the** lander will come down to about 100 feet and hover above that **surface** for 100 feet, and then we have a sky crane which will take that Rover and land it down on **the surface**. Hopefully it all will work, you know, it will work that way. And that Rover will be more kind of like a chemist. What we are going to be doing with that Rover as it drives around, it ’ s going to go and analyze **the** chemical composition of **rocks**. So it will have an arm which will take samples, put them in an oven, crush and analyze them. But also, if there is something that we cannot reach because it is too high on a cliff, we have a little laser system which will actually zap **the rock**, evaporate some of it, and actually analyze what ’ s coming from that **rock**. So it ’ s a little bit like”Star Wars,”you know, but it ’ s real. It ’ s real stuff. And also to help you, to help **the** community so you can do ads on that Rover, we are going to train that Rover to actually in addition to do this, to actually serve cocktails, you know, also on Mars. So that ’ s kind of giving you an idea of **the** kind of, you know, fun things we are doing on Mars. I thought I ’ d go to”**The** Lord of **the** Rings”now and show you some of **the** things we have there. Now,”**The** Lord of **the** Rings”has two things played through it. One, it ’ s a very attractive **planet** — it just has **the** beauty of **the** rings and so on. But for scientists, also **the** rings have a special meaning, because we believe they represent, on a small scale, how **the** Solar System actually formed. Some of **the** scientists believe that **the** way **the** Solar System formed, that **the** Sun when it collapsed and actually created **the** Sun, a lot of **the** dust around it created rings and then **the** particles in those rings accumulated together, and they formed bigger **rocks**, and then that ’ s how **the planets**, you know, were formed. So, **the** idea is, by watching Saturn we ’ re actually watching our solar system in real time being formed on a smaller scale, so it ’ s like a test bed for it. So, let me show you a little bit on what that Saturnian system looks like. First, I ’ m going to fly you over **the** rings. By **the** way, all of this is real stuff. This is not animation or anything like this. This is actually taken from **the** satellite that we have in orbit around Saturn, **the** Cassini. And you see **the** amount of detail that is in those rings, which are **the** particles. Some of them are agglomerating together to form larger particles. So that ’ s why you have these gaps, is because a small satellite, you know, is being formed in that location. Now, you think that those rings are very large **objects**. Yes, they are very large in one **dimension** ; in **the** other **dimension** they are paper thin. Very, very thin. What you are seeing here is **the** shadow of **the** ring on Saturn itself. And that ’ s one of **the** satellites which was actually formed on that one. So, think about it as a paper-thin, huge area of many hundreds of thousands of miles, which is rotating. And we have a wide variety of kind of satellites which will form, each one looking very different and very odd, and that keeps scientists busy for tens of years trying to explain this, and telling NASA we need more money so we can explain what these things look like, or why they formed that way. Well, there were two satellites which were particularly interesting. One of them is called Enceladus. It ’ s a satellite which was all made of ice, and we measured it from orbit. Made of ice. But there was something bizarre about it. If you look at these stripes in here, what we call **tiger** stripes, when we flew over them, all of a sudden we saw an increase in **the** temperature, which said that those stripes are warmer than **the** rest of **the** **planet**. So as we flew by away from it, we looked back. And guess what? We saw geysers coming out. So this is a Yellowstone, you know, of Saturn. We are seeing geysers of ice which are coming out of that **planet**, which indicate that most likely there is an ocean, you know, below **the surface**. And somehow, through some dynamic effect, we ’ re having these geysers which are being, you know, emitted from it. And **the** reason I showed **the** little arrow there, I think that should say 30 miles, we decided a few months ago to actually fly **the** spacecraft through **the** plume of that geyser so we can actually measure **the** material that it is made of. That was [**unclear**] also — you know, because we were worried about **the** risk of it, but it worked pretty well. We flew at **the** top of it, and we found that there is a fair amount of **organic** material which is being emitted in combination with **the** ice. And over **the** next few years, as we keep orbiting, you know, Saturn, we are planning to get closer and closer down to **the surface** and make more accurate measurements. Now, another satellite also attracted a lot of attention, and that ’ s Titan. And **the** reason Titan is particularly interesting, it ’ s a satellite bigger than our moon, and it has an atmosphere. And that atmosphere is very — as dense as our own atmosphere. So if you were on Titan, you would feel **the** same pressure that you feel in here. Except it ’ s a lot colder, and that atmosphere is heavily made of methane. Now, methane gets people all excited, because it ’ s **organic** material, so immediately people start thinking, could life have **evolved** in that location, when you have a lot of **organic** material. So people believe now that Titan is most likely what we call a pre-biotic **planet**, because it ’ s so cold **organic** material did not get to **the** stage of becoming biological material, and therefore life could have **evolved** on it. So it could be Earth, frozen three billion years ago before life actually started on it. So that ’ s getting a lot of interest, and to show you some example of what we did in there, we actually dropped a probe, which was developed by our colleagues in Europe, we dropped a probe as we were orbiting Saturn. We dropped a probe in **the** atmosphere of Titan. And this is a picture of an area as we were coming down. Just looked like **the** coast of California for me. You see **the** rivers which are coming along **the** coast, and you see that white area which looks like Catalina Island, and that looks like an ocean. And then with an instrument we have on board, a radar instrument, we found there are lakes like **the** Great Lakes in here, so it looks very much like Earth. It looks like there are rivers on it, there are oceans or lakes, we know there are clouds. We think it ’ s raining also on it. So it ’ s very much like **the** cycle on Earth except because it ’ s so cold, it could not be water, you know, because water would have frozen. What it turned out, that all that we are seeing, all this liquid, [is made of] hydrocarbon and ethane and methane, similar to what you put in your car. So here we have a cycle of a **planet** which is like our Earth, but is all made of ethane and methane and **organic** material. So if you were on Mars — sorry, on Titan, you don ’ t have to worry about four-dollar gasoline. You just drive to **the** nearest lake, stick your hose in it, and you ’ ve got your car filled up. On **the** other hand, if you light a match **the** whole **planet** will blow up. So in closing, I said I want to close by a couple of pictures. And just to kind of put us in perspective, this is a picture of Saturn taken with a spacecraft from behind Saturn, looking towards **the** Sun. **The** Sun is behind Saturn, so we see what we call”forward scattering,”so it highlights all **the** rings. And I ’ m going to zoom. There is a — I ’ m not sure you can see it very well, but on **the** top **left**, around 10 o ’ clock, there is a little teeny dot, and that ’ s Earth. You barely can see ourselves. So what I did, I thought I ’ d zoom on it. So as you zoom in, you know, you can see Earth, you know, just in **the** middle here. So we zoomed all **the** way on **the** art center. So thank you very much.

Text Sample 9: POS Dim 1 – 2008 – Score 22.00 – 2008/t000271.txt

Cultural **evolution** is a dangerous child for any species to let loose on its **planet**. By **the** time you realize what ’ s happening, **the** child is a toddler, up and causing havoc, and it ’ s too late to put it back. We humans are Earth ’ s Pandoran species. We ’ re **the** ones who let **the** second replicator out of its box, and we can ’ t push it back in. We ’ re seeing **the** consequences all around us. Now that, I suggest, is **the** view that comes out of taking memetics seriously. And it gives us a new way of thinking about not only what ’ s going on on our **planet**, but what might be going on elsewhere in **the** cosmos. So first of all, I ’ d like to say something about memetics and **the** theory of memes, and secondly, how this might answer questions about who ’ s out there, if indeed anyone is. So, memetics : memetics is founded on **the** principle of Universal Darwinism. Darwin had this amazing idea. Indeed, some people say it ’ s **the** best idea anybody ever had. Isn ’ t that a wonderful thought, that there could be such a thing as a best idea anybody ever had? Do you think there could? Audience : No. Susan Blackmore : Someone says no, very loudly, from over there. Well, I say yes, and if there is, I give **the** prize to Darwin. Why? Because **the** idea was so simple, and yet it explains all design in **the universe**. I would say not just biological design, but all of **the** design that we think of as human design. It ’ s all just **the** same thing happening. What did Darwin say? I know you know **the** idea, natural **selection**, but let me just paraphrase”**The** Origin of Species,”1859, in a few sentences. What Darwin said was something like this : if you have creatures that vary, and that can ’ t be doubted — I ’ ve been to **the** Galapagos, and I ’ ve measured **the** size of **the** beaks and **the** size of **the turtle** shells and so on, and so on. And 100 pages later. And if there is a struggle for life, such that nearly all of these creatures die — and this can ’ t be doubted, I ’ ve read Malthus and I ’ ve **calculated** how long it would take for **elephants** to cover **the** whole world if they bred unrestricted, and so on and so on. And another 100 pages later. And if **the** very few that survive pass onto their offspring whatever it was that helped them survive, then those offspring must be better adapted to **the** circumstances in which all this happened than their parents were. You see **the** idea? If, if, if, then. He had no concept of **the** idea of an algorithm, but that ’ s what he described in that book, and this is what we now know as **the evolutionary** algorithm. **The** principle is you just need those three things — variation, **selection** and heredity. And as Dan Dennett puts it, if you have those, then you must get **evolution**. Or design out of chaos, without **the** aid of mind. There ’ s one word I love on that **slide**. What do you think my favorite word is? Audience : Chaos. SB : Chaos? No. What? Mind? No. Audience : Without. SB : No, not without. You try them all in order : Mmm...? Audience : Must. SB : Must, at must. Must, must. This is what makes it so amazing. You don ’ t need a designer, or a plan, or foresight, or anything else. If there ’ s something that is **copied** with variation and it ’ s selected, then you must get design appearing out of nowhere. You can ’ t stop it. Must is my favorite word there. Now, what ’ s this to do with memes? Well, **the** principle here applies to anything that is **copied** with variation and **selection**. We ’ re so used to thinking in terms of **biology**, we think about genes this way. Darwin didn ’ t, of course ; he didn ’ t know about genes. He talked mostly about animals and plants, but also about languages **evolving** and becoming extinct. But **the** principle of Universal Darwinism is that any information that is varied and selected will produce design. And this is what Richard Dawkins was on about in his 1976 bestseller,”**The** Selfish Gene.”**The** information that is **copied**, he called **the** replicator. It selfishly **copies**. Not meaning it kind of sits around inside cells going,”I want to get **copied**.”But that it will get **copied** if it can, regardless of **the** consequences. It doesn ’ t care about **the** consequences because it can ’ t, because it ’ s just information being **copied**. And he wanted to get away from everybody thinking all **the** time about genes, and so he said,”Is there another replicator out there on **the planet**?”Ah, yes, there is. Look around you — here will do, in this room. All around us, still clumsily drifting about in its primeval **soup** of culture, is another replicator. Information that we **copy** from person to person, by imitation, by language, by talking, by telling stories, by wearing clothes, by doing things. This is information **copied** with variation and **selection**. This is design process going on. He wanted a name for **the** new replicator. So, he took **the** Greek word”mimeme,”which means that which is imitated. Remember that, that ’ s **the** core definition : that which is imitated. And abbreviated it to meme, just because it sounds good and made a good meme, an effective spreading meme. So that ’ s how **the** idea came about. It ’ s important to stick with that definition. **The** whole science of memetics is much maligned, much misunderstood, much feared. But a lot of these problems can be avoided by remembering **the** definition. A meme is not equivalent to an idea. It ’ s not an idea. It ’ s not equivalent to anything else, really. Stick with **the** definition. It ’ s that which is imitated, or information which is **copied** from person to person. So, let ’ s see some memes. Well, you sir, you ’ ve got those glasses hung around your neck in that particularly fetching way. I wonder whether you invented that idea for yourself, or **copied** it from someone else? If you **copied** it from someone else, it ’ s a meme. And what about, oh, I can ’ t see any interesting memes here. All right everyone, who ’ s got some interesting memes for me? Oh, well, your earrings, I don ’ t suppose you invented **the** idea of earrings. You probably went out and bought them. There are plenty more in **the** shops. That ’ s something that ’ s passed on from person to person. All **the** stories that we ’ re telling — well, of course, TED is a great meme-fest, masses of memes. **The** way to think about memes, though, is to think, why do they spread? They ’ re selfish information, they will get **copied**, if they can. But some of them will be **copied** because they ’ re good, or true, or useful, or beautiful. Some of them will be **copied** even though they ’ re not. Some, it ’ s quite hard to tell why. There ’ s one particular curious meme which I rather **enjoy**. And I ’ m glad to say, as I expected, I found it when I came here, and I ’ m sure all of you found it, too. You go to your nice, posh, international hotel somewhere, and you come in and you put down your clothes and you go to **the** bathroom, and what do you see? Audience : Bathroom soap. SB : Pardon? Audience : Soap. SB : Soap, yeah. What else do you see? Audience : SB : Mmm mmm. Audience : Sink, toilet! SB : Sink, toilet, yes, these are all memes, they ’ re all memes, but they ’ re sort of useful ones, and then there ’ s this one. What is this one doing? This has spread all over **the** world. It ’ s not surprising that you all found it when you arrived in your bathrooms here. But I took this photograph in a toilet at **the** back of a tent in **the** eco-camp in **the** jungle in Assam. Who folded that thing up there, and why? Some people get carried away. Other people are just lazy and make mistakes. Some hotels exploit **the** opportunity to put even more memes with a little sticker. What is this all about? I suppose it ’ s there to tell you that somebody ’ s cleaned **the** place, and it ’ s all lovely. And you know, actually, all it tells you is that another person has potentially spread germs from place to place. So, think of it this way. Imagine a world full of brains and far more memes than can possibly find homes. **The** memes are all trying to get **copied** — trying, in inverted commas — i. e., that ’ s **the** shorthand for, if they can get **copied**, they will. They ’ re using you and me as their propagating, **copying** machinery, and we are **the** meme machines. Now, why is this important? Why is this useful, or what does it tell us? It gives us a completely new view of human origins and what it means to be human, all conventional theories of cultural **evolution**, of **the** origin of humans, and what makes us so different from other species. All other theories explaining **the** big brain, and language, and tool use and all these things that make us unique, are based upon genes. Language must have been useful for **the** genes. Tool use must have enhanced our survival, mating and so on. It always comes back, as Richard Dawkins complained all that long time ago, it always comes back to genes. **The** point of memetics is to say,"Oh no, it doesn ' t."There are two replicators now on this **planet**. From **the** moment that our ancestors, perhaps two and a half million years ago or so, began imitating, there was a new copying process. **Copying** with variation and **selection**. A new replicator was let loose, and it could never be — right from **the** start — it could never be that human beings who let loose this new creature, could just **copy the** useful, beautiful, true things, and not **copy the** other things. While their brains were having an advantage from being able to **copy** — lighting fires, keeping fires going, new **techniques** of hunting, these kinds of things — inevitably they were also **copying** putting feathers in their hair, or wearing strange clothes, or painting their faces, or whatever. So, you get an arms race between **the** genes which are trying to get **the** humans to have small economical brains and not waste their time **copying** all this stuff, and **the** memes themselves, like **the** sounds that people made and **copied** — in other words, what turned out to be language — competing to get **the** brains to get bigger and bigger. So, **the** big brain, on this theory, is driven by **the** memes. This is why, in"**The** Meme Machine,"I called it memetic drive. As **the** memes **evolve**, as they inevitably must, they drive a bigger brain that is better at **copying the** memes that are doing **the** driving. This is why we ' ve ended up with such **peculiar** brains, that we like religion, and music, and art. Language is a parasite that we ' ve adapted to, not something that was there originally for our genes, on this view. And like most parasites, it can begin dangerous, but then it coevolves and adapts, and we end up with a symbiotic relationship with this new parasite. And so, from our perspective, we don ' t realize that that ' s how it began. So, this is a view of what humans are. All other species on this **planet** are gene machines only, they don ' t imitate at all well, hardly at all. We alone are gene machines and meme machines as well. **The** memes took a gene machine and turned it into a meme machine. But that ' s not all. We have a new kind of memes now. I ' ve been wondering for a long time, since I ' ve been thinking about memes a lot, is there a difference between **the** memes that we **copy** — **the** words we speak to each other, **the** gestures we **copy**, **the** human things — and all these technological things around us? I have always, until now, called them all memes, but I do honestly think now we need a new word for technological memes. Let ' s call them techno-memes or temes. Because **the** processes are getting different. We began, perhaps 5, 000 years ago, with writing. We put **the** storage of memes out there on a clay tablet, but in order to get true temes and true teme machines, you need to get **the** variation, **the selection** and **the** copying, all done outside of humans. And we ' re getting there. We ' re at this extraordinary point where we ' re nearly there, that there are machines like that. And indeed, in **the** short time I ' ve already been at TED, I see we ' re even closer than I thought we were before. So actually, now **the** temes are forcing our brains to become more like teme machines. Our children are growing up very quickly learning to read, learning to use machinery. We ' re going to have all kinds of implants, drugs that force us to stay awake all **the** time. We ' ll think we ' re choosing these things, but **the** temes are making us do it. So, we ' re at this cusp now of having a third replicator on our **planet**. Now, what about what else is going on out there in **the universe**? Is there anyone else out there? People have been asking this question for a long time. We ' ve been asking it here at TED already. In 1961, Frank Drake made his **famous** equation, but I think he concentrated on **the** wrong things. It ' s been very productive, that equation. He wanted to estimate N, **the** number of communicative civilizations out there in our galaxy, and he included in there **the** rate of star formation, **the** rate of **planets**, but crucially, intelligence. I think that ' s **the** wrong way to think about it. Intelligence appears all over **the** place, in all kinds of guises. Human intelligence is only one kind of a thing. But what ' s really important is **the** replicators you have and **the** levels of replicators, one **feeding** on **the** one before. So, I would suggest that we don ' t think intelligence, we think replicators. And on that basis, I ' ve suggested a different kind of equation. A very simple equation. N, **the** same thing, **the** number of communicative civilizations out there [that] we might expect in our galaxy. Just start with **the** number of **planets** there are in our galaxy. **The fraction** of those which get a first replicator. **The fraction** of those that get **the** second replicator. **The fraction** of those that get **the** third replicator. Because it ' s only **the** third replicator that ' s going to reach out — sending information, sending probes, getting out there, and communicating with anywhere else. OK, so if we take that equation, why haven ' t we heard from anybody out there? Because every step is dangerous. Getting a new replicator is dangerous. You can pull through, we have pulled through, but it ' s dangerous. Take **the** first step, as soon as life appeared on this earth. We may take **the** Gaian view. I loved Peter Ward ' s talk yesterday — it ' s not Gaian all **the** time. Actually, life forms produce things that kill themselves. Well, we did pull through on this **planet**. But then, a long time later, billions of years later, we got **the** second replicator, **the** memes. That was dangerous, all right. Think of **the** big brain. How many mothers do we have here? You know all about big brains. They are dangerous to give birth to, are agonizing to give birth to. My cat gave birth to four kittens, purring all **the** time. Ah, mm — slightly different. But not only is it painful, it kills lots of babies, it kills lots of mothers, and it ' s very expensive to produce. **The** genes are forced into producing all this myelin, all **the fat** to myelinate **the** brain. Do you know, sitting here, your brain is using about 20 percent of your body ' s energy output for two percent of your body weight? It ' s a really expensive organ to run. Why? Because it ' s producing **the** memes. Now, it could have killed us off. It could have killed us off, and maybe it nearly did, but you see, we don ' t know. But maybe it nearly did. Has it been tried before? What about all those other species? Louise Leakey talked yesterday about how we ' re **the** only one in this branch left. What happened to **the** others? Could it be that this experiment in imitation, this experiment in a second replicator, is dangerous enough to kill people off? Well, we did pull through, and we adapted. But now, we ' re hitting, as I ' ve just described, we ' re hitting **the** third replicator point. And this is even more dangerous — well, it ' s dangerous again. Why? Because **the** temes are selfish replicators and they don ' t care about us, or our **planet**, or anything else. They ' re just information, why would they? They are using us to suck up **the planet** ' s resources to produce more **computers**, and more of all these amazing things we ' re hearing about here at TED. Don ' t think,"Oh, we created **the** Internet for our own benefit."That ' s how it seems to us. Think, temes spreading because they must. We are **the** old machines. Now, are we going to pull through? What ' s going to happen? What does it mean to pull through? Well, there are kind of two ways of pulling through. One that is obviously happening all around us now, is that **the** temes turn us into teme machines, with these implants, with **the** drugs, with us merging with **the** technology. And why would they do that? Because we are self-replicating. We have babies. We make new ones, and so it ' s convenient to piggyback on us, because we ' re not yet at **the** stage on this **planet** where **the** other option is viable. Although it ' s closer, I heard this morning, it ' s closer than I thought it was. Where **the** teme machines themselves will replicate themselves. That way, it wouldn ' t matter if **the planet**

’ s climate was utterly destabilized, and it was no longer possible for humans to live here. Because those teme machines, they wouldn ’ t need — they ’ re not squishy, **wet**, oxygen-breathing, warmth-requiring creatures. They could carry on without us. So, those are **the** two possibilities. **The** second, I don ’ t think we ’ re that close. It ’ s coming, but we ’ re not there yet. **The** first, it ’ s coming too. But **the** damage that is already being done to **the planet** is showing us how dangerous **the** third point is, that third danger point, getting a third replicator. And will we get through this third danger point, like we got through **the** second and like we got through **the** first? Maybe we will, maybe we won ’ t. I have no idea. Chris Anderson : That was an incredible talk. SB : Thank you. I scared myself. CA :

My talk is”Flapping Birds and Space Telescopes.”And you would think that should have nothing to do with one another, but I hope by **the** end of these 18 minutes, you ’ ll see a little bit of a relation. It ties to origami. So let me start. What is origami? Most people think they know what origami is. It ’ s this : flapping birds, toys, cootie catchers, that sort of thing. And that is what origami used to be. But it ’ s become something else. It ’ s become an art form, a form of sculpture. **The** common **theme** — what makes it origami — is folding is how we create **the** form. You know, it ’ s very old. This is a **plate** from 1797. It shows these women playing with these toys. If you look close, it ’ s this shape, called a crane. Every Japanese kid learns how to fold that crane. So this art has been around for hundreds of years, and you would think something that ’ s been around that long — so restrictive, folding only — everything that could be done has been done a long time ago. And that might have been **the** case. But in **the** twentieth century, a Japanese folder named Yoshizawa came along, and he created tens of thousands of new designs. But even more importantly, he created a language, a way we could communicate, a code of dots, dashes and arrows. Harkening back to Susan Blackmore ’ s talk, we now have a means of transmitting information with heredity and **selection**, and we know where that leads. And where it has led in origami is to things like this. This is an origami figure — one sheet, no cuts, folding only, hundreds of folds. This, too, is origami, and this shows where we ’ ve gone in **the** modern world. Naturalism. Detail. You can get horns, antlers — even, if you look close, cloven hooves. And it raises a question : what changed? And what changed is something you might not have expected in an art, which is math. That is, people applied mathematical principles to **the** art, to discover **the** underlying laws. And that leads to a very powerful tool. **The** secret to productivity in so many fields — and in origami — is letting dead people do your work for you. Because what you can do is take your problem, and turn it into a problem that someone else has solved, and use their solutions. And I want to tell you how we did that in origami. Origami revolves around crease patterns. **The** crease pattern shown here is **the** underlying blueprint for an origami figure. And you can ’ t just draw them arbitrarily. They have to obey four simple laws. And they ’ re very simple, easy to understand. **The** first law is two-colorability. You can color any crease pattern with just two colors without ever having **the** same color meeting. **The** directions of **the** folds at any vertex — **the** number of mountain folds, **the** number of valley folds — always differs by two. Two more or two less. Nothing else. If you look at **the** angles around **the** fold, you find that if you number **the** angles in a circle, all **the** even-numbered angles add up to a straight line, all **the** odd-numbered angles add up to a straight line. And if you look at how **the** layers **stack**, you ’ ll find that no matter how you **stack** folds and sheets, a sheet can never penetrate a fold. So that ’ s four simple laws. That ’ s all you need in origami. All of origami comes from that. And you ’ d think,”Can four simple laws give rise to that kind of complexity?”But indeed, **the** laws of quantum mechanics can be written down on a napkin, and yet they govern all of **chemistry**, all of life, all of history. If we obey these laws, we can do amazing things. So in origami, to obey these laws, we can take simple patterns — like this repeating pattern of folds, called textures — and by itself it ’ s nothing. But if we follow **the** laws of origami, we can put these patterns into another fold that itself might be something very, very simple, but when we put it together, we get something a little different. This **fish**, 400 scales — again, it is one uncut square, only folding. And if you don ’ t want to fold 400 scales, you can back off and just do a few things, and add **plates** to **the** back of a **turtle**, or toes. Or you can ramp up and go up to 50 stars on a flag, with 13 stripes. And if you want to go really crazy, 1, 000 scales on a rattlesnake. And this guy ’ s on display downstairs, so take a look if you get a chance. **The** most powerful tools in origami have related to how we get parts of creatures. And I can put it in this simple equation. We take an idea, combine it with a square, and you get an origami figure. What matters is what we mean by those symbols. And you might say,”Can you really be that specific? I mean, a stag beetle — it ’ s got two points for jaws, it ’ s got antennae. Can you be that specific in **the** detail?”And yeah, you really can. So how do we do that? Well, we break it down into a few smaller steps. So let me stretch out that equation. I start with my idea. I **abstract** it. What ’ s **the** most **abstract** form? It ’ s a stick figure. And from that stick figure, I somehow have to get to a folded shape that has a part for every bit of **the** subject, a flap for every leg. And then once I have that folded shape that we call **the** base, you can make **the** legs narrower, you can bend them, you can turn it into **the** finished shape. Now **the** first step, pretty easy. Take an idea, draw a stick figure. **The** last step is not so hard, but that middle step — going from **the abstract** description to **the** folded shape — that ’ s hard. But that ’ s **the** place where **the** mathematical ideas can get us over **the** hump. And I ’ m going to show you all how to do that so you can go out of here and fold something. But we ’ re going to start small. This base has a lot of flaps in it. We ’ re going to learn how to make one flap. How would you make a single flap? Take a square. Fold it in half, fold it in half, fold it again, until it gets long and narrow, and then we ’ ll say at **the** end of that, that ’ s a flap. I could use that for a leg, an arm, anything like that. What paper went into that flap? Well, if I unfold it and go back to **the** crease pattern, you can see that **the** upper **left** corner of that shape is **the** paper that went into **the** flap. So that ’ s **the** flap, and all **the** rest of **the** paper ’ s left over. I can use it for something else. Well, there are other ways of making a flap. There are other **dimensions** for flaps. If I make **the** flaps skinnier, I can use a bit less paper. If I make **the** flap as skinny as possible, I get to **the** limit of **the** minimum amount of paper needed. And you can see there, it needs a quarter-circle of paper to make a flap. There ’ s other ways of making flaps. If I put **the** flap on **the** edge, it uses a half circle of paper. And if I make **the** flap from **the** middle, it uses a full circle. So, no matter how I make a flap, it needs some part of a circular region of paper. So now we ’ re ready to scale up. What if I want to make something that has a lot of flaps? What do I need? I need a lot of circles. And in **the** 1990s, origami artists discovered these principles and realized we could make arbitrarily complicated figures just by packing circles. And here ’ s where **the** dead people start to help us out, because lots of people have studied **the** problem of packing circles. I can rely on that vast history of mathematicians and artists looking at disc packings and arrangements. And I can use those patterns now to create origami shapes. So we figured out these rules whereby you pack circles, you decorate **the** patterns of circles with lines according to more rules. That gives you **the** folds. Those folds fold into a base. You shape **the** base. You get a folded shape — in this case, a **cockroach**. And it ' s so simple. It ' s so simple that a **computer** could do it. And you say,"Well, you know, how simple is that?"But **computers** — you need to be able to describe things in very basic terms, and with this, we could. So I wrote a **computer** program a bunch of years ago called TreeMaker, and you can download it from my website. It ' s free. It runs on all **the** major platforms — even Windows. And you just draw a stick figure, and it **calculates the** crease pattern. It does **the** circle packing, **calculates the** crease pattern, and if you use that stick figure that I just showed — which you can kind of tell, it ' s a deer, it ' s got antlers — you ' ll get this crease pattern. And if you take this crease pattern, you fold on **the** dotted lines, you ' ll get a base that you can then shape into a deer, with exactly **the** crease pattern that you wanted. And if you want a different deer, not a white-tailed deer, but you want a mule deer, or an elk, you change **the** packing, and you can do an elk. Or you could do a moose. Or, really, any other kind of deer. These **techniques** revolutionized this art. We found we could do insects, **spiders**, which are close, things with legs, things with legs and **wings**, things with legs and antennae. And if folding a single praying mantis from a single uncut square wasn ' t interesting enough, then you could do two praying mantises from a single uncut square. She ' s eating him. I call it"Snack Time."And you can do more than just insects. This — you can put details, toes and claws. A grizzly bear has claws. This tree frog has toes. Actually, lots of people in origami now put toes into their models. Toes have become an origami meme, because everyone ' s doing it. You can make multiple subjects. So these are a couple of instrumentalists. **The** guitar player from a single square, **the** bass player from a single square. And if you say,"Well, but **the** guitar, bass — that ' s not so hot. Do a little more complicated instrument."Well, then you could do an organ. And what this has allowed is **the** creation of origami-on-demand. So now people can say,"I want exactly this and this and this,"and you can go out and fold it. And sometimes you create high art, and sometimes you pay **the** bills by doing some commercial work. But I want to show you some examples. Everything you ' ll see here, except **the** car, is origami. Just to show you, this really was folded paper. **Computers** made things move, but these were all real, folded **objects** that we made. And we can use this not just for visuals, but it turns out to be useful even in **the** real world. Surprisingly, origami and **the** structures that we ' ve developed in origami turn out to have applications in medicine, in science, in space, in **the** body, consumer electronics and more. And I want to show you some of these examples. One of **the** earliest was this pattern, this folded pattern, studied by Koryo Miura, a Japanese engineer. He studied a folding pattern, and realized this could fold down into an extremely compact package that had a very simple opening and closing structure. And he used it to design this solar **array**. It ' s an artist ' s rendition, but it flew in a Japanese telescope in 1995. Now, there is actually a little origami in **the** James Webb Space Telescope, but it ' s very simple. **The** telescope, going up in space, it unfolds in two places. It folds in thirds. It ' s a very simple pattern — you wouldn ' t even call that origami. They certainly didn ' t need to talk to origami artists. But if you want to go higher and go larger than this, then you might need some origami. Engineers at Lawrence Livermore National Lab had an idea for a telescope much larger. They called it **the** Eyeglass. **The** design called for geosynchronous orbit 25, 000 miles up, 100-meter **diameter** lens. So, imagine a lens **the** size of a football field. There were two groups of people who were interested in this : planetary scientists, who want to look up, and then other people, who wanted to look down. Whether you look up or look down, how do you get it up in space? You ’ ve got to get it up there in a rocket. And rockets are small. So you have to make it smaller. How do you make a large sheet of glass smaller? Well, about **the** only way is to fold it up somehow. So you have to do something like this. This was a small model. Folded lens, you divide up **the** panels, you add flexures. But this pattern ’ s not going to work to get something 100 meters down to a few meters. So **the** Livermore engineers, wanting to make use of **the** work of dead people, or perhaps live origamists, said,”Let ’ s see if someone else is doing this sort of thing.”So they looked into **the** origami community, we got in touch with them, and I started working with them. And we developed a pattern together that scales to arbitrarily large size, but that allows any flat ring or disc to fold down into a very neat, compact cylinder. And they adopted that for their first generation, which was not 100 meters — it was a five-meter. But this is a five-meter telescope — has about a quarter-mile focal length. And it works perfectly on its test range, and it indeed folds up into a neat little bundle. Now, there is other origami in space. Japan Aerospace [Exploration] Agency flew a solar sail, and you can see here that **the** sail expands out, and you can still see **the** fold lines. **The** problem that ’ s being solved here is something that needs to be big and sheet-like at its destination, but needs to be small for **the** journey. And that works whether you ’ re going into space, or whether you ’ re just going into a body. And this example is **the** latter. This is a heart stent developed by Zhong You at Oxford University. It holds open a blocked **artery** when it gets to its destination, but it needs to be much smaller for **the** trip there, through your **blood** vessels. And this stent folds down using an origami pattern, based on a model called **the** water bomb base. Airbag designers also have **the** problem of getting flat sheets into a small space. And they want to do their design by simulation. So they need to figure out how, in a **computer**, to flatten an airbag. And **the** algorithms that we developed to do insects turned out to be **the** solution for airbags to do their simulation. And so they can do a simulation like this. Those are **the** origami creases forming, and now you can see **the** airbag inflate and find out, does it work? And that leads to a really interesting idea. You know, where did these things come from? Well, **the** heart stent came from that little blow-up box that you might have learned in elementary school. It ’ s **the** same pattern, called **the** water bomb base. **The** airbag-flattening algorithm came from all **the** developments of circle packing and **the** mathematical theory that was really developed just to create insects — things with legs. **The** thing is, that this often happens in math and science. When you get math involved, problems that you solve for aesthetic value only, or to create something beautiful, turn around and turn out to have an application in **the** real world. And as weird and surprising as it may sound, origami may someday even save a life. Thanks.

Text Sample 11: POS Dim 1 – 2006 – Score 22.00 – 2006/t000498.txt

I ’ m **the** luckiest guy in **the** world. I got to see **the** last case of killer smallpox in **the** world. I was in India this past year, and I may have seen **the** last cases of polio in **the** world. There ’ s nothing that makes you feel more â **the** blessing and **the** honor of working in a program like that â than to know that something that horrible no longer exists. So I ’ m going to tell you â so I ’ m going to show you some dirty pictures. They are difficult to watch, but you should look at them with optimism, because **the** horror of these pictures will be matched by **the** uplifting quality of knowing that they no longer exist. But first, I ’ m going to tell you a little bit about my own journey. My background is not exactly **the** conventional medical education that you might expect. When I was an intern in San Francisco, I heard about a group of Native Americans who had taken over Alcatraz Island, and a Native American who wanted to give birth on that **island**, and no other doctor wanted to go and help her give birth. I went out to Alcatraz, and I lived on **the island** for several weeks. She gave birth ; I caught **the** baby ; I got off **the island** ; I landed in San Francisco ; and all **the** press wanted to talk to me, because my three weeks on **the island** made me an expert in Indian affairs. I wound up on every television show. Someone saw me on television ; they called me up ; and they asked me if I ' d like to be in a movie and to play a young doctor for a bunch of **rock** and roll stars who were traveling in a bus ride from San Francisco to England. And I said, yes, I would do that, so I became **the** doctor in an absolutely awful movie called"Medicine Ball Caravan."Now, you know from **the** ' 60s, you ' re either on **the** bus or you ' re off **the** bus ; I was on **the** bus. My wife of 37 years and I joined **the** bus. Our bus ride took us from San Francisco to London, then we switched buses at **the** big pond. We then got on two more buses and we drove through Turkey and Iran, Afghanistan, over **the** Khyber Pass into Pakistan, like every other young doctor. This is us at **the** Khyber Pass, and that ' s our bus. We had some difficulty getting over **the** Khyber Pass. But we wound up in India. And then, like everyone else in our generation, we went to live in a Himalayan monastery. This is just like a residency program, for those of you that are in medical school. And we studied with a wise man, a guru named Karoli Baba, who then told me to get rid of **the** dress, put on a three-piece suit, go join **the** United Nations as a diplomat and work for **the** World Health Organization. And he made an outrageous prediction that smallpox would be eradicated, and that this was God ' s gift to humanity, because of **the** hard work of dedicated scientists. And that prediction came true. This little girl is Rahima Banu, and she was **the** last case of killer smallpox in **the** world. And this document is **the** certificate that **the** global commission signed, certifying **the** world to have eradicated **the** first disease in history. **The** key to eradicating smallpox was early detection, early response. I ' m going to ask you to repeat that : early detection, early response. Can you say that? Audience : Early detection, early response. Larry Brilliant : Smallpox was **the** worst disease in history. It killed more people than all **the** wars in history. In **the** last century, it killed 500 million people. You ' re reading about Larry Page already. Somebody reads very fast. In **the** year that Larry Page and Sergey Brin â with whom I have a certain affection and a new affiliation â in **the** year in which they were born, two million people died of smallpox. We declared smallpox eradicated in 1980. This is **the** most important **slide** that I ' ve ever seen in public health, [Sovereigns killed by smallpox] because it shows you to be **the** richest and **the** strongest, and to be kings and **queens** of **the** world, did not protect you from dying of smallpox. Never can you doubt that we are all in this together. But to see smallpox from **the** perspective of a sovereign is **the** wrong perspective. You should see it from **the** perspective of a mother, watching her child develop this disease and standing by helplessly. Day one, day two, day three, day four, day five, day six. You ' re a mother and you ' re watching your child, and on day six, you see pustules that become hard. Day seven, they show **the** classic scars of smallpox umbilication. Day eight. And Al Gore said earlier that **the** most photographed image in **the** world, **the** most printed image in **the** world, was that of **the** Earth. But this was in 1974, and as of that moment, this photograph was **the** photograph that was **the** most widely printed, because we printed two billion **copies** of this photograph, and we took them hand to hand, door to door, to show people and ask them if there was smallpox in their house, because that was our surveillance system. We didn ' t have Google, we didn ' t have **web** crawlers, we didn ' t have **computers**. By day nine â you look at this picture and you ’ re horrified ; I look at this picture and I say,”Thank God,”because it ’ s clear that this is only an ordinary case of smallpox, and I know this child will live. And by day 13, **the** lesions are scabbing, his eyelids are swollen, but you know this child has no other secondary infection. And by day 20, while he will be scarred for life, he will live. There are other kinds of smallpox that are not like that. This is confluent smallpox, in which there isn ’ t a single place on **the** body where you could put a finger and not be covered by lesions. Flat smallpox, which killed 100 percent of people who got it. And hemorrhagic smallpox, **the** most cruel of all, which had a predilection for pregnant women. I ’ ve probably had 50 women die. They all had hemorrhagic smallpox. I ’ ve never seen anybody die from it who wasn ’ t a pregnant woman. In 1967, **the** WHO embarked on what was an outrageous program to eradicate a disease. In that year, there were 34 countries affected with smallpox. By 1970, we were down to 18 countries. 1974, we were down to five countries. But in that year, smallpox exploded throughout India. And India was **the** place where smallpox made its last stand. In 1974, India had a population of 600 million. There are 21 linguistic states in India, which is like saying 21 different countries. There are 20 million people on **the** road at any time, in buses and trains, walking ; 500, 000 villages, 120 million households, and none of them wanted to report if they had a case of smallpox in their house, because they thought that smallpox was **the** visitation of a deity, Shitala Mata, **the** cooling mother, and it was wrong to bring strangers into your house when **the** deity was in **the** house. No incentive to report smallpox. It wasn ’ t just India that had smallpox deities ; smallpox deities were prevalent all over **the** world. So, how we eradicated smallpox was â mass vaccination wouldn ’ t work. You could vaccinate everybody in India, but one year later there ’ d be 21 million new babies, which was then **the** population of Canada. It wouldn ’ t do just to vaccinate everyone. You had to find every single case of smallpox in **the** world at **the** same time, and draw a circle of immunity around it. And that ’ s what we did. In India alone, my 150, 000 best friends and I went door to door, with that same picture, to every single house in India. We made over one billion house calls. And in **the** process, I learned something very important. Every time we did a house-to-house **search**, we had a spike in **the** number of reports of smallpox. When we didn ’ t **search**, we had **the** illusion that there was no disease. When we did **search**, we had **the** illusion that there was more disease. A surveillance system was necessary, because what we needed was early detection, early response. So we **searched** and we **searched**, and we found every case of smallpox in India. We had a reward. We raised **the** reward. We continued to increase **the** reward. We had a scorecard that we wrote on every house. And as we did that, **the** number of reported cases in **the** world dropped to zero. And in 1980, we declared **the** globe free of smallpox. It was **the** largest campaign in United Nations history, until **the** Iraq war. 150, 000 people from all over **the** world â doctors of every race, religion, culture and nation, who fought side by side, brothers and sisters, with each other, not against each other, in a common cause to make **the** world better. But smallpox was **the** fourth disease that was intended for eradication. We failed three other times. We failed against **malaria**, **yellow** fever and yaws. But soon we may see polio eradicated. But **the** key to eradicating polio is early detection, early response. This may be **the** year we eradicate polio. That will make it **the** second disease in history. And David Heymann, who ’ s watching this on **the** webcast â David, keep on going. We ’ re close! We ’ re down to four countries. I feel like Hank Aaron. Barry Bonds can replace me any time. Let ’ s get another disease off **the** list of terrible things to worry about. I was just in India working on **the** polio program. **The** polio surveillance program is four million people going door to door. That is **the** surveillance system. But we need to have early detection, early response. Blindness, **the** same thing. **The** key to discovering blindness is doing epidemiological surveys and finding out **the** causes of blindness, so you can mount **the** correct response. **The** Seva Foundation was started by a group of alumni of **the** Smallpox Eradication Programme, who, having climbed **the** highest mountain, tasted **the** elixir of **the** success of eradicating a disease, wanted to do it again. And over **the** last 27 years, Seva ' s programs in 15 countries have given back sight to more than two million blind people. Seva got started because we wanted to apply these lessons of surveillance and epidemiology to something which nobody else was looking at as a public health issue : blindness, which heretofore had been thought of only as a clinical disease. In 1980, Steve Jobs gave me that **computer**, which is Apple number 12, and it ' s still in Kathmandu, and it ' s still working, and we ought to go get it and auction it off and make more money for Seva. And we conducted **the** first Nepal survey ever done for health, and **the** first nationwide blindness survey ever done, and we had astonishing results. Instead of finding out what we thought was **the** case â that blindness was caused mostly by glaucoma and trachoma â we were astounded to find out that blindness was caused instead by cataract. You can ' t cure or prevent what you don ' t know is there. In your TED packages there ' s a DVD,"Infinite Vision,"about Dr. V and **the** Aravind Eye Hospital. I hope that you will take a look at it. Aravind, which started as a Seva project, is now **the** world ' s largest and best eye hospital. This year, that one hospital will give back sight to more than 300, 000 people in Tamil Nadu, India. Bird flu. I stand here as a representative of all terrible things â this might be **the** worst. **The** key to preventing or mitigating pandemic bird flu is early detection and rapid response. We will not have a vaccine or adequate supplies of an antiviral to combat bird flu if it **occurs** in **the** next three years. WHO stages **the** progress of a pandemic. We are now at stage three on **the** pandemic alert stage, with just a little bit of human-to-human transmission, but no human-to-human-to-human sustained transmission. **The** moment WHO says we ' ve moved to category four â this will not be like Katrina. **The** world as we know it will stop. There ' ll be no **airplanes** flying. Would you get in an **airplane** with 250 people you didn ' t know, coughing and sneezing, when you knew that some of them might carry a disease that could kill you, for which you had no antivirals or vaccine? I did a study of **the** top epidemiologists in **the** world in October. I asked them â these are all fluologists and specialists in influenza â and I asked them **the** questions you ' d like to ask them : What do you think **the** likelihood is that there ' ll be a pandemic? If it happens, how bad do you think it will be? Fifteen percent said they thought there ' d be a pandemic within three years. But much worse than that, 90 percent said they thought there ' d be a pandemic within your children or your grandchildren ' s lifetime. And they thought that if there was a pandemic, a billion people would get sick. As many as 165 million people would die. There would be a global recession and depression as our just-in-time inventory system and **the** tight rubber band of globalization broke, and **the** cost to our economy of one to three trillion dollars would be far worse for everyone than merely 100 million people dying, because so many more people would lose their job and their healthcare benefits, that **the** consequences are almost unthinkable. And it ' s getting worse, because travel is getting so much better. Let me show you a simulation of what a pandemic looks like. So we know what we ' re talking about. Let ' s assume, for example, that **the** first case **occurs** in South Asia. It initially goes quite slowly. You get two or three discrete locations. Then there ' ll be secondary outbreaks, and **the** disease will spread from country to country so fast that you won ' t know what hit you. Within three weeks it will be everywhere in **the** world. Now, if we had an”undo”button, and we could go back and isolate it and grab it when it first started â if we could find it early, and we had early detection and early response, and we could put each one of those viruses in jail â that ’ s **the** only way to deal with something like a pandemic. And let me show you why that is. We have a joke. This is an epidemic curve, and everyone in medicine, I think, ultimately gets to know what it is. But **the** joke is, an epidemiologist likes to arrive at an epidemic right here and ride to glory on **the** downhill curve. But you don ’ t get to do that usually. You usually arrive right about here. What we really want is to arrive right here, so we can stop **the** epidemic. But you can ’ t always do that. But there ’ s an organization that has been able to find a way to learn when **the** first cases **occur**, and that is called GPHIN ; it ’ s **the** Global Public Health Information Network. And that simulation that I showed you that you thought was bird flu â that was SARS. And SARS is **the** pandemic that did not **occur**. And it didn ’ t **occur** because GPHIN found **the** pandemic-to-be of SARS three months before WHO actually announced it, and because of that, we were able to stop **the** SARS pandemic. And I think we owe a great debt of gratitude to GPHIN and to Ron St. John, who I hope is in **the** audience some place â over there â who ’ s **the** founder of GPHIN. Hello, Ron! And TED has flown Ron here from Ottawa, where GPHIN is located, because not only did GPHIN find SARS early, but you may have seen last week that Iran announced that they had bird flu in Iran, but GPHIN found **the** bird flu in Iran not February 14 â but last September. We need an early-warning system to protect us against **the** things that are humanity ’ s worst nightmare. And so my TED wish is based on **the** common denominator of these experiences. Smallpox â early detection, early response. Blindness, polio â early detection, early response. Pandemic bird flu â early detection, early response. It is a litany. It is so obvious that our only way of dealing with these new diseases is to find them early and to kill them before they spread. So, my TED wish is for you to help build a global system â an early-warning system â to protect us against humanity ’ s worst nightmares. And what I thought I would call it is”Early Detection,”But it should really be called...”Total Early Detection.”[TED] What? What? But in all seriousness, because this idea is birthed in TED, I would like it to be a legacy of TED, and I ’ d like to call it **the**”International System for Total Early Disease Detection.”[INSTEDD] And INSTEDD then becomes our mantra. So instead of a hidden pandemic of bird flu, we find it and immediately contain it. Instead of a novel virus caused by bio-terror or bio-error, or shift or drift, we find it and we contain it. Instead of industrial accidents like **oil spills** or **the** catastrophe in Bhopal, we find them, and we respond to them. Instead of famine, hidden until it is too late, we **detect** it, and we respond. And instead of a system which is owned by a government, and hidden in **the** bowels of government, let ’ s build an early detection system that ’ s freely available to anyone in **the** world in their own language. Let ’ s make it transparent, non-governmental, not owned by any single country or company, housed in a neutral country, with redundant backup in a different time zone and a different **continent**. And let ’ s build it on GPHIN. Let ’ s start with GPHIN. Let ’ s increase **the** websites that they crawl from 20, 000 to 20 million. Let ’ s increase **the** languages they crawl from seven to 70, or more. Let ’ s build in outbound confirmation messages, using text messages or SMS or instant messaging to find out from people who are within 100 meters of **the** rumor that you hear, if it is, in fact, valid. And let ’ s add satellite confirmation. And we ’ ll add Gapminder ’ s amazing **graphics** to **the** front end. And we ’ ll grow it as a moral force in **the** world, finding out those terrible things before anybody else knows about them, and sending our response to them, so that next year, instead of us meeting here, lamenting how many terrible things there are in **the** world, we will have pulled together, used **the** unique skills and **the** magic of this community, and be proud that we have done everything we can to stop pandemics, other catastrophes, and change **the** world, beginning right now. Chris Anderson : An amazing presentation. First of all, just so everyone understands : you ’ re saying that by creating **web** crawlers, looking on **the** Internet for patterns, they can **detect** something suspicious before WHO, before anyone else can see it? Give an example of how that could possibly be true. Larry Brilliant : You ’ re not mad about **the** copyright violation? CA : No. I love it. LB : Well, as Ron St. John â I hope you ’ ll go and meet him in **the** dinner afterwards and talk to him. When he started GPHIN â In 1997, there was an outbreak of bird flu â H5N1. It was in Hong Kong. And a remarkable doctor in Hong Kong responded immediately, by slaughtering 1. 5 million chickens and birds, and they stopped that outbreak in its tracks. Immediate detection, immediate response. Then a number of years went by, and there were a lot of rumors about bird flu. Ron and his team in Ottawa began to crawl **the web** â only crawling 20, 000 different websites, mostly periodicals â and they read about and heard about a concern, of a lot of children who had high fever and symptoms of bird flu. They reported this to WHO. WHO took a little while taking action, because WHO will only receive a report from a government, because it ’ s **the** United Nations. But they were able to point to WHO and let them know that there was this surprising and unexplained cluster of illnesses that looked like bird flu. That turned out to be SARS. That ’ s how **the** world found out about SARS. And because of that, we were able to stop SARS. Now, what ’ s really important is that, before there was GPHIN, 100 percent of all **the** world ’ s reports of bad things â whether you ’ re talking about famine or you ’ re talking about bird flu or you ’ re talking about Ebola â 100 percent of all those reports came from nations. **The** moment these guys in Ottawa â on a budget of 800, 000 dollars a year â got cracking, 75 percent of all **the** reports in **the** world came from GPHIN, 25 percent of all **the** reports in **the** world came from all **the** other 180 nations. Now, here ’ s what ’ s really interesting : after they ’ d been working for a couple years, what do you think happened to those nations? They felt pretty stupid. So they started sending in their reports early. And now, their reporting percentage is down to 50 percent, because other nations have started to report. So, can you find diseases early by crawling **the web**? Of course you can. Can you find it even earlier than GPHIN does now? Of course you can. You saw that they found SARS using their Chinese **web** crawler a full six weeks before they found it using their English **web** crawler. Well, they ’ re only crawling in seven languages. These bad viruses really don ’ t have any intention of showing up first in English or Spanish or French. So yes, I want to take GPHIN, I want to build on it. I want to add all **the** languages of **the** world that we possibly can. I want to make this open to everybody, so that **the** health officer in Nairobi or in Patna, Bihar will have as much access to it as **the** folks in Ottawa or in CDC. And I want to make it part of our culture that there is a community of people who are watching out for **the** worst nightmares of humanity, and that it ’ s accessible to everyone.

The future that we will create can be a future that we ’ ll be proud of. I think about this every day ; it ’ s quite literally my job. I ’ m co-founder and senior columnist at Worldchanging. com. Alex Steffen and I founded Worldchanging in late 2003, and since then we and our growing global team of contributors have documented **the** ever-expanding variety of solutions that are out there, right now and on **the** near horizon. In a little over two years, we ' ve written up about 4, 000 items — replicable models, technological tools, emerging ideas — all providing a path to a future that ' s more sustainable, more equitable and more desirable. Our emphasis on solutions is quite intentional. There are tons of places to go, online and off, if what you want to find is **the** latest bit of news about just how quickly our hell-bound handbasket is moving. We want to offer people an idea of what they can do about it. We focus primarily on **the planet** ' s environment, but we also address issues of global development, international conflict, responsible use of emerging technologies, even **the** rise of **the** so-called Second Superpower and much, much more. **The** scope of solutions that we discuss is actually pretty broad, but that reflects both **the** range of challenges that need to be met and **the** kinds of innovations that will allow us to do so. A quick sampling really can barely scratch **the surface**, but to give you a sense of what we cover : tools for rapid disaster relief, such as this inflatable concrete shelter ; innovative uses of bioscience, such as a flower that changes color in **the** presence of landmines ; ultra high-efficiency designs for homes and offices ; distributed power generation using solar power, wind power, ocean power, other clean energy sources ; ultra, ultra high-efficiency vehicles of **the** future ; ultra high- efficiency vehicles you can get right now ; and better urban design, so you don ' t need to drive as much in **the** first place ; bio-mimetic approaches to design that take advantage of **the** efficiencies of natural models in both vehicles and buildings ; distributed computing projects that will help us model **the** future of **the** climate. Also, a number of **the** topics that we ' ve been talking about this week at TED are things that we ' ve addressed in **the** past on Worldchanging : cradle-to-cradle design, MIT ' s Fab Labs, **the** consequences of extreme longevity, **the** One **Laptop** per Child project, even Gapminder. As a born-in-the-mid-1960s Gen X-er, hurtling all too quickly to my fortieth birthday, I ' m naturally inclined to pessimism. But working at Worldchanging has convinced me, much to my own surprise, that successful responses to **the** world ' s problems are nonetheless possible. Moreover, I ' ve come to realize that focusing only on negative outcomes can really blind you to **the** very possibility of success. As Norwegian social scientist Evelin Lindner has observed,"Pessimism is a luxury of good times... In difficult times, pessimism is a self- fulfilling, self-inflicted death sentence."**The** truth is, we can build a better world, and we can do so right now. We have **the** tools : we saw a hint of that a moment ago, and we ' re coming up with new ones all **the** time. We have **the** knowledge, and our understanding of **the planet** improves every day. Most importantly, we have **the** motive : we have a world that needs fixing, and nobody ' s going to do it for us. Many of **the** solutions that I and my colleagues seek out and write up every day have some important aspects in common : transparency, collaboration, a willingness to experiment, and an appreciation of science — or, more appropriately, science! **The** majority of models, tools and ideas on Worldchanging encompass combinations of these characteristics, so I want to give you a few concrete examples of how these principles combine in world- changing ways. We can see world-changing values in **the** emergence of tools to make **the** invisible visible — that is, to make apparent **the** conditions of **the** world around us that would otherwise be largely imperceptible. We know that people often change their behavior when they can see and understand **the** impact of their actions. As a small example, many of us have experienced **the** change in driving behavior that comes from having a real time display of mileage showing precisely how one ' s driving habits affect **the** vehicle ' s efficiency. **The** last few years have all seen **the** rise of innovations in how we measure and display aspects of **the** world that can be too big, or too intangible, or too slippery to grasp easily. Simple technologies, like wall-mounted **devices** that display how much power your household is using, and what kind of results you ' ll get if you turn off a few lights — these can actually have a direct positive impact on your energy footprint. Community tools, like text messaging, that can tell you when pollen counts are up or smog levels are rising or a natural disaster is unfolding, can give you **the** information you need to act in a timely fashion. Data-rich displays like maps of campaign contributions, or maps of **the disappearing** polar ice caps, allow us to better understand **the** context and **the** flow of processes that affect us all. We can see world-changing values in research projects that seek to meet **the** world ' s medical needs through open access to data and collaborative action. Now, some people emphasize **the** risks of knowledge-enabled dangers, but I ' m convinced that **the** benefits of knowledge-enabled solutions are far more important. For example, open-access journals, like **the** Public Library of Science, make cutting-edge scientific research free to all — everyone in **the** world. And actually, a growing number of science publishers are adopting this model. Last year, hundreds of volunteer **biology** and **chemistry** researchers around **the** world worked together to sequence **the genome** of **the** parasite responsible for some of **the** developing world ' s worst diseases : African sleeping sickness, leishmaniasis and Chagas disease. That **genome** data can now be found on open-access genetic data banks around **the** world, and it ' s an enormous boon to researchers trying to come up with treatments. But my favorite example has to be **the** global response to **the** SARS epidemic in 2003, 2004, which relied on worldwide access to **the** full gene sequence of **the** SARS virus. **The** U. S. National Research Council in its follow-up report on **the** outbreak specifically cited this open availability of **the** sequence as a key reason why **the** treatment for SARS could be developed so quickly. And we can see world-changing values in something as humble as a cell phone. I can probably count on my fingers **the** number of people in this room who do not use a mobile phone — and where is Aubrey, because I know he doesn ' t? For many of us, cell phones have really become almost an extension of ourselves, and we ' re really now beginning to see **the** social changes that mobile phones can bring about. You may already know some of **the** big-picture aspects : globally, more camera phones were sold last year than any other kind of camera, and a growing number of people live lives mediated through **the** lens, and over **the** network — and sometimes enter history books. In **the** developing world, mobile phones have become economic drivers. A study last year showed a direct correlation between **the** growth of mobile phone use and subsequent GDP increases across Africa. In Kenya, mobile phone minutes have actually become an alternative currency. **The** political aspects of mobile phones can ' t be ignored either, from text message swarms in Korea helping to bring down a government, to **the** Blairwatch Project in **the** UK, keeping tabs on politicians who try to avoid **the** press. And it ' s just going to get more wild. Pervasive, always-on networks, high quality sound and video, even **devices** made to be worn instead of carried in **the pocket**, will transform how we live on a scale that few really appreciate. It ' s no exaggeration to say that **the** mobile phone may be among **the** world ' s most important technologies. And in this rapidly **evolving** context, it ' s possible to imagine a world in which **the** mobile phone becomes something far more than a medium for social interaction. I ' ve long admired **the** Witness project, and Peter Gabriel told us more details about it on Wednesday, in his profoundly moving presentation. And I ' m just incredibly happy to see **the** news that Witness is going to be opening up a Web portal to enable users of digital cameras and camera phones to send in their recordings over **the** Internet, rather than just hand-carrying **the** videotape. Not only does this add a new and potentially safer avenue for documenting abuses, it opens up **the** program to **the** growing global digital generation. Now, imagine a similar model for networking environmentalists. Imagine a Web portal collecting recordings and evidence of what ' s happening to **the planet** : putting news and data at **the** fingertips of people of all kinds, from activists and researchers to businesspeople and political figures. It would highlight **the** changes that are underway, but would more importantly give voice to **the** people who are willing to work to see a new world, a better world, come about. It would give everyday citizens a chance to play a role in **the** protection of **the planet**. It would be, in essence, an"Earth Witness"project. Now, just to be clear, in this talk I ' m using **the** name"Earth Witness"as part of **the** scenario, simply as a shorthand, for what this imaginary project could aspire to, not to piggyback on **the** wonderful work of **the** Witness organization. It could just as easily be called,"Environmental Transparency Project,""Smart Mobs for Natural Security"— but Earth Witness is a lot easier to say. Now, many of **the** people who participate in Earth Witness would focus on ecological problems, human-caused or otherwise, especially environmental crimes and significant sources of **greenhouse** gases and **emissions**. That ' s understandable and important. We need better documentation of what ' s happening to **the planet** if we ' re ever going to have a chance of repairing **the** damage. But **the** Earth Witness project wouldn ' t need to be limited to problems. In **the** best Worldchanging tradition, it might also serve as a showcase for good ideas, successful projects and efforts to make a difference that deserve much more visibility. Earth Witness would show us two worlds : **the** world we ' re leaving behind, and **the** world we ' re building for generations to come. And what makes this scenario particularly appealing to me is we could do it today. **The** key components are already widely available. Camera phones, of course, would be fundamental to **the** project. And for a lot of us, they ' re as close as we have yet to always-on, widely available information tools. We may not remember to bring our digital cameras with us wherever we go, but very few of us forget our phones. You could even imagine a version of this scenario in which people actually build their own phones. Over **the** course of last year, **open-source** hardware hackers have come up with multiple models for usable, Linux-based mobile phones, and **the** Earth Phone could spin off from this kind of project. At **the** other end of **the** network, there ' d be a server for people to send photos and messages to, accessible over **the** Web, combining a photo-sharing service, social networking platforms and a collaborative filtering system. Now, you Web 2. 0 folks in **the** audience know what I ' m talking about, but for those of you for whom that last sentence was in a crazy moon language, I mean simply this : **the** online part of **the** Earth Witness project would be created by **the** users, working together and working openly. That ' s enough right there to start to build a compelling chronicle of what ' s now happening to our **planet**, but we could do more. An Earth Witness site could also serve as a **collection** spot for all sorts of data about conditions around **the planet** picked up by environmental sensors that attach to your cell phone. Now, you don ' t see these **devices** as add-ons for phones yet, but students and engineers around **the** world have attached atmospheric sensors to bicycles and handheld **computers** and cheap robots and **the** backs of pigeons — that being a project that ' s actually underway right now at U. C. Irvine, using bird-mounted sensors as a way of measuring smog-forming pollution. It ' s hardly a stretch to imagine putting **the** same thing on a phone carried by a person. Now, **the** idea of connecting a sensor to your phone is not new : phone-makers around **the** world offer phones that sniff for bad breath, or tell you to worry about too much sun exposure. Swedish firm Uppsala Biomedical, more seriously, makes a mobile phone add-on that can process **blood** tests in **the** field, uploading **the** data, displaying **the** results. Even **the** Lawrence Livermore National Labs have gotten into **the** act, designing a prototype phone that has radiation sensors to find dirty bombs. Now, there ’ s an enormous variety of tiny, inexpensive sensors on **the** market, and you can easily imagine someone putting together a phone that could measure temperature, CO2 or methane levels, **the** presence of some biotoxins — potentially, in a few years, maybe even H5N1 avian flu virus. You could see that some kind of system like this would actually be a really good fit with Larry Brilliant ’ s InSTEDD project. Now, all of this data could be **tagged** with geographic information and mashed up with online maps for easy viewing and analysis. And that ’ s worth noting in particular. **The** impact of open-access online maps over **the** last year or two has been simply phenomenal. Developers around **the** world have come up with an amazing variety of ways to layer useful data on top of **the** maps, from bus routes and crime statistics to **the** global progress of avian flu. Earth Witness would take this further, linking what you see with what thousands or millions of other people see around **the** world. It ’ s kind of exciting to think about what might be accomplished if something like this ever existed. We ’ d have a far better — far better knowledge of what ’ s happening on our **planet** environmentally than could be gathered with satellites and a handful of government sensor nets alone. It would be a collaborative, bottom-up approach to environmental awareness and protection, able to respond to emerging concerns in a smart mobs kind of way — and if you need greater sensor density, just have more people show up. And most important, you can ’ t ignore how important mobile phones are to global youth. This is a system that could put **the** next generation at **the** front lines of gathering environmental data. And as we work to figure out ways to mitigate **the** worst effects of climate disruption, every little bit of information matters. A system like Earth Witness would be a tool for all of us to participate in **the** improvement of our knowledge and, ultimately, **the** improvement of **the planet** itself. Now, as I suggested at **the** outset, there are thousands upon thousands of good ideas out there, so why have I spent **the** bulk of my time telling you about something that doesn ’ t exist? Because this is what tomorrow could look like : bottom-up, technology-enabled global collaboration to handle **the** biggest crisis our civilization has ever faced. We can save **the planet**, but we can ’ t do it alone — we need each other. Nobody ’ s going to fix **the** world for us, but working together, making use of technological innovations and human communities alike, we might just be able to fix it ourselves. We have at our fingertips a cornucopia of compelling models, powerful tools, and innovative ideas that can make a meaningful difference in our **planet** ’ s future. We don ’ t need to wait for a magic **bullet** to save us all ; we already have an arsenal of solutions just waiting to be used. There ’ s a staggering **array** of wonders out there, across diverse disciplines, all telling us **the** same thing : success can be ours if we ’ re willing to try. And as we say at Worldchanging, another world isn ’ t just possible ; another world is here. We just need to open our eyes. Thank you very much.

Text Sample 13: POS Dim 1 – 2006 – Score 20.00 – 2006/t000417.txt

I just want to say, over **the** last few years I ’ ve been â had **the** opportunity to do this closing conference. And I ’ ve had some incredible warm-up acts. About eight years ago, Billy Graham opened for me. And I thought that there was â I thought that there was absolutely no way in hell to top that. But I just wanted to say â and I mean this without irony â I think I can speak for everybody in **the** audience when I say that I wish to God that you were **the** President of **the** United States. OK, this is **the** title of my talk today. I just want to give you a quick overview. First of all, please remember I ’ m completely politically correct, and I mean everything with great affection. If any of you have sensitive stomachs or are feeling queasy, now is **the** time to check your Blackberry. Just to review, this is my TEDTalk. We ’ re going to do some jokes, some gags, some little skits â and then we ’ re going to talk about **the** L1 point. So, one of **the** questions I ask myself is, was this **the** most distressing TED ever? Let ’ s try and **sum** things up, shall we? Images of limb regeneration and faces filled with smallpox : 21 percent of **the** conference. Mentions of polar bears drowning : four percent. Images of **the** earth being **wiped** out by flood or bird flu : 64 percent. And David Pogue singing show tunes. Because this is **the** most distressing TED ever, I ’ ve been working with Neil Gershenfeld on next year ’ s TED Bag. And if **the** â if **the** conference is anywhere near this distressing, then we ’ re going to have a scream bag next year. It ’ s going to be a cradle-to-cradle scream bag, of course. So you ’ re going to be able to go like this. Bring it over here and open it up. Aaaah! Meanwhile, back at TED University, this wonderful woman is teaching you how to chop Sun Chips. So Robert Wright â I don ’ t know, I felt like if there was anyone that Helen needed to give antidepressants to, it might have been him. I want to deliberately interfere with his dopamine levels. He was talking about morality. Economy class morality is, we want to bomb you back to **the** Stone Age. Business class morality is, don ’ t bomb Japan â they built my car. And first-class morality is, don ’ t bomb Mexico â they clean my house. Yes, it is politically incorrect. All right, now I want to do a little bit of a thing for you... All right, now these are **the** wha â I ’ d say, [mumble, mumble â mumble, mumble, mumble, mumble, mumble] â ahh! So I wanted to show you guys â I wanted to talk about a revolutionary new **computer** interface that lets you work with images just as easily as you â as a completely natural user interface. And you can â you can use really natural hand gestures to like, go like this. Now we had a Harvard professor here â she was from Harvard, I just wanted to mention and â and she was actually a professor from Harvard. And she was talking about seven-dimensional, inverted **universes**. With, you know, of course, there ’ s **the** gravity brain. There ’ s **the** weak brain. And then there ’ s my weak brain, which is too â too â absolutely too weak to understand what **the** fuck she was talking about. Now â one of **the** things that is very important to me is to try and figure out what on Earth am I here for. And that ’ s why I went out and I picked up a best-selling business book. You know, it basically uses as its central premise Greek mythology. And it ’ s by a guy named Pastor Rick Warren, and it ’ s called”**The** Porpoise Driven Life.”And Rick is as a pagan god, which I thought was kind of appropriate, in a certain way. And now we ’ re going to have kind of a little more visualization about Rick Warren. OK. All right. Now, red is Rick Warren, and green is Daniel Dennett, OK? **The** scales here are religiosity from zero percent, or atheist, to 100 percent, Bible literally true. And then this is books sold â **the** logarithmic scale. 30, 000, 300, 000, three million, 30 million, 300 million. OK, now they ’ re duking it out. Now they ’ re duking it out. And Rick Warren ’ s kind of pulling ahead, kind of pulling ahead. Yup, and his installed base is getting a little bigger. But Darwin ’ s dangerous idea is coming back. It ’ s coming back. Let me turn **the** trails on, so you can see that a little bit better. Now, one of **the** things that ’ s very important is, Nicholas Negroponte talked to us about one lap dance per â I ’ m sorry â about One **Laptop** Per Child. Now let ’ s talk about some of **the** characteristics that are important for this revolutionary **device**. I ’ ll tell you a little bit about **the** design parameters, and then I ’ ll show it to you in person. First of all, it needs to be small. It needs to be flat, so it ’ s transportable. Lightweight. Portable. Uses very, very little power. Very, very high resolution. Has to be visible in bright daylight. Will work anywhere. And broadly applicable across many platforms. Now, we ’ ve actually done some research â□□ Neil Gershenfeld and **the** Fab Labs went out into **the** market. They did some research ; we came back ; and we think we have **the** perfect prototype of what **the** students in **the** field are actually asking for. And here it is, **the** $100 **computer**. OK, OK, OK, OK â□□ excellent, excellent. Now, I bought this **device** from Clifford Stoll for about 900 **bucks**. And he and his team of junior-high school students were doing real science. So we ’ re trying to check and trying to douse here, and see who uses marijuana. See who uses marijuana. Are we going to be able to find any marijuana, Jim Young? Only if we open enough locker doors. OK, now smallpox is an extremely distressing illness. We had Dr. Larry Brilliant talking about how we eradicated smallpox. I wanted to show you **the** stages of smallpox. We start. This is day one. Day two. Day three, she gets a massively big pox on her shoulder. Day three. Day four. Day five and day six. Now **the** good news is, because I ’ m a trained medical professional, I know that even though she ’ ll be scarred for life, she ’ s going to make a full recovery. Now **the** good news about Architects for Humanity is they ’ re really kind of **the** most amazing group. They ’ ve been sponsoring a design competition to come up with innovative medical housing solutions, clinic solutions, in Africa, and they ’ ve had a design competition. Now **the** wonderful thing is, Larry Brilliant was just appointed **the** head of **the** Google Foundation, and so he decided that he would support â□□ he would support Cameron ’ s work. And **the** way he decided to support that work was by shipping over 50, 000 **shipping** containers of Google snacks. So I want to show you some prototypes. **The** U. N. â□□ you know, they took 20 years just to add a flap to a tent, but I think we have some more exciting things. This is a home made entirely out of Fruit Roll-Ups. And those roll-up cookies coated with white chocolate. And **the** really wonderful thing about this is, when you ’ re done, well â□□ you can eat it. But **the** thing that I ’ m really, really excited about is this incredible granola house. And **the** granola house has a special Sun Chip roof to collect water and recycle it. And it ’ s â□□ well, on this side it has regular Sour Patch Kids and Gummy Bears to let in **the** light. But on this side, it has sugary Gummy Bears, to diffuse **the** light more slightly. And we â□□ we wanted just to show you what this might look like in situ. So, Einstein â□□ Einstein, tell me â□□ what ’ s your favorite song? No, I said what ’ s your favorite song? No, I said what ’ s your favorite song?”Free Bird.”OK, so, Einstein, what ’ s your favorite singing group? Could you say that again? What ’ s your favorite singing group? OK, one more time â□□ I ’ m just going to give you a little help. Your favorite singing group â□□ it ’ s Diana Ross and **the** â□□ Audience : Supremes! Tom Reilly : Exactly. Could we have **the** sound up on **the laptop**, please?”Free Bird”kind of reminds me that if you â□□ if you listen to”Free Bird”**backwards**, this is what you might hear. **Computer** : Satan. Satan. Satan. Satan. Satan. Satan. Satan. TR : Now it ’ s a little hard to hear **the** whole message, so I wanted to â□□ so I wanted to help you a little bit. **Computer** : My sweet Satan. Dan Dennett worships Satan. Buy”**The** Purpose-Driven Life,”or Satan will take your soul. TR : So, we ’ ve talked a lot about global warming, but, you know, as Jill said, it sounds kind of nice â□□ good weather in **the** wintertime, and New York City. And as Jay Walker pointed out, that is just not scary enough. So Al, I actually think I ’ m rather good at branding. So I ’ ve tried to figure out a good design process to come up with a new term to replace”global warming.”So we started with Babel Fish. We put in global warming. And then we decided that we ’ d change it from English to Dutch â□□ into”Het globale Verwarmen.”From Dutch to [Korean], into”Hordahordaneecheewa.”[Korean] to Portuguese : Aquecer-se Global. Then Portuguese to Pig Latin. Aquecer-se ucked-fay. And then finally back into **the** English, which is, we ’ re totally fucked. Now I don ’ t know about you, but Michael Shermer talked about **the** willingness for human beings â evolutionarily, they ’ re designed to see patterns in things. For example, in cheese sandwiches. Now can you look at that carefully and see if you see **the** Virgin Mary? I tried to make it a little bit clearer. Is it **the** Virgin Mary? Or is it Mena Trott? So, I talked to Josh Prince-Ramus about **the** convention center and **the** conferences. It ’ s getting awfully big. It ’ s getting just a little bit too big. It ’ s bursting at **the** seams here a little bit. So we tried to come up with a program â how we could remake this structure to better accommodate TED. So first of all we decided â that we needed about **one-third** bookstore, **one-third** Google cafe, about 20 percent registration, 80 percent luxury hotel, about five percent for restrooms. And then of course, we wanted to have **the** simulcast lounge, **the** lobby and **the** Steinbeck forum. Now let me show you how that literally translated into **the** design program. So first, one of **the** problems with Monterey is that if there is global warming and Greenland melts as you say, **the** ocean level is going to rise 20 feet and flood **the** hell out of **the** convention center. So we ’ re going to build this new building on stilts. So we build this building on stilts, then up here â is where we ’ re going to put **the** new Steinbeck auditorium. And **the** wonderful thing about **the** new bookstore is, it ’ s going to be shaped in a spiral that ’ s organized by **the** Dewey Decimal System. Then we ’ re going to make an escalator that helps you get up there. And finally, we ’ re going to put **the** Marriott Hotel and **the** Portola Plaza on **the** top. Now I don ’ t know about you, but sometimes I have these images in my head of separated at birth. I don ’ t know about you, but when I see Aubrey de Grey, I immediately go to Gandalf **the** Grey. OK. Now, we ’ ve heard, of course, that we ’ re all soldiers here. So what I ’ d really, really like you to do now is, pick up your white piece of paper. Does everybody have their white piece of paper? And I want you to get out a pen, and I want you to write a **terrorist** note. If we put up **the** ELMO for a moment â if we put up **the** ELMO, then we ’ ll get, you know, I ’ ll give you a model that you can work from, OK? And then I want you to fold that note into a paper **airplane**. And once you ’ ve folded it into a paper **airplane**, I want you to take some anthrax â and I want you to put that in **the** paper **airplane**. And then I want you to throw it on Jim Young. Luckily, I was **the** recipient of **the** TED Prize this year. And I wanted to see â I want to dedicate this film to my father, Homer. OK. Now this film isn ’ t really hard enough, so I wanted to make it a little bit harder. So I ’ m going to try and do this while reciting pi. 3. 1415, 2657, 753, 8567, 24972 â â 85871, 25871, 3928, 5657, 2592, 5624. Can we cue **the** music please? Now I wanted to use this talk to talk about global warming a little bit. Back in 1968, you can see that **the** mountain range of Brokeback Mountain was covered in 151 **inches** of snow pack. Parenthetically, over there on **the** **slopes**, I did want to show you that black men ski. But over **the** years, 10 years later, **the** snow packs eroded, and, if you notice, **the** trees have started turning **yellow**. **The** water level of **the** lake has started drying up. A few years later, there ’ s no snow left at all. And all **the** trees have turned brown. This year, unfortunately **the** lakebed ’ s turned into an absolute cracked dry bed. And I fear, if we do nothing for our **planet**, in 20 years, it ’ s going to look like this. Mr. Vice President, I wish I knew how to quit you. Thank you very much.

Text Sample 14: POS Dim 1 – 1998 – Score 21.00 – 1998/t000216.txt

David Gallo : This is Bill Lange. I ’ m Dave Gallo. And we ’ re going to tell you some stories from **the sea** here in video. We ’ ve got some of **the** most incredible video of Titanic that ’ s ever been seen, and we ’ re not going to show you any of it. **The** truth of **the** matter is that **the** Titanic — even though it ’ s breaking all sorts of box office records — it ’ s not **the** most exciting story from **the sea**. And **the** problem, I think, is that we take **the** ocean for granted. When you think about it, **the** oceans are 75 percent of **the planet**. Most of **the planet** is ocean water. **The** average depth is about two miles. Part of **the** problem, I think, is we stand at **the** beach, or we see images like this of **the** ocean, and you look out at this great big **blue** expanse, and it ’ s shimmering and it ’ s moving and there ’ s waves and there ’ s **surf** and there ’ s tides, but you have no idea for what lies in there. And in **the** oceans, there are **the** longest mountain ranges on **the planet**. Most of **the** animals are in **the** oceans. Most of **the earthquakes** and volcanoes are in **the sea**, at **the** bottom of **the sea**. **The** biodiversity and **the** biodensity in **the** ocean is higher, in places, than it is in **the** rainforests. It ’ s mostly unexplored, and yet there are beautiful sights like this that captivate us and make us become familiar with it. But when you ’ re standing at **the** beach, I want you to think that you ’ re standing at **the** edge of a very unfamiliar world. We have to have a very special technology to get into that unfamiliar world. We use **the** submarine Alvin and we use cameras, and **the** cameras are something that Bill Lange has developed with **the** help of Sony. Marcel Proust said,”**The** true voyage of discovery is not so much in seeking new landscapes as in having new eyes.”People that have partnered with us have given us new eyes, not only on what exists — **the** new landscapes at **the** bottom of **the sea** — but also how we think about life on **the planet** itself. Here ’ s a jelly. It ’ s one of my favorites, because it ’ s got all sorts of working parts. This turns out to be **the** longest creature in **the** oceans. It gets up to about 150 feet long. But see all those different working things? I love that kind of stuff. It ’ s got these **fishing** lures on **the** bottom. They ’ re going up and down. It ’ s got tentacles dangling, swirling around like that. It ’ s a colonial animal. These are all individual animals banding together to make this one creature. And it ’ s got these jet thrusters up in front that it ’ ll use in a moment, and a little light. If you take all **the** big **fish** and schooling **fish** and all that, put them on one side of **the** scale, put all **the** jelly-type of animals on **the** other side, those guys win hands down. Most of **the** biomass in **the** ocean is made out of creatures like this. Here ’ s **the** X-wing death jelly. **The** bioluminescence — they use **the** lights for attracting **mates** and attracting prey and communicating. We couldn ’ t begin to show you our archival stuff from **the** jellies. They come in all different sizes and shapes. Bill Lange : We tend to forget about **the** fact that **the** ocean is miles deep on average, and that we ’ re real familiar with **the** animals that are in **the** first 200 or 300 feet, but we ’ re not familiar with what exists from there all **the** way down to **the** bottom. And these are **the** types of animals that live in that three- dimensional space, that micro-gravity environment that we really haven ’ t explored. You hear about giant squid and things like that, but some of these animals get up to be approximately 140, 160 feet long. They ’ re very little understood. DG : This is one of them, another one of our favorites, because it ’ s a little octopod. You can actually see through his head. And here he is, flapping with his ears and very gracefully going up. We see those at all depths and even at **the** greatest depths. They go from a couple of **inches** to a couple of feet. They come right up to **the** submarine — they ’ ll put their eyes right up to **the** window and peek inside **the** sub. This is really a world within a world, and we ’ re going to show you two. In this case, we ’ re passing down through **the** mid-ocean and we see creatures like this. This is kind of like an undersea rooster. This guy, that looks incredibly formal, in a way. And then one of my favorites. What a face! This is basically scientific data that you ’ re looking at. It ’ s footage that we ’ ve collected for scientific purposes. And that ’ s one of **the** things that Bill ’ s been doing, is providing scientists with this first view of animals like this, in **the** world where they belong. They don ’ t catch them in a net. They ’ re actually looking at them down in that world. We ’ re going to take a joystick, sit in front of our **computer**, on **the** Earth, and press **the** joystick forward, and fly around **the planet**. We ’ re going to look at **the** mid-ocean ridge, a 40, 000-mile long mountain range. **The** average depth at **the** top of it is about a mile and a half. And we ’ re over **the** Atlantic — that ’ s **the** ridge right there — but we ’ re going to go across **the** Caribbean, Central America, and end up against **the** Pacific, nine degrees north. We make maps of these mountain ranges with sound, with sonar, and this is one of those mountain ranges. We ’ re coming around a cliff here on **the** right. **The** height of these mountains on either side of this valley is greater than **the** Alps in most cases. And there ’ s tens of thousands of those mountains out there that haven ’ t been mapped yet. This is a volcanic ridge. We ’ re getting down further and further in scale. And eventually, we can come up with something like this. This is an icon of our robot, Jason, it ’ s called. And you can sit in a room like this, with a joystick and a headset, and drive a robot like that around **the** bottom of **the** ocean in real time. One of **the** things we ’ re trying to do at Woods Hole with our partners is to bring this virtual world — this world, this unexplored region — back to **the** laboratory. Because we see it in bits and pieces right now. We see it either as sound, or we see it as video, or we see it as photographs, or we see it as chemical sensors, but we never have yet put it all together into one interesting picture. Here ’ s where Bill ’ s cameras really do shine. This is what ’ s called a hydrothermal vent. And what you ’ re seeing here is a cloud of densely packed, hydrogen-sulfide-rich water coming out of a volcanic axis on **the sea** floor. Gets up to 600, 700 degrees F, somewhere in that range. So that ’ s all water under **the sea** — a mile and a half, two miles, three miles down. And we knew it was volcanic back in **the** ’ 60s, ’ 70s. And then we had some hint that these things existed all along **the** axis of it, because if you ’ ve got volcanism, water ’ s going to get down from **the sea** into cracks in **the sea** floor, come in contact with magma, and come shooting out hot. We weren ’ t really aware that it would be so rich with sulfides, hydrogen sulfides. We didn ’ t have any idea about these things, which we call chimneys. This is one of these hydrothermal vents. Six hundred degree F water coming out of **the** Earth. On either side of us are mountain ranges that are higher than **the** Alps, so **the** setting here is very dramatic. BL : **The** white material is a type of bacteria that thrives at 180 degrees C. DG : I think that ’ s one of **the** greatest stories right now that we ’ re seeing from **the** bottom of **the sea**, is that **the** first thing we see coming out of **the sea** floor after a volcanic eruption is bacteria. And we started to wonder for a long time, how did it all get down there? What we find out now is that it ’ s probably coming from inside **the** Earth. Not only is it coming out of **the** Earth — so, biogenesis made from volcanic activity — but that bacteria supports these colonies of life. **The** pressure here is 4, 000 **pounds** per square **inch**. A mile and a half from **the surface** to two miles to three miles — no sun has ever gotten down here. All **the** energy to support these life forms is coming from inside **the** Earth — so, chemosynthesis. And you can see how dense **the** population is. These are called tube worms. BL : These worms have no digestive system. They have no mouth. But they have two types of gill structures. One for extracting oxygen out of **the** deep-sea water, another one which houses this chemosynthetic bacteria, which takes **the** hydrothermal fluid — that hot water that you saw coming out of **the** bottom — and converts that into simple sugars that **the** tube worm can digest. DG : You can see, here ’ s a **crab** that lives down there. He ’ s managed to grab a tip of these worms. Now, they normally retract as soon as a **crab** touches them. Oh! Good going. So, as soon as a **crab** touches them, they retract down into their shells, just like your fingernails. There ' s a whole story being played out here that we ' re just now beginning to have some idea of because of this new camera technology. BL : These worms live in a real temperature extreme. Their foot is at about 200 degrees C and their head is out at three degrees C, so it ' s like having your hand in boiling water and your foot in freezing water. That ' s how they like to live. DG : This is a female of this kind of worm. And here ' s a male. You watch. It doesn ' t take long before two guys here — this one and one that will show up over here — start to fight. Everything you see is played out in **the** pitch black of **the** deep **sea**. There are never any lights there, except **the** lights that we bring. Here they go. On one of **the** last dive series, we counted 200 species in these areas — 198 were new, new species. BL : One of **the** big problems is that for **the** biologists working at these sites, it ' s rather difficult to collect these animals. And they disintegrate on **the** way up, so **the** imagery is critical for **the** science. DG : Two octopods at about two miles depth. This pressure thing really amazes me — that these animals can exist there at a depth with pressure enough to crush **the** Titanic like an empty Pepsi can. What we saw up till now was from **the** Pacific. This is from **the** Atlantic. Even greater depth. You can see this **shrimp** is harassing this poor little guy here, and he ' ll bat it away with his claw. Whack! And **the** same thing ' s going on over here. What they ' re getting at is that — on **the** back of this **crab** — **the** foodstuff here is this very strange bacteria that lives on **the** backs of all these animals. And what these **shrimp** are trying to do is actually harvest **the** bacteria from **the** backs of these animals. And **the crabs** don ' t like it at all. These long filaments that you see on **the** back of **the crab** are actually created by **the** product of that bacteria. So, **the** bacteria grows hair on **the crab**. On **the** back, you see this again. **The** red dot is **the** laser light of **the** submarine Alvin to give us an idea about how far away we are from **the** vents. Those are all **shrimp**. You see **the** hot water over here, here and here, coming out. They ' re clinging to a **rock** face and actually scraping bacteria off that **rock** face. Here ' s a tiny, little vent that ' s come out of **the** side of that pillar. Those pillars get up to several stories. So here, you ' ve got this valley with this incredible alien landscape of pillars and hot **springs** and volcanic eruptions and **earthquakes**, inhabited by these very strange animals that live only on chemical energy coming out of **the** ground. They don ' t need **the** sun at all. BL : You see this white V-shaped mark on **the** back of **the shrimp**? It ' s actually a light-sensing organ. It ' s how they find **the** hydrothermal vents. **The** vents are emitting a black body radiation — an IR signature — and so they ' re able to find these vents at considerable distances. DG : All this stuff is happening along that 40, 000-mile long mountain range that we ' re calling **the** ribbon of life, because just even today, as we speak, there ' s life being generated there from volcanic activity. This is **the** first time we ' ve ever tried this any place. We ' re going to try to show you high definition from **the** Pacific. We ' re moving up one of these pillars. This one ' s several stories tall. In it, you ' ll see that it ' s a **habitat** for a lot of different animals. There ' s a funny kind of hot **plate** here, with vent water coming out of it. So all of these are individual homes for worms. Now here ' s a closer view of that community. Here ' s **crabs** here, worms here. There are smaller animals crawling around. Here ' s pagoda structures. I think this is **the** neatest-looking thing. I just can ' t get over this — that you ' ve got these little chimneys sitting here smoking away. This stuff is toxic as hell, by **the** way. You could never get a permit to dump this in **the** ocean, and it ' s coming out all from it. It ' s unbelievable. It ' s basically sulfuric acid, and it ' s being just dumped out, at incredible rates. And animals are thriving — and we probably came from here. That ' s probably where we **evolved** from. BL : This bacteria that we ' ve been talking about turns out to be **the** most simplest form of life found. There are a number of groups that are proposing that life **evolved** at these vent sites. Although **the** vent sites are short-lived — an individual site may last only 10 years or so — as an ecosystem they ’ ve been stable for millions — well, billions — of years. DG : It works too well. You see there ’ re some **fish** inside here as well. There ’ s a **fish** sitting here. Here ’ s a **crab** with his claw right at **the** end of that tube worm, waiting for that worm to stick his head out. BL : **The** biologists right now cannot explain why these animals are so active. **The** worms are growing **inches** per week! DG : I already said that this site, from a human perspective, is toxic as hell. Not only that, but on top — **the** lifeblood — that plumbing system turns off every year or so. Their plumbing system turns off, so **the** sites have to move. And then there ’ s **earthquakes**, and then volcanic eruptions, on **the** order of one every five years, that completely **wipes the** area out. Despite that, these animals grow back in about a year ’ s time. You ’ re talking about biodensities and biodiversity, again, higher than **the** rainforest that just **springs** back to life. Is it sensitive? Yes. Is it fragile? No, it ’ s not really very fragile. I ’ ll end up with saying one thing. There ’ s a story in **the** **sea**, in **the** waters of **the sea**, in **the** sediments and **the rocks** of **the sea** floor. It ’ s an incredible story. What we see when we look back in time, in those sediments and **rocks**, is a record of Earth history. Everything on this **planet** — everything — works by cycles and rhythms. **The continents** move apart. They come back together. Oceans come and go. Mountains come and go. Glaciers come and go. El Nino comes and goes. It ’ s not a disaster, it ’ s rhythmic. What we ’ re learning now, it ’ s almost like a symphony. It ’ s just like music — it really is just like music. And what we ’ re **learning** now is that you can ’ t listen to a five-billion-year long symphony, get to today and say,”Stop! We want tomorrow ’ s note to be **the** same as it was today.”It ’ s absurd. It ’ s just absurd. So, what we ’ ve got to learn now is to find out where this **planet** ’ s going at all these different scales and work with it. Learn to manage it. **The** concept of preservation is futile. Conservation ’ s tougher, but we can probably get there. Thank you very much. Thank you.

Text Sample 15: POS Dim 1 – 1998 – Score 17.00 – 1998/t000200.txt

You hear that this is **the** era of environment â or **biology**, or information technology... Well, it ’ s **the** era of a lot of different things that we ’ re in right now. But one thing for sure : it ’ s **the** era of change. There ’ s more change going on than ever has **occurred** in **the** history of human life on earth. And you all sort of know it, but it ’ s hard to get it so that you really understand it. And I ’ ve tried to put together something that ’ s a good start for this. I ’ ve tried to show in this â though **the** color doesn ’ t come out â that what I ’ m concerned with is **the** little 50-year time bubble that you are in. You tend to be interested in a generation past, a generation future â your parents, your kids, things you can change over **the** next few decades â and this 50-year time bubble you kind of move along in. And in that 50 years, if you look at **the** population curve, you find **the** population of humans on **the** earth more than doubles and we ’ re up three-and-a-half times since I was born. When you have a new baby, by **the** time that kid gets out of high school more people will be added than existed on earth when I was born. This is unprecedented, and it ’ s big. Where it goes in **the** future is questioned. So that ’ s **the** human part. Now, **the** human part related to animals : look at **the** left side of that. What I call **the** human portion â humans and their livestock and pets â versus **the** natural portion â all **the** other wild animals and just â these are vertebrates and all **the** birds, etc., in **the** land and air, not in **the** water. How does it balance? Certainly, 10, 000 years ago, **the** civilization ’ s beginning, **the** human portion was less than one tenth of one percent. Let ’ s look at it now. You follow this curve and you see **the** whiter spot in **the** middle â that ’ s your 50- year time bubble. Humans, livestock and pets are now 97 percent of that integrated total mass on earth and all wild nature is three percent. We have won. **The** next generation doesn ’ t even have to worry about this game â it is over. And **the** biggest problem came in **the** last 25 years : it went from 25 percent up to that 97 percent. And this really is a sobering picture upon realizing that we, humans, are in charge of life on earth ; we ’ re like **the** capricious Gods of old Greek myths, kind of playing with life â and not a great deal of wisdom injected into it. Now, **the** third curve is information technology. This is Moore ’ s Law plotted here, which relates to density of information, but it has been pretty good for showing a lot of other things about information technology â **computers**, their use, Internet, etc. And what ’ s important is it just goes straight up through **the** top of **the** curve, and has no real limits to it. Now try and contrast these. This is **the** size of **the** earth going through that same â â frame. And to make it really clear, I ’ ve put all four on one graph. There ’ s no need to see **the** little detailed words on it. That first one is humans-versus-nature ; we ’ ve won, there ’ s no more gain. Human population. And so if you ’ re looking for growth industries to get into, that ’ s not a good one â protecting natural creatures. Human population is going up ; it ’ s going to continue for quite a while. Good business in obstetricians, morticians, and farming, housing, etc. â they all deal with human bodies, which require being fed, transported, housed and so on. And **the** information technology, which connects to our brains, has no limit â now, that is a wonderful field to be in. You ’ re looking for growth opportunity? It ’ s just going up through **the** roof. And then, **the** size of **the** Earth. Somehow making these all compatible with **the** Earth looks like a pretty bad industry to be involved with. So, that ’ s **the** stage out of all this. I find, for reasons I don ’ t understand, I really do have a goal. And **the** goal is that **the** world be desirable and sustainable when my kids reach my age â and I think that ’ s â in other words, **the** next generation. I think that ’ s a goal that we probably all share. I think it ’ s a hopeless goal. Technologically, it ’ s achievable ; economically, it ’ s achievable ; politically, it means sort of **the** habits, institutions of people â it ’ s impossible. **The** institutions of **the** past with all their inertia are just irrelevant for **the** future, except they ’ re there and we have to deal with them. I spend about 15 percent of my time trying to save **the** world, **the** other 85 percent, **the** usual â and whatever else we devote ourselves to. And in that 15 percent, **the** main focus is on human mind, thinking skills, somehow trying to unleash kids from **the** straightjacket of school, which is putting information and dogma into them, get them so they really think, ask tough questions, argue about serious subjects, don ’ t believe everything that ’ s in **the** book, think broadly or creative. They can be. Our school systems are very flawed and do not reward you for **the** things that are important in life or for **the** survival of civilization ; they reward you for a lot of learning and sopping up stuff. We can ’ t go into that today because there isn ’ t time â it ’ s a broad subject. One thing for sure, in **the** future there is an essential feature â necessary, but not sufficient â which is doing more with less. We ’ ve got to be doing things with more efficiency using less energy, less material. Your great-great grandparents got by on muscle power, and yet we all think there ’ s this huge power that ’ s essential for our lifestyle. And with all **the** wonderful technology we have we can do things that are much more efficient : conserve, recycle, etc. Let me just rush very quickly through things that we ’ ve done. Human-powered **airplane** â Gossamer Condor sort of started me in this direction in 1976 and 77, winning **the** Kremer prize in aviation history, followed by **the** Albatross. And we began making various odd planes and creatures. Here ’ s a giant flying replica of a pterosaur that has no tail. Trying to have it fly straight is like trying to shoot an arrow with **the** feathered end forward. It was a tough job, and boy it made me have a lot of respect for nature. This was **the** full size of **the** original creature. We did things on land, in **the** air, on water â vehicles of all different kinds, usually with some electronics or electric power systems in them. I find they ’ re all **the** same, whether its land, air or water. I ’ ll be focusing on **the** air here. This is a solar-powered **airplane** â 165 miles carrying a person from France to England as a symbol that solar power is going to be an important part of our future. Then we did **the** solar car for General Motors â **the** Sunracer â that won **the** race in Australia. We got a lot of people thinking about electric cars, what you could do with them. A few years later, when we suggested to GM that now is **the** time and we could do a thing called **the** Impact, they sponsored it, and here ’ s **the** Impact that we developed with them on their programs. This is **the** demonstrator. And they put huge effort into turning it into a commercial product. With that preamble, let ’ s show **the** first two-minute videotape, which shows a little **airplane** for surveillance and moving to a giant **airplane**. Narrator : A tiny **airplane**, **the** AV Pointer serves for surveillance â in effect, a pair of roving eyeglasses. A cutting-edge example of where miniaturization can lead if **the** operator is remote from **the** vehicle. It is convenient to carry, assemble and launch by hand. Battery-powered, it is silent and rarely noticed. It sends high-resolution video pictures back to **the** operator. With onboard GPS, it can navigate autonomously, and it is rugged enough to self-land without damage. **The** modern sailplane is superbly efficient. Some can glide as flat as 60 feet forward for every foot of descent. They are powered only by **the** energy they can extract from **the** atmosphere â an atmosphere nature stirs up by solar energy. Humans and soaring birds have found nature to be generous in providing replenishable energy. Sailplanes have flown over 1, 000 miles, and **the altitude** record is over 50, 000 feet. **The** Solar Challenger was made to serve as a symbol that photovoltaic cells can produce real power and will be part of **the** world ’ s energy future. In 1981, it flew 163 miles from Paris to England, solely on **the** power of sunbeams, and established a basis for **the** Pathfinder. **The** message from all these vehicles is that ideas and technology can be harnessed to produce remarkable gains in doing more with less â gains that can help us attain a desirable balance between technology and nature. **The** stakes are high as we speed toward a challenging future. Buckminster Fuller said it clearly :”there are no passengers on spaceship Earth, only crew. We, **the** crew, can and must do more with less â much less.”Paul MacCready : If we could have **the** second video, **the** one-minute, put in as quickly as you can, which â this will show **the** Pathfinder **airplane** in some flights this past year in Hawaii, and will show a sequence of some of **the** beauty behind it after it had just flown to 71, 530 feet â higher than any propeller **airplane** has ever flown. It ’ s amazing : just on **the** puny power of **the** sun â by having a super lightweight plane, you ’ re able to get it up there. It ’ s part of a long-term program NASA sponsored. And we worked very closely with **the** whole thing being a team effort, and with wonderful results like that flight. And we ’ re working on a bigger plane â 220-foot span â and an intermediate-size, one with a regenerative fuel cell that can store excess energy during **the** day, feed it back at night, and stay up 65, 000 feet for months at a time. Ray Morgan ’ s voice will come in here. There he ’ s **the** project manager. Anything they do is certainly a team effort. He ran this program. Here ’ s... some things he showed as a celebration at **the** very end. Ray Morgan : We ’ d just ended a seven-month deployment of Hawaii. For those who live on **the** mainland, it was tough being away from home. **The friendly** support, **the** quiet confidence, congenial hospitality shown by our Hawaiian and military hosts â this is starting â made **the** experience enjoyable and unforgettable. PM : We have real-time IR scans going out through **the** Internet while **the** plane is flying. And it ’ s exploring without **polluting the** stratosphere. That ’ s its goal : **the** stratosphere, **the** blanket that really controls **the** radiation of **the** earth and permits life on earth to be **the** success that it is â probing that is very important. And also we consider it as a sort of poor man ’ s stationary satellite, because it can stay right overhead for months at a time, 2, 000 times closer than **the** real GFC synchronous satellite. We couldn ’ t bring one here to fly it and show you. But now let ’ s look at **the** other end. In **the** video you saw that nine-pound or eight-pound Pointer **airplane** surveillance drone that Keenan has developed and just done a remarkable job. Where some have servos that have gotten down to, oh, 18 or 25 grams, his weigh **one-third** of a gram. And what he ’ s going to bring out here is a surveillance drone that weighs about 2 ounces â that includes **the** video camera, **the** batteries that run it, **the** telemetry, **the** receiver and so on. And we ’ ll fly it, we hope, with **the** same success that we had last night when we did **the** practice. So Matt Keenan, just any time you ’ re â all right â ready to let her go. But first, we ’ re going to make sure that it ’ s appearing on **the** screen, so you see what it sees. You can imagine yourself being a mouse or fly inside of it, looking out of its camera. Matt Keenan : It ’ s switched on. PM : But now we ’ re trying to get **the** video. There we go. MK : Can you bring up **the** house lights? PM : Yeah, **the** house lights and we ’ ll see you all better and be able to fly **the** plane better. MK : All right, we ’ ll try to do a few laps around and bring it back in. Here we go. PM : **The** video worked right for **the** first few and I don ’ t know why it â there it goes. Oh, that was only a minute, but I think you ’ d be safe to have that near **the** end of **the** flight, perhaps. We get to do **the** classic. All right. If this hits you, it will not hurt you. OK. Thank you very much. Thank you. But now, as they say in infomercials, we have something much better for you, which we ’ re working on : planes that are only six **inches** â 15 centimeters â in size. And Matt ’ s plane was on **the** cover of Popular Science last month, showing what this can lead to. And in a while, something this size will have GPS and a video camera in it. We ’ ve had one of these fly nine miles through **the** air at 35 miles an hour with just a little battery in it. But there ’ s a lot of technology going. There are just milestones along **the** way of some remarkable things. This one doesn ’ t have **the** video in it, but you get a little feel from what it can do. OK, here we go. MK : Sorry. OK. PM : If you can pass it down when you ’ re done. Yeah, I think â I lost a little orientation ; I looked up into this light. It hit **the** building. And **the** building was poorly placed, actually. But you ’ re beginning to see what can be done. We ’ re working on projects now â even wing-flapping things **the** size of hawk moths â DARPA contracts, working with Caltech, UCLA. Where all this leads, I don ’ t know. Is it practical? I don ’ t know. But like any basic research, when you ’ re really forced to do things that are way beyond existing technology, you can get there with micro-technology, nanotechnology. You can do amazing things when you realize what nature has been doing all along. As you get to these small scales, you realize we have a lot to learn from nature â not with 747s â but when you get down to **the** nature ’ s realm, nature has 200 million years of experience. It never makes a mistake. Because if you make a mistake, you don ’ t leave any progeny. We should have nothing but success stories from nature, for you or for birds, and we ’ re learning a lot from its fascinating subjects. In **concluding**, I want to get back to **the** big picture and I have just two final **slides** to try and put it in perspective. **The** first I ’ ll just read. At last, I put in three sentences and had it say what I wanted. Over billions of years on a unique **sphere**, chance has painted a thin covering of life â complex, improbable, wonderful and fragile. Suddenly, we humans â a recently arrived species, no longer subject to **the** checks and balances inherent in nature â have grown in population, technology and intelligence to a position of terrible power. We now wield **the** paintbrush. And that ' s serious : we ' re not very bright. We ' re short on wisdom ; we ' re high on technology. Where ' s it going to lead? Well, inspired by **the** sentences, I decided to wield **the** paintbrush. Every 25 years I do a picture. Here ' s **the** one â tries to show that **the** world isn ' t getting any bigger. Sort of a timeline, very non-linear scale, nature rates and trilobites and dinosaurs, and eventually we saw some humans with caves... Birds were flying overhead, after pterosaurs. And then we get to **the** civilization above **the** little TV set with a gun on it. Then traffic jams, and power systems, and some dots for digital. Where it ' s going to lead â I have no idea. And so I just put robotic and natural **cockroaches** out there, but you can fill in whatever you want. This is not a forecast. This is a warning, and we have to think seriously about it. And that time when this is happening is not 100 years or 500 years. Things are going on this decade, next decade ; it ' s a very short time that we have to decide what we are going to do. And if we can get some agreement on where we want **the** world to be â desirable, sustainable when your kids reach your age â I think we actually can reach it. Now, I said this was a warning, not a forecast. That was before â I painted this before we started in on making robotic versions of hawk moths and **cockroaches**, and now I ' m beginning to wonder seriously â was this more of a forecast than I wanted? I personally think **the** surviving intelligent life form on earth is not going to be carbon-based ; it ' s going to be silicon-based. And so where it all goes, I don ' t know. **The** one final bit of sparkle we ' ll put in at **the** very end here is an utterly impractical flight vehicle, which is a little ornithopter wing-flapping **device** that â rubber-band powered â that we ' ll show you. MK : 32 gram. Sorry, one gram. PM : Last night we gave it a few too many turns and it tried to bash **the** roof out also. It ' s about a gram. **The** tube there ' s hollow, about paper-thin. And if this lands on you, I assure you it will not hurt you. But if you reach out to grab it or hold it, you will destroy it. So, be gentle, just act like a wooden Indian or something. And when it comes down â and we ' ll see how it goes. We consider this to be sort of **the** spirit of TED. And you wonder, is it practical? And it turns out if I had not been â Unfortunately, we have some light bulb changes. We can probably get it down, but it ' s possible it ' s gone up to a greater destiny up there â â than it ever had. And I wanted to make â just â But I want to make just two points. One is, you think it ' s frivolous ; there ' s nothing to it. And yet if I had not been making ornithopters like that, a little bit **cruder**, in 1939 â a long, long time ago â there wouldn ' t have been a Gossamer Condor, there wouldn ' t have been an Albatross, a Solar Challenger, there wouldn ' t be an Impact car, there wouldn ' t be a mandate on zero-emission vehicles in California. A lot of these things â or similar â would have happened some time, probably a decade later. I didn ' t realize at **the** time I was doing inquiry-based, hands-on things with teams, like they ' re trying to get in education systems. So I think that, as a symbol, it ' s important. And I believe that also is important. You can think of it as a sort of a symbol for **learning** and TED that somehow gets you thinking of technology and nature, and puts it all together in things that are â that make this conference, I think, more important than any that ' s taken place in this country in this decade. Thank you.

Text Sample 16: POS Dim 1 – 1998 – Score 15.00 – 1998/t000250.txt

As a clergyman, you can imagine how out of place I feel. I feel like a **fish** out of water, or maybe an owl out of **the** air. I was preaching in San Jose some time ago, and my friend Mark Kvamme, who helped introduce me to this conference, brought several CEOs and leaders of some of **the** companies here in **the** Silicon Valley to have breakfast with me, or I with them. And I was so stimulated. And had such — it was an eye-opening experience to hear them talk about **the** world that is yet to come through technology and science. I know that we ' re near **the** end of this conference, and some of you may be wondering why they have a speaker from **the** field of religion. Richard can answer that, because he made that decision. But some years ago I was on an elevator in Philadelphia, coming down. I was to address a conference at a hotel. And on that elevator a man said,"I hear Billy Graham is staying in this hotel."And another man looked in my direction and said,"Yes, there he is. He ' s on this elevator with us."And this man looked me up and down for about 10 seconds, and he said,"My, what an anticlimax!"I hope that you won ' t feel that these few moments with me is not a — is an anticlimax, after all these tremendous talks that you ' ve heard, and addresses, which I intend to listen to every one of them. But I was on an **airplane** in **the** east some years ago, and **the** man sitting across **the** aisle from me was **the** mayor of Charlotte, North Carolina. His name was John Belk. Some of you will probably know him. And there was a drunk man on there, and he got up out of his seat two or three times, and he was making everybody upset by what he was trying to do. And he was slapping **the** stewardess and pinching her as she went by, and everybody was upset with him. And finally, John Belk said,"Do you know who ' s sitting here?"And **the** man said,"No, who?"He said,"It ' s Billy Graham, **the** preacher."He said,"You don ' t say!"And he turned to me, and he said,"Put her there!"He said,"Your sermons have certainly helped me."And I suppose that that ' s true with thousands of people. I know that as you have been peering into **the** future, and as we ' ve heard some of it here tonight, I would like to live in that age and see what is going to be. But I won ' t, because I ' m 80 years old. This is my eightieth year, and I know that my time is brief. I have phlebitis at **the** moment, in both legs, and that ' s **the** reason that I had to have a little help in getting up here, because I have Parkinson ' s disease in addition to that, and some other problems that I won ' t talk about. But this is not **the** first time that we ' ve had a technological revolution. We ' ve had others. And there ' s one that I want to talk about. In one generation, **the** nation of **the** people of Israel had a tremendous and dramatic change that made them a great power in **the** Near East. A man by **the** name of David came to **the** throne, and King David became one of **the** great leaders of his generation. He was a man of tremendous leadership. He had **the** favor of God with him. He was a brilliant poet, philosopher, writer, soldier — with strategies in battle and conflict that people study even today. But about two centuries before David, **the** Hittites had discovered **the** secret of smelting and processing of **iron**, and, slowly, that skill spread. But they wouldn ' t allow **the** Israelis to look into it, or to have any. But David changed all of that, and he introduced **the** Iron Age to Israel. And **the** Bible says that David laid up great stores of **iron**, and which archaeologists have found, that in present-day Palestine, there are evidences of that generation. Now, instead of **crude** tools made of sticks and stones, Israel now had **iron** plows, and sickles, and hoes and military weapons. And in **the** course of one generation, Israel was completely changed. **The** introduction of **iron**, in some ways, had an impact a little bit like **the** microchip has had on our generation. And David found that there were many problems that technology could not solve. There were many problems still left. And they ' re still with us, and you haven ' t solved them, and I haven ' t heard anybody here speak to that.

How do we solve these three problems that I ’ d like to mention? **The** first one that David saw was human evil. Where does it come from? How do we solve it? Over again and again in **the** Psalms, which Gladstone said was **the** greatest book in **the** world, David describes **the** evils of **the** human race. And yet he says,”He restores my soul.”Have you ever thought about what a contradiction we are? On one hand, we can probe **the** deepest secrets of **the universe** and dramatically push back **the** frontiers of technology, as this conference vividly demonstrates. We ’ ve seen under **the sea**, three miles down, or galaxies hundreds of billions of years out in **the** future. But on **the** other hand, something is wrong. Our battleships, our soldiers, are on a frontier now, almost ready to go to war with Iraq. Now, what causes this? Why do we have these wars in every generation, and in every part of **the** world? And revolutions? We can ’ t get along with other people, even in our own families. We find ourselves in **the** paralyzing grip of self-destructive habits we can ’ t break. Racism and injustice and violence sweep our world, bringing a tragic harvest of heartache and death. Even **the** most sophisticated among us seem powerless to break this cycle. I would like to see Oracle take up that, or some other technological geniuses work on this. How do we change man, so that he doesn ’ t lie and cheat, and our newspapers are not filled with stories of fraud in business or labor or athletics or wherever? **The** Bible says **the** problem is within us, within our hearts and our souls. Our problem is that we are separated from our Creator, which we call God, and we need to have our souls restored, something only God can do. Jesus said,”For out of **the** heart come evil thoughts : murders, sexual immorality, theft, false testimonies, slander.”**The** British philosopher Bertrand Russell was not a religious man, but he said,”It ’ s in our hearts that **the** evil lies, and it ’ s from our hearts that it must be plucked out.”Albert Einstein — I was just talking to someone, when I was speaking at Princeton, and I met Mr. Einstein. He didn ’ t have a doctor ’ s degree, because he said nobody was qualified to give him one. But he made this statement. He said,”It ’ s easier to denature plutonium than to denature **the** evil spirit of man.”And many of you, I ’ m sure, have thought about that and puzzled over it. You ’ ve seen people take beneficial technological advances, such as **the** Internet we ’ ve heard about tonight, and twist them into something corrupting. You ’ ve seen brilliant people **devise computer** viruses that bring down whole systems. **The** Oklahoma City bombing was simple technology, horribly used. **The** problem is not technology. **The** problem is **the** person or persons using it. King David said that he knew **the** depths of his own soul. He couldn ’ t free himself from personal problems and personal evils that included murder and adultery. Yet King David sought God ’ s forgiveness, and said,”You can restore my soul.”You see, **the** Bible teaches that we ’ re more than a body and a mind. We are a soul. And there ’ s something inside of us that is beyond our understanding. That ’ s **the** part of us that yearns for God, or something more than we find in technology. Your soul is that part of you that yearns for meaning in life, and which seeks for something beyond this life. It ’ s **the** part of you that yearns, really, for God. I find [that] young people all over **the** world are **searching** for something. They don ’ t know what it is. I speak at many universities, and I have many questions and answer periods, and whether it ’ s Cambridge, or Harvard, or Oxford — I ’ ve spoken at all of those universities. I ’ m going to Harvard in about three or four — no, it ’ s about two months from now — to give a **lecture**. And I ’ ll be asked **the** same questions that I was asked **the** last few times I ’ ve been there. And it ’ ll be on these questions : where did I come from? Why am I here? Where am I going? What ’ s life all about? Why am I here? Even if you have no religious belief, there are times when you wonder that there ’ s something else. Thomas Edison also said,”When you see everything that happens in **the** world of science, and in **the** working of **the universe**, you cannot deny that there ’ s a captain on **the** bridge.”I remember once, I sat beside Mrs. Gorbachev at a White House dinner. I went to Ambassador Dobrynin, whom I knew very well. And I ’ d been to Russia several times under **the** Communists, and they ’ d given me marvelous freedom that I didn ’ t expect. And I knew Mr. Dobrynin very well, and I said,”I ’ m going to sit beside Mrs. Gorbachev tonight. What shall I talk to her about?”And he surprised me with **the** answer. He said,”Talk to her about religion and philosophy. That ’ s what she ’ s really interested in.”I was a little bit surprised, but that evening that ’ s what we talked about, and it was a stimulating conversation. And afterward, she said,”You know, I ’ m an atheist, but I know that there ’ s something up there higher than we are.”**The** second problem that King David realized he could not solve was **the** problem of human suffering. Writing **the** oldest book in **the** world was Job, and he said,”Man is born unto trouble as **the** sparks fly upward.”Yes, to be sure, science has done much to push back certain types of human suffering. But I ’ m — in a few months, I ’ ll be 80 years of age. I admit that I ’ m very grateful for all **the** medical advances that have kept me in relatively good health all these years. My doctors at **the** Mayo Clinic urged me not to take this trip out here to this — to be here. I haven ’ t given a talk in nearly four months. And when you speak as much as I do, three or four times a day, you get rusty. That ’ s **the** reason I ’ m using this podium and using these notes. Every time you ever hear me on **the** television or somewhere, I ’ m ad-libbing. I ’ m not reading. I never read an address. I never read a speech or a talk or a **lecture**. I talk ad lib. But tonight, I ’ ve got some notes here so that if I begin to forget, which I do sometimes, I ’ ve got something I can turn to. But even here among us, most — in **the** most advanced society in **the** world, we have poverty. We have families that self-destruct, friends that betray us. Unbearable psychological pressures bear down on us. I ’ ve never met a person in **the** world that didn ’ t have a problem or a worry. Why do we suffer? It ’ s an age- old question that we haven ’ t answered. Yet David again and again said that he would turn to God. He said,”**The** Lord is my shepherd.”**The** final problem that David knew he could not solve was death. Many commentators have said that death is **the** forbidden subject of our generation. Most people live as if they ’ re never going to die. Technology projects **the** myth of control over our mortality. We see people on our screens. Marilyn Monroe is just as beautiful on **the** screen as she was in person, and our — many young people think she ’ s still alive. They don ’ t know that she ’ s dead. Or Clark Gable, or whoever it is. **The** old stars, they come to life. And they ’ re — they ’ re just as great on that screen as they were in person. But death is inevitable. I spoke some time ago to a joint session of Congress, last year. And we were meeting in that room, **the** statue room. About 300 of them were there. And I said,”There ’ s one thing that we have in common in this room, all of us together, whether Republican or Democrat, or whoever.”I said,”We ’ re all going to die. And we have that in common with all these great men of **the** past that are staring down at us.”And it ’ s often difficult for young people to understand that. It ’ s difficult for them to understand that they ’ re going to die. As **the** ancient writer of Ecclesiastes wrote, he said, there ’ s every activity under heaven. There ’ s a time to be born, and there ’ s a time to die. I ’ ve stood at **the** deathbed of several **famous** people, whom you would know. I ’ ve talked to them. I ’ ve seen them in those agonizing moments when they were scared to death. And yet, a few years earlier, death never crossed their mind. I talked to a woman this past week whose father was a **famous** doctor. She said he never thought of God, never talked about God, didn ’ t believe in God. He was an atheist. But she said, as he came to die, he sat up on **the** side of **the** bed one day, and he asked **the** nurse if he could see **the** chaplain. And he said, for **the** first time in his life he ’ d thought about **the** inevitable, and about God. Was there a God? A few years ago, a university student asked me,”What is **the** greatest surprise in your life?”And I said,”**The** greatest surprise in my life is **the** brevity of life. It passes so fast.”But it does not need to have to be that way. Wernher von Braun, in **the** aftermath of World War II **concluded**, quote :”science and religion are not antagonists. On **the** contrary, they ’ re sisters.”He put it on a personal basis. I knew Dr. von Braun very well. And he said,”Speaking for myself, I can only say that **the** grandeur of **the** cosmos serves only to confirm a belief in **the** certainty of a creator.”He also said,”In our **search** to know God, I ’ ve come to believe that **the** life of Jesus Christ should be **the** focus of our efforts and inspiration. **The** reality of this life and His resurrection is **the** hope of mankind.”I ’ ve done a lot of speaking in Germany and in France, and in different parts of **the** world — 105 countries it ’ s been my privilege to speak in. And I was invited one day to visit Chancellor Adenauer, who was looked upon as sort of **the** founder of modern Germany, since **the** war. And he once — and he said to me, he said,”Young man.”He said,”Do you believe in **the** resurrection of Jesus Christ?”And I said,”Sir, I do.”He said,”So do I.”He said,”When I leave office, I ’ m going to spend my time writing a book on why Jesus Christ rose again, and why it ’ s so important to believe that.”In one of his plays, Alexander Solzhenitsyn depicts a man dying, who says to those gathered around his bed,”**The** moment when it ’ s terrible to feel regret is when one is dying.”How should one live in order not to feel regret when one is dying? Blaise Pascal asked exactly that question in seventeenth-century France. Pascal has been called **the** architect of modern civilization. He was a brilliant scientist at **the** frontiers of mathematics, even as a teenager. He is viewed by many as **the** founder of **the probability** theory, and a creator of **the** first model of a **computer**. And of course, you are all familiar with **the computer** language named for him. Pascal explored in depth our human dilemmas of evil, suffering and death. He was astounded at **the** phenomenon we ’ ve been considering : that people can achieve extraordinary heights in science, **the** arts and human enterprise, yet they also are full of anger, hypocrisy and have — and self- hatreds. Pascal saw us as a remarkable mixture of genius and self-delusion. On November 23, 1654, Pascal had a profound religious experience. He wrote in his journal these words :”I submit myself, absolutely, to Jesus Christ, my redeemer.”A French historian said, two centuries later,”Seldom has so mighty an intellect submitted with such humility to **the** authority of Jesus Christ.”Pascal came to believe not only **the** love and **the** grace of God could bring us back into harmony, but he believed that his own sins and failures could be forgiven, and that when he died he would go to a place called heaven. He experienced it in a way that went beyond scientific observation and reason. It was he who penned **the** well-known words,”**The** heart has its reasons, which reason knows not of.”Equally well known is Pascal ’ s Wager. Essentially, he said this :”if you bet on God, and open yourself to his love, you lose nothing, even if you ’ re wrong. But if instead you bet that there is no God, then you can lose it all, in this life and **the** life to come.”For Pascal, scientific knowledge paled beside **the** knowledge of God. **The** knowledge of God was far beyond anything that ever crossed his mind. He was ready to face him when he died at **the** age of 39. King David lived to be 70, a long time in his era. Yet he too had to face death, and he wrote these words :”even though I walk through **the** valley of **the** shadow of death, I will fear no evil, for you are with me.”This was David ’ s answer to three dilemmas of evil, suffering and death. It can be yours, as well, as you seek **the** living God and allow him to fill your life and give you hope for **the** future. When I was 17 years of age, I was born and reared on a farm in North Carolina. I milked cows every morning, and I had to milk **the** same cows every evening when I came home from school. And there were 20 of them that I had — that I was responsible for, and I worked on **the** farm and tried to keep up with my studies. I didn ’ t make good grades in high school. I didn ’ t make them in college, until something happened in my heart. One day, I was faced face-to-face with Christ. He said,”I am **the** way, **the** truth and **the** life.”Can you imagine that?”I am **the** truth. I ’ m **the** embodiment of all truth.”He was a liar. Or he was insane. Or he was what he claimed to be. Which was he? I had to make that decision. I couldn ’ t prove it. I couldn ’ t take it to a laboratory and experiment with it. But by faith I said, I believe him, and he came into my heart and changed my life. And now I ’ m ready, when I hear that call, to go into **the** presence of God. Thank you, and God bless all of you. Thank you for **the** privilege. It was great. Richard Wurman : You did it. Thanks.

Text Sample 17: POS Dim 1 – 2002 – Score 27.00 – 2002/t000368.txt

The advances that have taken place in astronomy, cosmology and **biology**, in **the** last 10 years, are really extraordinary â to **the** point where we know more about our **universe** and how it works than many of you might imagine. But there was something else that I ’ ve noticed as those changes were taking place, as people were starting to find out that hmm... yeah, there really is a black hole at **the** center of every galaxy. **The** science writers and editors â I shouldn ’ t say science writers, I should say people who write about science â and editors would sit down over a couple of beers, after a hard day of work, and start talking about some of these incredible perceptions about how **the** **universe** works. And they would inevitably end up in what I thought was a very bizarre place, which is ways **the** world could end very suddenly. And that ’ s what I want to talk about today. Ah, you laugh, you fools. Yeah, we need **the** time! Stephen Petranek : At first, it all seemed a little fantastical to me, but after challenging a lot of these ideas, I began to take a lot of them seriously. And then September 11 happened, and I thought, ah, God, I can ’ t go to **the** TED conference and talk about how **the** world is going to end. Nobody wants to hear that. Not after this! And that got me into a discussion with some other people, other scientists, about maybe some other subjects, and one of **the** guys I talked to, who was a neuroscientist, said,”You know, I think there are a lot of solutions to **the** problems you brought up,”and reminds me of Michael ’ s talk yesterday and his mother saying you can ’ t have a solution if you don ’ t have a problem. So, we went out looking for solutions to ways that **the** world might end tomorrow, and lo and behold, we found them. Which leads me to a videotape of a President Bush press conference from a couple of weeks ago. Can we run that, Andrew? President George W. Bush : Whatever it costs to defend our security, and whatever it costs to defend our freedom, we must pay it. SP : I agree with **the** president. He wants two trillion dollars to protect us from **terrorists** next year, a two-trillion-dollar federal budget, which will land us back into deficit spending real fast. But **terrorists** aren ’ t **the** only threat we face. There are really serious calamities staring us in **the** eye that we ’ re in **the** same kind of denial about that we were about terrorism, and what could ’ ve happened on September 11. I would propose, therefore, that if we took 10 billion dollars from that 2. 13 trillion dollar budget â which is two one hundredths of that budget â and we doled out a billion dollars to each one of these problems I ’ m going to talk to you about, **the** vast majority could be solved, and **the** rest we could deal with. So, I hope you find this both fascinating â I ’ m fascinated by this kind of stuff, I gotta admit â to me these are Richard ’ s **cockroaches**. But I also hope, because I think **the** people in this room can literally change **the** world, I hope you take some of this stuff away with you, and when you have an opportunity to be influential, that you try to get some heavy-duty money spent on some of these ideas. So let ' s start. Number 10 : we lose **the** will to survive. We live in an incredible age of modern medicine. We are all much healthier than we were 20 years ago. People around **the** world are getting better medicine â but mentally, we ' re falling apart. **The** World Health Organization now estimates that one out of five people on **the planet** is clinically depressed. And **the** World Health Organization also says that depression is **the** biggest epidemic that humankind has ever faced. Soon, genetic breakthroughs and even better medicine are going to allow us to think of 100 as a normal lifespan. A female child born tomorrow, on average â median â will live to age 83. Our life longevity is going up almost a year for every year that passes. Now **the** problem with all of this, getting older, is that people over 65 are **the** most likely people to commit suicide. So, what are **the** solutions? We don ' t really have mental health insurance in this country, and it ' s â â it ' s really a crime. Something like 98 percent of all people with depression, and I mean really severe depression â I have a friend with stunningly severe depression â this is a curable disease, with present medicine and present technology. But it is often a combination of talk therapy and pills. Pills alone don ' t do it, especially in clinically depressed people. You ought to be able to go to a psychiatrist or a psychologist, and put down your 10-dollar copay, and get treated, just like you do when you got a cut on your arm. It ' s ridiculous. Secondly, drug companies are not going to develop really sophisticated psychoactive drugs. We know that most mental illnesses have a biological component that can be dealt with. And we know just an amazing amount more about **the** brain now than we did 10 years ago. We need a pump-push from **the** federal government, through NIH and National Science â NSF â and places like that to start helping **the** drug companies develop some advanced psychoactive drugs. Moving on. Number nine â don ' t laugh â aliens invade Earth. Ten years ago, you couldn ' t have found an astronomer â well, very few astronomers â in **the** world who would ' ve told you that there are any **planets** anywhere outside our solar system. 1995, we found three. **The** count now is up to 80 â we ' re finding about two or three a month. All of **the** ones we ' ve found, by **the** way, are in this little, teeny, tiny corner where we live, in **the** Milky Way. There must be millions of **planets** in **the** Milky Way, and as Carl Sagan insisted for many years, and was laughed at for it, there must be billions and billions in **the universe**. In a few years, NASA is going to launch four or five telescopes out to Jupiter, where there ' s less dust, and start looking for Earth-like **planets**, which we cannot see with present technology, nor **detect**. It ' s becoming obvious that **the** chance that life does not exist elsewhere in **the universe**, and probably fairly close to us, is a fairly remote idea. And **the** chance that some of it isn ' t more intelligent than ours is also a remote idea. Remember, we ' ve only been an advanced civilization â an industrial civilization, if you would â for 200 years. Although every time I go to Pompeii, I ' m amazed that they had **the** equivalent of a McDonald ' s on every street corner, too. So, I don ' t know how much civilization really has progressed since AD 79, but there ' s a great likelihood. I really believe this, and I don ' t believe in aliens, and I don ' t believe there are any aliens on **the** Earth or anything like that. But there ' s a likelihood that we will confront a civilization that is more intelligent than our own. Now, what will happen? What if they come to, you know, suck up our oceans for **the** hydrogen? And swat us away like flies, **the** way we swat away flies when we go into **the** rainforest and start logging it. We can look at our own history. **The** late physicist Gerard O ' Neill said,"Advanced Western civilization has had a destructive effect on all primitive civilizations it has come in contact with, even in those cases where every attempt was made to protect and guard **the** primitive civilization."If **the** aliens come visiting, we ' re **the** primitive civilization. So, what are **the** solutions to this? Thank God you can all read! It may seem ridiculous, but we have a really lousy history of anticipating things like this and actually being prepared for them. How much energy and money does it take to actually have a plan to negotiate with an advanced species? Secondly â and you ' re going to hear more from me about this â we have to become an outward-looking, space-faring nation. We have got to develop **the** idea that **the** Earth doesn ' t last forever, our sun doesn ' t last forever. If we want humanity to last forever, we have to colonize **the** Milky Way. And that is not something that is beyond comprehension at this point. It ' ll also help us a lot, if we meet an advanced civilization along **the** way, if we ' re trying to be an advanced civilization. Number eight â SP : You ' ve got it! You ' ve got **the** job. Number eight : **the** ecosystem collapses. Last July, in Science, **the** journal Science, 19 oceanographers published a very, very unusual article. It wasn ' t really a research report ; it was a screed. They said, we ' ve been looking at **the** oceans for a long time now, and we want to tell you they ' re not in trouble, they ' re near collapse. Many other ecosystems on Earth are in real, real danger. We ' re living in a time of mass extinctions that exceeds **the fossil** record by a factor of 10, 000. We have lost 25 percent of **the** unique species in Hawaii in **the** last 20 years. California is expected to lose 25 percent of its species in **the** next 40 years. Somewhere in **the** Amazon forest is **the** marginal tree. You cut down that tree, **the** rain forest collapses as an ecosystem. There ' s really a tree like that out there. That ' s really what it comes to. And when that ecosystem collapses, it could take a major ecosystem with it, like our atmosphere. So, what do we do about this? What are **the** solutions? There is some modeling of ecosystems going on now. **The** problem with ecosystems is that we understand them so poorly, that we don ' t know they ' re really in trouble until it ' s almost too late. We need to know earlier that they ' re getting in trouble, and we need to be able to pump possible solutions into models. And with **the** kind of computing power we have now, there is, as I say, some of this going on, but it needs money. National Science Foundation needs to say â you know, almost all **the** money that ' s spent on science in this country comes from **the** federal government, one way or another. And they get to prioritize, you know? There are people at **the** National Science Foundation who get to say, this is **the** most important thing. This is one of **the** things they ought to be thinking more about. Secondly, we need to create huge biodiversity reserves on **the planet**, and start moving them around. There ' s been an experiment for **the** last four or five years on **the** Georges Bank, or **the** Grand Banks off of Newfoundland. It ' s a no-take **fishing** zone. They can ' t **fish** there for a radius of 200 miles. And an amazing thing has happened : almost all **the fish** have come back, and they ' re reproducing like crazy. We ' re going to have to start doing this around **the** globe. We ' re going to have to have no-take zones. We ' re going to have to say, no more logging in **the** Amazon for 20 years. Let it recover, before we start logging again. Number seven : particle accelerator mishap. You all remember Ted Kaczynski, **the** Unabomber? One of **the** things he raved about was that a particle accelerator experiment could go haywire and set off a chain reaction that would destroy **the** world. A lot of very sober-minded physicists, believe it or not, have had exactly **the** same thought. This **spring** â there ' s a collider at Brookhaven, on Long Island â this **spring**, it ' s going to have an experiment in which it creates black holes. They are expecting to create little, tiny black holes. They expect them to evaporate. I hope they ' re right. Other collider experiments â there ' s one that ' s going to take place next summer at CERN â have **the** possibility of creating something called strangelets, which are kind of like antimatter. Whenever they hit other matter, they destroy it and obliterate it. Most physicists say that **the** accelerators we have now are not really powerful enough to create black holes and strangelets that we need to worry about, and they ’ re probably right. But, all around **the** world, in Japan, in Canada, there ’ s talk about this, of reviving this in **the** United States. We shut one down that was going to be big. But there ’ s talk of building very big accelerators. What can we do about this? What are **the** solutions? We ’ ve got **the** fox watching **the** henhouse here. We need to â we need **the** advice of particle physicists to talk about particle physics and what should be done in particle physics, but we need some outside thinking and watchdogging of what ’ s going on with these experiments. Secondly, we have a natural laboratory surrounding **the** Earth. We have an electromagnetic field around **the** Earth, and it ’ s constantly bombarded by high- energy particles, like protons. And in my opinion, we don ’ t spend enough time looking at that natural laboratory and figuring out first what ’ s safe to do on Earth. Number six : biotech disaster. It ’ s one of my favorite ones, because we ’ ve done several stories on Bt corn. Bt corn is a corn that creates its own pesticide to kill a corn borer. You may of heard of it â heard it called StarLink, especially when all those taco shells were taken out of **the supermarkets** about a year and a half ago. This stuff was supposed to only be feed for animals in **the** United States, and it got into **the** human food supply, and somebody should ’ ve figured out that it would get in **the** human food supply very easily. But **the** thing that ’ s alarming is a couple of months ago, in Mexico, where Bt corn and all genetically altered corn is totally illegal, they found Bt corn genes in wild corn plants. Now, corn originated, we think, in Mexico. This is **the** genetic biodiversity storehouse of corn. This brings back a skepticism that has gone away recently, that superweeds and superpests could spread around **the** world, from biotechnology, that literally could destroy **the** world ’ s food supply in very short order. So, what do we do about that? We treat biotechnology with **the** same scrutiny we apply to nuclear power plants. It ’ s that simple. This is an amazingly unregulated field. When **the** StarLink disaster happened, there was a battle between **the** EPA and **the** FDA over who really had authority, and over what parts of this, and they didn ’ t get it straightened out for months. That ’ s kind of crazy. Number five, one of my favorites : reversal of **the** Earth ’ s magnetic field. Believe it or not, this happens every few hundred thousand years, and has happened many times in our history. North Pole goes to **the** South, South Pole goes to **the** North, and vice versa. But what happens, as this **occurs**, is that we lose our magnetic field around **the** Earth over **the** period of about 100 years, and that means that all these cosmic rays and particles that are to come streaming at us from **the** sun, that this field protects us from, are â well, basically, we ’ re gonna fry. SP : So, what can we do about this? Oh, by **the** way, we ’ re overdue. It ’ s been 780, 000 years since this happened. So, it should have happened about 480, 000 years ago. Oh, and here ’ s one other thing. Scientists think now our magnetic field may be diminished by about five percent. So, maybe we ’ re in **the** throes of it. One of **the** problems of trying to figure out how healthy **the** Earth is, is that we have â you know, we don ’ t have good weather data from 60 years ago, much less data on things like **the** ozone layer. So, there ’ s a fairly simple solution to this. There ’ s going to be a lot of cheap rocketry that ’ s going to come online in about six or seven years that gets us into **the** low atmosphere very cheaply. You know, we can make ozone from car tailpipes. It ’ s not hard : it ’ s just three oxygen atoms. If you brought **the** entire ozone layer down to **the surface** of **the** Earth, it would be **the** thickness of two pennies, at 14 **pounds** per square **inch**. You don ’ t need that much up there. We need to learn how to repair and replenish **the** Earth ’ s ozone layer. Number four

: giant solar flares. Solar flares are enormous magnetic outbursts from **the** Sun that bombard **the** Earth with high-speed subatomic particles. So far, our atmosphere has done, and our magnetic field has done pretty well protecting us from this. Occasionally, we get a flare from **the** Sun that causes havoc with communications and so forth, and electricity. But **the** alarming thing is that astronomers recently have been studying stars that are similar to our Sun, and they ' ve found that a number of them, when they ' re about **the** age of our Sun, brighten by a factor of as much as 20. Doesn ' t last for very long. And they think these are super-flares, millions of times more powerful than any flares we ' ve had from our Sun so far. Obviously, we don ' t want one of those. There ' s a flip side to it. In studying stars like our Sun, we ' ve found that they go through periods of diminishment, when their total amount of energy that ' s expelled from them goes down by maybe one percent. One percent doesn ' t sound like a lot, but it would cause one hell of an ice age here. So, what can we do about this? Start terraforming Mars. This is one of my favorite subjects. I wrote a story about this in Life magazine in 1993. This is rocket science, but it ' s not hard rocket science. Everything that we need to make an atmosphere on Mars, and to make a livable **planet** on Mars, is probably there. And you just, literally, have to send little nuclear factories up there that gobble up **the iron** oxide on **the surface** of Mars and spit out **the** oxygen. **The** problem is it takes 300 years to terraform Mars, minimum. Really more like 500 years to do it right. There ' s no reason why we shouldn ' t start now. Number three â isn ' t this stuff cool? A new global epidemic. People have been at war with germs ever since there have been people, and from time to time, **the** germs sure get **the** upper hand. In 1918, we had a flu epidemic in **the** United States that killed 20 million people. That was back when **the** population was around 100 million people. **The** bubonic plague in Europe, in **the** Middle Ages, killed one out of four Europeans. AIDS is coming back. Ebola seems to be rearing its head with much too much **frequency**, and old diseases like cholera are becoming resistant to antibiotics. We ' ve all learned what â **the** kind of panic that can **occur** when an old disease rears its head, like anthrax. **The** worst possibility is that a very simple germ, like staph, for which we have one antibiotic that still works, mutates. And we know staph can do amazing things. A staph cell can be next to a muscle cell in your body and borrow genes from it when antibiotics come, and change and mutate. **The** danger is that some germ like staph will be â will mutate into something that ' s really virulent, very contagious, and will sweep through populations before we can do anything about it. That ' s happened before. About 12, 000 years ago, there was a massive wave of mammal extinctions in **the** Americas, and that is thought to have been a virulent disease. So, what can we do about it? It is nuts. We give antibiotics â â every cow, every lamb, every chicken, they get antibiotics every day, all. You know, you go to a restaurant, you eat **fish**, I got news for you, it ' s all farmed. You know, you gotta ask when you go to a restaurant if it ' s a wild **fish**, cause they ' re not going to tell you. We ' re giving away **the** code. This is like being at war and giving somebody your secret code. We ' re telling **the** germs out there how to fight us. We gotta fix that. We gotta outlaw that right away. Secondly, our public health system, as we saw with anthrax, is a real disaster. We have a real, major outbreak of disease in **the** United States, we are not prepared to cope with it. Now, there is money in **the** federal budget, next year, to build up **the** public health service. But I don ' t think to any extent that it really needs to be done. Number two â my favorite â we meet a rogue black hole. You know, 10 years ago, or 15 years ago, really, you walk into an astronomy convention, and you say,"You know, there ' s probably a black hole at **the** center of every galaxy,"and they ' re going to hoot you off **the** stage. And now, if you went into one of those conventions and you said,”Well, I don ’ t think black holes are out there,”they ’ d hoot you off **the** stage. Our comprehension of **the** way **the universe** works is really â has just gained unbelievably in recent years. We think that there are about 10 million dead stars in **the** Milky Way alone, our galaxy. And these stars have compressed down to maybe something like 12, 15 miles wide, and they are black holes. And they are gobbling up everything around them, including light, which is why we can ’ t see them. Most of them should be in orbit around something. But galaxies are very violent places, and things can be spun out of orbit. And also, space is incredibly vast. So even if you flung a million of these things out of orbit, **the** chances that one would actually hit us is fairly remote. But it only has to get close, about a billion miles away, one of these things. About a billion miles away, here ’ s what happens to Earth ’ s orbit : it becomes elliptical instead of circular. And for three months out of **the** year, **the surface** temperatures go up to 150 to 180. For three months out of **the** year, they go to 50 below zero. That won ’ t work too well. What can we do about this? And this is my scariest. I don ’ t have a good answer for this one. Again, we gotta think about being a colonizing race. And finally, number one : biggest danger to life as we know it, I think, a really big **asteroid** heads for Earth. **The** important thing to remember here â this is not a question of if, this is a question of when, and how big. In 1908, just a 200-foot piece of a comet exploded over Siberia and flattened forests for maybe 100 miles. It had **the** effect of about 1, 000 Hiroshima bombs. Astronomers estimate that little **asteroids** like that come about every hundred years. In 1989, a large **asteroid** passed 400, 000 miles away from Earth. Nothing to worry about, right? It passed directly through Earth ’ s orbit. We were in that that spot six hours earlier. A small **asteroid**, say a half mile wide, would touch off firestorms followed by severe global cooling from **the** debris kicked up â Carl Sagan ’ s nuclear winter thing. An **asteroid** five miles wide causes major extinctions. We think **the** one that got **the** dinosaurs was about five miles wide. Where are they? There ’ s something called **the** Kuiper belt, which â some people think Pluto ’ s not a **planet**, that ’ s where Pluto is, it ’ s in **the** Kuiper belt. There ’ s also something a little farther out, called **the** Oort cloud. There are about 100, 000 balls of ice and **rock** â comets, really â out there, that are 50 miles in **diameter** or more, and they regularly take a little spin, in towards **the** Sun and pass reasonably close to us. Of more concern, I think, is **the asteroids** that exist between Mars and Jupiter. **The** folks at **the** Sloan Digital Sky Survey told us last fall â they ’ re making **the** first map of **the universe**, three-dimensional map of **the universe** â that there are probably 700, 000 **asteroids** between Mars and Jupiter that are a half a mile big or bigger. So you say, yeah, well, what are really **the** chances of this happening? Andrew, can you put that chart up? This is a chart that Dr. Clark Chapman at **the** Southwest Research Institute presented to Congress a few years ago. You ’ ll notice that **the** chance of an asteroid-slash-comet impact killing you is about one in 20, 000, according to **the** work they ’ ve done. Now look at **the** one right below that. Passenger aircraft crash, one in 20, 000. We spend an awful lot of money trying to be sure that we don ’ t die in **airplane** accidents, and we ’ re not spending hardly anything on this. And yet, this is completely preventable. We finally have, just in **the** last year, **the** technology to stop this cold. Could we have **the** solutions? NASA ’ s spending three million dollars a year, three million **bucks** â that is like **pocket** change â to **search** for **asteroids**. Because we can actually figure out every **asteroid** that ’ s out there, and if it might hit Earth, and when it might hit Earth. And they ’ re trying to do that. But it ’ s going to take them 10 years, at spending three million dollars a year, and even then, they claim they ’ ll only have about 80 percent of them catalogued. Comets are a tougher act.

We don ’ t really have **the** technology to predict comet trajectories, or when one with our name on it might arrive. But we would have lots of time, if we see it coming. We really need a dedicated observatory. You ’ ll notice that a lot of comets are named after people you never heard of, **amateur** astronomers? That ’ s because nobody ’ s looking for them, except **amateurs**. We need a dedicated observatory that looks for comets. Part two of **the** solutions : we need to figure out how to blow up an **asteroid**, or alter its trajectory. Now, a year ago, we did an amazing thing. We sent a probe out to this **asteroid** belt, called NEAR, Near Earth **Asteroid** Rendezvous. And these guys orbited a 30 â or no, about a 22-mile long **asteroid** called Eros. And then, of course, you know, they pulled one of those sneaky NASA things, where they had extra batteries and extra gas aboard and everything, and then, at **the** last minute, they landed. When **the** mission was over, they actually landed on **the** thing. We have landed a rocket ship on an **asteroid**. It ’ s not a big deal. Now, **the** trouble with just sending a bomb out for this thing is that you don ’ t have anything to push against in space, because there ’ s no air. A nuclear **explosion** is just as hot, but we don ’ t really have anything big enough to melt a 22-mile long **asteroid**, or vaporize it, would be more like it. But we can learn to land on these **asteroids** that have our name on them and put something like a small ion propulsion motor on it, which would gently, slowly, after a period of time, push it into a different trajectory, which, if we ’ ve done our math right, would keep it from hitting Earth. This is just a matter of finding ’ em, going there, and doing something about it. I know your head is spinning from all this stuff. Yikes! So many big threats! **The** thing, I think, to remember, is September 11. We don ’ t want to get caught flat-footed again. We know about this stuff. Science has **the** power to predict **the** future in many cases now. Knowledge is power. **The** worst thing we can do is say, jeez, I got enough to worry about without worrying about an **asteroid**. That ’ s a mistake that could literally cost us our future. Thank you.

Text Sample 18: POS Dim 1 – 2002 – Score 21.00 – 2002/t000165.txt

I ’ ll just start talking about **the** 17th century. I hope nobody finds that offensive. I â you know, when I â after I had invented PCR, I kind of needed a change. And I moved down to La Jolla and learned how to **surf**. And I started living down there on **the** beach for a long time. And when surfers are out waiting for waves, you probably wonder, if you ’ ve never been out there, what are they doing? You know, sometimes there ’ s a 10-, 15-minute break out there when you ’ re waiting for a wave to come in. They usually talk about **the** 17th century. You know, they get a real bad rap in **the** world. People think they ’ re sort of lowbrows. One day, somebody suggested I read this book. It was called â it was called”**The** Air Pump,”or something like”**The** Leviathan and **The** Air Pump.”It was a real weird book about **the** 17th century. And I realized, **the** roots of **the** way I sort of thought was just **the** only natural way to think about things. That â you know, I was born thinking about things that way, and I had always been like a little scientist guy. And when I went to find out something, I used scientific methods. I wasn ’ t real surprised, you know, when they first told me how â how you were supposed to do science, because I ’ d already been doing it for fun and whatever. But it didn ’ t â it never **occurred** to me that it had to be invented and that it had been invented only 350 years ago. You know, it was â like it happened in England, and Germany, and Italy sort of all at **the** same time. And **the** story of that, I thought, was really fascinating. So I ’ m going to talk a little bit about that, and what exactly is it that scientists are supposed to do. And it ’ s, it ’ s a kind of â You know, Charles I got beheaded somewhere early in **the** 17th century. And **the** English set up Cromwell and a whole bunch of Republicans or whatever, and not **the** kind of Republicans we had. They changed **the** government, and it didn ’ t work. And Charles II, **the** son, was finally put back on **the** throne of England. He was really nervous, because his dad had been, you know, beheaded for being **the** King of England And he was nervous about **the** fact that conversations that got going in, like, bars and stuff would turn to â this is kind of â it ’ s hard to believe, but people in **the** 17th century in England were starting to talk about, you know, philosophy and stuff in bars. They didn ’ t have TV screens, and they didn ’ t have any football games to watch. And they would get really pissy, and all of a sudden people would **spill** out into **the** street and fight about issues like whether or not it was **okay** if Robert Boyle made a **device** called **the** vacuum pump. Now, Boyle was a friend of Charles II. He was a Christian guy during **the** weekends, but during **the** week he was a scientist. Which was â back then it was sort of, you know, well, you know â if you made this thing â he made this little **device**, like kind of like a bicycle pump in reverse that could suck all **the** air out of â you know what a bell jar is? One of these things, you pick it up, put it down, and it ’ s got a **seal**, and you can see inside of it, so you can see what ’ s going on inside this thing. But what he was trying to do was to pump all **the** air out of there, and see what would happen inside there. I mean, **the** first â I think one of **the** first experiments he did was he put a bird in there. And people in **the** 17th century, they didn ’ t really understand **the** same way we do about you know, this stuff is a bunch of different kinds of molecules, and we breathe it in for a purpose and all that. I mean, **fish** don ’ t know much about water, and people didn ’ t know much about air. But both started exploring it. One thing, he put a bird in there, and he pumped all **the** air out, and **the** bird died. So he said, hmm... He said â he called what he ’ d done as making â they didn ’ t call it a vacuum pump at **the** time. Now you call it a vacuum pump ; he called it a vacuum. Right? And immediately, he got into trouble with **the** local clergy who said, you can ’ t make a vacuum. Ah, uh â Aristotle said that nature abhors one. I think it was a poor translation, probably, but people relied on authorities like that. And you know, Boyle says, well, shit. I make them all **the** time. I mean, whatever that is that kills **the** bird â and I ’ m calling it a vacuum. And **the** religious people said that if God wanted you to make â I mean, God is everywhere, that was one of their rules, is God is everywhere. And a vacuum â there ’ s nothing in a vacuum, so you ’ ve â God couldn ’ t be in there. So therefore **the** church said that you can ’ t make a vacuum, you know. And Boyle said, bullshit. I mean, you want to call it Godless, you know, you call it Godless. But that ’ s not my job. I ’ m not into that. I do that on **the** weekend. And like â what I ’ m trying to do is figure out what happens when you suck everything out of a compartment. And he did all these cute little experiments. Like he did one with â he had a little wheel, like a fan, that was sort of loosely attached, so it could spin by itself. He had another fan opposed to it that he had like a â I mean, **the** way I would have done this would be, like, a rubber band, and, you know, around a tinker toy kind of fan. I know exactly how he did it ; I ’ ve seen **the** drawings. It ’ s two fans, one which he could turn from outside after he got **the** vacuum established, and he discovered that if he pulled all **the** air out of it, **the** one fan would no longer turn **the** other one, right? Something was missing, you know. I mean, these are â it ’ s kind of weird to think that someone had to do an experiment to show that, but that was what was going on at **the** time. And like, there was big arguments about it in **the** â you know, **the** gin houses and in **the** coffee shops and stuff. And Charles started not liking that. Charles II was kind of saying, you know, you should keep that â let ' s make a place where you can do this stuff where people don ' t get so â you know, we don ' t want **the** â we don ' t want to get **the** people mad at me again. And so â because when they started talking about religion and science and stuff like that, that ' s when it had sort of gotten his father in trouble. And so, Charles said, I ' m going to put up **the** money give you guys a building, come here and you can meet in **the** building, but just don ' t talk about religion in there. And that was fine with Boyle. He said, OK, we ' re going to start having these meetings. And anybody who wants to do science is â this is about **the** time that Isaac Newton was starting to whip out a lot of really interesting things. And there was all kind of people that would come to **the** Royal Society, they called it. You had to be dressed up pretty well. It wasn ' t like a TED conference. That was **the** only criteria, was that you be â you looked like a gentleman, and they ' d let anybody could come. You didn ' t have to be a member then. And so, they would come in and you would do â Anybody that was going to show an experiment, which was kind of a new word at **the** time, demonstrate some principle, they had to do it on stage, where everybody could see it. So they were â **the** really important part of this was, you were not supposed to talk about final causes, for instance. And God was out of **the** picture. **The** actual nature of reality was not at issue. You ' re not supposed to talk about **the** absolute nature of anything. You were not supposed to talk about anything that you couldn ' t demonstrate. So if somebody could see it, you could say, here ' s how **the** machine works, here ' s what we do, and then here ' s what happens. And seeing what happens, it was OK to generalize, and say, I ' m sure that this will happen anytime we make one of these things. And so you can start making up some rules. You say, anytime you have a vacuum state, you will discover that one wheel will not turn another one, if **the** only connection between them is whatever was there before **the** vacuum. That kind of thing. Candles can ' t burn in a vacuum, therefore, probably sparklers wouldn ' t either. It ' s not clear ; actually sparklers will, but they didn ' t know that. They didn ' t have sparklers. But, they â â you can make up rules, but they have to relate only to **the** things that you ' ve been able to demonstrate. And most **the** demonstrations had to do with visuals. Like if you do an experiment on stage, and nobody can see it, they can just hear it, they would probably think you were freaky. I mean, reality is what you can see. That wasn ' t an explicit rule in **the** meeting, but I ' m sure that was part of it, you know. If people hear voices, and they can ' t see and associate it with somebody, that person ' s probably not there. But **the** general idea that you could only â you could only really talk about things in that place that had some kind of experimental basis. It didn ' t matter what Thomas Hobbes, who was a local philosopher, said about it, you know, because you weren ' t going to be talking final causes. What ' s happening here, in **the** middle of **the** 17th century, was that what became my field â science, experimental science â was pulling itself away, and it was in a physical way, because we ' re going to do it in this room over here, but it was also what â it was an amazing thing that happened. Science had been all interlocked with theology, and philosophy, and â and â and mathematics, which is really not science. But experimental science had been tied up with all those things. And **the** mathematics part and **the** experimental science part was pulling away from philosophy. And â things â we never looked back. It ' s been so cool since then. I mean, it just â it just â untangled a thing that was really impeding technology from being developed. And, I mean, everybody in this room â now, this is 350 short years ago. Remember, that ' s a short time. It was 300, 000, probably, years ago that most of us, **the** ancestors of most of us in this room came up out of Africa and turned to **the left**. You know, **the** ones that turned to **the** right, there are some of those in **the** Japanese translation. But that happened very â a long time ago compared to 350 short years ago. But in that 350 years, **the** place has just undergone a lot of changes. In fact, everybody in this room probably, especially if you picked up your bag â some of you, I know, didn ' t pick up your bags â but if you picked up your bag, everybody in this room has got in their **pocket**, or back in their room, something that 350 years ago, kings would have gone to war to have. I mean, if you can think how important â If you have a GPS system and there are no satellites, it ' s not going to be much use. But, like â but, you know, if somebody had a GPS system in **the** 17th century some king would have gotten together an army and gone to get it, you know. If that person â Audience : For **the** teddy bear? **The** teddy bear? Kary Mullis : They might have done it for **the** teddy bear, yeah. But â all of us own stuff. I mean, individuals own things that kings would have definitely gone to war to get. And this is just 350 years. Not a whole lot of people doing this stuff. You know, **the** important people â you can almost read about their lives, about all **the** really important people that made advances, you know. And, I mean â this kind of stuff, you know, all this stuff came from that separation of this little sort of thing that we do â now I, when I was a boy was born sort of with this idea that if you want to know something â you know, maybe it ' s because my old man was gone a lot, and my mother didn ' t really know much science, but I thought if you want to know something about stuff, you do it â you make an experiment, you know. You get â you get, like â I just had a natural feeling for science and setting up experiments. I thought that was **the** way everybody had always thought. I thought that anybody with any brains will do it that way. It isn ' t true. I mean, there ' s a lot of people â You know, I was one of those scientists that was â got into trouble **the** other night at dinner because of **the** post-modernism thing. And I didn ' t mean, you know â where is that lady? Audience : Here. KM : I mean, I didn ' t really think of that as an argument so much as just a lively discussion. I didn ' t take it personally, but â I just â I had â I naively had thought, until this surfing experience started me into **the** 17th century, I ' d thought that ' s just **the** way people thought, and everybody did, and they recognized reality by what they could see or touch or feel or hear. At any rate, when I was a boy, I, like, for instance, I had this â I got this little book from Fort Sill, Oklahoma â This is about **the** time that George Dyson ' s dad was starting to blow nuclear â thinking about blowing up nuclear rockets and stuff. I was thinking about making my own little rockets. And I knew that frogs â little frogs â had aspirations of space travel, just like people. And I â I was looking for a â a propulsion system that would like, make a rocket, like, maybe about four feet high go up a couple of miles. And, I mean, that was my sort of goal. I wanted it to go out of sight and then I wanted this little parachute to come back with **the** frog in it. And â I â I â I got this book from Fort Sill, Oklahoma, where there ' s a missile base. They send it out for **amateur** rocketeers, and it said in there do not ever heat a mixture of potassium perchlorate and sugar. You know, that ' s what you call a lead. You sort of â now you say, well, let ' s see if I can get hold of some potassium chlorate and sugar, perchlorate and sugar, and heat it ; it would be interesting to see what it is they don ' t want me to do, and what it is going to â and how is it going to work. And we didn ' t have â like, my mother presided over **the** back yard from an upstairs window, where she would be **ironing** or something like that. And she was usually just sort of keeping an eye on, and if there was any puffs of smoke out there, she ' d lean out and admonish us all not to blow our eyes out. That was her â You know, that was kind of **the** worst thing that could happen to us. That ' s why I thought, as long as I don ' t blow my eyes out... I may not care about **the** fact that it ’ s prohibited from heating this solution. I ’ m going to do it carefully, but I ’ ll do it. It ’ s like anything else that ’ s prohibited : you do it behind **the** garage. So, I went to **the** drug store and I tried to buy some potassium perchlorate and it wasn ’ t unreasonable then for a kid to walk into a drug store and buy chemicals. Nowadays, it ’ s no ma ’ am, check your shoes. And like â But then it wasn ’ t â they didn ’ t have any, but **the** guy had â I said, what kind of salts of potassium do you have? You know. And he had potassium nitrate. And I said, that might do **the** same thing, whatever it is. I ’ m sure it ’ s got to do with rockets or it wouldn ’ t be in that manual. And so I â I did some experiments. You know, I started off with little tiny amounts of potassium nitrate and sugar, which was readily available, and I mixed it in different proportions, and I tried to light it on fire. Just to see what would happen, if you mixed it together. And it â they burned. It burned kind of slow, but it made a nice smell, compared to other rocket fuels I had tried, that all had sulfur in them. And, it smelt like burnt candy. And then I tried **the** melting business, and I melted it. And then it melted into a little sort of syrupy liquid, brown. And then it cooled down to a brick-hard substance, that when you lit that, it went off like a bat. I mean, **the** little bowl of that stuff that had cooled down â you ’ d light it, and it would just start dancing around **the** yard. And I said, there is a way to get a frog up to where he wants to go. So I started developing â you know, George ’ s dad had a lot of help. I just had my brother. But I â it took me about â it took me about, I ’ d say, six months to finally figure out all **the** little things. There ’ s a lot of little things involved in making a rocket that it will actually work, even after you have **the** fuel. But you do it, by â what I justâ you know, you do experiments, and you write down things sometimes, you make observations, you know. And then you slowly build up a theory of how this stuff works. And it was â I was following all **the** rules. I didn ’ t know what **the** rules were, I ’ m a natural born scientist, I guess, or some kind of a throwback to **the** 17th century, whatever. But at any rate, we finally did have a **device** that would reproduceably put a frog out of sight and get him back alive. And we had not â I mean, we weren ’ t frightened by it. We should have been, because it made a lot of smoke and it made a lot of noise, and it was powerful, you know. And once in a while, they would blow up. But I wasn ’ t worried, by **the** way, about, you know, **the explosion** causing **the** destruction of **the planet**. I hadn ’ t heard about **the** 10 ways that we should be afraid of **the** â By **the** way, I could have thought, I ’ d better not do this because they say not to, you know. And I ’ d better get permission from **the** government. If I ’ d have waited around for that, I would have never â **the** frog would have died, you know. At any rate, I bring it up because it ’ s a good story, and he said, tell personal things, you know, and that ’ s a personal â I was going to tell you about **the** first night that I met my wife, but that would be too personal, wouldn ’ t it. So, so I ’ ve got something else that ’ s not personal. But that... process is what I think of as science, see, where you start with some idea, and then instead of, like, looking up, every authority that you ’ ve ever heard of I â sometimes you do that, if you ’ re going to write a paper later, you want to figure out who else has worked on it. But in **the** actual process, you get an idea â like, when I got **the** idea one night that I could amplify DNA with two oligonucleotides, and I could make lots of **copies** of some little piece of DNA, you know, **the** thinking for that was about 20 minutes while I was driving my car, and then instead of going â I went back and I did talk to people about it, but if I ’ d listened to what I heard from all my friends who were molecular biologists â I would have abandoned it. You know, if I had gone back looking for an authority figure who could tell me if it would work or not, he would have said, no, it probably won ’ t. Because **the** results of it were so spectacular that if it worked it was going to change everybody ’ s goddamn way of doing molecular **biology**. Nobody wants a chemist to come in and poke around in their stuff like that and change things. But if you go to authority, and you always don ’ t â you don ’ t always get **the** right answer, see. But I knew, you ’ d go into **the** lab and you ’ d try to make it work yourself. And then you ’ re **the** authority, and you can say, I know it works, because right there in that tube is where it happened, and here, on this gel, there ’ s a little band there that I know that ’ s DNA, and that ’ s **the** DNA I wanted to amplify, so there! So it does work. You know, that ’ s how you do science. And then you say, well, what can make it work better? And then you figure out better and better ways to do it. But you always work from, from like, facts that you have made available to you by doing experiments : things that you could do on a stage. And no tricky shit behind **the** thing. I mean, it ’ s all â you ’ ve got to be very honest with what you ’ re doing if it really is going to work. I mean, you can ’ t make up results, and then do another experiment based on that one. So you have to be honest. And I ’ m basically honest. I have a fairly bad memory, and dishonesty would always get me in trouble, if I, like â so I ’ ve just sort of been naturally honest and naturally inquisitive, and that sort of leads to that kind of science. Now, let ’ s see... I ’ ve got another five minutes, right? OK. All scientists aren ’ t like that. You know â and there is a lot â There is a lot â a lot has been going on since Isaac Newton and all that stuff happened. One of **the** things that happened right around World War II in that same time period before, and as sure as hell afterwards, government got â realized that scientists aren ’ t strange dudes that, you know, hide in ivory towers and do ridiculous things with test tube. Scientists, you know, made World War II as we know it quite possible. They made faster things. They made bigger guns to shoot them down with. You know, they made drugs to give **the** pilots if they were broken up in **the** process. They made all kinds of â and then finally one giant bomb to end **the** whole thing, right? And everybody stepped back a little and said, you know, we ought to invest in this shit, because whoever has got **the** most of these people working in **the** places is going to have a dominant position, at least in **the** military, and probably in all kind of economic ways. And they got involved in it, and **the** scientific and industrial establishment was born, and out of that came a lot of scientists who were in there for **the** money, you know, because it was suddenly available. And they weren ’ t **the** curious little boys that liked to put frogs up in **the** air. They were **the** same people that later went in to medical school, you know, because there was money in it, you know. I mean, later, then they all got into business â I mean, there are waves of â going into your high school, person saying, you want to be rich, you know, be a scientist. You know, not anymore. You want to be rich, you be a businessman. But a lot of people got in it for **the** money and **the** power and **the** travel. That ’ s back when travel was easy. And those people don ’ t think â they don ’ t â they don ’ t always tell you **the** truth, you know. There is nothing in their contract, in fact, that makes it to their advantage always, to tell you **the** truth. And **the** people I ’ m talking about are people that like â they say that they ’ re a member of **the** committee called, say, **the** Inter- Governmental Panel on Climate Change. And they â and they have these big meetings where they try to figure out how we ’ re going to â how we ’ re going to continually prove that **the planet** is getting warmer, when that ’ s actually contrary to most people ’ s sensations. I mean, if you actually measure **the** temperature over a period â I mean, **the** temperature has been measured now pretty carefully for about 50, 60 years â longer than that it ’ s been measured, but in really nice, precise ways, and records have been kept for 50 or 60 years, and in fact, **the** temperature hadn ’ t really gone up. It ’ s like, **the** average temperature has gone up a tiny little bit, because **the** nighttime temperatures at **the** weather stations have come up just a little bit. But there ' s a good explanation for that. And it ' s that **the** weather stations are all built outside of town, where **the** airport was, and now **the** town ' s moved out there, there ' s concrete all around and they call it **the** skyline effect. And most responsible people that measure temperatures realize you have to shield your measuring **device** from that. And even then, you know, because **the** buildings get warm in **the** daytime, and they keep it a little warmer at night. So **the** temperature has been, sort of, **inching** up. It should have been. But not a lot. Not like, you know â **the** first guy â **the** first guy that got **the** idea that we ' re going to fry ourselves here, actually, he didn ' t think of it that way. His name was Sven Arrhenius. He was Swedish, and he said, if you double **the** CO2 level in **the** atmosphere, which he thought might â this is in 1900 â **the** temperature ought to go up about 5. 5 degrees, he **calculated**. He was thinking of **the** earth as, kind of like, you know, like a completely insulated thing with no stuff in it, really, just energy coming down, energy leaving. And so he came up with this theory, and he said, this will be cool, because it ' ll be a longer growing season in Sweden, you know, and **the** surfers liked it, **the** surfers thought, that ' s a cool idea, because it ' s pretty cold in **the** ocean sometimes, and â but a lot of other people later on started thinking it would be bad, you know. But nobody actually demonstrated it, right? I mean, **the** temperature as measured â and you can find this on our wonderful Internet, you just go and look for all NASAs records, and all **the** Weather Bureau ' s records, and you ' ll look at it yourself, and you ' ll see, **the** temperature has just â **the** nighttime temperature measured on **the surface** of **the planet** has gone up a tiny little bit. So if you just average that and **the** daytime temperature, it looks like it went up about. 7 degrees in this century. But in fact, it was just coming up â it was **the** nighttime ; **the** daytime temperatures didn ' t go up. So â and Arrhenius ' theory â and all **the** global warmers think â they would say, yeah, it should go up in **the** daytime, too, if it ' s **the greenhouse** effect. Now, people like things that have, like, names like that, that they can envision it, right? I mean â but people don ' t like things like this, so â most â I mean, you don ' t get all excited about things like **the** actual evidence, you know, which would be evidence for strengthening of **the** tropical circulation in **the** 1990s. It ' s a paper that came out in February, and most of you probably hadn ' t heard about it."Evidence for Large Decadal Variability in **the** Tropical Mean Radiative Energy Budget."Excuse me. Those papers were published by NASA, and some scientists at Columbia, and Viliki and a whole bunch of people, Princeton. And those two papers came out in Science Magazine, February **the** first, and these â **the** conclusion in both of these papers, and in also **the** Science editor ' s, like, descriptions of these papers, for, you know, for **the** quickie, is that our theories about global warming are completely wrong. I mean, what these guys were doing, and this is what â **the** NASA people have been saying this for a long time. They say, if you measure **the** temperature of **the** atmosphere, it isn ' t going up â it ' s not going up at all. We ' ve doing it very carefully now for 20 years, from satellites, and it isn ' t going up. And in this paper, they show something much more striking, and that was that they did what they call a radiation â and I ' m not going to go into **the** details of it, actually it ' s quite complicated, but it isn ' t as complicated as they might make you think it is by **the** words they use in those papers. If you really get down to it, they say, **the** sun puts out a certain amount of energy â we know how much that is â it falls on **the** earth, **the** earth gives back a certain amount. When it gets warm it generates â it makes redder energy â I mean, like infra-red, like something that ' s warm gives off infra-red. **The** whole business of **the** global warming â trash, really, is that â if **the** â if there ' s too much CO2 in **the** atmosphere, **the** heat that ' s trying to escape won ' t be able to get out. But **the** heat coming from **the** sun, which is mostly down in **the** â it ' s like 350 nanometers, which is where it ' s centered â that goes right through CO2. So you still get heated, but you don ' t dissipate any. Well, these guys measured all of those things. I mean, you can talk about that stuff, and you can write these large reports, and you can get government money to do it, but these â they actually measured it, and it turns out that in **the** last 10 years â that ' s why they say"decadal"there â that **the** energy â that **the** level of what they call"imbalance"has been way **the** hell over what was expected. Like, **the** amount of imbalance â meaning, heat ' s coming in and it ' s not going out that you would get from having double **the** CO2, which we ' re not anywhere near that, by **the** way. But if we did, in 2025 or something, have double **the** CO2 as we had in 1900, they say it would be increase **the** energy budget by about â in other words, one watt per square centimeter more would be coming in than going out. So **the planet** should get warmer. Well, they found out in this study â these two studies by two different teams â that five and a half watts per square meter had been coming in from 1998, 1999, and **the** place didn ' t get warmer. So **the** theory ' s kaput â it ' s nothing. These papers should have been called,"**The** End to **the** Global Warming Fiasco,"you know. They ' re concerned, and you can tell they have very guarded conclusions in these papers, because they ' re talking about big laboratories that are funded by lots of money and by scared people. You know, if they said, you know what? There isn ' t a problem with global warming any longer, so we can â you know, they ' re funding. And if you start a grant request with something like that, and say, global warming obviously hadn ' t happened... if they â if they â if they actually â if they actually said that, I ' m getting out. I ' ll stand up too, and â They have to say that. They had to be very cautious. But what I ' m saying is, you can be delighted, because **the** editor of Science, who is no dummy, and both of these fairly professional â really professional teams, have really come to **the** same conclusion and in **the** bottom lines in their papers they have to say, what this means is, that what we ' ve been thinking, was **the** global circulation model that we predict that **the** earth is going to get overheated that it ' s all wrong. It ' s wrong by a large factor. It ' s not by a small one. They just â they just misinterpreted **the** fact that **the** earth â there ' s obviously some mechanisms going on that nobody knew about, because **the** heat ' s coming in and it isn ' t getting warmer. So **the planet** is a pretty amazing thing, you know, it ' s big and horrible â and big and wonderful, and it does all kinds of things we don ' t know anything about. So I mean, **the** reason I put those things all together, OK, here ' s **the** way you ' re supposed to do science â some science is done for other reasons, and just curiosity. And there ' s a lot of things like global warming, and ozone hole and you know, a whole bunch of scientific public issues, that if you ' re interested in them, then you have to get down **the** details, and read **the** papers called,"Large Decadal Variability in **the**..."You have to figure out what all those words mean. And if you just listen to **the** guys who are hyping those issues, and making a lot of money out of it, you ' ll be misinformed, and you ' ll be worrying about **the** wrong things. Remember **the** 10 things that are going to get you. **The** â one of them â And **the asteroids** is **the** one I really agree with there. I mean, you ' ve got to watch out for **asteroids**. OK, thank you for having me here.

Text Sample 19: POS Dim 1 – 2002 – Score 21.00 – 2002/t000269.txt

Welcome. If I could have **the** first **slide**, please? Contrary to calculations made by some engineers, bees can fly, dolphins can swim, and geckos can even climb up **the** smoothest **surfaces**. Now, what I want to do, in **the** short time I have, is to try to allow each of you to experience **the** thrill of revealing nature ' s design. I get to do this all **the** time, and it ' s just incredible. I want to try to share just a little bit of that with you in this presentation. **The** challenge of looking at nature ' s designs — and I ' ll tell you **the** way that we perceive it, and **the** way we ' ve used it. **The** challenge, of course, is to answer this question : what permits this extraordinary performance of animals that allows them basically to go anywhere? And if we could figure that out, how can we implement those designs? Well, many biologists will tell engineers, and others, organisms have millions of years to get it right ; they ' re spectacular ; they can do everything wonderfully well. So, **the** answer is bio-mimicry : just **copy** nature directly. We know from working on animals that **the** truth is that ' s exactly what you don ' t want to do — because **evolution** works on **the** just-good-enough principle, not on a perfecting principle. And **the** constraints in building any organism, when you look at it, are really severe. Natural technologies have incredible constraints. Think about it. If you were an engineer and I told you that you had to build an automobile, but it had to start off to be this big, then it had to grow to be full size and had to work every step along **the** way. Or think about **the** fact that if you build an automobile, I ' ll tell you that you also — inside it — have to put a factory that allows you to make another automobile. And you can absolutely never, absolutely never, because of history and **the** inherited plan, start with a clean slate. So, organisms have this important history. Really **evolution** works more like a tinkerer than an engineer. And this is really important when you begin to look at animals. Instead, we believe you need to be inspired by **biology**. You need to discover **the** general principles of nature, and then use these analogies when they ' re advantageous. This is a real challenge to do this, because animals, when you start to really look inside them — how they work — appear hopelessly complex. There ' s no detailed history of **the** design plans, you can ' t go look it up anywhere. They have way too many motions for their joints, too many muscles. Even **the** simplest animal we think of, something like an insect, and they have more neurons and connections than you can imagine. How can you make sense of this? Well, we believed — and we hypothesized — that one way animals could work simply, is if **the** control of their movements tended to be built into their bodies themselves. What we discovered was that two-, four-, six- and eight-legged animals all produce **the** same forces on **the** ground when they move. They all work like this kangaroo, they bounce. And they can be modeled by a spring-mass system that we call **the spring** mass system because we ' re biomechanists. It ' s actually a pogo stick. They all produce **the** pattern of a pogo stick. How is that true? Well, a human, one of your legs works like two legs of a trotting dog, or works like three legs, together as one, of a trotting insect, or four legs as one of a trotting **crab**. And then they alternate in their propulsion, but **the** patterns are all **the** same. Almost every organism we ' ve looked at this way — you ' ll see next week, I ' ll give you a hint, there ' ll be an article coming out that says that really big things like T. rex probably couldn ' t do this, but you ' ll see that next week. Now, what ' s interesting is **the** animals, then — we said — bounce along **the** vertical plane this way, and in our collaborations with Pixar, in"A Bug ' s Life,"we discussed **the** bipedal nature of **the** characters of **the** ants. And we told them, of course, they move in another plane as well. And they asked us this question. They say,"Why model just in **the** sagittal plane or **the** vertical plane, when you ' re telling us these animals are moving in **the** **horizontal** plane?"This is a good question. Nobody in **biology** ever modeled it this way. We took their advice and we modeled **the** animals moving in **the horizontal** plane as well. We took their three legs, we collapsed them down as one. We got some of **the** best mathematicians in **the** world from Princeton to work on this problem. And we were able to create a model where animals are not only bouncing up and down, but they ’ re also bouncing side to side at **the** same time. And many organisms fit this kind of pattern. Now, why is this important to have this model? Because it ’ s very interesting. When you take this model and you perturb it, you give it a push, as it bumps into something, it self-stabilizes, with no brain or no reflexes, just by **the** structure alone. It ’ s a beautiful model. Let ’ s look at **the** mathematics. That ’ s enough! **The** animals, when you look at them running, appear to be self-stabilizing like this, using basically springy legs. That is, **the** legs can do computations on their own ; **the** control algorithms, in a sense, are embedded in **the** form of **the** animal itself. Why haven ’ t we been more inspired by nature and these kinds of discoveries? Well, I would argue that human technologies are really different from natural technologies, at least they have been so far. Think about **the** typical kind of robot that you see. Human technologies have tended to be large, flat, with right angles, stiff, made of metal. They have rolling **devices** and axles. There are very few motors, very few sensors. Whereas nature tends to be small, and curved, and it bends and twists, and has legs instead, and appendages, and has many muscles and many, many sensors. So it ’ s a very different design. However, what ’ s changing, what ’ s really exciting — and I ’ ll show you some of that next — is that as human technology takes on more of **the** characteristics of nature, then nature really can become a much more useful teacher. And here ’ s one example that ’ s really exciting. This is a collaboration we have with Stanford. And they developed this new **technique**, called Shape Deposition Manufacturing. It ’ s a **technique** where they can mix materials together and mold any shape that they like, and put in **the** material properties. They can embed sensors and actuators right in **the** form itself. For example, here ’ s a leg : **the** clear part is stiff, **the** white part is compliant, and you don ’ t need any axles there or anything. It just bends by itself beautifully. So, you can put those properties in. It inspired them to show off this design by producing a little robot they named Sprawl. Our work has also inspired another robot, a biologically inspired bouncing robot, from **the** University of Michigan and McGill named RHex, for robot hexapod, and this one ’ s autonomous. Let ’ s go to **the** video, and let me show you some of these animals moving and then some of **the** simple robots that have been inspired by our discoveries. Here ’ s what some of you did this morning, although you did it outside, not on a treadmill. Here ’ s what we do. This is a death ’ s head **cockroach**. This is an American **cockroach** you think you don ’ t have in your kitchen. This is an eight-legged scorpion, six-legged ant, forty-four-legged centipede. Now, I said all these animals are sort of working like pogo sticks — they ’ re bouncing along as they move. And you can see that in this ghost **crab**, from **the** beaches of Panama and North Carolina. It goes up to four meters per second when it runs. It actually leaps into **the** air, and has aerial phases when it does it, like a horse, and you ’ ll see it ’ s bouncing here. What we discovered is whether you look at **the** leg of a human like Richard, or a **cockroach**, or a **crab**, or a kangaroo, **the relative** leg stiffness of that **spring** is **the** same for everything we ’ ve seen so far. Now, what good are springy legs then? What can they do? Well, we wanted to see if they allowed **the** animals to have greater stability and maneuverability. So, we built a terrain that had obstacles three times **the** hip height of **the** animals that we ’ re looking at. And we were certain they couldn ’ t do this. And here ’ s what they did. **The** animal ran over it and it didn ’ t even slow down! It didn ’ t decrease its preferred speed at all. We couldn ’ t believe that it could do this.

It said to us that if you could build a robot with very simple, springy legs, you could make it as maneuverable as any that ’ s ever been built. Here ’ s **the** first example of that. This is **the** Stanford Shape Deposition Manufactured robot, named Sprawl. It has six legs — there are **the** tuned, springy legs. It moves in a gait that an insect uses, and here it is going on **the** treadmill. Now, what ’ s important about this robot, compared to other robots, is that it can ’ t see anything, it can ’ t feel anything, it doesn ’ t have a brain, yet it can maneuver over these obstacles without any difficulty whatsoever. It ’ s this **technique** of building **the** properties into **the** form. This is a graduate student. This is what he ’ s doing to his thesis project — very robust, if a graduate student does that to his thesis project. This is from McGill and University of Michigan. This is **the** RHex, making its first outing in a demo. Same principle : it only has six moving parts, six motors, but it has springy, tuned legs. It moves in **the** gait of **the** insect. It has **the** middle leg moving in synchrony with **the** front, and **the** hind leg on **the** other side. Sort of an alternating tripod, and they can negotiate obstacles just like **the** animal. Robert Full : It ’ ll go on different **surfaces** — here ’ s sand — although we haven ’ t perfected **the** feet yet, but I ’ ll talk about that later. Here ’ s RHex entering **the** woods. Again, this robot can ’ t see anything, it can ’ t feel anything, it has no brain. It ’ s just working with a tuned mechanical system, with very simple parts, but inspired from **the** fundamental dynamics of **the** animal. RF : Here ’ s it going down a pathway. I presented this to **the** jet propulsion lab at NASA, and they said that they had no ability to go down craters to look for ice, and life, ultimately, on Mars. And he said — especially with legged-robots, because they ’ re way too complicated. Nothing can do that. And I talk next. I showed them this video with **the** simple design of RHex here. And just to convince them we should go to Mars in 2011, I tinted **the** video orange just to give them **the** sense of being on Mars. Another reason why animals have extraordinary performance, and can go anywhere, is because they have an effective interaction with **the** environment. **The** animal I ’ m going to show you, that we studied to look at this, is **the** gecko. We have one here and notice its position. It ’ s holding on. Now I ’ m going to challenge you. I ’ m going show you a video. One of **the** animals is going to be running on **the** level, and **the** other one ’ s going to be running up a wall. Which one ’ s which? They ’ re going at a meter a second. How many think **the** one on **the** **left** is running up **the** wall? **Okay**. **The** point is it ’ s really hard to tell, isn ’ t it? It ’ s incredible, we looked at students do this and they couldn ’ t tell. They can run up a wall at a meter a second, 15 steps per second, and they look like they ’ re running on **the** level. How do they do this? It ’ s just phenomenal. **The** one on **the** right was going up **the** hill. How do they do this? They have bizarre toes. They have toes that uncurl like party favors when you blow them out, and then peel off **the surface**, like tape. Like if we had a piece of tape now, we ’ d peel it this way. They do this with their toes. It ’ s bizarre! This peeling inspired iRobot — that we work with — to build Mecho-Geckos. Here ’ s a legged version and a tractor version, or a bulldozer version. Let ’ s see some of **the** geckos move with some video, and then I ’ ll show you a little bit of a **clip** of **the** robots. Here ’ s **the** gecko running up a vertical **surface**. There it goes, in real time. There it goes again. Obviously, we have to slow this down a little bit. You can ’ t use regular cameras. You have to take 1, 000 pictures per second to see this. And here ’ s some video at 1, 000 frames per second. Now, I want you to look at **the** animal ’ s back. Do you see how much it ’ s bending like that? We can ’ t figure that out — that ’ s an unsolved mystery. We don ’ t know how it works. If you have a son or a daughter that wants to come to Berkeley, come to my lab and we ’ ll figure this out. **Okay**, send them to Berkeley because that ’ s **the** next thing I want to do. Here ’ s **the** gecko mill. It ’ s a see-through treadmill with a see-through treadmill belt, so we can watch **the** animal ’ s feet, and videotape them through **the** treadmill belt, to see how they move. Here ’ s **the** animal that we have here, running on a vertical **surface**. Pick a foot and try to watch a toe, and see if you can see what **the** animal ’ s doing. See it uncurl and then peel these toes. It can do this in 14 milliseconds. It ’ s unbelievable. Here are **the** robots that they inspire, **the** Mecho-Geckos from iRobot. First we ’ ll see **the** animals toes peeling — look at that. And here ’ s **the** peeling action of **the** Mecho-Gecko. It uses a pressure-sensitive adhesive to do it. Peeling in **the** animal. Peeling in **the** Mecho-Gecko — that allows them climb autonomously. Can go on **the** flat **surface**, transition to a wall, and then go onto a ceiling. There ’ s **the** bulldozer version. Now, it doesn ’ t use pressure-sensitive glue. **The** animal does not use that. But that ’ s what we ’ re limited to, at **the** moment. What does **the** animal do? **The** animal has weird toes. And if you look at **the** toes, they have these little leaves there, and if you blow them up and zoom in, you ’ ll see that ’ s there ’ s little striations in these leaves. And if you zoom in 270 times, you ’ ll see it looks like a rug. And if you blow that up, and zoom in 900 times, you see there are hairs there, tiny hairs. And if you look carefully, those tiny hairs have striations. And if you zoom in on those 30, 000 times, you ’ ll see each hair has split ends. And if you blow those up, they have these little structures on **the** end. **The** smallest branch of **the** hairs looks like spatulae, and an animal like that has one billion of these nano-size split ends, to get very close to **the surface**. In fact, there ’ s **the diameter** of your hair — a gecko has two million of these, and each hair has 100 to 1, 000 split ends. Think of **the** contact of that that ’ s possible. We were fortunate to work with another group at Stanford that built us a special manned sensor, that we were able to measure **the** force of an individual hair. Here ’ s an individual hair with a little split end there. When we measured **the** forces, they were enormous. They were so large that a patch of hairs about this size — **the** gecko ’ s foot could support **the** weight of a small child, about 40 **pounds**, easily. Now, how do they do it? We ’ ve recently discovered this. Do they do it by friction? No, force is too low. Do they do it by electrostatics? No, you can change **the** charge — they still hold on. Do they do it by interlocking? That ’ s kind of a like a Velcro-like thing. No, you can put them on molecular smooth **surfaces** — they don ’ t do it. How about suction? They stick on in a vacuum. How about **wet** adhesion? Or capillary adhesion? They don ’ t have any glue, and they even stick under water just fine. If you put their foot under water, they grab on. How do they do it then? Believe it or not, they grab on by intermolecular forces, by Van der Waals forces. You know, you probably had this a long time ago in **chemistry**, where you had these two atoms, they ’ re close together, and **the** electrons are moving around. That tiny force is sufficient to allow them to do that because it ’ s added up so many times with these small structures. What we ’ re doing is, we ’ re taking that inspiration of **the** hairs, and with another colleague at Berkeley, we ’ re manufacturing them. And just recently we ’ ve made a breakthrough, where we now believe we ’ re going to be able to create **the** first synthetic, self-cleaning, dry adhesive. Many companies are interested in this. We also presented to Nike even. We ’ ll see where this goes. We were so excited about this that we realized that that small-size scale — and where everything gets sticky, and gravity doesn ’ t matter anymore — we needed to look at ants and their feet, because one of my other colleagues at Berkeley has built a six-millimeter silicone robot with legs. But it gets stuck. It doesn ’ t move very well. But **the** ants do, and we ’ ll figure out why, so that ultimately we ’ ll make this move. And imagine : you ’ re going to be able to have swarms of these six-millimeter robots available to run around. Where ’ s this going? I think you can see it already. Clearly,

the Internet is already having eyes and ears, you have **web** cams and so forth. But it ’ s going to also have legs and hands. You ’ re going to be able to do programmable work through these kinds of robots, so that you can run, fly and swim anywhere. We saw David Kelly is at **the** beginning of that with his **fish**. So, in conclusion, I think **the** message is clear. If you need a message, if nature ’ s not enough, if you care about **search** and rescue, or mine clearance, or medicine, or **the** various things we ’ re working on, we must preserve nature ’ s designs, otherwise these secrets will be lost forever. Thank you.

Text Sample 20: POS Dim 1 – 2007 – Score 34.00 – 2007/t000298.txt

As an architect you design for **the** present, with an awareness of **the** past, for a future which is essentially unknown. **The** green agenda is probably **the** most important agenda and issue of **the** day. And I ’ d like to share some experience over **the** last 40 years â we celebrate our fortieth anniversary this year â and to explore and to touch on some observations about **the** nature of **sustainability**. How far you can anticipate, what follows from it, what are **the** threats, what are **the** possibilities, **the** challenges, **the** opportunities? I think that â I ’ ve said in **the** past, many, many years ago, before anybody even invented **the** concept of a green agenda, that it wasn ’ t about fashion â it was about survival. But what I never said, and what I ’ m really going to make **the** point is, that really, green is cool. I mean, all **the** projects which have, in some way, been inspired by that agenda are about a celebratory lifestyle, in a way celebrating **the** places and **the** spaces which determine **the** quality of life. I rarely actually quote anything, so I ’ m going to try and find a piece of paper if I can, [in] which somebody, at **the** end of last year, ventured **the** thought about what for that individual, as a kind of important observer, analyst, writer â a guy called Thomas Friedman, who wrote in **the** Herald Tribune, about 2006. He said,”I think **the** most important thing to happen in 2006 was that living and thinking green hit Main Street. We reached a tipping point this year where living, acting, designing, investing and manufacturing green came to be understood by a critical mass of citizens, entrepreneurs and officials as **the** most patriotic, capitalistic, geo-political and competitive thing they could do. Hence my motto : green is **the** new red, white and **blue**.”And I asked myself, in a way, looking back,”When did that kind of awareness of **the planet** and its fragility first appear?”And I think it was July 20, 1969, when, for **the** first time, man could look back at **planet** Earth. And, in a way, it was Buckminster Fuller who coined that phrase. And before **the** kind of collapse of **the** communist system, I was privileged to meet a lot of cosmonauts in Space City and other places in Russia. And interestingly, as I think back, they were **the** first true environmentalists. They were filled with a kind of pioneering passion, fired about **the** problems of **the** Aral Sea. And at that period it was â in a way, a number of things were happening. Buckminster Fuller was **the** kind of green guru â again, a word that had not been coined. He was a design scientist, if you like, a poet, but he foresaw all **the** things that are happening now. It ’ s another subject. It ’ s another conversation. You can go back to his writings : it ’ s quite extraordinary. It was at that time, with an awareness fired by Bucky ’ s prophecies, his concerns as a citizen, as a kind of citizen of **the planet**, that influenced my thinking and what we were doing at that time. And it ’ s a number of projects. I select this one because it was 1973, and it was a master plan for one of **the** Canary Islands. And this probably coincided with **the** time when you had **the planet** Earth ’ s sourcebook, and you had **the** hippie movement. And there are some of those qualities in this drawing, which seeks to **sum** up **the** recommendations.

And all **the** components are there which are now in common parlance, in our vocabulary, you know, 30-odd years later : wind energy, recycling, biomass, solar cells. And in parallel at that time, there was a very kind of exclusive design club. People who were really design conscious were inspired by **the** work of Dieter Rams, and **the objects** that he would create for **the** company called Braun. This is going back **the** mid- ’ 50s, ’ 60s. And despite Bucky ’ s prophecies that everything would be miniaturized and technology would make an incredible style â access to comfort, to amenities â it was very, very difficult to imagine that everything that we see in this image, would be very, very stylishly packaged. And that, and more besides, would be in **the** palm of your hand. And I think that that digital revolution now is coming to **the** point where, as **the** virtual world, which brings so many people together here, finally connects with **the** physical world, there is **the** reality that that has become humanized, so that digital world has all **the** friendliness, all **the** immediacy, **the** orientation of **the** analog world. Probably **summed** up in a way by **the** stylish or alternative available here, as we generously had gifted at lunchtime, **the** [**unclear**], which is a further kind of development â and again, inspired by **the** incredible sort of sensual feel. A very, very beautiful **object**. So, something which in [**the**] ’ 50s, ’ 60s was very exclusive has now become, interestingly, quite inclusive. And **the** reference to **the** iPod as iconic, and in a way evocative of performance, delivery â quite interesting that [in] **the** beginning of **the** year 2007, **the** Financial Times commented that **the** Detroit companies envy **the** halo effect that Toyota has gained from **the** Prius as **the** hybrid, energy-conscious vehicle, which rivals **the** iPod as an iconic product. And I think it ’ s very tempting to, in a way, seduce ourselves â as architects, or anybody involved with **the** design process â that **the** answer to our problems lies with buildings. Buildings are important, but they ’ re only a component of a much bigger picture. In other words, as I might seek to demonstrate, if you could achieve **the** impossible, **the** equivalent of perpetual motion, you could design a carbon-free house, for example. That would be **the** answer. Unfortunately, it ’ s not **the** answer. It ’ s only **the** beginning of **the** problem. You cannot separate **the** buildings out from **the** infrastructure of cites and **the** mobility of transit. For example, if, in that Bucky-inspired phrase, we draw back and we look at **planet** Earth, and we take a kind of typical, industrialized society, then **the** energy consumed would be split between **the** buildings, 44 percent, transport, 34 percent, and industry. But again, that only shows part of **the** picture. If you looked at **the** buildings together with **the** associated transport, in other words, **the** transport of people, which is 26 percent, then 70 percent of **the** energy **consumption** is influenced by **the** way that our cites and infrastructure work together. So **the** problems of **sustainability** cannot be separated from **the** nature of **the** cities, of which **the** buildings are a part. For example, if you take, and you make a comparison between a recent kind of city, what I ’ ll call, simplistically, a North American city â and Detroit is not a bad example, it is very car dependent. **The** city goes out in annular rings, consuming more and more green space, and more and more roads, and more and more energy in **the** transport of people between **the** city center â which again, **the** city center, as it becomes deprived of **the** living and just becomes commercial, again becomes dead. If you compared Detroit with a city of a Northern European example â and Munich is not a bad example of that, with **the** greater dependence on walking and cycling â then a city which is really only twice as dense, is only using one-tenth of **the** energy. In other words, you take these comparable examples and **the** energy leap is enormous. So basically, if you wanted to generalize, you can demonstrate that as **the** density increases along **the** bottom there, that **the** energy consumed reduces dramatically. Of course you can ’ t separate this out from issues like social diversity, mass transit, **the** ability to be able to walk a convenient distance, **the** quality of civic spaces. But again, you can see Detroit, in **yellow** at **the** top, extraordinary **consumption**, down below Copenhagen. And Copenhagen, although it ’ s a dense city, is not dense compared with **the** really dense cities. In **the** year 2000, a rather interesting thing happened. You had for **the** first time mega-cities, [of] 5 million or more, which were **occurring** in **the** developing world. And now, out of typically 46 cities, 33 of those mega-cities are in **the** developing world. So you have to ask yourself â□□ **the** environmental impact of, for example, China or India. If you take China, and you just take Beijing, you can see on that traffic system, and **the** pollution associated with **the consumption** of energy as **the** cars expand at **the** price of **the** bicycles. In other words, if you put onto **the** roads, as is currently happening, 1, 000 new cars every day â□□ statistically, it ’ s **the** biggest booming auto market in **the** world â□□ and **the** half a billion bicycles serving one and a third billion people are reducing. And that urbanization is extraordinary, accelerated pace. So, if we think of **the** transition in our society of **the** movement from **the** land to **the** cities, which took 200 years, then that same process is happening in 20 years. In other words, it is accelerating by a factor of 10. And quite interestingly, over something like a 60-year period, we ’ re seeing **the** doubling in life expectancy, over that period where **the** urbanization has trebled. If I pull back from that global picture, and I look at **the** implication over a similar period of time in terms of **the** technology â□□ which, as a tool, is a tool for designers, and I cite our own experience as a company, and I just illustrate that by a small **selection** of projects â□□ then how do you measure that change of technology? How does it affect **the** design of buildings? And particularly, how can it lead to **the** creation of buildings which consume less energy, create less pollution and are more socially responsible? That story, in terms of buildings, started in **the** late ’ 60s, early ’ 70s. **The** one example I take is a corporate headquarters for a company called Willis and Faber, in a small market town in **the** northeast of England, commuting distance with London. And here, **the** first thing you can see is that this building, **the** roof is a very warm kind of overcoat blanket, a kind of insulating garden, which is also about **the** celebration of public space. In other words, for this community, they have this garden in **the** sky. So **the** humanistic ideal is very, very strong in all this work, encapsulated perhaps by one of my early sketches here, where you can see greenery, you can see sunlight, you have a connection with nature. And nature is part of **the** generator, **the** driver for this building. And symbolically, **the** colors of **the** interior are green and **yellow**. It has facilities like swimming pools, it has flextime, it has a social heart, a space, you have contact with nature. Now this was 1973. In 2001, this building received an award. And **the** award was about a celebration for a building which had been in use over a long period of time. And **the** people who ’ d created it came back : **the** project managers, **the** company chairmen then. And they were saying, you know,”**The** architects, Norman was always going on about designing for **the** future, and you know, it didn ’ t seem to cost us any more. So we humored him, we kept him happy.”**The** image at **the** top, what it doesn ’ t â□□ if you look at it in detail, really what it is saying is you can wire this building. This building was wired for change. So, in 1975, **the** image there is of typewriters. And when **the** photograph was taken, it ’ s word processors. And what they were saying on this occasion was that our competitors had to build new buildings for **the** new technology. We were fortunate, because in a way our building was future-proofed. It anticipated change, even though those changes were not known. Round about that design period leading up to this building, I did a sketch, which we pulled out of **the** archive recently. And I was saying, and I wrote,”But we don ’ t have **the** time, and we really don ’ t have **the** immediate expertise at a technical level."In other words, we didn ' t have **the** technology to do what would be really interesting on that building. And that would be to create a kind of three- dimensional bubble â a really interesting overcoat that would naturally ventilate, would breathe and would seriously reduce **the** energy loads. Notwithstanding **the** fact that **the** building, as a green building, is very much a pioneering building. And if I fast-forward in time, what is interesting is that **the** technology is now available and celebratory. **The** library of **the** Free University, which opened last year, is an example of that. And again, **the** transition from one of **the** many thousands of sketches and **computer** images to **the** reality. And a combination of **devices** here, **the** kind of heavy mass concrete of these book **stacks**, and **the** way in which that is enclosed by this skin, which enables **the** building to be ventilated, to consume dramatically less energy, and where it ' s really working with **the** forces of nature. And what is interesting is that this is hugely popular by **the** people who use it. Again, coming back to that thing about **the** lifestyle, and in a way, **the** ecological agenda is very much at one with **the** spirit. So it ' s not a kind of sacrifice, quite **the** reverse. I think it ' s a great â it ' s a celebration. And you can measure **the** performance, in terms of energy **consumption**, of that building against a typical library. If I show another aspect of that technology then, in a completely different context â this apartment building in **the** Alps in Switzerland. Prefabricated from **the** most traditional of materials, but that material â because of **the** technology, **the** computing ability, **the** ability to prefabricate, make high-performance components out of timber â very much at **the** cutting edge. And just to give a sort of glimpse of that technology, **the** ability to plot points in **the** sky and to transmit, to transfer that information now, directly into **the** factory. So if you cross **the** border â just across **the** border â a small factory in Germany, and here you can see **the** guy with his **computer** screen, and those points in space are communicated. And on **the** **left** are **the** cutting machines, which then, in **the** factory, enable those individual pieces to be fabricated and plus or minus very, very few millimeters, to be slotted together on site. And then interestingly, that building to then be clad in **the** oldest technology, which is **the** kind of hand-cut shingles. One quarter of a million of them applied by hand as **the** final finish. And again, **the** way in which that works as a building, for those of us who can **enjoy the** spaces, to live and visit there. If I made **the** leap into these new technologies, then how did we â what happened before that? I mean, you know, what was life like before **the** mobile phone, **the** things that you take for granted? Well, obviously **the** building still happened. I mean, this is a glimpse of **the** interior of our Hong Kong bank of 1979, which opened in 1985, with **the** ability to be able to reflect sunlight deep into **the** heart of this space here. And in **the** absence of **computers**, you have to physically model. So for example, we would put models under an **artificial** sky. For wind tunnels, we would literally put them in a wind tunnel and blast air, and **the** many kilometers of cable and so on. And **the** turning point was probably, in our terms, when we had **the** first **computer**. And that was at **the** time that we sought to redesign, reinvent **the** airport. This is Terminal Four at Heathrow, typical of any terminal â big, heavy roof, blocking out **the** sunlight, lots of machinery, big pipes, whirring machinery. And Stansted, **the** green alternative, which uses natural light, is a **friendly** place : you know where you are, you can relate to **the** outside. And for a large part of its cycle, not needing electric light â electric light, which in turn creates more heat, which creates more cooling loads and so on. And at that particular point in time, this was one of **the** few solitary **computers**. And that ' s a little image of **the** tree of Stansted. Not going back very far in time, 1990, that ' s our office. And if you looked very closely, you ' d see that people were drawing with pencils, and they were pushing, you know, big rulers and **triangles**. It ' s not that long ago, 17 years, and here we are now. I mean, major transformation. Going back in time, there was a lady called Valerie Larkin, and in 1987, she had all our information on one **disk**. Now, every week, we have **the** equivalent of 84 million **disks**, which record our archival information on past, current and future projects. That reaches 21 kilometers into **the** sky. This is **the** view you would get, if you looked down on that. But meanwhile, as you know, wonderful protagonists like Al Gore are noting **the** inexorable rise in temperature, set in **the** context of that, interestingly, those buildings which are celebratory and very, very relevant to this place. Our Reichstag project, which has a very familiar agenda, I ' m sure, as a public place where we sought to, in a way, through a process of advocacy, reinterpret **the** relationship between society and politicians, public space. And maybe its hidden agenda, an energy manifesto â something that would be free, completely free of fuel as we know it. So it would be totally **renewable**. And again, **the** humanistic sketch, **the** translation into **the** public space, but this very, very much a part of **the** **ecology**. But here, not having to model it for real. Obviously **the** wind tunnel had a place, but **the** ability now with **the** **computer** to explore, to plan, to see how that would work in terms of **the** forces of nature : natural ventilation, to be able to model **the** chamber below, and to look at biomass. A combination of biomass, aquifers, burning vegetable **oil** â a process that, quite interestingly, was developed in Eastern Germany, at **the** time of its dependence on **the** Soviet Bloc. So really, retranslating that technology and developing something which was so clean, it was virtually pollution-free. You can measure it again. You can compare how that building, in terms of its **emission** in tons of **carbon** dioxide per year â at **the** time that we took that project, over 7, 000 tons â what it would have been with natural gas and finally, with **the** vegetable **oil**, 450 tons. I mean, a 94 percent reduction â virtually clean. We can see **the** same processes at work in terms of **the** Commerce Bank â its dependence on natural ventilation, **the** way that you can model those gardens, **the** way they spiral around. But again, very much about **the** lifestyle, **the** quality â something that would be more enjoyable as a place to work. And again, we can measure **the** reduction in terms of energy **consumption**. There is an **evolution** here between **the** projects, and Swiss Re again develops that a little bit further â **the** project in **the** city in London. And this sequence shows **the** buildup of that model. But what it shows first, which I think is quite interesting, is that here you see **the** circle, you see **the** public space around it. What are **the** other ways of putting **the** same amount of space on **the** site? If, for example, you seek to do a building which goes right to **the** edge of **the** pavement, it ' s **the** same amount of space. And finally, you profile this, you cut grooves into it. **The** grooves become **the** kind of green lungs which give views, which give light, ventilation, make **the** building fresher. And you enclose that with something that also is central to its appearance, which is a mesh of triangulated structures â again, in a long connection evocative of some of those works of Buckminster Fuller, and **the** way in which triangulation can increase performance and also give that building its sense of identity. And here, if we look at a detail of **the** way that **the** building opens up and breathes into those atria, **the** way in which now, with a **computer**, we can model **the** forces, we can see **the** high pressure, **the** low pressure, **the** way in which **the** building behaves rather like an aircraft **wing**. So it also has **the** ability, all **the** time, regardless of **the** direction of **the** wind, to be able to make **the** building fresh and efficient. And unlike conventional buildings, **the** top of **the** building is celebratory. It ' s a viewing place for people, not machinery. And **the** base of **the** building is again about public space. Comparing it with a typical building, what happens if we seek to use such design strategies in terms of really large-scale thinking? And I ’ m just going to give two images out of a kind of company research project. It ’ s been well known that **the** Dead Sea is dying. **The** level is dropping, rather like **the** Aral Sea. And **the** Dead Sea is obviously much lower than **the** oceans and **seas** around it. So there has been a project which rescues **the** Dead Sea by creating a pipeline, a pipe, sometimes above **the surface**, sometimes buried, that will redress that, and will feed from **the** Gulf of Aqaba into **the** Dead Sea. And our translation of that, using a lot of **the** thinking built up over **the** 40 years, is to say, what if that, instead of being just a pipe, what if it is a lifeline? What if it is **the** equivalent, depending on where you are, of **the** Grand Canal, in terms of tourists, habitation, desalination, **agriculture**? In other words, water is **the** lifeblood. And if you just go back to **the** previous image, and you look at this area of volatility and hostility, that a unifying design idea as a humanitarian gesture could have **the** affect of bringing all those warring factions together in a united cause, in terms of something that would be genuinely green and productive in **the** widest sense. Infrastructure at that large scale is also inseparable from communication. And whether that communication is **the** virtual world or it is **the** physical world, then it ’ s absolutely central to society. And how do we make more legible in this growing world, especially in some of **the** places that I ’ m talking about â□□ China, for example, which in **the** next ten years will create 400 new airports. Now what form do they take? How do you make them more **friendly** at that scale? Hong Kong I refer to as a kind of analog experience in a digital age, because you always have a point of reference. So what happens when we take that and you expand that further into **the** Chinese society? And what is interesting is that that produces in a way perhaps **the** ultimate mega-building. It is physically **the** largest project on **the planet** at **the** moment. 250 â□□ excuse me, 50, 000 people working 24 hours, seven days. Larger by 17 percent than every terminal put together at Heathrow â□□ built â□□ plus **the** new, un-built Terminal Five. And **the** challenge here is a building that will be green, that is compact despite its size and is about **the** human experience of travel, is about **friendly**, is coming back to that starting point, is very, very much about **the** lifestyle. And perhaps these, in **the** end, as celebratory spaces. As Hubert was talking over lunch, as we sort of engaged in conversation, talked about this, talked about cities. Hubert was saying, absolutely correctly,”These are **the** new cathedrals.”And in a way, one aspect of this conversation was triggered on New Year ’ s Eve, when I was talking about **the** Olympic agenda in China in terms of its green ambitions and aspirations. And I was voicing **the** thought that â□□ it just crossed my mind that New Year ’ s Eve, a sort of symbolic turning point as we move from 2006 to 2007 â□□ that maybe, you know, **the** future was **the** most powerful, innovative sort of nation. **The** way in which somebody like Kennedy inspirationally could say,”We put a man on **the** moon.”You know, who is going to say that we cracked this thing of **the** dependence on **fossil** fuels, with all that being held to ransom by rogue regimes, and so on. And that ’ s a concerted platform. It ’ s more than one **device**, you know, it ’ s **renewable**. And I voiced **the** thought that maybe at **the** turn of **the** year, I thought that **the** inspiration was more likely to come from those other, larger countries out there â□□ **the** Chinas, **the** Indias, **the** Asian-Pacific **tigers**. Thank you very much.

Text Sample 21: POS Dim 1 – 2007 – Score 32.00 – 2007/t000238.txt

Well, good morning. You know, **the computer** and television both recently turned 60, and today I ’ d like to talk about their relationship. Despite their middle age, if you ' ve been following **the themes** of this conference or **the** entertainment industry, it ' s pretty clear that one has been picking on **the** other. So it ' s about time that we talked about how **the computer** ambushed television, or why **the** invention of **the** atomic bomb unleashed forces that lead to **the** writers ' strike. And it ' s not just what these are doing to each other, but it ' s what **the** audience thinks that really frames this matter. To get a sense of this, and it ' s been a **theme** we ' ve talked about all week, I recently talked to a bunch of tweeners. I wrote on cards :"television,""radio,""MySpace,""Internet,""PC."And I said, just arrange these, from what ' s important to you and what ' s not, and then tell me why. Let ' s listen to what happens when they get to **the** portion of **the** discussion on television. Girl 1 : Well, I think it ' s important but, like, not necessary because you can do a lot of other stuff with your free time than watch programs. Peter Hirshberg : Which is more fun, Internet or TV? Girls : Internet. Girl 2 : I think we — **the** reasons, one of **the** reasons we put **computer** before TV is because nowadays, like, we have TV shows on **the computer**. Girl 2 : And then you can download onto your iPod. PH : Would you like to be **the** president of a TV network? Girl 4 : I wouldn ' t like it. Girl 2 : That would be so stressful. Girl 5 : No. PH : How come? Girl 5 : Because they ' re going to lose all their money eventually. Girl 3 : Like **the** stock market, it goes up and down and stuff. I think right now **the computers** will be at **the** top and everything will be kind of going down and stuff. PH : There ' s been an uneasy relationship between **the** TV business and **the** tech business, really ever since they both turned about 30. We go through periods of enthrallment, followed by reactions in boardrooms, in **the** finance community best characterized as, what ' s **the** finance term? Ick pooey. Let me give you an example of this. **The** year is 1976, and Warner buys Atari because video games are on **the** rise. **The** next year they march forward and they introduce Qube, **the** first interactive cable TV system, and **the** New York Times heralds this as telecommunications moving to **the** home, convergence, great things are happening. Everybody in **the** East Coast gets in **the** pictures — Citicorp, Penney, RCA — all getting into this big vision. By **the** way, this is about when I enter **the** picture. I ' m going to do a summer internship at Time Warner. That summer I ' m all — I ' m at Warner that summer — I ' m all excited to work on convergence, and then **the** bottom falls out. Doesn ' t work out too well for them, they lose money. And I had a happy brush with convergence until, kind of, Warner basically has to liquidate **the** whole thing. That ' s when I leave graduate school, and I can ' t work in New York on kind of entertainment and technology because I have to be exiled to California, where **the** remaining jobs are, almost to **the sea**, to go to work for Apple Computer. Warner, of course, writes off more than 400 million dollars. Four hundred million dollars, which was real money back in **the** ' 70s. But they were onto something and they got better at it. By **the** year 2000, **the** process was perfected. They merged with AOL, and in just four years, managed to shed about 200 billion dollars of market capitalization, showing that they ' d actually mastered **the** art of applying Moore ' s law of successive miniaturization to their balance sheet. Now, I think that one reason that **the** media and **the** entertainment communities, or **the** media community, is driven so crazy by **the** tech community is that tech folks talk differently. You know, for 50 years, we ' ve talked about changing **the** world, about total transformation. For 50 years, it ' s been about hopes and fears and promises of a better world. And I got to thinking, you know, who else talks that way? And **the** answer is pretty clearly — it ' s people in religion and in politics. And so I realized that actually **the** tech world is best understood, not as a business cycle, but as a messianic movement. We promise something great, we evangelize it, we ' re going to change **the** world. It doesn ' t work out too well, and so we actually go back to

the well and start all over again, as **the** people in New York and L. A. look on in absolute, morbid astonishment. But it ' s this irrational view of things that drives us on to **the** next thing. So, what I ' d like to ask is, if **the computer** is becoming a principal tool of media and entertainment, how did we get here? I mean, how did a machine that was built for accounting and artillery morph into media? Of course, **the** first **computer** was built just after World War II to solve military problems, but things got really interesting just a couple of years later — 1949 with Whirlwind, built at MIT ' s Lincoln Lab. Jay Forrester was building this for **the** Navy, but you can ' t help but see that **the** creator of this machine had in mind a machine that might actually be a potential media star. So take a look at what happens when **the** foremost journalist of early television meets one of **the** foremost **computer** pioneers, and **the computer** begins to express itself. Journalist : It ' s a Whirlwind electronic **computer**. With considerable trepidation, we **undertake** to interview this new machine. Jay Forrester : Hello New York, this is Cambridge. And this is **the** oscilloscope of **the** Whirlwind electronic **computer**. Would you like if I used **the** machine? Journalist : Yes, of course. But I have an idea, Mr. Forrester. Since this **computer** was made in conjunction with **the** Office of Naval Research, why don ' t we switch down to **the** Pentagon in Washington and let **the** Navy ' s research chief, Admiral Bolster, give Whirlwind **the** workout? Calvin Bolster : Well, Ed, this problem concerns **the** Navy ' s Viking rocket. This rocket goes up 135 miles into **the** sky. Now, at **the** standard rate of fuel **consumption**, I would like to see **the computer** trace **the** flight path of this rocket and see how it can determine, at any instant, say at **the** end of 40 seconds, **the** amount of fuel remaining, and **the** velocity at that set instant. JF : Over on **the** left-hand side, you will notice fuel **consumption** decreasing as **the** rocket takes off. And on **the right-hand** side, there ' s a scale that shows **the** rocket ' s velocity. **The** rocket ' s position is shown by **the** trajectory that we ' re now looking at. And as it reaches **the** peak of its trajectory, **the** velocity, you will notice, has dropped off to a minimum. Then, as **the** rocket dives down, velocity picks up again toward a maximum velocity and **the** rocket hits **the** ground. How ' s that? Journalist : What about that, Admiral? CB : Looks very good to me. JF : And before leaving, we would like to show you another kind of mathematical problem that some of **the** boys have worked out in their spare time, in a less serious vein, for a Sunday afternoon. Journalist : Thank you very much indeed, Mr. Forrester and **the** MIT lab. PH : You know, so much was worked out : **the** first real-time interaction, **the** video display, pointing a gun. It lead to **the** microcomputer, but unfortunately, it was too pricey for **the** Navy, and all of this would have been lost if it weren ' t for a happy coincidence. Enter **the** atomic bomb. We ' re threatened by **the** greatest weapon ever, and knowing a good thing when it sees it, **the** Air Force decides it needs **the** biggest **computer** ever to protect us. They adapt Whirlwind to a massive air defense system, deploy it all across **the** frozen north, and spend nearly three times as much on this **computer** as was spent on **the** Manhattan Project building **the** A-Bomb in **the** first place. Talk about a shot in **the** arm for **the computer** industry. And you can imagine that **the** Air Force became a pretty good salesman. Here ' s their marketing video. Narrator : In a mass raid, high-speed bombers could be in on us before we could determine their tracks. And then it would be too late to act. We cannot afford to take that chance. It is to meet this threat that **the** Air Force has been developing SAGE, **the** Semi-Automatic Ground Environment system, to strengthen our air defenses. This new **computer**, built to become **the** nerve center of a defense network, is able to perform all **the** complex mathematical problems involved in countering a mass enemy raid. It is provided with its own powerhouse containing large diesel-driven generators, air-conditioning equipment, and cooling towers required to cool **the** thousands of vacuum tubes in **the computer**. PH : You know, that one **computer** was huge. There ' s an interesting marketing lesson from it, which is basically, when you market a product, you can either say, this is going to be wonderful, it will make you feel better and enliven you. Or there ' s one other marketing proposition : if you don ' t use our product, you ' ll die. This is a really good example of that. This had **the** first pointing **device**. It was distributed, so it worked out — distributed computing and modems — so all these things could talk to each other. About 20 percent of all **the** nation ' s programmers were wrapped up in this thing, and it led to an awful lot of what we have today. It also used vacuum tubes. You saw how huge it was, and to give you a sense for this — because we ' ve talked a lot about Moore ' s law and making things small at this conference, so let ' s talk about making things large. If we took Whirlwind and put it in a place that you all know, say, Century City, it would fit beautifully. You ' d kind of have to take Century City out, but it could fit in there. But like, let ' s imagine we took **the** latest Pentium processor, **the** latest Core 2 Extreme, which is a four-core processor that Intel ' s working on, it will be our **laptop** tomorrow. To build that, what we ' d do with Whirlwind technology is we ' d have to take up roughly from **the** 10 to Mulholland, and from **the** 405 to La Cienega just with those Whirlwinds. And then, **the** 92 nuclear power plants that it would take to provide **the** power would fill up **the** rest of Los Angeles. That ' s roughly a third more nuclear power than all of France creates. So, **the** next time they tell you they ' re on to something, clearly they ' re not. So — and we haven ' t even worked out **the** cooling needs. But it gives you **the** kind of power that people have, that **the** audience has, and **the** reasons these transformations are happening. All of this stuff starts moving into industry. DEC kind of reduces all this and makes **the** first mini-computer. It shows up at places like MIT, and then a mutation happens. Spacewar! is built, **the** first **computer** game, and all of a sudden, interactivity and involvement and passion is worked out. Actually, many MIT students stayed up all night long working on this thing, and many of **the** principles of gaming today were worked out. DEC knew a good thing about wasting time. It shipped every one of its **computers** with that game. Meanwhile, as all of this is happening, by **the** mid- ' 50s, **the** business model of traditional broadcasting and cinema has been busted completely. A new technology has confounded radio men and movie moguls and they ' re quite certain that television is about to do them in. In fact, despair is in **the** air. And a quote that sounds largely reminiscent from everything I ' ve been reading all week. RCA had David Sarnoff, who basically commercialized radio, said this,"I don ' t say that radio networks must die. Every effort has been made and will continue to be made to find a new pattern, new selling arrangements and new types of programs that may arrest **the** declining revenues. It may yet be possible to eke out a poor existence for radio, but I don ' t know how."And of course, as **the** **computer** industry develops interactively, producers in **the** emerging TV business actually hit on **the** same idea. And they fake it. Jack Berry : Boys and girls, I think you all know how to get your magic windows up on **the** set, you just get them out. First of all, get your Winky Dink kits out. Put out your Magic Window and your erasing glove, and rub it like this. That ' s **the** way we get some of **the** magic into it, boys and girls. Then take it and put it right up against **the** screen of your own television set, and rub it out from **the** center to **the** corners, like this. Make sure you keep your magic crayons handy, your Winky Dink crayons and your erasing glove, because you ' ll be using them during **the** show to draw like that. You all set? OK, let ' s get right to **the** first story about Dusty Man. Come on into **the** secret lab. PH : It was **the** dawn of interactive TV, and you may have noticed they wanted to sell you **the** Winky Dink kits. Those are **the**

Winky Dink crayons. I know what you ’ re saying.”Pete, I could use any ordinary **open-source** crayon, why do I have to buy theirs?”I assure you, that ’ s not **the** case. Turns out they told us directly that these are **the** only crayons you should ever use with your Winky Dink Magic Window, other crayons may discolor or hurt **the** window. This proprietary principle of vendor lock-in would go on to be perfected with great success as one of **the** enduring principles of windowing systems everywhere. It led to lawsuits — — federal investigations, and lots of repercussions, and that ’ s a scandal we won ’ t discuss today. But we will discuss this scandal, because this man, Jack Berry, **the** host of”Winky Dink,”went on to become **the** host of”Twenty One,”one of **the** most important quiz shows ever. And it was rigged, and it became unraveled when this man, Charles van Doren, was outed after an unnatural winning streak, ending Berry ’ s career. And actually, ending **the** career of a lot of people at CBS. It turns out there was a lot to learn about how this new medium worked. And 50 years ago, if you ’ d been at a meeting like this and were trying to understand **the** media, there was one prophet and only but one you wanted to hear from, Professor Marshall McLuhan. He actually understood something about a **theme** that we ’ ve been discussing all week. It ’ s **the** role of **the** audience in an era of pervasive electronic communications. Here he is talking from **the** 1960s. Marshall McLuhan : If **the** audience can become involved in **the** actual process of making **the** ad, then it ’ s happy. It ’ s like **the** old quiz shows. They were great TV because it gave **the** audience a role, something to do. They were horrified when they discovered they ’ d really been left out all **the** time because **the** shows were rigged. Now, then, this was a horrible misunderstanding of TV on **the** part of **the** programmers. PH : You know, McLuhan talked about **the** global village. If you substitute **the** word blogosphere, of **the** Internet today, it is very true that his understanding is probably very enlightening now. Let ’ s listen in to him. MM : **The** global village is a world in which you don ’ t necessarily have harmony. You have extreme concern with everybody else ’ s business and much involvement in everybody else ’ s life. It ’ s a sort of Ann Landers ’ column writ large. And it doesn ’ t necessarily mean harmony and peace and quiet, but it does mean huge involvement in everybody else ’ s affairs. And so **the** global village is as big as a **planet**, and as small as a village post office. PH : We ’ ll talk a little bit more about him later. We ’ re now right into **the** 1960s. It ’ s **the** era of big business and data centers for computing. But all that was about to change. You know, **the** expression of technology reflects **the** people and **the** time of **the** culture it was built in. And when I say that code expresses our hopes and aspirations, it ’ s not just a joke about messianism, it ’ s actually what we do. But for this part of **the** story, I ’ d actually like to throw it to America ’ s leading technology correspondent, John Markoff. John Markoff : Do you want to know what **the** counterculture in drugs, sex, **rock** ’ n ’ roll and **the** anti-war movement had to do with computing? Everything. It all happened within five miles of where I ’ m standing, at Stanford University, between 1960 and 1975. In **the** midst of revolution in **the** streets and **rock** and roll concerts in **the** parks, a group of researchers led by people like John McCarthy, a **computer** scientist at **the** Stanford **Artificial** Intelligence Lab, and Doug Engelbart, a **computer** scientist at SRI, changed **the** world. Engelbart came out of a pretty dry engineering culture, but while he was beginning to do his work, all of this stuff was bubbling on **the** mid-peninsula. There was LSD leaking out of Kesey ’ s Veterans ’ Hospital experiments and other areas around **the** campus, and there was music literally in **the** streets. **The** Grateful Dead was playing in **the** pizza parlors. People were leaving to go back to **the** land. There was **the** Vietnam War. There was black liberation. There was women ’ s liberation. This was a remarkable place, at a remarkable time. And into that ferment came **the** microprocessor. I think it was that interaction that led to personal computing. They saw these tools that were controlled by **the** establishment as ones that could actually be liberated and put to use by these communities that they were trying to build. And most importantly, they had this ethos of sharing information. I think these ideas are difficult to understand, because when you ’ re trapped in one paradigm, **the** next paradigm is always like a science fiction **universe** — it makes no sense. **The** stories were so compelling that I decided to write a book about them. **The** title of **the** book is,”What **the** Dormouse Said : How **the** ’ 60s Counterculture Shaped **the** Personal Computer Industry.”**The** title was taken from **the** lyrics to a Jefferson **Airplane** song. **The** lyrics go,”Remember what **the** dormouse said. Feed your head, feed your head, feed your head.”PH : By this time, computing had kind of leapt into media territory, and in short order much of what we ’ re doing today was imagined in Cambridge and Silicon Valley. Here ’ s **the** Architecture Machine Group, **the** predecessor of **the** Media Lab, in 1981. Meanwhile, in California, we were trying to commercialize a lot of this stuff. HyperCard was **the** first program to introduce **the** public to hyperlinks, where you could randomly hook to any kind of picture, or piece of text, or data across a file system, and we had no way of explaining it. There was no metaphor. Was it a database? A prototyping tool? A scripted language? Heck, it was everything. So we ended up writing a marketing brochure. We asked a question about how **the** mind works, and we let our customers play **the** role of so many blind men filling out **the elephant**. A few years later, we then hit on **the** idea of explaining to people **the** secret of, how do you get **the** content you want, **the** way you want it and **the** easy way? Here ’ s **the** Apple marketing video. James Burke : You ’ ll be pleased to know, I ’ m sure, that there are several ways to create a HyperCard interactive video. **The** most involved method is to go ahead and produce your own videodisc as well as build your own HyperCard **stacks**. By far **the** simplest method is to buy a pre-made videodisc and HyperCard **stacks** from a commercial supplier. **The** method we illustrate in this video uses a pre-made videodisc but creates custom HyperCard **stacks**. This method allows you to use existing videodisc materials in ways which suit your specific needs and interests. PH : I hope you realize how subversive that is. That ’ s like a Dick Cheney speech. You think he ’ s a nice balding guy, but he ’ s just declared war on **the** content business. Find **the** commercial stuff, mash it up, tell **the** story your way. Now, as long as we confine this to **the** education market, and a personal matter between **the computer** and **the** file system, that ’ s fine, but as you can see, it was about to leap out and upset Jack Valenti and a lot of other people. By **the** way, speaking of **the** filing system, it never **occurred** to us that these hyperlinks could go beyond **the** local area network. A few years later, Tim Berners-Lee worked that out. It became a killer app of links, and today, of course, we call that **the** World Wide Web. Now, not only was I instrumental in helping Apple miss **the** Internet, but a couple of years later, I helped Bill Gates do **the** same thing. **The** year is 1993 and he was working on a book and I was working on a video to help him kind of explain where we were all heading and how to popularize all this. We were plenty aware that we were messing with media, and on **the surface**, it looks like we predicted a lot of **the** right things, but we also missed an awful lot. Let ’ s take a look. Narrator : **The** pyramids, **the** Colosseum, **the** New York subway system and TV dinners, ancient and modern wonders of **the** man-made world all. Yet each pales to insignificance with **the** completion of that magnificent accomplishment of twenty-first-century technology, **the** Digital Superhighway. Once it was only a dream of technoids and a few long-forgotten politicians. **The** Digital Highway arrived in America ’ s living rooms late in **the** twentieth century. Let us recall **the** pioneers who made this technical marvel possible.

The Digital Highway would follow **the** rutted trail first blazed by Alexander Graham Bell. Though some were incredulous... Man 1 : **The** phone company! Narrator : Stirred by **the** prospects of mass communication and making big **bucks** on advertising, David Sarnoff commercializes radio. Man 2 : Never had scientists been put under such pressure and demand. Narrator : **The** medium introduced America to new products. Voice 1 : Say, mom, Windows for Radio means more enjoyment and greater ease of use for **the** whole family. Be sure to **enjoy** Windows for Radio at home and at work. Narrator : In 1939, **the** Radio Corporation of America introduced television. Man 2 : Never had scientists been put under such pressure and demand. Narrator : Eventually, **the** race to **the** future took on added momentum with **the** breakup of **the** telephone company. And further stimulus came with **the** deregulation of **the** cable television industry, and **the** re-regulation of **the** cable television industry. Ted Turner : We did **the** work to build this, this cable industry, now **the** broadcasters want some of our money. I mean, it ' s ridiculous. Narrator : **Computers**, once **the** unwieldy tools of accountants and other **geeks**, escaped **the** backrooms to enter **the** media fracas. **The** world and all its culture reduced to bits, **the** lingua franca of all media. And **the** forces of convergence exploded. Finally, four great industrial sectors combined. Telecommunications, entertainment, computing and everything else. Man 3 : We ' ll see channels for **the** gourmet and we ' ll see channels for **the** pet lover. Voice 2 : Next on **the** gourmet pet channel, decorating birthday cakes for your schnauzer. Narrator : All of industry was in play, as investors flocked to place their bets. At stake : **the** battle for you, **the** consumer, and **the** right to spend billions to send a lot of information into **the** parlors of America. PH : We missed a lot. You know, you missed, we missed **the** Internet, **the** long tail, **the** role of **the** audience, open systems, social networks. It just goes to show how tough it is to come up with **the** right uses of media. Thomas Edison had **the** same problem. He wrote a list of what **the** phonograph might be good for when he invented it, and kind of only one of his ideas turned out to have been **the** right early idea. Well, you know where we ' re going on from here. We come into **the** era of **the** dotcom, **the** World Wide Web, and I don ' t need to tell you about that because we all went through that bubble together. But when we emerge from this and what we call Web 2. 0, things actually are quite different. And I think it ' s **the** reason that TV ' s so challenged. If Internet one was about pages, now it ' s about people. It ' s a customer, it ' s an audience, it ' s a person who ' s participating. It ' s **the** formidable thing that is changing entertainment now. MM : Because it gave **the** audience a role, something to do. PH : In my own company, Technorati, we see something like 67, 000 blog posts an hour come in. That ' s about 2, 700 fresh, connective links across about 112 million blogs that are out there. And it ' s no wonder that as we head into **the** writers ' strike, odd things happen. You know, it reminds me of that old saw in Hollywood, that a producer is anyone who knows a writer. I now think a network boss is anyone who has a cable modem. But it ' s not a joke. This is a real headline."Websites attract striking writers : operators of sites like MyDamnChannel. com could benefit from labor disputes."Meanwhile, you have **the** TV bloggers going out on strike, in sympathy with **the** television writers. And then you have TV Guide, a Fox property, which is about to sponsor **the** online video awards — but cancels it out of sympathy with traditional television, not appearing to gloat. To show you how schizophrenic this all is, here ' s **the** head of MySpace, or Fox Interactive, a News Corp company, being asked, well, with **the** writers ' strike, isn ' t this going to hurt News Corp and help you online? Man : But I, yeah, I think there ' s an opportunity. As **the** strike continues, there ' s an opportunity for more people to experience video on places like MySpace TV. PH : Oh, but then he remembers he works for Rupert Murdoch. Man : Yes, well, first, you know, I ' m part of News Corporation as part of Fox Entertainment Group. Obviously, we hope that **the** strike is — that **the** issues are resolved as quickly as possible. PH : One of **the** great things that ' s going on here is **the** globalization of content really is happening. Here is a **clip** from a video, from a piece of animation that was written by a writer in Hollywood, animation worked out in Israel, farmed out to Croatia and India, and it ' s now an international series. Narrator : **The** following takes place between **the** minutes of 2:15 p. m. and 2:18 p. m., in **the** months preceding **the** presidential primaries. Voice 1 : You ' ll have to stay here in **the** safe house until we get word **the terrorist** threat is over. Voice 2 : You mean we ' ll have to live here, together? Voices 2, 3 and 4 : With her? Voice 2 : Well, there goes **the** neighborhood. PH : **The** company that created this, Aniboom, is an interesting example of where this is headed. Traditional TV animation costs, say, between 80, 000 and 10, 000 dollars a minute. They ' re producing things for between 1, 500 and 800 dollars a minute. And they ' re offering their creators 30 percent of **the** back end, in a much more entrepreneurial manner. So, it ' s a different model. What **the** entertainment business is struggling with, **the** world of brands is figuring out. For example, Nike now understands that Nike Plus is not just a **device** in its shoe, it ' s a network to hook its customers together. And **the** head of marketing at Nike says,"People are coming to our site an average of three times a week. We don ' t have to go to them."Which means television advertising is down 57 percent for Nike. Or, as Nike ' s head of marketing says,"We ' re not in **the** business of keeping media companies alive. We ' re in **the** business of connecting with consumers."And media companies realize **the** audience is important also. Here ' s a man announcing **the** new Market Watch from Dow Jones, powered 100 percent by **the** user experience on **the** home page — user-generated content married up with traditional content. It turns out you have a bigger audience and more interest if you hook up with them. Or, as Geoffrey Moore once told me, it ' s intellectual curiosity that ' s **the** trade that brands need in **the** age of **the** blogosphere. And I think this is beginning to happen in **the** entertainment business. One of my heroes is songwriter, Ally Willis, who just wrote"**The** Color Purple"and has been an R and — rhythm and **blues** writer, and this is what she said about where songwriting ' s going. Ally Willis : Where millions of collaborators wanted **the** song, because to look at them strictly as spam is missing what this medium is about. PH : So, to wrap up, I ' d love to throw it back to Marshall McLuhan, who, 40 years ago, was dealing with audiences that were going through just as much change, and I think that, today, traditional Hollywood and **the** writers are framing this perhaps in **the** way that it was being framed before. But I don ' t need to tell you this, let ' s throw it back to him. Narrator : We are in **the** middle of a tremendous clash between **the** old and **the** new. MM : **The** medium does things to people and they are always completely unaware of this. They don ' t really notice **the** new medium that is wrapping them up. They think of **the** old medium, because **the** old medium is always **the** content of **the** new medium, as movies tend to be **the** content of TV, and as books used to be **the** content, novels used to be **the** content of movies. And so every time a new medium arrives, **the** old medium is **the** content, and it is highly observable, highly noticeable, but **the** real, real roughing up and massaging is done by **the** new medium, and it is ignored. PH : I think it ' s a great time of enthrallment. There ' s been more raw DNA of communications and media thrown out there. Content is moving from shows to particles that are batted back and forth, and part of social communications, and I think this is going to be a time of great renaissance and opportunity. And whereas television may have gotten beat up, what ' s getting built is a really exciting new form of communication, and we kind of have **the** merger of **the** two industries and a new way of thinking to look at it. Thanks very much.

Text Sample 22: POS Dim 1 – 2007 – Score 24.00 – 2007/t000223.txt

Good afternoon, good evening, whatever. We can go, jambo, guten Abend, bonsoir, but we can also ooh, ooh, ooh, ooh, ooh, ooh, ooh, ooh, ooh. That is **the** call that chimpanzees make before they go to sleep in **the** evening. You hear it going from one side of **the** valley to **the** other, from one group of nests to **the** next. And I want to pick up with my talk this evening from where Zeray left off yesterday. He was talking about this amazing, three-year-old Australopithecine child, Selam. And we ’ ve also been hearing about **the** history, **the** family tree, of mankind through DNA genetic profiling. And it was a paleontologist, **the** late Louis Leakey, who actually set me on **the** path for studying chimpanzees. And it was pretty extraordinary, way back then. It ’ s kind of commonplace now, but his argument was — because he ’ d been **searching** for **the** fossilized remains of early humans in Africa. And you can tell an awful lot about what those beings looked like from **the fossils**, from **the** shape of **the** muscle attachments, something about **the** way they lived from **the** various artifacts found with them. But what about how they behaved? That ’ s what he wanted to know. And of course, behavior doesn ’ t fossilize. He argued — and it ’ s now a fairly common theory — that if we found behavior patterns similar or **the** same in our closest living **relatives**, **the** great apes, and humans today, then maybe those behaviors were present in **the** ape-like, human-like ancestor some seven million years ago. And therefore, perhaps we had brought those characteristics with us from that ancient, ancient past. Well, if you look in **textbooks** today that deal with human **evolution**, you very often find people **speculating** about how early humans may have behaved, based on **the** behavior of chimpanzees. They are more like us than any other living creature, and we ’ ve heard about that during this TED Conference. So it remains for me to comment on **the** ways in which chimpanzees are so like us, in certain aspects of their behavior. Every chimpanzee has his or her own personality. Of course, I gave them names. They can live to be 60 years or more, although we think most of them probably don ’ t make it to 60 in **the** wild. Mr. Wurzel. **The** female has her first baby when she ’ s 11 or 12. Thereafter, she has one baby only every five or six years, a long period of childhood dependency when **the** child is nursing, sleeping with **the** mother at night, and riding on her back. And we believe that this long period of childhood is important for chimpanzees, just as it is for us, in relation to learning. As **the** brain becomes ever more complex during **evolution** in different forms of animals, so we find that **learning** plays an ever more important role in an individual ’ s life history. And young chimpanzees spend a lot of time watching what their elders do. We know now that they ’ re capable of imitating behaviors that they see. And we believe that it ’ s in this way that **the** different tool-using behaviors — that have now been seen in all **the** different chimpanzee populations studied in Africa — how these are passed from one generation to **the** next, through observation, imitation and practice, so that we can describe these tool-using behaviors as primitive culture. Chimpanzees don ’ t have a spoken language. We ’ ve talked about that. They do have a very rich repertoire of postures and gestures, many of which are similar, or even **identical**, to ours and formed in **the** same context. Greeting chimpanzees embracing. They also kiss, hold hands, pat one another on **the** back. And they swagger and they throw **rocks**. In chimpanzee society, we find many, many examples of compassion, precursors to love and true altruism. Unfortunately, they, like us, have a dark side to their nature. They ' re capable of extreme brutality, even a kind of primitive war. And these really aggressive behaviors, for **the** most part, are directed against individuals of **the** neighboring social group. They are very territorially aggressive. Chimpanzees, I believe, more than any other living creature, have helped us to understand that, after all, there is no sharp line between humans and **the** rest of **the** animal kingdom. It ' s a very blurry line, and it ' s getting more blurry all **the** time as we make even more observations. **The** study that I began in 1960 is still continuing to this day. And these chimpanzees, living their complex social lives in **the** wild, have helped — more than anything else — to make us realize we are part of, and not separated from, **the** amazing animals with whom we share **the planet**. So it ' s pretty sad to find that chimpanzees, like so many other creatures around **the** world, are losing their **habitats**. This is just one photograph from **the** air, and it shows you **the** forested highlands of Gombe. And it was when I flew over **the** whole area, about 16 years ago, and realized that outside **the** park, this forest, which in 1960 had stretched almost unbroken along **the eastern** shore of Lake Tanganyika, which is where **the** tiny, 30-square-mile Gombe National Park lies, that a question came to my mind."How can we even try to save these **famous** chimpanzees, when **the** people living around **the** National Park are struggling to survive?"More people are living there than **the** land could possibly support. **The** numbers increased by refugees pouring in from Burundi and over **the** lake from Congo. And very poor people — they couldn ' t afford to buy food from elsewhere. This led to a program, which we call TACARE. It ' s a very holistic way of improving **the** lives of **the** people living in **the** villages around **the** park. It started small with 12 villages. It ' s now in 24. There isn ' t time to go into it, but it ' s including things like tree nurseries, methods of farming most suitable to this now very degraded, almost desert-like land up in these mountains. Ways of controlling, preventing soil erosion. Ways of reclaiming overused farmland, so that within two years they can again be productive. Working to help **the** villagers obtain fresh water from wells. Perhaps build some schoolrooms. Most important of all, I believe, is working with small groups of women, providing them with opportunities for micro-credit loans. And we ' ve got, as is **the** case around **the** world, about 95 percent of all loans returned. Empowering women, working with education, providing scholarships for girls so they can finish secondary school, in **the** clear understanding that, all around **the** world, as women ' s education improves, family size drops. We provide information about family planning and about HIV / AIDS. And as a result of this program, something ' s happening for conservation. What ' s happening for conservation is that **the** farmers living in these 24 villages, instead of looking on us as a bunch of white people coming to study a whole bunch of monkeys — and by **the** way, many of **the** staff are now Tanzanian — but when we began **the** TACARE program, it was a Tanzanian team going into **the** villages. It was a Tanzanian team talking to **the** villagers, asking what they were interested in. Were they interested in conservation? Absolutely not. They were interested in health ; they were interested in education. And as time went on, and as their situation began to improve, they began to understand ever more about **the** need for conservation. They began to understand that as **the** upper levels of **the** hills were denuded of trees, so you ' ve got this terrible soil erosion and mudslides. Today, we are developing what we call **the** Greater Gombe Ecosystem. This is an area way outside **the** National Park, stretching out into all these very degraded lands. And as these villages have a better standard of life, they are actually agreeing to put between 10 percent and 20 percent of their land in **the** highlands aside, so that once again, as **the** trees grow back, **the** chimpanzees will have leafy corridors through which they can travel to interact — as they must for genetic viability — with other remnant groups outside **the** National Park. So TACARE is a success. We ’ re replicating it in other parts of Africa, around other wilderness areas which are faced with extreme population pressure. **The** problems in Africa, however, as we ’ ve been discussing for **the** whole of these first couple of days of TED, are major problems. There is a great deal of poverty. And when you get large numbers of people living in land that is not that fertile, particularly when you cut down trees, and you leave **the** soil open to **the** wind for erosion, as desperate populations cut down more and more trees, so that they can try and grow food for themselves and their families, what ’ s going to happen? Something ’ s got to give. And **the** other problems — in not only Africa, but **the** rest of **the** developing world and, indeed, everywhere — what are we doing to our **planet**? You know, **the famous** scientist, E. O. Wilson said that if every person on this **planet** attains **the** standard of living of **the** average European or American, we need three new **planets**. Today, they are saying four. But we don ’ t have them. We ’ ve got one. And what ’ s happened? I mean, **the** question here is, here we are, arguably **the** most intelligent being that ’ s ever walked **planet** Earth, with this extraordinary brain, capable of **the** kind of technology that is so well illustrated by these TED Conferences, and yet we ’ re destroying **the** only home we have. **The** indigenous people around **the** world, before they made a major decision, used to sit around and ask themselves,”How does this decision affect our people seven generations ahead?”Today, major decisions — and I ’ m not particularly talking about Africa here, but **the** developed world — major decisions involving millions of dollars, and millions of people, are often based on,”How will this affect **the** next shareholders ’ meeting?”And these decisions affect Africa. As I began traveling around Africa talking about **the** problems faced by chimpanzees and their vanishing forests, I realized more and more how so many of Africa ’ s problems could be laid at **the** door of previous colonial exploitation. So I began traveling outside Africa, talking in Europe, talking in **the** United States, going to Asia. And everywhere there were these terrible problems. And you know **the** kind I ’ m talking about. I ’ m talking about pollution. **The** air that we breathe that often poisons us. **The** earth is poisoning our foods. **The** water — water is perhaps one of **the** most crucial issues that we ’ re going to face in this century — and everywhere water is being **polluted** by agricultural, industrial and household chemicals that still are being sprayed around **the** world, seemingly with **the** inability to profit from past experience. **The** mangroves are being cut down ; **the** effects of things like **the** **tsunami** get worse. We ’ ve talked about **the** soil erosion. We have **the** reckless burning of **fossil** fuels along with other **greenhouse** gasses, so called, leading to climate change. Finally, all around **the** world, people have begun to believe that there is something going on very wrong with our climate. All around **the** world climates are mixed up. And it ’ s **the** poor people who are affected worse. It ’ s Africa that already is affected. In many parts of sub- Saharan Africa, **the** **droughts** are so much worse. And when **the** rain does come, it so often leads to flooding and added distress, and **the** cycle of poverty and hunger and disease. And **the** numbers of people living in an area that **the** land cannot support, who are too poor to buy food, who can ’ t move away because **the** whole land is degraded. And so you get desertification — creeping, creeping, creeping — as **the** last of **the** trees are cut down. And this kind of thing is not just in Africa. It ’ s all over **the** world. So it wasn ’ t surprising to me that as I was traveling around **the** world I met so many young people who seemed to have lost hope. We seem to have lost wisdom, **the** wisdom of **the** indigenous people. I asked a question.”Why?”Well, do you think there could be some kind of disconnect between this extraordinarily clever brain, **the** kind of brain that **the** TED technologies exemplify, and **the** human heart? Talking about it in **the** non-scientific term, in terms of love and compassion. Is there some disconnect? And these young people, when I talk to them, basically they were either depressed or apathetic, or bitter and angry. And they said more or less **the** same thing,"We feel this way because we feel you ' ve compromised our future and there ' s nothing we can do about it."We have compromised their future. I ' ve got three little grandchildren, and every time I look at them and I think how we ' ve harmed this beautiful **planet** since I was their age, I feel this desperation. And that led to this program we call Roots and Shoots, which began right here in Tanzania and has now spread to 97 countries around **the** world. It ' s symbolic. Roots make a firm foundation. Shoots seem tiny ; to reach **the** sun they can break through a brick wall. See **the** brick wall as all these problems we ' ve inflicted on **the planet**, environmental and social. It ' s a message of hope. Hundreds and thousands of young people around **the** world can break through and can make this a better world for all living things. **The** most important message of Roots and Shoots : every single one of us makes a difference, every single day. We have a choice. Every one of us in this room, we have a choice as to what kind of difference we want to make. **The** very poor have no choice. It ' s up to us to change things so that **the** poor have choice as well. **The** Roots and Shoots groups all choose three projects. It depends on how old they are, and which country, whether they ' re in a city or rural, as to what kinds of projects. But basically, we have programs now from preschool right through university, with more and more adults starting their own Roots and Shoots groups. And every group chooses, between them, three different kinds of project to make this a better world, recognizing that all these different problems are interconnected and impinge on each other. So one of their projects will be to help their own human community. And then, if they ' re able, they may raise money to help communities in other parts of **the** world. One of their projects will be to help animals — not just wildlife, domestic animals as well. And one of their projects will be to help **the** environment that we all share. And woven throughout all of this is a message of learning to live in peace and harmony within ourselves, in our families, in our communities, between nations, between cultures, between religions and between us and **the** natural world. We need **the** natural world. We cannot go on destroying it at **the** rate we are. We not do have more than this one **planet**. Just picking one or two of **the** projects right here in Africa that **the** Roots and Shoots groups are doing, one or two projects only — in Tanzania, in Uganda, Kenya, South Africa, Congo-Brazzaville, Sierra Leone, Cameroon and other groups. And as I say, it ' s in 97 countries around **the** world. Of course, they ' re planting trees. They ' re growing **organic** vegetables. They ' re working in **the** refugee camps, with chickens and selling **the** eggs for a little amount of money, or just using them to feed their families, and feeling a sense of pride and empowerment, because they ' re no longer helpless and depending on others with their vegetables and their chickens. It ' s being used in Uganda to give some psychological help to ex-child soldiers. Doing projects like this is bringing them out of themselves. Once again, they ' re useful members of society. We have this program in prisons as well. So, there ' s no time for more Roots and Shoots now. But — oh, they ' re also working on HIV / AIDS. That ' s a very important component of Roots and Shoots, with older kids talking to younger ones. And unwanted pregnancies and things like that, which young people listen to better from other youth, rather than adults. Hope. That ' s **the** question I get asked as I ' m going around **the** world :"Jane, you ' ve seen so many terrible things, you ' ve seen your chimpanzees decrease in number from about one million, at **the** turn of **the** century, to no more than 150, 000 now, and **the** same with so many other animals. Forests **disappearing**, deserts where once there was forest. Do you really have hope?"Well, yes. You can ' t come to a conference like TED and not have hope, can you? And of course, there ' s hope. One is this amazing human brain. And I mean, think of **the** technologies. And I ' ve just been so thrilled, finally, to come to people talking about compost latrines. It ' s one of my hobbyhorses. We just flush all this water down **the** lavatory, it ' s terrible. And then talking about **renewable** energy — desperately important. Do we care about **the planet** for our children? How many of us have children or grandchildren, nieces, nephews? Do we care about their future? And if we care about their future, we, as **the** elite around **the** world, we can do something about it. We can make choices as to how we live each day. What we buy. What we wear. And choose to make these choices with **the** question, how will this affect **the** environment around me? How will it affect **the** life of my child when he or she grows up? Or my grandchild, or whatever it is. So **the** human brain, coupled with **the** human heart, and we join hands around **the** world. And that ' s what TED is helping so well with, and Google who help us, and Esri are helping us with mapping in Gombe National Park. All of these technologies we can use. Now let ' s link them, and it ' s beginning to happen, isn ' t it? You ' ve heard about it this afternoon. It ' s beginning to happen. This change, this change. To see change that we must have if we care about **the** future. And **the** next reason for hope — nature is amazingly resilient. You can take an area that ' s absolutely destroyed, with time and perhaps some help it can regenerate. And an example is **the** TACARE program. I told you, where a seemingly dead tree stump — if you stop hacking them for firewood, which you don ' t need to because you have wood lots, then in five years you can have a 30-foot tree. And animals, almost on **the** brink of extinction, can be given a second chance. That ' s my next book. It ' s inspiring. And it brings me to my last category of hope, and we ' ve heard about this so much in **the** last two days : this indomitable human spirit. This determination of people, **the** resilience of **the** human spirit, So that people who you would think would be battered by poverty, or disease, or whatever, can pull themselves up out of it, sometimes with a helping hand, and take their part in society, and take their part in changing **the** world. And just to think of one or two people out of Africa who are just really inspiring. We could make a very long list, but obviously Nelson Mandela, emerging from 17 years of hard physical labor, 23 years of imprisonment, with this amazing ability to forgive, so that he could lead his nation out **the** evil regime of apartheid without a bloodbath. Ken Saro-Wiwa, in Nigeria, who took on **the** giant **oil** companies, and although people around **the** world tried their best, was executed. People like this are so inspirational. People like this are **the** role models we need for young Africans. And we need some environmental role models as well, and I ' ve been hearing some of them today. So I ' m really grateful for this opportunity to share this message again, with everyone at TED. And I hope that some of us can get together and talk about some of these things, especially **the** Roots and Shoots program. And just a last word on that — **the** young woman who ' s running this entire conference center, I met her today. She came up so excited, with her certificate. She was [in] Roots and Shoots. She was in **the** leadership in Dar es Salaam. She said it ' s helped her to do what she ' s doing. And it was very, very exciting for me to meet her and see just one example of how young people, when they are empowered, given **the** opportunity to take action, to make **the** world a better place, truly are our hope for tomorrow. Thank you.

Text Sample 23: POS Dim 1 – 2004 – Score 20.00 – 2004/t000140.txt

This is **the** first of two rather extraordinary photographs I ' m going to show you today. It was taken 18 years ago. I was 19 years old at **the** time. I had just returned from one of **the** deepest dives I ’ d ever made at that time â a little over 200 feet. And I had caught this little **fish**. It turns out that particular one was **the** first of its kind ever taken alive. I ’ m not just an ichthyologist, I ’ m a bona fide **fish** nerd. And to a **fish** nerd, this is some pretty exciting stuff. More exciting was **the** fact that **the** person who took this photo is a guy named Jack Randall, **the** greatest living ichthyologist on earth â **the** Grand Poobah of **fish** nerds, if you will. And so, it was really exciting to me to have this moment in time. It set **the** course for **the** rest of my life. But really, **the** most significant, most profound thing about this picture is it was taken two days before I was completely paralyzed from **the** neck down. I made a really stupid kind of mistake that most 19-year-old males do when they think they ’ re immortal, and I got a bad case of **the** bends and was paralyzed, and had to be flown back for treatment. I learned two really important things that day. **The** first thing I learned â well, I ’ m mortal. That ’ s a really big one. And **the** second thing I learned was that I knew, with profound certainty, that this is exactly what I was going to do for **the** rest of my life. I had to focus all my energies towards going to find new species of things down on deep coral reefs. When you think of a coral reef, this is what most people think of : these big, hard, elaborate corals, lots of bright, colorful **fishes** and things. But this is really just **the** tip of **the** iceberg. If you look at this diagram of a coral reef, we know a lot about that part up near **the** top. **The** reason we know so much about it is scuba divers can very easily go down there and access it. There is a problem with scuba, though, in that it imposes some limitations on how deep you can go. It turns out that depth is about 200 feet. I ’ ll get into why that is in just a minute, but **the** point is, scuba divers generally stay less than 100 feet deep, and very rarely go much below this, at least, not with any kind of sanity. So to go deeper, most biologists have turned to submersibles. Now, submersibles are great, wonderful things, but if you ’ re going to spend 30, 000 dollars a day to use one of these things and it ’ s capable of going 2, 000 feet, you ’ re not going to go farting around up here in a couple of hundred feet, you ’ re going to go way down deep. So **the** bottom line is, almost all research using submersibles has taken place well below 500 feet. Now, it ’ s pretty obvious at this point there ’ s a zone here in **the** middle. That ’ s **the** zone that centers around my own personal pursuit of happiness. I want to find out what ’ s in this zone ; we know almost nothing about it. Scuba divers can ’ t get there, submarines go right on past it. It took me a year to learn to walk again after my diving accident in Palau. During that year, I spent a lot of time learning about **the** physics and physiology of diving and how to overcome these limitations. I ’ m just going to show you a basic idea. We ’ re all breathing air right now. Air is a mixture of oxygen and nitrogen, 20 percent oxygen, 80 percent nitrogen. It ’ s in our lungs. And there ’ s a phenomenon called Henry ’ s law, that says gases will dissolve into a fluid in proportion to **the** partial pressures you ’ re exposing them to. So, basically **the** gas dissolves into our body. **The** oxygen is bound by metabolism, we use it for energy. **The** nitrogen sort of floats around in our **blood** and tissues. That ’ s fine, it ’ s how we ’ re designed. **The** problem happens when you go **underwater**. **The** deeper you go **underwater**, **the** higher **the** pressure is. If you were to go down to a depth of about 130 feet, which is **the** recommended limit for most scuba divers, you ’ d get this pressure effect. **The** effect of that pressure is you have an increased density of gas molecules in every breath you take. Over time, those gas molecules dissolve into your **blood** and tissues and start to fill you up. Now, if you were to go down to, say, 300 feet, you don ’ t have five times as many gas molecules in your lungs, you ’ ve got 10 times as many gas molecules in your lungs. And, sure enough, they dissolve into your

blood and tissues as well. And if you were to go down to where there ’ s 15 times as much â **the** deeper you go, **the** more exacerbating **the** problem becomes. **The** limitation of diving with air is all those dots in your body, all **the** nitrogen and all **the** oxygen. There are three basic limitations of scuba diving. **The** first limitation is **the** oxygen â oxygen toxicity. Now, we all know **the** song :”Love is like oxygen. You get too much, you get too high. Not enough, and you ’ re gonna die.”Well, in **the** context of diving, you get too much, you die also. You die because oxygen toxicity can cause a seizure. It makes you convulse **underwater** â not a good thing to happen **underwater**. It happens because there ’ s too much concentration of oxygen in your body. **The** nitrogen has two problems. One of them is what Jacques Cousteau called”rapture of **the** deep.”It ’ s nitrogen narcosis. It makes you loopy ; **the** deeper you go, **the** loopier you get. You don ’ t want to drive drunk, you don ’ t want to dive drunk. So that ’ s a real big problem. And of course, **the** third problem is **the** one I found out **the** hard way in Palau, which is **the** bends. One thing I forgot to mention is that to obviate **the** problem of nitrogen narcosis â all of those **blue** dots in our body â you remove **the** nitrogen and replace it with helium. Helium ’ s a gas ; there ’ re a lot of reasons why helium ’ s good, it ’ s a tiny molecule, it ’ s inert, it doesn ’ t give you narcosis. So that ’ s **the** basic concept we use. But **the** theory ’ s relatively easy. **The** tricky part is **the** implementation. So this is how I began about 15 years ago. I ’ ll admit, it wasn ’ t exactly **the** smartest of starts, but you ’ ve got to start somewhere. At **the** time, I wasn ’ t **the** only one who didn ’ t know what I was doing. Almost nobody did. This rig was actually used for a dive of 300 feet. But over time we got better at it, and we came up with this really sophisticated-looking rig with four scuba tanks, five regulators and all **the** right gas mixtures, all that good stuff. It was fine and dandy, it allowed us to go down and find new species. This picture was taken at 300 feet, catching new species of **fish**. **The** problem was it didn ’ t allow us much time. For all its bulk and size, it only gave us about 15 minutes at most down at those sorts of depths. We needed more time. There had to be a better way. And indeed, there is a better way. In 1994, I was fortunate enough to get access to these prototype closed-circuit rebreathers. Closed-circuit rebreather : what makes it different from scuba, and why is it better? Well, there are three main advantages to a rebreather. One, they ’ re quiet, they don ’ t make any noise. Two, they allow you to stay **underwater** longer. Three, they allow you to go deeper. How is it that they do that? In order to really understand how they do that, you have to look underneath **the** hood and see what ’ s going on. There are three basic systems to a closed-circuit rebreather. **The** most fundamental is called **the** breathing loop. It ’ s a breathing loop because you breathe off of it ; it ’ s a closed loop, and you breathe **the** same gas around and around. There ’ s a mouthpiece that you put in your mouth, and there ’ s a counter lung, or in this case, two counter lungs. **The** counter lungs aren ’ t high tech, they ’ re simply flexible bags. They allow you to mechanically breathe, mechanically ventilate. When you exhale, it goes in **the** exhale counter lung ; when you inhale, it comes from **the** inhale counter lung. It ’ s just pure mechanics, allowing you to cycle air through this breathing loop. **The** other component on a breathing loop is **the** carbon-dioxide-absorbent canister. Now, as we breathe, we produce **carbon** dioxide, and that **carbon** dioxide needs to be scrubbed out of **the** system. There ’ s a chemical filter in there that pulls **the carbon** dioxide out of **the** breathing gas, so that when it comes back to us, it ’ s safe to breathe again. That ’ s **the** breathing loop in a nutshell. **The** second main component of a closed-circuit rebreather is **the** gas system. **The** primary purpose of **the** gas system is to provide oxygen, to replenish **the** oxygen that your body consumes. So **the**

main tank, **the** main critical thing, is this oxygen gas supply cylinder we have here. But if we only had an oxygen gas supply cylinder, we wouldn ’ t be able to go very deep, because we ’ d run into oxygen toxicity very quickly. So we need another gas, something to dilute **the** oxygen with. And that, fittingly enough, is called **the** diluent gas supply. In our applications, we generally put air inside this diluent gas supply, because it ’ s a very cheap and easy source of nitrogen. So that ’ s where we get our nitrogen from. But if we want to go deeper, of course, we need another gas supply, and helium is what we really need to go deep. Usually we ’ ll have a slightly larger cylinder, mounted exterior on **the** rebreather, like this. That ’ s what we use to inject, as we start to do our deep dives. We also have a second oxygen cylinder, solely as a backup ; if there ’ s a problem with our first oxygen supply, we can continue to breathe. **The** way you manage all these different gases and different gas supplies is this really high-tech, sophisticated gas block up on **the** front here, where it ’ s easy to reach. It ’ s got **the valves** and knobs and things you need to inject **the** right gases at **the** right time. Normally, you don ’ t have to do that, because all of it ’ s done automatically with **the** electronics, **the** third system of a rebreather. **The** most critical part of a rebreather are **the** oxygen sensors. You need three, so if one goes bad, you know which one it is. You need voting logic. You also have three microprocessors. Any one of those **computers** can run **the** entire system, so if you have to lose two of them, there ’ s back-up power supplies. And there are multiple displays, to get **the** information to **the** diver. This is **the** high-tech gadgetry that allows us to do what we do on these deep dives. I can talk about it all day â just ask my wife â but I want to move on to something much more interesting. I ’ m going to take you on a deep dive, and show you what it ’ s like to do one. We start up on **the** boat, For all this high-tech, expensive equipment, this is still **the** best way to get in **the** water, just flop over **the** side of **the** boat. Now, as I showed you in **the** earlier diagram, these reefs that we dive on start out near **the surface** and they go almost vertically, completely straight down. So we drop in **the** water and go over **the** edge of this cliff, and then we start dropping, dropping, dropping. People ask if it takes a long time to get there. No ; it only takes a couple minutes to get down to three or four hundred feet, which is what we ’ re aiming for. It ’ s like skydiving in slow motion. It ’ s really very interesting. You ever see”**The Abyss**,”where Ed Harris is sinking down along **the** side of **the** wall? That ’ s what it feels like. Amazing. And down there, you find that **the** water is very clear, extremely clear, because there ’ s hardly any plankton. When you turn on your light and look around **the** caves, you ’ re confronted with a tremendous amount of diversity, much more than anyone used to believe. Now, not all of it is new species â that **fish** you see with **the** white stripe, that ’ s a known species. But if you look carefully into **the** cracks and crevices, you ’ ll see little things scurrying all over **the** place. There ’ s a just unbelievable diversity. It ’ s not just **fish**, either. These are crinoids, sponges, black corals. There ’ re some more **fishes**. Those **fishes** that you see now are new species. They ’ re still new species, because I had a video camera instead of my net, so they ’ re still waiting down there for someone to go find them. But this is what it looks like. And this kind of **habitat** just goes on and on and on for miles. This is Papua, New Guinea. Now little **fishes** and invertebrates aren ’ t **the** only things we see down there. We also see sharks, much more regularly than I would have expected to. We ’ re not quite sure why. What I want you to do now is imagine yourself 400 feet **underwater**, with all this high-tech gear on your back, you ’ re in a remote reef off Papua, New Guinea, thousands of miles from **the** nearest recompression chamber, and you ’ re completely surrounded by sharks. Diver 1 : Look at those... Diver 2 : Uh, oh... Uh, oh! Audience : Diver 1 : I think we have their attention... Richard Pyle : When you start talking like Donald Duck, there ’ s no situation in **the** world that can seem tense. So we ’ re down there â this is at 400 feet. That ’ s looking straight up, by **the** way, to give a sense of how far **the surface** is. And if you ’ re a biologist and know about sharks, and you want to assess, how much jeopardy am I really in here, there ’ s one question that sort of jumps to **the** forefront of your mind immediately, which is â Diver 1 : What kind of sharks? Diver 2 : Silvertip sharks. Diver 1 : Oh. RP : There are actually three species of sharks here. **The** silvertips are **the** ones with **the** white edges on **the fins**, and there ’ re also gray reef sharks and hammerheads off in **the** distance. And yes, it ’ s a little nerve-racking. Diver 2 : Hoo! That little guy is frisky! Audience : Now, you ’ ve seen video like this on TV a lot, and it ’ s very intimidating. I think it gives **the** wrong impression about sharks ; they ’ re actually not very dangerous animals. That ’ s why we weren ’ t worried much and were joking around. More people are killed by pigs, by lightning strikes, more people are killed at soccer games in England. There ’ s a lot of other ways you can die. And I ’ m not making that stuff up. Coconuts! You can get killed by a coconut more likely than killed by a shark. So sharks aren ’ t quite as dangerous as most people make them out to be. Now, I don ’ t know if any of you get US News and World Report â I got **the** recent issue. There ’ s a cover story about **the** great explorers of our time. **The** last article is entitled,”No New Frontiers.”It questions whether or not there really are any new frontiers out there, whether there are any true, hardcore discoveries that can still be made. My favorite line from **the** article : [... ’ discovery ’ can mean finding a guppy with an extra spine in its dorsal **fin**.”] I have to laugh ; they don ’ t call us **fish** nerds for nothing. We actually do get excited about finding a new dorsal spine in a guppy. But it ’ s much more than that. I want to show you a few of **the** guppies we ’ ve found over **the** years. This one â you can see how ugly it is. Even if you ignore **the** scientific value of this thing, look at **the** monetary value of this thing. A couple of these were sold through **the** aquarium trade to Japan, where they sold for 15, 000 dollars apiece. That ’ s half a million dollars a **pound**. Here ’ s another new angelfish we discovered. This one we first discovered back in **the** air days â **the** bad old air days, when we were doing these kind of dives with air. We were at 360 feet. I remember coming up from one of these deep dives and I had this fog, and **the** narcosis takes a little while to fade away, sort of like sobering up. I had this vague recollection of seeing this **yellow fish** with a black spot, and thought,”Damn, I should have caught one â I think that ’ s a new species.”Eventually, I looked in my bucket. Sure enough, I had caught one, I just completely forgot. So this one, we decided to give **the** name Centropyge narcosis to. That ’ s its official scientific name, in reference to its deep-dwelling habits. This is another neat one. When we first found it, we weren ’ t even sure what family it belonged to, so we just called it **the** Dr. Seuss **fish**, since it looked like something from one of those books. Now, this one ’ s pretty cool. If you go to Papua, New Guinea and go down 300 feet, you ’ ll see these big mounds. This may be hard to see, but they ’ re a couple meters in **diameter**. If you look closely, you ’ ll see there ’ s a little white and gray **fish** that hangs out near them. It turns out this little white **fish** builds these giant mounds, one pebble at a time. It ’ s extraordinary to find something like this. It ’ s not just new species, it ’ s new behaviors, new **ecology**, all kind of new things. What I ’ m going to show you now, quickly, is a sampling of **the** new species we ’ ve discovered. What ’ s extraordinary is not just **the** number of species we ’ re finding â though as you can see, that ’ s pretty amazing ; this is only half of what we ’ ve found â what ’ s extraordinary is how quickly we find them. We ’ re up to seven new species per hour of time we spend at that depth. If you go to an Amazon jungle and fog a tree, you may get a lot of bugs, but for **fishes**, there ’ s nowhere in **the** world you can get seven new species per hour of time. Now, we ’ ve done some back-of-the-envelope calculations, and we ’ re predicting there are probably about 2, 000 to 2, 500 new species in **the** Indo-Pacific alone. There are only five to six thousand known species, so a very large percentage of what is out there isn ’ t really known. We thought we had a handle on all **the** reef **fish** diversity â evidently not. I ’ m going to just close on a very somber note. At **the** beginning, I said I ’ d show you two extraordinary photographs. This is **the** second extraordinary photograph I ’ m going to show you. This one was taken at **the exact** moment I was down there filming those sharks. This was taken exactly 300 feet above my head. **The** reason this photograph is extraordinary is because it captures a moment in **the** very last minute of a person ’ s life. Less than 60 seconds after this picture was taken, this guy was dead. When we recovered his body, we figured out what had gone wrong. He had made a very simple mistake ; he turned **the** wrong **valve** when he filled his cylinder. he had 80 percent oxygen in his tank when he should have had 40. He had an oxygen toxicity seizure and he drowned. **The** reason I show this â not to put a downer on everything â but I just want to use it to key off my philosophy of life in general, which is that we all have two goals. **The** first goal we share with every other living thing on this **planet**, which is to survive. I call it perpetuation : **the** survival of **the** species and survival of ourselves, And those are both about perpetuating **the** **genome**. **The** second goal, for those of us who have mastered **the** first goal â call it spiritual fulfillment, call it financial success, you can call it any number of different things. I call it seeking joy, this pursuit of happiness. So, I guess my **theme** on this is this guy lived his life to **the** fullest, he absolutely did. You have to balance those two goals. If you live your whole life in fear â I mean, life is a sexually transmitted disease with 100 percent mortality. So you can ’ t live your life in fear. I thought that was an old one! But at **the** same time, you don ’ t want to get so focused on rule number two, goal number two, that you neglect goal number one. Because once you ’ re dead, you really can ’ t **enjoy** anything after that. So I wish you all **the** best of luck in maintaining that balance in your future **endeavors**. Thanks.

Text Sample 24: POS Dim 1 – 2004 – Score 19.00 – 2004/t000177.txt

I was trying to think, how is sync connected to happiness, and it **occurred** to me that for some reason we take pleasure in synchronizing. We like to dance together, we like singing together. And so, if you ’ ll put up with this, I would like to enlist your help with a first experiment today. **The** experiment is — and I notice, by **the** way, that when you applauded, that you did it in a typical North American way, that is, you were raucous and incoherent. You were not organized. It didn ’ t even **occur** to you to clap in unison. Do you think you could do it? I would like to see if this audience would — no, you haven ’ t practiced, as far as I know — can you get it together to clap in sync? Whoa! Now, that ’ s what we call emergent behavior. So I didn ’ t expect that, but — I mean, I expected you could synchronize. It didn ’ t **occur** to me you ’ d increase your **frequency**. It ’ s interesting. So what do we make of that? First of all, we know that you ’ re all brilliant. This is a room full of intelligent people, highly sensitive. Some trained musicians out there. Is that what enabled you to synchronize? So to put **the** question a little more seriously, let ’ s ask ourselves what are **the** minimum requirements for what you just did, for spontaneous synchronization. Do you need, for instance, to be as smart as you are? Do you even need a brain at all just to synchronize? Do you need to be alive? I mean, that ’ s a spooky thought, right? Inanimate **objects** that might spontaneously synchronize themselves. It ’ s real. In fact, I ’ ll try to explain today that sync is maybe one of, if not one of **the** most, perhaps **the** most pervasive drive in all of nature. It extends from **the** subatomic scale to **the** farthest reaches of **the** cosmos. It ’ s a deep tendency toward order in nature that opposes what we ’ ve all been taught about entropy. I mean, I ’ m not saying **the** law of entropy is wrong — it ’ s not. But there is a countervailing force in **the universe** — **the** tendency towards spontaneous order. And so that ’ s our **theme**. Now, to get into that, let me begin with what might have **occurred** to you immediately when you hear that we ’ re talking about synchrony in nature, which is **the** glorious example of birds that flock together, or **fish** swimming in organized schools. So these are not particularly intelligent creatures, and yet, as we ’ ll see, they exhibit beautiful ballets. This is from a BBC show called”Predators,”and what we ’ re looking at here are examples of synchrony that have to do with defense. When you ’ re small and vulnerable, like these starlings, or like **the fish**, it helps to swarm to avoid predators, to confuse predators. Let me be quiet for a second because this is so gorgeous. For a long time, biologists were puzzled by this behavior, wondering how it could be possible. We ’ re so used to choreography giving rise to synchrony. These creatures are not choreographed. They ’ re choreographing themselves. And only today is science starting to figure out how it works. I ’ ll show you a **computer** model made by Iain Couzin, a researcher at Oxford, that shows how swarms work. There are just three simple rules. First, all **the** individuals are only aware of their nearest neighbors. Second, all **the** individuals have a tendency to line up. And third, they ’ re all attracted to each other, but they try to keep a small distance apart. And when you build those three rules in, automatically you start to see swarms that look very much like **fish** schools or bird flocks. Now, **fish** like to stay close together, about a body length apart. Birds try to stay about three or four body lengths apart. But except for that difference, **the** rules are **the** same for both. Now, all this changes when a predator enters **the** scene. There ’ s a fourth rule : when a predator ’ s coming, get out of **the** way. Here on **the** model you see **the** predator attacking. **The** prey move out in random directions, and then **the** rule of attraction brings them back together again, so there ’ s this constant splitting and reforming. And you see that in nature. Keep in mind that, although it looks as if each individual is acting to cooperate, what ’ s really going on is a kind of selfish Darwinian behavior. Each is scattering away at random to try to save its scales or feathers. That is, out of **the** desire to save itself, each creature is following these rules, and that leads to something that ’ s safe for all of them. Even though it looks like they ’ re thinking as a group, they ’ re not. You might wonder what exactly is **the** advantage to being in a swarm, so you can think of several. As I say, if you ’ re in a swarm, your odds of being **the** unlucky one are reduced as compared to a small group. There are many eyes to spot danger. And you ’ ll see in **the** example with **the** starlings, with **the** birds, when this peregrine hawk is about to attack them, that actually waves of panic can propagate, sending messages over great distances. You ’ ll see — let ’ s see, it ’ s coming up possibly at **the** very end — maybe not. Information can be sent over half a kilometer away in a very short time through this mechanism. Yes, it ’ s happening here. See if you can see those waves propagating through **the** swarm. It ’ s beautiful. **The** birds are, we sort of understand, we think, from that **computer** model, what ’ s going on. As I say, it ’ s just those three simple rules, plus **the** one about watch out for predators. There doesn ’ t seem to be anything mystical about this. We don ’ t, however, really understand at a mathematical level. I ’ m a mathematician. We would like to be able to understand better. I mean, I showed you a **com-**

puter model, but a **computer** is not understanding. A **computer** is, in a way, just another experiment. We would really like to have a deeper insight into how this works and to understand, you know, exactly where this organization comes from. How do **the** rules give rise to **the** patterns? There is one case that we have begun to understand better, and it ’ s **the** case of fireflies. If you see fireflies in North America, like so many North American sorts of things, they tend to be independent operators. They ignore each other. They each do their own thing, flashing on and off, paying no attention to their neighbors. But in Southeast Asia — places like Thailand or Malaysia or Borneo — there ’ s a beautiful cooperative behavior that **occurs** among male fireflies. You can see it every night along **the** river banks. **The** trees, mangrove trees, are filled with fireflies communicating with light. Specifically, it ’ s male fireflies who are all flashing in perfect time together, in perfect synchrony, to reinforce a message to **the** females. And **the** message, as you can imagine, is”Come hither. **Mate** with me.”In a second I ’ m going to show you a slow motion of a single firefly so that you can get a sense. This is a single frame. Then on, and then off — a 30th of a second, there. And then watch this whole river bank, and watch how precise **the** synchrony is. On, more on and then off. **The** combined light from these beetles — these are actually tiny beetles — is so bright that fishermen out at **sea** can use them as navigating beacons to find their way back to their home rivers. It ’ s **stunning**. For a long time it was not believed when **the** first Western travelers, like Sir Francis Drake, went to Thailand and came back with tales of this unbelievable spectacle. No one believed them. We don ’ t see anything like this in Europe or in **the** West. And for a long time, even after it was documented, it was thought to be some kind of optical illusion. Scientific papers were published saying it was twitching eyelids that explained it, or, you know, a human being ’ s tendency to see patterns where there are none. But I hope you ’ ve convinced yourself now, with this nighttime video, that they really were very well synchronized. **Okay**, well, **the** issue then is, do we need to be alive to see this kind of spontaneous order, and I ’ ve already hinted that **the** answer is no. Well, you don ’ t have to be a whole creature. You can even be just a single cell. Like, take, for instance, your pacemaker cells in your heart right now. They ’ re keeping you alive. Every beat of your heart depends on this crucial region, **the** sinoatrial node, which has about 10, 000 independent cells that would each beep, have an **electrical** rhythm — a voltage up and down — to send a signal to **the** ventricles to pump. Now, your pacemaker is not a single cell. It ’ s this democracy of 10, 000 cells that all have to fire in unison for **the** pacemaker to work correctly. I don ’ t want to give you **the** idea that synchrony is always a good idea. If you have epilepsy, there is an instance of billions of brain cells, or at least millions, discharging in pathological concert. So this tendency towards order is not always a good thing. You don ’ t have to be alive. You don ’ t have to be even a single cell. If you look, for instance, at how lasers work, that would be a case of atomic synchrony. In a laser, what makes laser light so different from **the** light above my head here is that this light is incoherent — many different colors and different **frequencies**, sort of like **the** way you clapped initially — but if you were a laser, it would be rhythmic applause. It would be all atoms pulsating in unison, emitting light of one color, one **frequency**. Now comes **the** very risky part of my talk, which is to demonstrate that inanimate things can synchronize. Hold your breath for me. What I have here are two empty water bottles. This is not Keith Barry doing a magic trick. This is a klutz just playing with some water bottles. I have some metronomes here. Can you hear that? All right, so, I ’ ve got a metronome, and it ’ s **the** world ’ s smallest metronome, **the** — well, I shouldn ’ t advertise. Anyway, so this is **the** world ’ s smallest metronome. I ’ ve set it on **the** fastest setting, and

I ’ m going to now take another one set to **the** same setting. We can try this first. If I just put them on **the** table together, there ’ s no reason for them to synchronize, and they probably won ’ t. Maybe you ’ d better listen to them. I ’ ll stand here. What I ’ m hoping is that they might just drift apart because their **frequencies** aren ’ t perfectly **the** same. Right? They did. They were in sync for a while, but then they drifted apart. And **the** reason is that they ’ re not able to communicate. Now, you might think that ’ s a bizarre idea. How can metronomes communicate? Well, they can communicate through mechanical forces. So I ’ m going to give them a chance to do that. I also want to wind this one up a bit. How can they communicate? I ’ m going to put them on a movable platform, which is **the**”Guide to Graduate Study at Cornell.”**Okay**? So here it is. Let ’ s see if we can get this to work. My wife pointed out to me that it will work better if I put both on at **the** same time because otherwise **the** whole thing will tip over. All right. So there we go. Let ’ s see. OK, I ’ m not trying to cheat — let me start them out of sync. No, hard to even do that. All right. So before any one goes out of sync, I ’ ll just put those right there. Now, that might seem a bit whimsical, but this pervasiveness of this tendency towards spontaneous order sometimes has unexpected consequences. And a clear case of that, was something that happened in London in **the** year 2000. **The** Millennium Bridge was supposed to be **the** pride of London — a beautiful new footbridge erected across **the** Thames, first river crossing in over 100 years in London. There was a big competition for **the** design of this bridge, and **the** winning proposal was submitted by an unusual team — in **the** TED spirit, actually — of an architect — perhaps **the** greatest architect in **the** United Kingdom, Lord Norman Foster — working with an artist, a sculptor, Sir Anthony Caro, and an engineering firm, Ove Arup. And together they submitted a design based on Lord Foster ’ s vision, which was — he remembered as a kid reading Flash Gordon comic books, and he said that when Flash Gordon would come to an **abyss**, he would shoot what today would be a kind of a light saber. He would shoot his light saber across **the abyss**, making a blade of light, and then scamper across on this blade of light. He said,”That ’ s **the** vision I want to give to London. I want a blade of light across **the** Thames.”So they built **the** blade of light, and it ’ s a very thin ribbon of steel, **the** world ’ s — probably **the** flattest and thinnest suspension bridge there is, with cables that are out on **the** side. You ’ re used to suspension bridges with big droopy cables on **the** top. These cables were on **the** side of **the** bridge, like if you took a rubber band and stretched it taut across **the** Thames — that ’ s what ’ s holding up this bridge. Now, everyone was very excited to try it out. On opening day, thousands of Londoners came out, and something happened. And within two days **the** bridge was closed to **the** public. So I want to first show you some interviews with people who were on **the** bridge on opening day, who will describe what happened. Man : It really started moving sideways and slightly up and down, rather like being on **the** boat. Woman : Yeah, it felt unstable, and it was very windy, and I remember it had lots of flags up and down **the** sides, so you could definitely — there was something going on sideways, it felt, maybe. Interviewer : Not up and down? Boy : No. Interviewer : And not forwards and **backwards**? Boy : No. Interviewer : Just sideways. About how much was it moving, do you think? Boy : It was about — Interviewer : I mean, that much, or this much? Boy : About **the** second one. Interviewer : This much? Boy : Yeah. Man : It was at least six, six to eight **inches**, I would have thought. Interviewer : Right, so, at least this much? Man : Oh, yes. Woman : I remember wanting to get off. Interviewer : Oh, did you? Woman : Yeah. It felt odd. Interviewer : So it was enough to be scary? Woman : Yeah, but I thought that was just me. Interviewer : Ah! Now, tell me why you had to do this? Boy : We had to do this because, to keep in balance because if you didn ’ t keep your balance, then you would just fall over about, like, to **the left** or right, about 45 degrees. Interviewer : So just show me how you walk normally. Right. And then show me what it was like when **the** bridge started to go. Right. So you had to deliberately push your feet out sideways and — oh, and short steps? Man : That ’ s right. And it seemed obvious to me that it was probably **the** number of people on it. Interviewer : Were they deliberately walking in step, or anything like that? Man : No, they just had to conform to **the** movement of **the** bridge. Steven Strogatz : All right, so that already gives you a hint of what happened. Think of **the** bridge as being like this platform. Think of **the** people as being like metronomes. Now, you might not be used to thinking of yourself as a metronome, but after all, we do walk like — I mean, we oscillate back and forth as we walk. And especially if we start to walk like those people did, right? They all showed this strange sort of skating gait that they adopted once **the** bridge started to move. And so let me show you now **the** footage of **the** bridge. But also, after you see **the** bridge on opening day, you ’ ll see an interesting **clip** of work done by a bridge engineer at Cambridge named Allan McRobie, who figured out what happened on **the** bridge, and who built a bridge simulator to explain exactly what **the** problem was. It was a kind of unintended positive feedback loop between **the** way **the** people walked and **the** way **the** bridge began to move, that engineers knew nothing about. Actually, I think **the** first person you ’ ll see is **the** young engineer who was put in charge of this project. **Okay**. Interviewer : Did anyone get hurt? Engineer : No. Interviewer : Right. So it was quite small — Engineer : Yes. Interviewer : — but real? Engineer : Absolutely. Interviewer : You thought,”Oh, bother.”Engineer : I felt I was disappointed about it. We ’ d spent a lot of time designing this bridge, and we ’ d analyzed it, we ’ d checked it to codes — to heavier loads than **the** codes — and here it was doing something that we didn ’ t know about. Interviewer : You didn ’ t expect. Engineer : Exactly. Narrator : **The** most dramatic and shocking footage shows whole sections of **the** crowd — hundreds of people — apparently **rocking** from side to side in unison, not only with each other, but with **the** bridge. This synchronized movement seemed to be driving **the** bridge. But how could **the** crowd become synchronized? Was there something special about **the** Millennium Bridge that caused this effect? This was to be **the** focus of **the** investigation. Interviewer : Well, at last **the** simulated bridge is finished, and I can make it wobble. Now, Allan, this is all your fault, isn ’ t it? Allan McRobie : Yes. Interviewer : You designed this, yes, this simulated bridge, and this, you reckon, mimics **the** action of **the** real bridge? AM : It captures a lot of **the** physics, yes. Interviewer : Right. So if we get on it, we should be able to wobble it, yes? Allan McRobie is a bridge engineer from Cambridge who wrote to me, suggesting that a bridge simulator ought to wobble in **the** same way as **the** real bridge — provided we hung it on pendulums of exactly **the** right length. AM : This one ’ s only a couple of tons, so it ’ s fairly easy to get going. Just by walking. Interviewer : Well, it ’ s certainly going now. AM : It doesn ’ t have to be a real dangle. Just walk. It starts to go. Interviewer : It ’ s actually quite difficult to walk. You have to be careful where you put your feet down, don ’ t you, because if you get it wrong, it just throws you off your feet. AM : It certainly affects **the** way you walk, yes. You can ’ t walk normally on it. Interviewer : No. If you try and put one foot in front of another, it ’ s moving your feet away from under you. AM : Yes. Interviewer : So you ’ ve got to put your feet out sideways. So already, **the** simulator is making me walk in exactly **the** same way as our witnesses walked on **the** real bridge. AM :... ice-skating gait. There isn ’ t all this sort of snake way of walking. Interviewer : For a more convincing experiment, I wanted my own opening-day crowd, **the** sound check team. Their instructions : just walk normally. It ’ s really intriguing because none of these people is trying to drive it. They ’ re all having some difficulty walking. And **the** only way you can walk comfortably is by getting in step. But then, of course, everyone is driving **the** bridge. You can ’ t help it. You ’ re actually forced by **the** movement of **the** bridge to get into step, and therefore to drive it to move further. SS : All right, well, with that from **the** Ministry of Silly Walks, maybe I ’ d better end. I see I ’ ve gone over. But I hope that you ’ ll go outside and see **the** world in a new way, to see all **the** amazing synchrony around us. Thank you.

Text Sample 25: POS Dim 1 – 2004 – Score 19.00 – 2004/t000211.txt

You might be wondering why I ’ m wearing sunglasses, and one answer to that is, because I ’ m here to talk about glamour. So, we all think we know what glamour is. Here it is. It ’ s glamorous movie stars, like Marlene Dietrich. And it comes in a male form, too â very glamorous. Not only can he shoot, drive, **drink** â you know, he **drinks** wine, there actually is a little wine in there â and of course, always wears a tuxedo. But I think that glamour actually has a much broader meaning â one that is true for **the** movie stars and **the** fictional characters, but also comes in other forms. A magazine? Well, it ’ s certainly not this one. This is **the** least glamorous magazine on **the** newsstand â it ’ s all about sex tips. Sex tips are not glamorous. And Drew Barrymore, for all her wonderful charm, is not glamorous either. But there is a glamour of industry. This is Margaret Bourke-White ’ s â one of her pictures she did. **Fantastic**, glamorous pictures of steel mills and paper mills and all kinds of glamorous industrial places. And there ’ s **the** mythic glamour of **the** garage entrepreneur. This is **the** Hewlett-Packard garage. We know everyone who starts a business in a garage ends up founding Hewlett- Packard. There ’ s **the** glamour of physics. What could be more glamorous than understanding **the** entire **universe**, grand unification? And, by **the** way, it helps if you ’ re Brian Greene â he has other kinds of glamour. And there is, of course, this glamour. This is very, very glamorous : **the** glamour of outer space â and not **the** alien-style glamour, but **the** nice, clean, early ’ 60s version. So what do we mean by glamour? Well, one thing you can do if you want to know what glamour means is you can look in **the** dictionary. And it actually helps a lot more if you look in a very old dictionary, in this case **the** 1913 dictionary. Because for centuries, glamour had a very particular meaning, and **the** word was actually used differently from **the** way we think of it. You had”a”glamour. It wasn ’ t glamour as a quality â you”cast a glamour.”Glamour was a literal magic spell. Not a metaphorical one, **the** way we use it today, but a literal magic spell associated with witches and gypsies and to some extent, Celtic magic. And over **the** years, around **the** turn of **the** 20th century, it started to take on this other kind of deception â this definition for any **artificial** interest in, or association with, an **object** through which it appears delusively magnified or glorified. But still, glamour is an illusion. Glamour is a magic spell. And there ’ s something dangerous about glamour throughout most of history. When **the** witches cast a magic spell on you, it was not in your self-interest â it was to get you to act against your interest. Well of course, in **the** 20th century, glamour came to have this different meaning associated with Hollywood. And this is Hedy Lamarr. Hedy Lamarr said,”Anyone can look glamorous, all you have to do is sit there and look stupid.”But in fact, with all due respect to Hedy â about whom we ’ ll hear more later â there ’ s a lot more to it. There was a tremendous amount of technical achievement associated with creating this Hollywood glamour. There were scores of retouchers and lighting experts and make-up experts. You can go to **the** museum of Hollywood history in Hollywood and see Max Factor ’ s special rooms that he painted different colors depending on **the** complexion of **the** star he was going to make up. So you ’ ve got this highly stylized portrait of something that was not entirely of this earth â it was a portrait of a star. And actually, we see glamorized photos of stars all **the** time â they call them false color. Glamour is a form of falsification, but falsification to achieve a particular purpose. It may be to illuminate **the** star ; it may be to sell a film. And it involves a great deal of **technique**. It ’ s not â glamour is not something â you don ’ t wake up in **the** morning glamorous. I don ’ t care who you are. Even Nicole Kidman doesn ’ t wake up in **the** morning glamorous. There is a process of”idealization, glorification and dramatization,”and it ’ s not just **the** case for people. Glamour doesn ’ t have to be people. Architectural photography â Julius Schulman, who has talked about transfiguration, took this fabulous, **famous** picture of **the** Kauffman House. Architectural photography is extremely glamorous. It puts you into this special, special world. This is Alex Ross ’ s comic book art, which appears to be extremely realistic, as part of his style is he gives you a kind of realism in his comic art. Except that light doesn ’ t work this way in **the** real world. When you **stack** people in rows, **the** ones in **the** background look smaller than **the** ones in **the** foreground â but not in **the** world of glamour. What glamour is all about â I took this from a blurb in **the** table of contents of New York magazine, which was telling us that glamour is back â glamour is all about transcending **the** everyday. And I think that that ’ s starting to get at what **the** core that combines all sorts of glamour is. This is Filippino Lippi ’ s 1543 portrait of Saint Apollonia. And I don ’ t know who she is either, but this is **the** [16th] century equivalent of a supermodel. It ’ s a very glamorous portrait. Why is it glamorous? It ’ s glamorous, first, because she is beautiful â but that does not make you glamorous, that only makes you beautiful. She is graceful, she is mysterious and she is transcendent, and those are **the** central qualities of glamour. You don ’ t see her eyes ; they ’ re looking downward. She ’ s not looking away from you exactly, but you have to mentally imagine her world. She ’ s encouraging you to contemplate this higher world to which she belongs, where she can be completely tranquil while holding **the iron** instruments of her death by torture. Mel Gibson ’ s”Passion Of **The** Christ”â not glamorous. That ’ s glamour : that ’ s Michelangelo ’ s”Pieta,”where Mary is **the** same age as Jesus and they ’ re both awfully happy and pleasant. Glamour invites us to live in a different world. It has to simultaneously be mysterious, a little bit distant â that ’ s why, often in these glamour shots, **the** person is not looking at **the** audience, it ’ s why sunglasses are glamorous â but also not so far above us that we can ’ t identify with **the** person. In some sense, there has to be something like us. So as I say, in religious art, you know, God is not glamorous. God cannot be glamorous because God is omnipotent, omniscient â too far above us. And yet you will see in religious art, saints or **the** Virgin Mary will often be portrayed â not always â in glamorous forms. As I said earlier, glamour does not have to be about people, but it has to have this transcendent quality. What is it about Superman? Aside from Alex Ross ’ s style, which is very glamorous, one thing about Superman is he makes you believe that a man can fly. Glamour is all about transcending this world and getting to an idealized, perfect place. And this is one reason that modes of **transportation** tend to be extremely glamorous. **The** less experience we have with them, **the** more glamorous they are. So you can do a glamorized picture of a car, but you can ’ t do a glamorized picture of traffic. You can do a glamorized picture of an **airplane**, but not **the** inside. **The** notion is that it ’ s going to transport you, and **the** story is not about, you know, **the** guy in front of you in **the airplane**, who has this nasty little kid, or **the** big cough. **The** story is about where you ’ re arriving, or thinking about where you ’ re arriving. And this sense of being transported is one reason that we have glamour styling. This sort of streamlining styling is not just glamorous because we associate it with movies of that period, but because, in it ’ s streamlining, it transports us from **the** everyday. **The** same thing â□□ arches are very glamorous. Arches with stained glass â□□ even more glamorous. Staircases that curve away from you are glamorous. I happen to find that particular staircase picture very glamorous because, to me, it captures **the** whole promise of **the** academic contemplative life â□□ but maybe that ’ s because I went to Princeton. Anyway, skylines are super glamorous, city streets â□□ not so glamorous. You know, when you get, actually to this town it has reality. **The** horizon, **the** open road, is very, very glamorous. There are few things more glamorous than **the** horizon â□□ except, possibly, multiple horizons. Of course, here you don ’ t feel **the** cold, or **the** heat â□□ you just see **the** possibilities. In order to pull glamour off, you need this Renaissance quality of sprezzatura, which is a term coined by Castiglione in his book,”**The** Book Of **The** Courtier.”There ’ s **the** not-glamorous version of what it looks like today, after a few centuries. And sprezzatura is **the** art that conceals art. It makes things look effortless. You don ’ t think about how Nicole Kidman is maneuvering that dress â□□ she just looks completely natural. And I remember reading, after **the** Lara Croft movies, how Angelina Jolie would go home completely black and **blue**. Of course, they covered that with make-up, because Lara Croft did all those same stunts â□□ but she doesn ’ t get black and **blue**, because she has sprezzatura.”To conceal all art and make whatever is done or said appear to be without effort”: And this is one of **the** critical aspects of glamour. Glamour is about editing. How do you create **the** sense of transcendence, **the** sense of evoking a perfect world? **The** sense of, you know, life could be better, I could join this â□□ I could be a perfect person, I could join this perfect world. We don ’ t tell you all **the** grubby details. Now, this was kindly lent to me by Jeff Bezos, from last year. This is underneath Jeff ’ s desk. This is what **the** real world of **computers**, **lamps**, **electrical** appliances of all kinds, looks like. But if you look in a catalog â□□ particularly a catalog of modern, beautiful **objects** for your home â□□ it looks like this. There are no cords. Look next time you get these catalogs in your mail â□□ you can usually figure out where they hid **the** cord. But there ’ s always this illusion that if you buy this **lamp**, you will live in a world without cords. And **the** same thing is true of, if you buy this **laptop** or you buy this **computer** â□□ and even in these wireless eras, you don ’ t get to live in **the** world without cords. You have to have mystery and you have to have grace. And there she is â□□ Grace. This is **the** most glamorous picture, I think, ever. Part of **the** thing is that, in”Rear Window,”**the** question is, is she too glamorous to live in his world? And **the** answer is no, but of course it ’ s really just a movie. Here ’ s Hedy Lamarr again. And, you know, this kind of head covering is extremely glamorous because, like sunglasses, it conceals and reveals at **the** same time. Translucence is glamorous â□□ that ’ s why all these people wear pearls. It ’ s why barware is glamorous. Glamour is translucent â□□ not transparent, not opaque. It invites us into **the** world but it doesn ’ t give us a completely clear picture. And I think if Grace Kelly is **the** most glamorous person, maybe a spiral staircase with glass block may be **the** most glamorous interior shot, because a spiral staircase is incredibly glamorous. It has that sense of going up and away, and yet you never think about how you would really trip if you were â□□ particularly going down. And of course glass block has that sense of translucence. So, this session ’ s supposed to be about pure pleasure but glamour ’ s really partly about meaning. All individuals and all cultures have ideals that cannot possibly be realized in reality. They have contradictions, they uphold principles that are incommensurable with each other â whatever it is â and yet these ideals give meaning and purpose to our lives as cultures and as individuals. And **the** way we deal with that is we displace them â we put them into a golden world, an imagined world, an age of heroes, **the** world to come. And in **the** life of an individual, we often associate that with some **object**. **The** white picket fence, **the** perfect house. **The** perfect kitchen â no bills on **the** counter in **the** perfect kitchen. You know, you buy that Viking range, this is what your kitchen will look like. **The** perfect love life â symbolized by **the** perfect necklace, **the** perfect diamond ring. **The** perfect getaway in your perfect car. This is an interior design firm that is literally called Utopia. **The** perfect office â again, no cords, as far as I can tell. And certainly, no, it doesn ' t look a thing like my office. I mean, there ' s no paper on **the** desk. We want this golden world. And some people get rich enough, and if they have their ideals â in a sort of domestic sense, they get to acquire their perfect world. Dean Koontz built this fabulous home theater, which is â I don ' t think accidentally â in Art Deco style. That symbolizes this sense of being safe and at home. This is not always good, because what is your perfect world? What is your ideal, and also, what has been edited out? Is it something important?"**The** Matrix"is a movie that is all about glamour. I could do a whole talk on"**The** Matrix"and glamour. It was criticized for glamorizing violence, because, look â sunglasses and those long coats, and, of course, they could walk up walls and do all these kinds of things that are impossible in **the** real world. This is another Margaret Bourke-White photo. This is from Soviet Union. Attractive. I mean, look how happy **the** people are, and good-looking too. You know, we ' re marching toward Utopia. I ' m not a fan of PETA, but I think this is a great ad. Because what they ' re doing is they ' re saying, your coat ' s not so glamorous, what ' s been edited out is something important. But actually, what ' s even more important than remembering what ' s been edited out is thinking, are **the** ideals good? Because glamour can be very totalitarian and deceptive. And it ' s not just a matter of glamorizing cleaning your floor. This is from"Triumph Of **The** Will"â brilliant editing to cut together things. There ' s a glamour shot. National Socialism is all about glamour. It was a very aesthetic ideology. It was all about cleaning up Germany, and **the** West, and **the** world, and ridding it of anything unglamorous. So glamour can be dangerous. I think glamour has a genuine appeal, has a genuine value. I ' m not against glamour. But there ' s a kind of wonder in **the** stuff that gets edited away in **the** cords of life. And there is both a way to avoid **the** dangers of glamour and a way to broaden your appreciation of it. And that ' s to take Isaac Mizrahi ' s advice and confront **the** manipulation of it all, and sort of admit that manipulation is something that we **enjoy**, but also **enjoy** how it happens. And here ' s Hedy Lamarr. She ' s very glamorous but, you know, she invented spread- spectrum technology. So she ' s even more glamorous if you know that she really wasn ' t stupid, even though she thought she could look stupid. David Hockney talks about how **the** appreciation of this very glamorous painting is heightened if you think about **the** fact that it takes two weeks to paint this splash, which only took a **fraction** of a second to happen. There is a book out in **the** bookstore â it ' s called"Symphony In Steel,"and it ' s about **the** stuff that ' s hidden under **the** skin of **the** Disney Center. And that has a fascination. It ' s not necessarily glamorous, but **unveiling the** glamour has an appeal. There ' s a wonderful book called"Crowns"that ' s all these glamour pictures of black women in their church hats. And there ' s a quote from one of these women, and she talks about,"As a little girl, I ' d admire women at church with beautiful hats. They looked like beautiful dolls, like they ' d just stepped out of a magazine. But I also knew how hard they worked all week. Sometimes under those hats there ' s a lot of joy and a lot of sorrow."And, actually, you get more appreciation for glamour when you realize what went into creating it. Thank you.

Text Sample 26: POS Dim 1 – 2010 – Score 31.00 – 2010/t002836.txt

In **the** spirit of Jacques Cousteau, who said,"People protect what they love,"I want to share with you today what I love most in **the** ocean, and that ' s **the** incredible number and variety of animals in it that make light. My addiction began with this strange looking diving suit called Wasp ; that ' s not an acronym — just somebody thought it looked like **the** insect. It was actually developed for use by **the** offshore **oil** industry for diving on **oil** rigs down to a depth of 2, 000 feet. Right after I completed my Ph. D., I was lucky enough to be included with a group of scientists that was using it for **the** first time as a tool for ocean exploration. We trained in a tank in Port Hueneme, and then my first open ocean dive was in Santa Barbara Channel. It was an evening dive. I went down to a depth of 880 feet and turned out **the** lights. And **the** reason I turned out **the** lights is because I knew I would see this phenomenon of animals making light called bioluminescence. But I was totally unprepared for how much there was and how spectacular it was. I saw chains of jellyfish called siphonophores that were longer than this room, pumping out so much light that I could read **the** dials and gauges inside **the** suit without a flashlight ; and puffs and billows of what looked like luminous **blue** smoke ; and **explosions** of sparks that would swirl up out of **the** thrusters — just like when you throw a log on a campfire and **the** embers swirl up off **the** campfire, but these were icy, **blue** embers. It was breathtaking. Now, usually if people are familiar with bioluminescence at all, it ' s these guys ; it ' s fireflies. And there are a few other land-dwellers that can make light — some insects, earthworms, fungi — but in general, on land, it ' s really rare. In **the** ocean, it ' s **the** rule rather than **the** exception. If I go out in **the** open ocean environment, virtually anywhere in **the** world, and I drag a net from 3, 000 feet to **the surface**, most of **the** animals — in fact, in many places, 80 to 90 percent of **the** animals that I bring up in that net — make light. This makes for some pretty spectacular light shows. Now I want to share with you a little video that I shot from a submersible. I first developed this **technique** working from a little single-person submersible called Deep Rover and then adapted it for use on **the** Johnson Sea-Link, which you see here. So, mounted in front of **the** observation **sphere**, there ' s a a three-foot **diameter** hoop with a screen stretched across it. And inside **the sphere** with me is an intensified camera that ' s about as sensitive as a fully dark-adapted human eye, albeit a little fuzzy. So you turn on **the** camera, turn out **the** lights. That sparkle you ' re seeing is not luminescence, that ' s just electronic noise on these super intensified cameras. You don ' t see luminescence until **the** submersible begins to move forward through **the** water, but as it does, animals bumping into **the** screen are stimulated to bioluminesce. Now, when I was first doing this, all I was trying to do was count **the** numbers of sources. I knew my forward speed, I knew **the** area, and so I could figure out how many hundreds of sources there were per cubic meter. But I started to realize that I could actually identify animals by **the** type of flashes they produced. And so, here, in **the** Gulf of Maine at 740 feet, I can name pretty much everything you ' re seeing there to **the** species level. Like those big **explosions**, sparks, are from a little comb jelly, and there ' s krill and other kinds of crustaceans, and jellyfish. There was another one of those comb jellies. And so I ' ve worked with **computer** image analysis engineers to develop automatic recognition systems that can identify these animals and then extract **the** XYZ coordinate of **the** initial impact point. And we can then do **the** kinds of things that ecologists do on land, and do nearest neighbor distances. But you don ’ t always have to go down to **the** depths of **the** ocean to see a light show like this. You can actually see it in **surface** waters. This is some shot, by Dr. Mike Latz at Scripps Institution, of a dolphin swimming through bioluminescent plankton. And this isn ’ t someplace exotic like one of **the** bioluminescent **bays** in Puerto Rico, this was actually shot in San Diego Harbor. And sometimes you can see it even closer than that, because **the** heads on ships — that ’ s toilets, for any land lovers that are listening — are flushed with unfiltered seawater that often has bioluminescent plankton in it. So, if you stagger into **the** head late at night and you ’ re so toilet-hugging sick that you forget to turn on **the** light, you may think that you ’ re having a religious experience. So, how does a living creature make light? Well, that was **the** question that 19th century French physiologist Raphael Dubois, asked about this bioluminescent clam. He ground it up and he managed to get out a couple of chemicals ; one, **the** enzyme, he called luciferase ; **the** substrate, he called luciferin after Lucifer **the** Lightbearer. That terminology has stuck, but it doesn ’ t actually refer to specific chemicals because these chemicals come in a lot of different shapes and forms. In fact, most of **the** people studying bioluminescence today are focused on **the chemistry**, because these chemicals have proved so incredibly valuable for developing antibacterial agents, cancer fighting drugs, testing for **the** presence of life on Mars, **detecting** pollutants in our waters — which is how we use it at ORCA. In 2008, **the** Nobel Prize in **Chemistry** was awarded for work done on a molecule called green fluorescent protein that was isolated from **the** bioluminescent **chemistry** of a jellyfish, and it ’ s been equated to **the** invention of **the** microscope, in terms of **the** impact that it has had on cell **biology** and genetic engineering. Another thing all these molecules are telling us that, apparently, bioluminescence has **evolved** at least 40 times, maybe as many as 50 separate times in **evolutionary** history, which is a clear indication of how spectacularly important this trait is for survival. So, what is it about bioluminescence that ’ s so important to so many animals? Well, for animals that are trying to avoid predators by staying in **the** darkness, light can still be very useful for **the** three basic things that animals have to do to survive : and that ’ s find food, attract a **mate** and avoid being eaten. So, for example, this **fish** has a built-in headlight behind its eye that it can use for finding food or attracting a **mate**. And then when it ’ s not using it, it actually can roll it down into its head just like **the** headlights on your Lamborghini. This **fish** actually has high beams. And this **fish**, which is one of my favorites, has three headlights on each side of its head. Now, this one is **blue**, and that ’ s **the** color of most bioluminescence in **the** ocean because **evolution** has selected for **the** color that travels farthest through seawater in order to optimize communication. So, most animals make **blue** light, and most animals can only see **blue** light, but this **fish** is a really fascinating exception because it has two red light organs. And I have no idea why there ’ s two, and that ’ s something I want to solve some day — but not only can it see **blue** light, but it can see red light. So it uses its red bioluminescence like a sniper ’ s scope to be able to sneak up on animals that are blind to red light and be able to see them without being seen. It ’ s also got a little chin barbel here with a **blue** luminescent lure on it that it can use to attract prey from a long way off. And a lot of animals will use their bioluminescence as a lure. This is another one of my favorite **fish**. This is a viperfish, and it ’ s got a lure on **the** end of a long **fishing** rod that it arches in front of **the** toothy jaw that gives **the** viperfish its name. **The** teeth on this **fish** are so long that if they closed inside **the** mouth of **the fish**, it would actually impale its own brain. So instead, it **slides** in grooves on **the** outside of

the head. This is a Christmas tree of a **fish** ; everything on this **fish** lights up, it ' s not just that lure. It ' s got a built-in flashlight. It ' s got these jewel-like light organs on its belly that it uses for a type of camouflage that obliterates its shadow, so when it ' s swimming around and there ' s a predator looking up from below, it makes itself **disappear**. It ' s got light organs in **the** mouth, it ' s got light organs in every single scale, in **the fins**, in a mucus layer on **the** back and **the** belly, all used for different things — some of which we know about, some of which we don ' t. And we know a little bit more about bioluminescence thanks to Pixar, and I ' m very grateful to Pixar for sharing my favorite topic with so many people. I do wish, with their budget, that they might have spent just a tiny bit more money to pay a consulting fee to some poor, starving graduate student, who could have told them that those are **the** eyes of a **fish** that ' s been preserved in formalin. These are **the** eyes of a living anglerfish. So, she ' s got a lure that she sticks out in front of this living mousetrap of needle-sharp teeth in order to attract in some unsuspecting prey. And this one has a lure with all kinds of little interesting threads coming off it. Now we used to think that **the** different shape of **the** lure was to attract different types of prey, but then stomach content analyses on these **fish** done by scientists, or more likely their graduate students, have revealed that they all eat pretty much **the** same thing. So, now we believe that **the** different shape of **the** lure is how **the** male recognizes **the** female in **the** anglerfish world, because many of these males are what are known as **dwarf** males. This little guy has no visible means of self-support. He has no lure for attracting food and no teeth for eating it when it gets there. His only hope for existence on this **planet** is as a gigolo. He ' s got to find himself a babe and then he ' s got to latch on for life. So this little guy has found himself this babe, and you will note that he ' s had **the** good sense to attach himself in a way that he doesn ' t actually have to look at her. But he still knows a good thing when he sees it, and so he **seals the** relationship with an eternal kiss. His flesh fuses with her flesh, her bloodstream grows into his body, and he becomes nothing more than a little sperm sac. Well, this is a deep-**sea** version of Women ' s Lib. She always knows where he is, and she doesn ' t have to be monogamous, because some of these females come up with multiple males attached. So they can use it for finding food, for attracting **mates**. They use it a lot for defense, many different ways. A lot of them can release their luciferin or luferase in **the** water just **the** way a squid or an octopus will release an ink cloud. This **shrimp** is actually spewing light out of its mouth like a fire breathing dragon in order to blind or distract this viperfish so that **the shrimp** can swim away into **the** darkness. And there are a lot of different animals that can do this : There ' s jellyfish, there ' s squid, there ' s a whole lot of different crustaceans, there ' s even **fish** that can do this. This **fish** is called **the** shining tubeshoulder because it actually has a tube on its shoulder that can squirt out light. And I was luck enough to capture one of these when we were on a trawling expedition off **the** northwest coast of Africa for"Blue Planet,"for **the** deep portion of"Blue Planet."And we were using a special trawling net that we were able to bring these animals up alive. So we captured one of these, and I brought it into **the** lab. So I ' m holding it, and I ' m about to touch that tube on its shoulder, and when I do, you ' ll see bioluminescence coming out. But to me, what ' s shocking is not just **the** amount of light, but **the** fact that it ' s not just luciferin and luciferase. For this **fish**, it ' s actually whole cells with nuclei and membranes. It ' s energetically very costly for this **fish** to do this, and we have no idea why it does it — another one of these great mysteries that needs to be solved. Now, another form of defense is something called a burglar alarm — same reason you have a burglar alarm on your car ; **the** honking horn and flashing lights are meant to attract **the** attention of, hopefully, **the** police that will come and take **the** burglar away — when an animal ’ s caught in **the** clutches of a predator, its only hope for escape may be to attract **the** attention of something bigger and nastier that will attack their attacker, thereby affording them a chance for escape. This jellyfish, for example, has a spectacular bioluminescent display. This is us chasing it in **the** submersible. That ’ s not luminescence, that ’ s reflected light from **the** gonads. We capture it in a very special **device** on **the** front of **the** submersible that allows us to bring it up in really pristine condition, bring it into **the** lab on **the** ship. And then to generate **the** display you ’ re about to see, all I did was touch it once per second on its nerve ring with a sharp pick that ’ s sort of like **the** sharp tooth of a **fish**. And once this display gets going, I ’ m not touching it anymore. This is an unbelievable light show. It ’ s this pinwheel of light, and I ’ ve done calculations that show that this could be seen from as much as 300 feet away by a predator. And I thought,”You know, that might actually make a pretty good lure.”Because one of **the** things that ’ s frustrated me as a deep-sea explorer is how many animals there probably are in **the** ocean that we know nothing about because of **the** way we explore **the** ocean. **The** primary way that we know about what lives in **the** ocean is we go out and drag nets behind ships. And I defy you to name any other branch of science that still depends on hundreds of **year-old** technology. **The** other primary way is we go down with submersibles and remote-operated vehicles. I ’ ve made hundreds of dives in submersibles. When I ’ m sitting in a submersible though, I know that I ’ m not unobtrusive at all — I ’ ve got bright lights and noisy thrusters — any animal with any sense is going to be long gone. So, I ’ ve wanted for a long time to figure out a different way to explore. And so, sometime ago, I got this idea for a camera system. It ’ s not exactly rocket science. We call this thing Eye-in-the-Sea. And scientists have done this on land for years ; we just use a color that **the** animals can ’ t see and then a camera that can see that color. You can ’ t use infrared in **the sea**. We use far-red light, but even that ’ s a problem because it gets absorbed so quickly. Made an intensified camera, wanted to make this electronic jellyfish. Thing is, in science, you basically have to tell **the** funding agencies what you ’ re going to discover before they ’ ll give you **the** money. And I didn ’ t know what I was going to discover, so I couldn ’ t get **the** funding for this. So I kluged this together, I got **the** Harvey Mudd Engineering Clinic to actually do it as an undergraduate student project initially, and then I kluged funding from a whole bunch of different sources. Monterey Bay Aquarium Research Institute gave me time with their ROV so that I could test it and we could figure out, you know, for example, which colors of red light we had to use so that we could see **the** animals, but they couldn ’ t see us — get **the** electronic jellyfish working. And you can see just what a shoestring operation this really was, because we cast these 16 **blue** LEDs in epoxy and you can see in **the** epoxy mold that we used, **the** word Ziploc is still visible. Needless to say, when it ’ s kluged together like this, there were a lot of trials and tribulations getting this working. But there came a moment when it all came together, and everything worked. And, remarkably, that moment got caught on film by photographer Mark Richards, who happened to be there at **the** precise moment that we discovered that it all came together. That ’ s me on **the left**, my graduate student at **the** time, Erika Raymond, and Lee Fry, who was **the** engineer on **the** project. And we have this photograph posted in our lab in a place of honor with **the** caption :”Engineer satisfying two women at once.”And we were very, very happy. So now we had a system that we could actually take to some place that was kind of like an oasis on **the** bottom of **the** ocean that might be patrolled by large predators. And so, **the** place that we took it to was this place called a Brine Pool, which is in **the** northern part of **the** Gulf of Mexico. It ’ s a magical place. And I know this footage isn ’ t going to look like anything to you — we had a crummy camera at **the** time — but I was ecstatic. We ’ re at **the** edge of **the** Brine Pool, there ’ s a **fish** that ’ s swimming towards **the** camera. It ’ s clearly undisturbed by us. And I had my window into **the** deep **sea**. I, for **the** first time, could see what animals were doing down there when we weren ’ t down there disturbing them in some way. Four hours into **the** deployment, we had programmed **the** electronic jellyfish to come on for **the** first time. Eighty-six seconds after it went into its pinwheel display, we recorded this : This is a squid, over six feet long, that is so new to science, it cannot be placed in any known scientific family. I could not have asked for a better proof of concept. And based on this, I went back to **the** National Science Foundation and said,”This is what we will discover.”And they gave me enough money to do it right, which has involved developing **the** world ’ s first deep-sea webcam — which has been installed in **the** Monterey Canyon for **the** past year — and now, more recently, a modular form of this system, a much more mobile form that ’ s a lot easier to launch and recover, that I hope can be used on Sylvia ’ s”hope spots”to help explore and protect these areas, and, for me, learn more about **the** bioluminescence in these”hope spots.”So one of these take-home messages here is, there is still a lot to explore in **the** oceans. And Sylvia has said that we are destroying **the** oceans before we even know what ’ s in them, and she ’ s right. So if you ever, ever get an opportunity to take a dive in a submersible, say yes — a thousand times, yes — and please turn out **the** lights. I promise, you ’ ll love it. Thank you.

Text Sample 27: POS Dim 1 – 2010 – Score 29.00 – 2010/t002739.txt

I ’ ve been fascinated for a lifetime by **the** beauty, form and function of giant bluefin tuna. Bluefin are warmblooded like us. They ’ re **the** largest of **the** tunas, **the** second-largest **fish** in **the sea** â bony **fish**. They actually are a **fish** that is endothermic â powers through **the** ocean with warm muscles like a mammal. That ’ s one of our bluefin at **the** Monterey Bay Aquarium. You can see in its shape and its streamlined design it ’ s powered for ocean swimming. It flies through **the** ocean on its pectoral **fins**, gets lift, powers its movements with a lunate tail. It ’ s actually got a naked skin for most of its body, so it reduces friction with **the** water. This is what one of nature ’ s finest machines. Now, bluefin were revered by Man for all of human history. For 4, 000 years, we **fished** sustainably for this animal, and it ’ s evidenced in **the** art that we see from thousands of years ago. Bluefin are in cave paintings in France. They ’ re on coins that date back 3, 000 years. This **fish** was revered by humankind. It was **fished** sustainably till all of time, except for our generation. Bluefin are pursued wherever they go â there is a gold rush on Earth, and this is a gold rush for bluefin. There are traps that **fish** sustainably up until recently. And yet, **the** type of **fishing** going on today, with pens, with enormous stakes, is really **wiping** bluefin ecologically off **the planet**. Now bluefin, in general, goes to one place : Japan. Some of you may be guilty of having contributed to **the** demise of bluefin. They ’ re delectable muscle, rich in **fat** â absolutely taste delicious. And that ’ s their problem ; we ’ re eating them to death. Now in **the** Atlantic, **the** story is pretty simple. Bluefin have two populations : one large, one small. **The** North American population is **fished** at about 2, 000 ton. **The** European population and North African â **the Eastern** bluefin tuna â is **fished** at tremendous levels : 50, 000 tons over **the** last decade almost every year. **The** result is whether you ’ re looking at **the** West or **the** Eastern bluefin population, there ’ s been tremendous decline on both sides, as much as 90 percent if you go back with your baseline to 1950. For that, bluefin have been given a status equivalent to **tigers**, to **lions**, to certain African **elephants** and to pandas. These **fish** have been proposed for an endangered species listing in **the** past two months. They were voted on and rejected just two weeks ago, despite outstanding science that shows from two committees this **fish** meets **the** criteria of CITES I. And if it ’ s tunas you don ’ t care about, perhaps you might be interested that international long lines and pursing chase down tunas and bycatch animals such as leatherbacks, sharks, marlin, albatross. These animals and their demise **occurs** in **the** tuna fisheries. **The** challenge we face is that we know very little about tuna, and everyone in **the** room knows what it looks like when an African **lion** takes down its prey. I doubt anyone has seen a giant bluefin feed. This tuna symbolizes what ’ s **the** problem for all of us in **the** room. It ’ s **the** 21st century, but we really have only just begun to really study our oceans in a deep way. Technology has come of age that ’ s allowing us to see **the** Earth from space and go deep into **the seas** remotely. And we ’ ve got to use these technologies immediately to get a better understanding of how our ocean realm works. Most of us from **the** ship â even I â look out at **the** ocean and see this homogeneous **sea**. We don ’ t know where **the** structure is. We can ’ t tell where are **the** watering holes like we can on an African plain. We can ’ t see **the** corridors, and we can ’ t see what it is that brings together a tuna, a leatherback and an albatross. We ’ re only just beginning to understand how **the** physical oceanography and **the** biological oceanography come together to create a seasonal force that actually causes **the** upwelling that might make a hot spot a hope spot. **The** reasons these challenges are great is that technically it ’ s difficult to go to **sea**. It ’ s hard to study a bluefin on its turf, **the** entire Pacific realm. It ’ s really tough to get up close and personal with a mako shark and try to put a **tag** on it. And then imagine being Bruce Mate ’ s team from OSU, getting up close to a **blue whale** and fixing a **tag** on **the blue whale** that stays, an engineering challenge we ’ ve yet to really overcome. So **the** story of our team, a dedicated team, is **fish** and chips. We basically are taking **the** same satellite phone parts, or **the** same parts that are in your **computer**, chips. We ’ re putting them together in unusual ways, and this is taking us into **the** ocean realm like never before. And for **the** first time, we ’ re able to watch **the** journey of a tuna beneath **the** ocean using light and **photons** to measure sunrise and sunset. Now, I ’ ve been working with tunas for over 15 years. I have **the** privilege of being a partner with **the** Monterey Bay Aquarium. We ’ ve actually taken a sliver of **the** ocean, put it behind glass, and we together have put bluefin tuna and yellowfin tuna on display. When **the** veil of bubbles lifts every morning, we can actually see a community from **the** Pelagic ocean, one of **the** only places on Earth you can see giant bluefin swim by. We can see in their beauty of form and function, their ceaseless activity. They ’ re flying through their space, ocean space. And we can bring two million people a year into contact with this **fish** and show them its beauty. Behind **the** scenes is a working lab at Stanford University partnered with **the** Monterey Bay Aquarium. Here, for over 14 or 15 years, we ’ ve actually brought in both bluefin and yellowfin in captivity. We ’ d been studying these **fish**, but first we had to learn how to husbandry them. What do they like to eat? What is it that they ’ re happy with? We go in **the** tanks with **the** tuna â we touch their naked skin â it ’ s pretty amazing. It feels wonderful. And then, better yet, we ’ ve got our own version of tuna whisperers, our own Chuck Farwell, Alex Norton, who can take a big tuna and in one motion, put it into an envelope of water, so that we can actually work with **the** tuna and learn **the techniques** it takes to not injure this **fish** who never sees a boundary in **the** open **sea**. Jeff and Jason there, are scientists who are going to take a tuna and put it in **the** equivalent of a treadmill, a flume. And that tuna thinks it ’ s going to Japan, but it ’ s staying in place. We ’ re actually measuring its oxygen **consumption**, its energy **consumption**. We ’ re taking this data and building better models. And when I see that tuna â this is my favorite view â I begin to wonder : how did this **fish** solve **the** longitude problem before we did? So take a look at that animal. That ’ s **the** closest you ’ ll probably ever get. Now, **the** activities from **the** lab have taught us now how to go out in **the** open ocean. So in a program called Tag-A-Giant we ’ ve actually gone from Ireland to Canada, from Corsica to Spain. We ’ ve **fished** with many nations around **the** world in an effort to basically put electronic **computers** inside giant tunas. We ’ ve actually **tagged** 1, 100 tunas. And I ’ m going to show you three **clips**, because I **tagged** 1, 100 tunas. It ’ s a very hard process, but it ’ s a ballet. We bring **the** tuna out, we measure it. A team of fishers, captains, scientists and technicians work together to keep this animal out of **the** ocean for about four to five minutes. We put water over its gills, give it oxygen. And then with a lot of effort, after **tagging**, putting in **the computer**, making sure **the** stalk is sticking out so it senses **the** environment, we send this **fish** back into **the sea**. And when it goes, we ’ re always happy. We see a flick of **the** tail. And from our data that gets collected, when that **tag** comes back, because a fisher returns it for a thousand-dollar reward, we can get tracks beneath **the sea** for up to five years now, on a backboned animal. Now sometimes **the** tunas are really large, such as this **fish** off Nantucket. But that ’ s about half **the** size of **the** biggest tuna we ’ ve ever **tagged**. It takes a human effort, a team effort, to bring **the fish** in. In this case, what we ’ re going to do is put a pop-up satellite archival **tag** on **the** tuna. This **tag** rides on **the** tuna, senses **the** environment around **the** tuna and actually will come off **the fish**, detach, float to **the surface** and send back to Earth-orbiting satellites position data estimated by math on **the tag**, pressure data and temperature data. And so what we get then from **the** pop-up satellite **tag** is we get away from having to have a human interaction to recapture **the tag**. Both **the** electronic **tags** I ’ m talking about are expensive. These **tags** have been engineered by a variety of teams in North America. They are some of our finest instruments, our new technology in **the** ocean today. One community in general has given more to help us than any other community. And that ’ s **the** fisheries off **the** state of North Carolina. There are two villages, Harris and Morehead City, every winter for over a decade, held a party called Tag-A-Giant, and together, fishers worked with us to **tag** 800 to 900 **fish**. In this case, we ’ re actually going to measure **the fish**. We ’ re going to do something that in recent years we ’ ve started : take a mucus sample. Watch how shiny **the** skin is ; you can see my reflection there. And from that mucus, we can get gene profiles, we can get information on gender, checking **the** pop-up **tag** one more time, and then it ’ s out in **the** ocean. And this is my favorite. With **the** help of my former postdoc, Gareth Lawson, this is a gorgeous picture of a single tuna. This tuna is actually moving on a numerical ocean. **The** warm is **the** Gulf Stream, **the** cold up there in **the** Gulf of Maine. That ’ s where **the** tuna wants to go â it wants to forage on schools of herring â but it can ’ t get there. It ’ s too cold. But then it warms up, and **the** tuna pops in, gets some **fish**, maybe comes back to home base, goes in again and then comes back to winter down there in North Carolina and then on to **the** Bahamas. And my favorite scene, three tunas going into **the** Gulf of Mexico. Three tunas **tagged**. Astronomically, we ’ re **calculating** positions. They ’ re coming together. That could be tuna sex â and there it is. That is where **the** tuna spawn. So from data like this, we ’ re able now to put **the** map up, and in this map you see thousands of positions generated by this decade and a half of **tagging**. And now we ’ re showing that tunas on **the** western side go to **the eastern** side. So two populations of tunas â that is, we have a Gulf population, one that we can **tag** â they go to **the** Gulf of Mexico, I showed you that â and a second population. Living amongst our tunas â our North American tunas â are European tunas that go back to **the** Med. On **the** hot spots â **the** hope spots â they ' re mixed populations. And so what we ' ve done with **the** science is we ' re showing **the** International Commission, building new models, showing them that a two-stock no-mixing model â to this day, used to reject **the** CITES treaty â that model isn ' t **the** right model. This model, a model of overlap, is **the** way to move forward. So we can then predict where management places should be. Places like **the** Gulf of Mexico and **the** Mediterranean are places where **the** single species, **the** single population, can be captured. These become forthright in places we need to protect. **The** center of **the** Atlantic where **the** mixing is, I could imagine a policy that lets Canada and America **fish**, because they manage their fisheries well, they ' re doing a good job. But in **the** international realm, where **fishing** and overfishing has really gone wild, these are **the** places that we have to make hope spots in. That ' s **the** size they have to be to protect **the** bluefin tuna. Now in a second project called **Tagging** of Pacific Pelagics, we took on **the planet** as a team, those of us in **the** Census of Marine Life. And, funded primarily through Sloan Foundation and others, we were able to actually go in, in our project â we ' re one of 17 field programs and begin to take on **tagging** large numbers of predators, not just tunas. So what we ' ve done is actually gone up to **tag** salmon shark in Alaska, met salmon shark on their home territory, followed them catching salmon and then went in and figured out that, if we take a salmon and put it on a line, we can actually take up a salmon shark â This is **the** cousin of **the** white shark â and very carefully â note, I say"very carefully,"â we can actually keep it calm, put a hose in its mouth, keep it off **the** deck and then **tag** it with a satellite **tag**. That satellite **tag** will now have your shark phone home and send in a message. And that shark leaping there, if you look carefully, has an antenna. It ' s a free swimming shark with a satellite **tag** jumping after salmon, sending home its data. Salmon sharks aren ' t **the** only sharks we **tag**. But there goes salmon sharks with this meter-level resolution on an ocean of temperature â warm colors are warmer. Salmon sharks go down to **the** tropics to pup and come into Monterey. Now right next door in Monterey and up at **the** Farallones are a white shark team led by Scott Anderson â there â and Sal Jorgensen. They can throw out a target â it ' s a carpet shaped like a **seal** â and in will come a white shark, a curious critter that will come right up to our 16-ft. boat. It ' s a several thousand-pound animal. And we ' ll wind in **the** target. And we ' ll place an acoustic **tag** that says,"OMSHARK 10165,"or something like that, acoustically with a ping. And then we ' ll put on a satellite **tag** that will give us **the** long- distance journeys with **the** light-based geolocation algorithms solved on **the computer** that ' s on **the fish**. So in this case, Sal ' s looking at two **tags** there, and there they are : **the** white sharks of California going off to **the** white shark cafe and coming back. We also **tag** makos with our NOAA colleagues, **blue** sharks. And now, together, what we can see on this ocean of color that ' s temperature, we can see ten-day worms of makos and salmon sharks. We have white sharks and **blue** sharks. For **the** first time, an ecoscape as large as ocean-scale, showing where **the** sharks go. **The** tuna team from TOPP has done **the** unthinkable : three teams **tagged** 1, 700 tunas, bluefin, yellowfin and albacore all at **the** same time â carefully rehearsed **tagging** programs in which we go out, pick up juvenile tunas, put in **the tags** that actually have **the** sensors, stick out **the** tuna and then let them go. They get returned, and when they get returned, here on a NASA numerical ocean you can see bluefin in **blue** go across their corridor, returning to **the** Western Pacific. Our team from UCSC has **tagged**

elephant seals with **tags** that are glued on their heads, that come off when they slough. These **elephant seals** cover half an ocean, take data down to 1, 800 feet â amazing data. And then there ’ s Scott Shaffer and our shearwaters wearing tuna **tags**, light-based **tags**, that now are going to take you from New Zealand to Monterey and back, journeys of 35, 000 nautical miles we had never seen before. But now with light-based geolocation **tags** that are very small, we can actually see these journeys. Same thing with Laysan albatross who travel an entire ocean on a trip sometimes, up to **the** same zone **the** tunas use. You can see why they might be caught. Then there ’ s George Schillinger and our leatherback team out of Playa Grande **tagging** leatherbacks that go right past where we are. And Scott Benson ’ s team that showed that leatherbacks go from Indonesia all **the** way to Monterey. So what we can see on this moving ocean is we can finally see where **the** predators are. We can actually see how they ’ re using ecospaces as large as an ocean. And from this information, we can begin to map **the** hope spots. So this is just three years of data right here â and there ’ s a decade of this data. We see **the pulse** and **the** seasonal activities that these animals are going on. So what we ’ re able to do with this information is boil it down to hot spots, 4, 000 deployments, a huge herculean task, 2, 000 **tags** in an area, shown here for **the** first time, off **the** California coast, that appears to be a gathering place. And then for sort of an encore from these animals, they ’ re helping us. They ’ re carrying instruments that are actually taking data down to 2, 000 meters. They ’ re taking information from our **planet** at very critical places like Antarctica and **the** Poles. Those are **seals** from many countries being released who are sampling underneath **the** ice sheets and giving us temperature data of oceanographic quality on both poles. This data, when visualized, is captivating to watch. We still haven ’ t figured out best how to visualize **the** data. And then, as these animals swim and give us **the** information that ’ s important to climate issues, we also think it ’ s critical to get this information to **the** public, to engage **the** public with this kind of data. We did this with **the** Great Turtle Race â **tagged turtles**, brought in four million hits. And now with Google ’ s Oceans, we can actually put a white shark in that ocean. And when we do and it swims, we see this magnificent bathymetry that **the** shark knows is there on its path as it goes from California to Hawaii. But maybe Mission Blue can fill in that ocean that we can ’ t see. We ’ ve got **the** capacity, NASA has **the** ocean. We just need to put it together. So in conclusion, we know where Yellowstone is for North America ; it ’ s off our coast. We have **the** technology that ’ s shown us where it is. What we need to think about perhaps for Mission Blue is increasing **the** biologging capacity. How is it that we can actually take this type of activity elsewhere? And then finally â to basically get **the** message home â maybe use live links from animals such as **blue whales** and white sharks. Make killer apps, if you will. A lot of people are excited when sharks actually went under **the** Golden Gate Bridge. Let ’ s connect **the** public to this activity right on their iPhone. That way we do away with a few internet myths. So we can save **the** bluefin tuna. We can save **the** white shark. We have **the** science and technology. Hope is here. Yes we can. We need just to apply this capacity further in **the** oceans. Thank you.

Text Sample 28: POS Dim 1 – 2010 – Score 28.00 – 2010/t002801.txt

I would like to share with you this morning some stories about **the** ocean through my work as a still photographer for National Geographic magazine. I guess I became an **underwater** photographer and a photojournalist because

I fell in love with **the sea** as a child. And I wanted to tell stories about all **the** amazing things I was seeing **underwater**, incredible wildlife and interesting behaviors. And after even 30 years of doing this, after 30 years of exploring **the** ocean, I never cease to be amazed at **the** extraordinary encounters that I have while I ’ m at **sea**. But more and more frequently these days I ’ m seeing terrible things **underwater** as well, things that I don ’ t think most people realize. And I ’ ve been compelled to turn my camera towards these issues to tell a more complete story. I want people to see what ’ s happening **underwater**, both **the** horror and **the** magic. **The** first story that I did for National Geographic, where I recognized **the** ability to include environmental issues within a natural history coverage, was a story I proposed on harp **seals**. **The** story I wanted to do initially was just a small focus to look at **the** few weeks each year where these animals migrate down from **the** Canadian arctic to **the** Gulf of St. Lawrence in Canada to engage in courtship, mating and to have their pups. And all of this is played out against **the** backdrop of transient pack ice that moves with wind and tide. And because I ’ m an **underwater** photographer, I wanted to do this story from both above and below, to make pictures like this that show one of these little pups making its very first swim in **the** icy 29-degree water. But as I got more involved in **the** story, I realized that there were two big environmental issues I couldn ’ t ignore. **The** first was that these animals continue to be hunted, killed with hakapiks at about eight, 15 days old. It actually is **the** largest marine mammal slaughter on **the planet**, with hundreds of thousands of these **seals** being killed every year. But as disturbing as that is, I think **the** bigger problem for harp **seals** is **the** loss of **sea** ice due to global warming. This is an aerial picture that I made that shows **the** Gulf of St. Lawrence during harp **seal** season. And even though we see a lot of ice in this picture, there ’ s a lot of water as well, which wasn ’ t there historically. And **the** ice that is there is quite thin. **The** problem is that these pups need a stable platform of solid ice in order to nurse from their moms. They only need 12 days from **the** moment they ’ re born until they ’ re on their own. But if they don ’ t get 12 days, they can fall into **the** ocean and die. This is a photo that I made showing one of these pups that ’ s only about five or seven days old — still has a little bit of **the** umbilical cord on its belly — that has fallen in because of **the** thin ice, and **the** mother is frantically trying to push it up to breathe and to get it back to stable purchase. This problem has continued to grow each year since I was there. I read that last year **the** pup mortality rate was 100 percent in parts of **the** Gulf of St. Lawrence. So, clearly, this species has a lot of problems going forward. This ended up becoming a cover story at National Geographic. And it received quite a bit of attention. And with that, I saw **the** potential to begin doing other stories about ocean problems. So I proposed a story on **the** global **fish** crisis, in part because I had personally witnessed a lot of degradation in **the** ocean over **the** last 30 years, but also because I read a scientific paper that stated that 90 percent of **the** big **fish** in **the** ocean have **disappeared** in **the** last 50 or 60 years. These are **the** tuna, **the** billfish and **the** sharks. When I read that, I was blown away by those numbers. I thought this was going to be headline news in every media outlet, but it really wasn ’ t, so I wanted to do a story that was a very different kind of **underwater** story. I wanted it to be more like war photography, where I was making harder-hitting pictures that showed readers what was happening to marine wildlife around **the planet**. **The** first component of **the** story that I thought was essential, however, was to give readers a sense of appreciation for **the** ocean animals that they were eating. You know, I think people go into a restaurant, and somebody orders a steak, and we all know where steak comes from, and somebody orders a chicken, and we know what a chicken is, but when they ’ re eating bluefin sushi, do they have any sense of **the** magnificent animal that they ’ re consuming? These are **the lions** and **tigers** of **the sea**. In reality, these animals have no terrestrial counterpart ; they ’ re unique in **the** world. These are animals that can practically swim from **the** equator to **the** poles and can crisscross entire oceans in **the** course of a year. If we weren ’ t so efficient at catching them, because they grow their entire life, would have 30-year-old bluefin out there that weigh a ton. But **the** truth is we ’ re way too efficient at catching them, and their stocks have collapsed worldwide. This is **the** daily auction at **the** Tsukiji Fish Market that I photographed a couple years ago. And every single day these tuna, bluefin like this, are **stacked** up like cordwood, just warehouse after warehouse. As I wandered around and made these pictures, it sort of **occurred** to me that **the** ocean ’ s not a grocery store, you know. We can ’ t keep taking without expecting serious consequences as a result. I also, with **the** story, wanted to show readers how **fish** are caught, some of **the** methods that are used to catch **fish**, like a bottom trawler, which is one of **the** most common methods in **the** world. This was a small net that was being used in Mexico to catch **shrimp**, but **the** way it works is essentially **the** same everywhere in **the** world. You have a large net in **the** middle with two steel doors on either end. And as this assembly is towed through **the** water, **the** doors meet resistance with **the** ocean, and it opens **the** mouth of **the** net, and they place floats at **the** top and a lead line on **the** bottom. And this just drags over **the** bottom, in this case to catch **shrimp**. But as you can imagine, it ’ s catching everything else in its path as well. And it ’ s destroying that precious benthic community on **the** bottom, things like sponges and corals, that critical **habitat** for other animals. This photograph I made of **the** fisherman holding **the shrimp** that he caught after towing his nets for one hour. So he had a handful of **shrimp**, maybe seven or eight **shrimp**, and all those other animals on **the** deck of **the** boat are bycatch. These are animals that died in **the** process, but have no commercial value. So this is **the** true cost of a **shrimp** dinner, maybe seven or eight **shrimp** and 10 **pounds** of other animals that had to die in **the** process. And to make that point even more visual, I swam under **the shrimp** boat and made this picture of **the** guy shoveling this bycatch into **the sea** as trash and photographed this cascade of death, you know, animals like guitarfish, bat rays, flounder, pufferfish, that only an hour before, were on **the** bottom of **the** ocean, alive, but now being thrown back as trash. I also wanted to focus on **the** shark **fishing** industry because, currently on **planet** Earth, we ’ re killing over 100 million sharks every single year. But before I went out to photograph this component, I sort of wrestled with **the** notion of how do you make a picture of a dead shark that will resonate with readers You know, I think there ’ s still a lot of people out there who think **the** only good shark is a dead shark. But this one morning I jumped in and found this thresher that had just recently died in **the** gill net. And with its huge pectoral **fins** and eyes still very visible, it struck me as sort of a crucifixion, if you will. This ended up being **the** lead picture in **the** global fishery story in National Geographic. And I hope that it helped readers to take notice of this problem of 100 million sharks. And because I love sharks — I ’ m somewhat obsessed with sharks — I wanted to do another, more celebratory, story about sharks, as a way of talking about **the** need for shark conservation. So I went to **the** Bahamas because there ’ re very few places in **the** world where sharks are doing well these days, but **the** Bahamas seem to be a place where stocks were reasonably healthy, largely due to **the** fact that **the** government there had outlawed longlining several years ago. And I wanted to show several species that we hadn ’ t shown much in **the** magazine and worked in a number of locations. One of **the** locations was this place called Tiger Beach, in **the** northern Bahamas where **tiger** sharks aggregate in shallow water. This is a low-altitude photograph that I made showing our dive boat with about a dozen of these big old **tiger** sharks sort of just swimming around behind. But **the** one thing I definitely didn ’ t want to do with this coverage was to continue to portray sharks as something like monsters. I didn ’ t want them to be overly threatening or scary. And with this photograph of a beautiful 15-feet, probably 14-feet, I guess, female **tiger** shark, I sort of think I got to that goal, where she was swimming with these little barjacks off her nose, and my strobe created a shadow on her face. And I think it ’ s a gentler picture, a little less threatening, a little more respectful of **the** species. I also **searched** on this story for **the** elusive great hammerhead, an animal that really hadn ’ t been photographed much until maybe about seven or 10 years ago. It ’ s a very solitary creature. But this is an animal that ’ s considered data deficient by science in both Florida and in **the** Bahamas. You know, we know almost nothing about them. We don ’ t know where they migrate to or from, where they **mate**, where they have their pups, and yet, hammerhead populations in **the** Atlantic have declined about 80 percent in **the** last 20 to 30 years. You know, we ’ re losing them faster than we can possibly find them. This is **the** oceanic whitetip shark, an animal that is considered **the** fourth most dangerous species, if you pay attention to such lists. But it ’ s an animal that ’ s about 98 percent in decline throughout most of its range. Because this is a pelagic animal and it lives out in **the** deeper water, and because we weren ’ t working on **the** bottom, I brought along a shark cage here, and my friend, shark biologist Wes Pratt is inside **the** cage. You ’ ll see that **the** photographer, of course, was not inside **the** cage here, so clearly **the** biologist is a little smarter than **the** photographer I guess. And lastly with this story, I also wanted to focus on baby sharks, shark nurseries. And I went to **the island** of Bimini, in **the** Bahamas, to work with lemon shark pups. This is a photo of a lemon shark pup, and it shows these animals where they live for **the** first two to three years of their lives in these protective mangroves. This is a very sort of un-shark-like photograph. It ’ s not what you typically might think of as a shark picture. But, you know, here we see a shark that ’ s maybe 10 or 11 **inches** long swimming in about a foot of water. But this is crucial **habitat** and it ’ s where they spend **the** first two, three years of their lives, until they ’ re big enough to go out on **the** rest of **the** reef. After I left Bimini, I actually learned that this **habitat** was being bulldozed to create a new **golf** course and resort. And other recent stories have looked at single, flagship species, if you will, that are at risk in **the** ocean as a way of talking about other threats. One such story I did documented **the** leatherback **sea turtle**. This is **the** largest, widest-ranging, deepest-diving and oldest of all **turtle** species. Here we see a female crawling out of **the** ocean under moonlight on **the island** of Trinidad. These are animals whose lineage dates back about 100 million years. And there was a time in their lifespan where they were coming out of **the** water to nest and saw Tyrannosaurus rex running by. And today, they crawl out and see condominiums. But despite this amazing longevity, they ’ re now considered critically endangered. In **the** Pacific, where I made this photograph, their stocks have declined about 90 percent in **the** last 15 years. This is a photograph that shows a hatchling about to taste saltwater for **the** very first time beginning this long and perilous journey. Only one in a thousand leatherback hatchlings will reach maturity. But that ’ s due to natural predators like vultures that pick them off on a beach or predatory **fish** that are waiting offshore. Nature has learned to compensate with that, and females have multiple clutches of eggs to overcome those odds. But what they can ’ t deal with is anthropogenic stresses, human things, like this picture that shows a leatherback caught at night in a gill net. I actually jumped in and photographed this, and with **the** fisherman ’ s permission, I cut **the turtle** out, and it was able to swim free. But, you know, thousands of other leatherbacks each year are not so fortunate, and **the** species ' future is in great danger. Another charismatic megafauna species that I worked with is **the** story I did on **the** right **whale**. And essentially, **the** story is this with right **whales**, that about a million years ago, there was one species of right **whale** on **the planet**, but as land masses moved around and oceans became isolated, **the** species sort of separated, and today we have essentially two distinct stocks. We have **the** Southern right **whale** that we see here and **the** North Atlantic right **whale** that we see here with a mom and calf off **the** coast of Florida. Now, both species were hunted to **the** brink of extinction by **the** early whalers, but **the** Southern right **whales** have rebounded a lot better because they ' re located in places farther away from human activity. **The** North Atlantic right **whale** is listed as **the** most endangered species on **the** **planet** today because they are urban **whales** ; they live along **the** east coast of North America, United States and Canada, and they have to deal with all these urban ills. This photo shows an animal popping its head out at sunset off **the** coast of Florida. You can see **the coal** burning plant in **the** background. They have to deal with things like toxins and pharmaceuticals that are flushed out into **the** ocean, and maybe even affecting their **reproduction**. They also get entangled in **fishing** gear. This is a picture that shows **the** tail of a right **whale**. And those white markings are not natural markings. These are entanglement scars. 72 percent of **the** population has such scars, but most don ' t shed **the** gear, things like lobster traps and **crab** pots. They hold on to them, and it eventually kills them. And **the** other problem is they get hit by ships. And this was an animal that was struck by a ship in Nova Scotia, Canada being towed in, where they did a necropsy to confirm **the** cause of death, which was indeed a ship strike. So all of these ills are **stacking** up against these animals and keeping their numbers very low. And to draw a contrast with that beleaguered North Atlantic population, I went to a new pristine population of Southern right **whales** that had only been discovered about 10 years ago in **the** sub-Antarctic of New Zealand, a place called **the** Auckland Islands. I went down there in **the** winter time. And these are animals that had never seen humans before, and I was one of **the** first people they probably had ever seen. And I got in **the** water with them, and I was amazed at how curious they were. This photograph shows my assistant standing on **the** bottom at about 70 feet and one of these amazingly beautiful, 45-foot, 70- ton **whales**, like a city bus just swimming up, you know. They were in perfect condition, very **fat** and healthy, robust, no entanglement scars, **the** way they ' re supposed to look. You know, I read that **the** pilgrims, when they landed at Plymouth Rock in Massachusetts in 1620, wrote that you could walk across Cape Cod Bay on **the** backs of right **whales**. And we can ' t go back and see that today, but maybe we can preserve what we have left. And I wanted to close this program with a story of hope, a story I did on marine reserves as sort of a solution to **the** problem of overfishing, **the** global **fish** crisis story. I settled on working in **the** country of New Zealand because New Zealand was rather progressive, and is rather progressive in terms of protecting their ocean. And I really wanted this story to be about three things : I wanted it to be about abundance, about diversity and about resilience. And one of **the** first places I worked was a reserve called Goat Island in Leigh of New Zealand. What **the** scientists there told me was that when protected this first marine reserve in 1975, they hoped and expected that certain things might happen. For example, they hoped that certain species of **fish** like **the** New Zealand snapper would return because they had been **fished** to **the** brink of commercial extinction. And they did come back. What they couldn ' t predict was that other things would happen. For example, these **fish** predate on **sea** urchins, and when **the fish** were all gone, all anyone ever saw **underwater** was just acres and acres of **sea** urchins. But when **the fish** came back and began predating and controlling **the** urchin population, low and behold, kelp forests emerged in shallow water. And that ’ s because **the** urchins eat kelp. So when **the fish** control **the** urchin population, **the** ocean was restored to its natural equilibrium. You know, this is probably how **the** ocean looked here one or 200 years ago, but nobody was around to tell us. I worked in other parts of New Zealand as well, in beautiful, fragile, protected areas like in Fiordland, where this **sea** pen colony was found. Little **blue** cod swimming in for a dash of color. In **the** northern part of New Zealand, I dove in **the blue** water, where **the** water ’ s a little warmer, and photographed animals like this giant sting ray swimming through an **underwater** canyon. Every part of **the** ecosystem in this place seems very healthy, from tiny, little animals like a nudibrank crawling over encrusting sponge or a leatherjacket that is a very important animal in this ecosystem because it grazes on **the** bottom and allows new life to take hold. And I wanted to finish with this photograph, a picture I made on a very stormy day in New Zealand when I just laid on **the** bottom amidst a school of **fish** swirling around me. And I was in a place that had only been protected about 20 years ago. And I talked to divers that had been diving there for many years, and they said that **the** marine life was better here today than it was in **the** 1960s. And that ’ s because it ’ s been protected, that it has come back. So I think **the** message is clear. **The** ocean is, indeed, resilient and tolerant to a point, but we must be good custodians. I became an **underwater** photographer because I fell in love with **the sea**, and I make pictures of it today because I want to protect it, and I don ’ t think it ’ s too late. Thank you very much.

Fifty years ago, when I began exploring **the** ocean, no one â not Jacques Perrin, not Jacques Cousteau or Rachel Carson â imagined that we could do anything to harm **the** ocean by what we put into it or by what we took out of it. It seemed, at that time, to be a **sea** of Eden, but now we know, and now we are facing paradise lost. I want to share with you my personal view of changes in **the sea** that affect all of us, and to consider why it matters that in 50 years, we ’ ve lost â actually, we ’ ve taken, we ’ ve eaten â more than 90 percent of **the** big **fish** in **the sea** ; why you should care that nearly half of **the** coral reefs have **disappeared** ; why a mysterious depletion of oxygen in large areas of **the** Pacific should concern not only **the** creatures that are dying, but it really should concern you. It does concern you, as well. I ’ m haunted by **the** thought of what Ray Anderson calls”tomorrow ’ s child,”asking why we didn ’ t do something on our watch to save sharks and bluefin tuna and squids and coral reefs and **the** living ocean while there still was time. Well, now is that time. I hope for your help to explore and protect **the** wild ocean in ways that will restore **the** health and, in so doing, secure hope for humankind. Health to **the** ocean means health for us. And I hope Jill Tarter ’ s wish to engage Earthlings includes dolphins and **whales** and other **sea** creatures in this quest to find intelligent life elsewhere in **the universe**. And I hope, Jill, that someday we will find evidence that there is intelligent life among humans on this **planet**. Did I say that? I guess I did. For me, as a scientist, it all began in 1953 when I first tried scuba. It ’ s when I first got to know **fish** swimming in something other than lemon slices and butter. I actually love diving at night ; you see a lot of **fish** then that you don ’ t see in **the** daytime. Diving day and night was really easy for me in 1970, when I led a team of aquanauts living **underwater** for weeks at a time â at **the** same time that astronauts were putting their footprints on **the** moon. In 1979 I had a chance to put my footprints on **the** ocean floor while using this personal submersible called Jim. It was six miles offshore and 1, 250 feet down. It ' s one of my favorite bathing suits. Since then, I ' ve used about 30 kinds of submarines and I ' ve started three companies and a nonprofit foundation called Deep Search to design and build systems to access **the** deep **sea**. I led a five-year National Geographic expedition, **the** Sustainable **Seas** expeditions, using these little subs. They ' re so simple to drive that even a scientist can do it. And I ' m living proof. Astronauts and aquanauts alike really appreciate **the** importance of air, food, water, temperature â all **the** things you need to stay alive in space or under **the sea**. I heard astronaut Joe Allen explain how he had to learn everything he could about his life support system and then do everything he could to take care of his life support system ; and then he pointed to this and he said,"Life support system."We need to learn everything we can about it and do everything we can to take care of it. **The** poet Auden said,"Thousands have lived without love ; none without water."Ninety-seven percent of Earth ' s water is ocean. No **blue**, no green. If you think **the** ocean isn ' t important, imagine Earth without it. Mars comes to mind. No ocean, no life support system. I gave a talk not so long ago at **the** World Bank and I showed this amazing image of Earth and I said,"There it is! **The** World Bank!"That ' s where all **the** assets are! And we ' ve been trawling them down much faster than **the** natural systems can replenish them. Tim Worth says **the** economy is a wholly-owned subsidiary of **the** environment. With every drop of water you **drink**, every breath you take, you ' re connected to **the sea**. No matter where on Earth you live. Most of **the** oxygen in **the** atmosphere is generated by **the sea**. Over time, most of **the planet** ' s **organic carbon** has been absorbed and stored there, mostly by microbes. **The** ocean drives climate and weather, stabilizes temperature, shapes Earth ' s **chemistry**. Water from **the sea** forms clouds that return to **the** land and **the seas** as rain, sleet and snow, and provides home for about 97 percent of life in **the** world, maybe in **the universe**. No water, no life ; no **blue**, no green. Yet we have this idea, we humans, that **the** Earth â all of it : **the** oceans, **the** skies â are so vast and so resilient it doesn ' t matter what we do to it. That may have been true 10, 000 years ago, and maybe even 1, 000 years ago but in **the** last 100, especially in **the** last 50, we ' ve drawn down **the** assets, **the** air, **the** water, **the** wildlife that make our lives possible. New technologies are helping us to understand **the** nature of nature ; **the** nature of what ' s happening, showing us our impact on **the** Earth. I mean, first you have to know that you ' ve got a problem. And fortunately, in our time, we ' ve learned more about **the** problems than in all preceding history. And with knowing comes caring. And with caring, there ' s hope that we can find an enduring place for ourselves within **the** natural systems that support us. But first we have to know. Three years ago, I met John Hanke, who ' s **the** head of Google Earth, and I told him how much I loved being able to hold **the** world in my hands and go exploring vicariously. But I asked him :"When are you going to finish it? You did a great job with **the** land, **the** dirt. What about **the** water?"Since then, I ' ve had **the** great pleasure of working with **the** Googlers, with DOER Marine, with National Geographic, with dozens of **the** best institutions and scientists around **the** world, ones that we could enlist, to put **the** ocean in Google Earth. And as of just this week, last Monday, Google Earth is now whole. Consider this : Starting right here at **the** convention center, we can find **the** nearby aquarium, we can look at where we ' re sitting, and then we can cruise up **the** coast to **the** big aquarium, **the** ocean, and California ' s four national marine sanctuaries, and **the** new network of state marine reserves that are beginning to protect and restore some of **the** assets We can flit over to Hawaii and see **the** real Hawaiian Islands : not just

the little bit that pokes through **the surface**, but also what ' s below. To see â wait a minute, we can go kshhplash! â right there, ha â under **the** ocean, see what **the whales** see. We can go explore **the** other side of **the** Hawaiian Islands. We can go actually and swim around on Google Earth and visit with humpback **whales**. These are **the** gentle giants that I ' ve had **the** pleasure of meeting face to face many times **underwater**. There ' s nothing quite like being personally inspected by a **whale**. We can pick up and fly to **the** deepest place : seven miles down, **the** Mariana Trench, where only two people have ever been. Imagine that. It ' s only seven miles, but only two people have been there, 49 years ago. One-way trips are easy. We need new deep-diving submarines. How about some X Prizes for ocean exploration? We need to see deep trenches, **the** undersea mountains, and understand life in **the** deep **sea**. We can now go to **the** Arctic. Just ten years ago I stood on **the** ice at **the** North Pole. An ice-free Arctic Ocean may happen in this century. That ' s bad news for **the** polar bears. That ' s bad news for us too. Excess **carbon** dioxide is not only driving global warming, it ' s also changing ocean **chemistry**, making **the sea** more acidic. That ' s bad news for coral reefs and oxygen-producing plankton. Also it ' s bad news for us. We ' re putting hundreds of millions of tons of plastic and other trash into **the sea**. Millions of tons of **discarded fishing** nets, gear that continues to kill. We ' re clogging **the** ocean, poisoning **the planet** ' s circulatory system, and we ' re taking out hundreds of millions of tons of wildlife, all carbon-based units. Barbarically, we ' re killing sharks for shark **fin soup**, undermining food chains that shape planetary **chemistry** and drive **the carbon** cycle, **the** nitrogen cycle, **the** oxygen cycle, **the** water cycle â our life support system. We ' re still killing bluefin tuna ; truly endangered and much more valuable alive than dead. All of these parts are part of our life support system. We kill using long lines, with baited hooks every few feet that may stretch for 50 miles or more. Industrial trawlers and draggers are scraping **the sea** floor like bulldozers, taking everything in their path. Using Google Earth you can witness trawlers â in China, **the** North Sea, **the** Gulf of Mexico â shaking **the** foundation of our life support system, leaving plumes of death in their path. **The** next time you dine on sushi â or sashimi, or swordfish steak, or **shrimp** cocktail, whatever wildlife you happen to **enjoy** from **the** ocean â think of **the** real cost. For every **pound** that goes to market, more than 10 **pounds**, even 100 **pounds**, may be thrown away as bycatch. This is **the** consequence of not knowing that there are limits to what we can take out of **the sea**. This chart shows **the** decline in ocean wildlife from 1900 to 2000. **The** highest concentrations are in red. In my lifetime, imagine, 90 percent of **the** big **fish** have been killed. Most of **the turtles**, sharks, tunas and **whales** are way down in numbers. But, there is good news. Ten percent of **the** big **fish** still remain. There are still some **blue whales**. There are still some krill in Antarctica. There are a few oysters in Chesapeake Bay. Half **the** coral reefs are still in pretty good shape, a jeweled belt around **the** middle of **the planet**. There ' s still time, but not a lot, to turn things around. But business as usual means that in 50 years, there may be no coral reefs â and no commercial **fishing**, because **the fish** will simply be gone. Imagine **the** ocean without **fish**. Imagine what that means to our life support system. Natural systems on **the** land are in big trouble too, but **the** problems are more obvious, and some actions are being taken to protect trees, watersheds and wildlife. And in 1872, with Yellowstone National Park, **the** United States began establishing a system of parks that some say was **the** best idea America ever had. About 12 percent of **the** land around **the** world is now protected : safeguarding biodiversity, providing a **carbon** sink, generating oxygen, protecting watersheds. And, in 1972, this nation began to establish a counterpart in **the sea**, National Marine

Sanctuaries. That ’ s another great idea. **The** good news is that there are now more than 4, 000 places in **the sea**, around **the** world, that have some kind of protection. And you can find them on Google Earth. **The** bad news is that you have to look hard to find them. In **the** last three years, for example, **the** U. S. protected 340, 000 square miles of ocean as national monuments. But it only increased from 0. 6 of one percent to 0. 8 of one percent of **the** ocean protected, globally. Protected areas do rebound, but it takes a long time to restore 50-year-old rockfish or monkfish, sharks or **sea** bass, or 200-year-old orange roughy. We don ’ t consume 200-year-old cows or chickens. Protected areas provide hope that **the** creatures of Ed Wilson ’ s dream of an encyclopedia of life, or **the** census of marine life, will live not just as a list, a photograph, or a paragraph. With scientists around **the** world, I ’ ve been looking at **the** 99 percent of **the** ocean that is open to **fishing** â and mining, and drilling, and dumping, and whatever â to **search** out hope spots, and try to find ways to give them and us a secure future. Such as **the** Arctic â we have one chance, right now, to get it right. Or **the** Antarctic, where **the continent** is protected, but **the** surrounding ocean is being stripped of its krill, **whales** and **fish**. Sargasso Sea ’ s three million square miles of floating forest is being gathered up to feed cows. 97 percent of **the** land in **the** Galapagos Islands is protected, but **the** adjacent **sea** is being ravaged by **fishing**. It ’ s true too in Argentina on **the** Patagonian shelf, which is now in serious trouble. **The** high **seas**, where **whales**, tuna and dolphins travel â **the** largest, least protected, ecosystem on Earth, filled with luminous creatures, living in dark waters that average two miles deep. They flash, and sparkle, and glow with their own living light. There are still places in **the sea** as pristine as I knew as a child. **The** next 10 years may be **the** most important, and **the** next 10, 000 years **the** best chance our species will have to protect what remains of **the** natural systems that give us life. To cope with climate change, we need new ways to generate power. We need new ways, better ways, to cope with poverty, wars and disease. We need many things to keep and maintain **the** world as a better place. But, nothing else will matter if we fail to protect **the** ocean. Our fate and **the** ocean ’ s are one. We need to do for **the** ocean what Al Gore did for **the** skies above. A global plan of action with a world conservation union, **the** IUCN, is underway to protect biodiversity, to mitigate and recover from **the** impacts of climate change, on **the** high **seas** and in coastal areas, wherever we can identify critical places. New technologies are needed to map, photograph and explore **the** 95 percent of **the** ocean that we have yet to see. **The** goal is to protect biodiversity, to provide stability and resilience. We need deep-diving subs, new technologies to explore **the** ocean. We need, maybe, an expedition â a TED at **sea** â that could help figure out **the** next steps. And so, I suppose you want to know what my wish is. I wish you would use all means at your disposal â films, expeditions, **the web**, new submarines â and campaign to ignite public support for a global network of marine protected areas â hope spots large enough to save and restore **the** ocean, **the blue** heart of **the planet**. How much? Some say 10 percent, some say 30 percent. You decide : how much of your heart do you want to protect? Whatever it is, a **fraction** of one percent is not enough. My wish is a big wish, but if we can make it happen, it can truly change **the** world, and help ensure **the** survival of what actually â as it turns out â is my favorite species ; that would be us. For **the** children of today, for tomorrow ’ s child : as never again, now is **the** time. Thank you.

The substance of things **unseen**. Cities, past and future. In Oxford, perhaps we can use Lewis Carroll and look in **the** looking glass that is New York City to try and see our true selves, or perhaps pass through to another world. Or, in **the** words of F. Scott Fitzgerald,"As **the** moon rose higher, **the** inessential houses began to melt away until gradually I became aware of **the** old **island** here that once flowered for Dutch sailors ' eyes, a fresh green breast of **the** new world."My colleagues and I have been working for 10 years to rediscover this lost world in a project we call **The** Mannahatta Project. We ' re trying to discover what Henry Hudson would have seen on **the** afternoon of September 12th, 1609, when he sailed into New York harbor. And I ' d like to tell you **the** story in three acts, and if I have time still, an epilogue. So, Act I : A Map Found. So, I didn ' t grow up in New York. I grew up out west in **the** Sierra Nevada Mountains, like you see here, in **the** Red Rock Canyon. And from these early experiences as a child I learned to love landscapes. And so when it became time for me to do my graduate studies, I studied this emerging field of landscape **ecology**. Landscape **ecology** concerns itself with how **the** stream and **the** meadow and **the** forest and **the** cliffs make **habitats** for plants and animals. This experience and this training lead me to get a wonderful job with **the** Wildlife Conservation Society, which works to save wildlife and wild places all over **the** world. And over **the** last decade, I traveled to over 40 countries to see jaguars and bears and **elephants** and **tigers** and rhinos. But every time I would return from my trips I ' d return back to New York City. And on my weekends I would go up, just like all **the** other tourists, to **the** top of **the** Empire State Building, and I ' d look down on this landscape, on these ecosystems, and I ' d wonder,"How does this landscape work to make **habitat** for plants and animals? How does it work to make **habitat** for animals like me?"I ' d go to Times Square and I ' d look at **the** amazing ladies on **the** wall, and wonder why nobody is looking at **the** historical figures just behind them. I ' d go to Central Park and see **the** rolling topography of Central Park come up against **the** abrupt and **sheer** topography of midtown Manhattan. I started reading about **the** history and **the** geography in New York City. I read that New York City was **the** first mega-city, a city of 10 million people or more, in 1950. I started seeing paintings like this. For those of you who are from New York, this is 125th street under **the** West Side Highway. It was once a beach. And this painting has John James Audubon, **the** painter, sitting on **the rock**. And it ' s looking up on **the** wooded heights of Washington Heights to Jeffrey ' s Hook, where **the** George Washington Bridge goes across today. Or this painting, from **the** 1740s, from Greenwich Village. Those are two students at King ' s College — later Columbia University — sitting on a hill, overlooking a valley. And so I ' d go down to Greenwich Village and I ' d look for this hill, and I couldn ' t find it. And I couldn ' t find that palm tree. What ' s that palm tree doing there? So, it was in **the** course of these investigations that I ran into a map. And it ' s this map you see here. It ' s held in a geographic information system which allows me to zoom in. This map isn ' t from Hudson ' s time, but from **the** American Revolution, 170 years later, made by British military cartographers during **the** occupation of New York City. And it ' s a remarkable map. It ' s in **the** National Archives here in Kew. And it ' s 10 feet long and three and a half feet wide. And if I zoom in to lower Manhattan you can see **the** extent of New York City as it was, right at **the** end of **the** American Revolution. Here ' s Bowling Green. And here ' s Broadway. And this is City Hall Park. So **the** city basically extended to City Hall Park. And just beyond it you can see features that have vanished, things that have **disappeared**. This is **the** Collect Pond, which was **the** fresh water source for New York City for its first 200 years, and for **the** Native Americans for thousands of years before that. You can see **the** Lispenard Meadows draining down through here, through what is TriBeCa now, and **the** beaches that come up from **the** Battery, all **the** way to 42nd St. This map was made for military reasons. They ’ re mapping **the** roads, **the** buildings, these fortifications that they built. But they ’ re also mapping things of ecological interest, also military interest : **the** hills, **the** marshes, **the** streams. This is Richmond Hill, and Minetta Water, which used to run its way through Greenwich Village. Or **the** swamp at Gramercy Park, right here. Or Murray Hill. And this is **the** Murrays ’ house on Murray Hill, 200 years ago. Here is Times Square, **the** two streams that came together to make a wetland in Times Square, as it was at **the** end of **the** American Revolution. So I saw this remarkable map in a book. And I thought to myself,”You know, if I could georeference this map, if I could place this map in **the** grid of **the** city today, I could find these lost features of **the** city, in **the** block-by-block geography that people know, **the** geography of where people go to work, and where they go to live, and where they like to eat.”So, after some work we were able to georeference it, which allows us to put **the** modern streets on **the** city, and **the** buildings, and **the** open spaces, so that we can zoom in to where **the** Collect Pond is. We can digitize **the** Collect Pond and **the** streams, and see where they actually are in **the** geography of **the** city today. So this is fun for finding where things are **relative** to **the** old topography. But I had another idea about this map. If we take away **the** streets, and if we take away **the** buildings, and if we take away **the** open spaces, then we could take this map. If we pull off **the** 18th century features we could drive it back in time. We could drive it back to its ecological fundamentals : to **the** hills, to **the** streams, to **the** basic hydrology and shoreline, to **the** beaches, **the** basic aspects that make **the** ecological landscape. Then, if we added maps like **the** geology, **the** bedrock geology, and **the surface** geology, what **the** glaciers leave, if we make **the** soil map, with **the** 17 soil classes, that are defined by **the** National Conservation Service, if we make a digital elevation model of **the** topography that tells us how high **the** hills were, then we can **calculate the slopes**. We can **calculate the** aspect. We can **calculate the** winter wind exposure — so, which way **the** winter winds blow across **the** landscape. **The** white areas on this map are **the** places protected from **the** winter winds. We compiled all **the** information about where **the** Native Americans were, **the** Lenape. And we built a **probability** map of where they might have been. So, **the** red areas on this map indicate **the** places that are best for human **sustainability** on Manhattan, places that are close to water, places that are near **the** harbor to **fish**, places protected from **the** winter winds. We know that there was a Lenape settlement down here by **the** Collect Pond. And we knew that they planted a kind of horticulture, that they grew these beautiful gardens of corn, beans, and squash, **the**”Three Sisters”garden. So, we built a model that explains where those fields might have been. And **the** old fields, **the** successional fields that go. And we might think of these as abandoned. But, in fact, they ’ re grassland **habitats** for grassland birds and plants. And they have become successional shrub lands, and these then mix in to a map of all **the** ecological communities. And it turns out that Manhattan had 55 different ecosystem types. You can think of these as neighborhoods, as distinctive as TriBeCa and **the** Upper East Side and Inwood — that these are **the** forest and **the** wetlands and **the** marine communities, **the** beaches. And 55 is a lot. On a per-area basis, Manhattan had more ecological communities per acre than Yosemite does, than Yellowstone, than Amboseli. It was really an extraordinary landscape that was capable of supporting an extraordinary biodiversity. So, Act II : A Home Reconstructed. So, we studied **the fish** and **the** frogs and **the** birds and **the** bees, **the** 85 different kinds of **fish** that were on Manhattan, **the** Heath hens, **the** species that aren ’ t there anymore, **the** beavers on all **the** streams, **the** black bears, and

the Native Americans, to study how they used and thought about their landscape. We wanted to try and map these. And to do that what we did was we mapped their **habitat** needs. Where do they get their food? Where do they get their water? Where do they get their shelter? Where do they get their reproductive resources? To an ecologist, **the** intersection of these is **habitat**, but to most people, **the** intersection of these is their home. So, we would read in field guides, **the** standard field guides that maybe you have on your shelves, you know, what beavers need is,"A slowly meandering stream with aspen trees and alders and willows, near **the** water."That ' s **the** best thing for a beaver. So we just started making a list. Here is **the** beaver. And here is **the** stream, and **the** aspen and **the** alder and **the** willow. As if these were **the** maps that we would need to predict where you would find **the** beaver. Or **the** bog **turtle**, needing **wet** meadows and insects and sunny places. Or **the** bobcat, needing rabbits and beavers and den sites. And rapidly we started to realize that beavers can be something that a bobcat needs. But a beaver also needs things. And that having it on either side means that we can link it together, that we can create **the** network of **the habitat** relationships for these species. Moreover, we realized that you can start out as being a beaver specialist, but you can look up what an aspen needs. An aspen needs fire and dry soils. And you can look at what a **wet** meadow needs. And it need beavers to create **the** wetlands, and maybe some other things. But you can also talk about sunny places. So, what does a sunny place need? Not **habitat** per se. But what are **the** conditions that make it possible? Or fire. Or dry soils. And that you can put these on a grid that ' s 1, 000 columns long across **the** top and 1, 000 rows down **the** other way. And then we can visualize this data like a network, like a social network. And this is **the** network of all **the habitat** relationships of all **the** plants and animals on Manhattan, and everything they needed, going back to **the** geology, going back to time and space at **the** very core of **the web**. We call this **the** Muir Web. And if you zoom in on it it looks like this. Each point is a different species or a different stream or a different soil type. And those little gray lines are **the** connections that connect them together. They are **the** connections that actually make nature resilient. And **the** structure of this is what makes nature work, seen with all its parts. We call these Muir **Webs** after **the** Scottish-American naturalist John Muir, who said,"When we try to pick out anything by itself, we find that it ' s bound fast by a thousand invisible cords that cannot be broken, to everything in **the universe**."So then we took **the** Muir **webs** and we took them back to **the** maps. So if we wanted to go between 85th and 86th, and Lex and Third, maybe there was a stream in that block. And these would be **the** kind of trees that might have been there, and **the** flowers and **the** lichens and **the** mosses, **the** butterflies, **the fish** in **the** stream, **the** birds in **the** trees. Maybe a timber rattlesnake lived there. And perhaps a black bear walked by. And maybe Native Americans were there. And then we took this data. You can see this for yourself on our website. You can zoom into any block on Manhattan, and see what might have been there 400 years ago. And we used it to try and reveal a landscape here in Act III. We used **the** tools they use in Hollywood to make these **fantastic** landscapes that we all see in **the** movies. And we tried to use it to visualize Third Avenue. So we would take **the** landscape and we would build up **the** topography. We ' d lay on top of that **the** soils and **the** waters, and illuminate **the** landscape. We would lay on top of that **the** map of **the** ecological communities. And feed into that **the** map of **the** species. So that we would actually take a photograph, flying above Times Square, looking toward **the** Hudson River, waiting for Hudson to come. Using this technology, we can make these **fantastic** georeferenced views. We can basically take a picture out of any window on Manhattan and see what that landscape looked like 400 years ago. This is **the** view from **the** East River, looking up Murray Hill at where **the** United Nations is today. This is **the** view looking down **the** Hudson River, with Manhattan on **the left**, and New Jersey out on **the** right, looking out toward **the** Atlantic Ocean. This is **the** view over Times Square, with **the** beaver pond there, looking out toward **the** east. So we can see **the** Collect Pond, and Lispenard Marshes back behind. We can see **the** fields that **the** Native Americans made. And we can see this in **the** geography of **the** city today. So when you ' re watching"Law and Order,"and **the** lawyers walk up **the** steps they could have walked back down those steps of **the** New York Court House, right into **the** Collect Pond, 400 years ago. So these images are **the** work of my friend and colleague, Mark Boyer, who is here in **the** audience today. And I ' d just like, if you would give him a hand, to call out for his fine work. There is such power in bringing science and visualization together, that we can create images like this, perhaps looking on either side of a looking glass. And even though I ' ve only had a brief time to speak, I hope you appreciate that Mannahatta was a very special place. **The** place that you see here on **the left** side was interconnected. It was based on this diversity. It had this resilience that is what we need in our modern world. But I wouldn ' t have you think that I don ' t like **the** place on **the** right, which I quite do. I ' ve come to love **the** city and its kind of diversity, and its resilience, and its dependence on density and how we ' re connected together. In fact, that I see them as reflections of each other, much as Lewis Carroll did in"Through **the** Looking Glass."We can compare these two and hold them in our minds at **the** same time, that they really are **the** same place, that there is no way that cities can escape from nature. And I think this is what we ' re learning about building cities in **the** future. So if you ' ll allow me a brief epilogue, not about **the** past, but about 400 years from now, what we ' re realizing is that cities are **habitats** for people, and need to supply what people need : a sense of home, food, water, shelter, reproductive resources, and a sense of meaning. This is **the** particular additional **habitat** requirement of humanity. And so many of **the** talks here at TED are about meaning, about bringing meaning to our lives in all kinds of different ways, through technology, through art, through science, so much so that I think we focus so much on that side of our lives, that we haven ' t given enough attention to **the** food and **the** water and **the** shelter, and what we need to raise **the** kids. So, how can we envision **the** city of **the** future? Well, what if we go to Madison Square Park, and we imagine it without all **the** cars, and bicycles instead and large forests, and streams instead of sewers and storm drains? What if we imagined **the** Upper East Side with green roofs, and streams winding through **the** city, and windmills supplying **the** power we need? Or if we imagine **the** New York City metropolitan area, currently home to 12 million people, but 12 million people in **the** future, perhaps living at **the** density of Manhattan, in only 36 percent of **the** area, with **the** areas in between covered by farmland, covered by wetlands, covered by **the** marshes we need. This is **the** kind of future I think we need, is a future that has **the** same diversity and abundance and dynamism of Manhattan, but that learns from **the sustainability** of **the** past, of **the ecology**, **the** original **ecology**, of nature with all its parts. Thank you very much.

So, my question : are we alone? **The** story of humans is **the** story of ideas â scientific ideas that shine light into dark corners, ideas that we embrace rationally and irrationally, ideas for which we ' ve lived and died and killed and been killed, ideas that have vanished in history, and ideas that have been set in dogma. It ' s a story of nations, of ideologies, of territories, and of conflicts among them. But, every moment of human history, from **the** Stone Age to **the** Information Age, from Sumer and Babylon to **the** iPod and celebrity gossip, they ' ve all been carried out â every book that you ' ve read, every poem, every laugh, every tear â they ' ve all happened here. Here. Here. Here. Perspective is a very powerful thing. Perspectives can change. Perspectives can be altered. From my perspective, we live on a fragile **island** of life, in a **universe** of possibilities. For many millennia, humans have been on a journey to find answers, answers to questions about naturalism and transcendence, about who we are and why we are, and of course, who else might be out there. Is it really just us? Are we alone in this vast **universe** of energy and matter and **chemistry** and physics? Well, if we are, it ' s an awful waste of space. But, what if we ' re not? What if, out there, others are asking and answering similar questions? What if they look up at **the** night sky, at **the** same stars, but from **the** opposite side? Would **the** discovery of an older cultural civilization out there inspire us to find ways to survive our increasingly uncertain technological adolescence? Might it be **the** discovery of a distant civilization and our common cosmic origins that finally drives home **the** message of **the** bond among all humans? Whether we ' re born in San Francisco, or Sudan, or close to **the** heart of **the** Milky Way galaxy, we are **the** products of a billion-year lineage of wandering stardust. We, all of us, are what happens when a primordial mixture of hydrogen and helium **evolves** for so long that it begins to ask where it came from. Fifty years ago, **the** journey to find answers took a different path and SETI, **the** Search for Extra-Terrestrial Intelligence, began. So, what exactly is SETI? Well, SETI uses **the** tools of astronomy to try and find evidence of someone else ' s technology out there. Our own technologies are visible over interstellar distances, and theirs might be as well. It might be that some massive network of communications, or some shield against asteroidal impact, or some huge astro-engineering project that we can ' t even begin to conceive of, could generate signals at radio or optical **frequencies** that a determined program of **searching** might **detect**. For millennia, we ' ve actually turned to **the** priests and **the** philosophers for guidance and instruction on this question of whether there ' s intelligent life out there. Now, we can use **the** tools of **the** 21st century to try and observe what is, rather than ask what should be, believed. SETI doesn ' t presume **the** existence of extra terrestrial intelligence ; it merely notes **the** possibility, if not **the probability** in this vast **universe**, which seems fairly uniform. **The** numbers suggest a **universe** of possibilities. Our sun is one of 400 billion stars in our galaxy, and we know that many other stars have planetary systems. We ' ve discovered over 350 in **the** last 14 years, including **the** small **planet**, announced earlier this week, which has a radius just twice **the** size of **the** Earth. And, if even all of **the** planetary systems in our galaxy were devoid of life, there are still 100 billion other galaxies out there, altogether 10^{22} stars. Now, I ' m going to try a trick, and recreate an experiment from this morning. Remember, one billion? But, this time not one billion dollars, one billion stars. Alright, one billion stars. Now, up there, 20 feet above **the** stage, that ' s 10 trillion. Well, what about 10^{22}? Where ' s **the** line that marks that? That line would have to be 3. 8 million miles above this stage. 16 times farther away than **the** moon, or four percent of **the** distance to **the** sun. So, there are many possibilities. And much of this vast **universe**, much more may be habitable than we once thought, as we study extremophiles on Earth â organisms that can live in conditions totally inhospitable for us, in **the** hot, high pressure thermal vents at **the** bottom of **the** ocean, frozen in ice, in boiling battery acid, in **the** cooling waters of nuclear reactors. These extremophiles tell us that life may exist in many other environments. But those environments are going to be widely spaced in this **universe**. Even our nearest star, **the** Sun â its **emissions** suffer **the** tyranny of light speed. It takes a full eight minutes for its radiation to reach us. And **the** nearest star is 4. 2 light years away, which means its light takes 4. 2 years to get here. And **the** edge of our galaxy is 75, 000 light years away, and **the** nearest galaxy to us, 2. 5 million light years. That means any signal we **detect** would have started its journey a long time ago. And a signal would give us a glimpse of their past, not their present. Which is why Phil Morrison calls SETI,"**the** archaeology of **the** future."It tells us about their past, but detection of a signal tells us it ' s possible for us to have a long future. I think this is what David Deutsch meant in 2005, when he ended his Oxford TEDTalk by saying he had two principles he ' d like to share for living, and he would like to carve them on stone tablets. **The** first is that problems are inevitable. **The** second is that problems are soluble. So, ultimately what ' s going to determine **the** success or failure of SETI is **the** longevity of technologies, and **the** mean distance between technologies in **the** cosmos â distance over space and distance over time. If technologies don ' t last and persist, we will not succeed. And we ' re a very young technology in an old galaxy, and we don ' t yet know whether it ' s possible for technologies to persist. So, up until now I ' ve been talking to you about really large numbers. Let me talk about a relatively small number. And that ' s **the** length of time that **the** Earth was lifeless. Zircons that are mined in **the** Jack Hills of western Australia, zircons taken from **the** Jack Hills of western Australia tell us that within a few hundred million years of **the** origin of **the planet** there was abundant water and perhaps even life. So, our **planet** has spent **the** vast majority of its 4. 56 billion year history developing life, not anticipating its emergence. Life happened very quickly, and that bodes well for **the** potential of life elsewhere in **the** cosmos. And **the** other thing that one should take away from this chart is **the** very narrow range of time over which humans can claim to be **the** dominant intelligence on **the planet**. It ' s only **the** last few hundred thousand years modern humans have been pursuing technology and civilization. So, one needs a very deep appreciation of **the** diversity and incredible scale of life on this **planet** as **the** first step in preparing to make contact with life elsewhere in **the** cosmos. We are not **the** pinnacle of **evolution**. We are not **the** determined product of billions of years of **evolutionary** plotting and planning. We are one outcome of a continuing adaptational process. We are residents of one small **planet** in a corner of **the** Milky Way galaxy. And Homo sapiens are one small leaf on a very extensive Tree of Life, which is densely populated by organisms that have been honed for survival over millions of years. We misuse language, and talk about **the**"ascent"of man. We understand **the** scientific basis for **the** interrelatedness of life but our ego hasn ' t caught up yet. So this"ascent"of man, pinnacle of **evolution**, has got to go. It ' s a sense of privilege that **the** natural **universe** doesn ' t share. Loren Eiseley has said,"One does not meet oneself until one catches **the** reflection from an eye other than human."One day that eye may be that of an intelligent alien, and **the** sooner we eschew our narrow view of **evolution the** sooner we can truly explore our ultimate origins and destinations. We are a small part of **the** story of cosmic **evolution**, and we are going to be responsible for our continued participation in that story, and perhaps SETI will help as well. Occasionally, throughout history, this concept of this very large cosmic perspective comes to **the surface**, and as a result we see transformative and profound discoveries. So in 1543, Nicholas Copernicus published"**The** Revolutions of Heavenly **Spheres**,"and by taking **the** Earth out of **the** center, and putting **the** sun in **the** center of **the** solar system, he opened our eyes to a much larger **universe**, of which we are just a small part. And that Copernican revolution continues today to influence science and philosophy and technology and theology. So, in 1959, Giuseppe Coccone and Philip Morrison published **the** first SETI article in a refereed journal, and brought SETI into **the** scientific mainstream. And in 1960, Frank Drake conducted **the** first SETI observation looking at two stars, Tau Ceti and Epsilon Eridani, for about 150 hours. Now Drake did not discover extraterrestrial intelligence, but he learned a very valuable lesson from a passing aircraft, and that ' s that terrestrial technology can interfere with **the search** for extraterrestrial technology. We ' ve been **searching** ever since, but it ' s impossible to overstate **the** magnitude of **the search** that remains. All of **the** concerted SETI efforts, over **the** last 40-some years, are equivalent to scooping a single glass of water from **the** oceans. And no one would decide that **the** ocean was without **fish** on **the** basis of one glass of water. **The** 21st century now allows us to build bigger glasses â much bigger glasses. In Northern California, we ' re beginning to take observations with **the** first 42 telescopes of **the** Allen Telescope **Array** â and I ' ve got to take a moment right now to publicly thank Paul Allen and Nathan Myhrvold and all **the** TeamSETI members in **the** TED community who have so generously supported this research. **The** ATA is **the** first telescope built from a large number of small dishes, and hooked together with **computers**. It ' s making silicon as important as aluminum, and we ' ll grow it in **the** future by adding more antennas to reach 350 for more sensitivity and leveraging Moore ' s law for more processing capability. Today, our signal detection algorithms can find very simple artifacts and noise. If you look very hard here you can see **the** signal from **the** Voyager 1 spacecraft, **the** most distant human **object** in **the universe**, 106 times as far away from us as **the** sun is. And over those long distances, its signal is very faint when it reaches us. It may be hard for your eye to see it, but it ' s easily found with our efficient algorithms. But this is a simple signal, and tomorrow we want to be able to find more complex signals. This is a very good year. 2009 is **the** 400th anniversary of Galileo ' s first use of **the** telescope, Darwin ' s 200th birthday, **the** 150th anniversary of **the** publication of"On **the** Origin of Species,"**the** 50th anniversary of SETI as a science, **the** 25th anniversary of **the** incorporation of **the** SETI Institute as a non-profit, and of course, **the** 25th anniversary of TED. And next month, **the** Kepler Spacecraft will launch and will begin to tell us just how frequent Earth-like **planets** are, **the** targets for SETI ' s **searches**. In 2009, **the** U. N. has declared it to be **the** International Year of Astronomy, a global festival to help us residents of Earth rediscover our cosmic origins and our place in **the universe**. And in 2009, change has come to Washington, with a promise to put science in its rightful position. So, what would change everything? Well, this is **the** question **the** Edge foundation asked this year, and four of **the** respondents said,"SETI."Why? Well, to quote :"**The** discovery of intelligent life beyond Earth would eradicate **the** loneliness and solipsism that has plagued our species since its inception. And it wouldn ' t simply change everything, it would change everything all at once."So, if that ' s right, why did we only capture four out of those 151 minds? I think it ' s a problem of completion and delivery, because **the** fine print said,"What game-changing ideas and scientific developments would you expect to live to see?"So, we have a fulfillment problem. We need bigger glasses and more hands in **the** water, and then working together, maybe we can all live to see **the** detection of **the** first extraterrestrial signal. That brings me to my wish. I wish that you would empower Earthlings everywhere to become active participants in **the** ultimate **search** for cosmic company. **The** first step would be to tap into **the** global brain trust, to build an environment where raw data could be stored, and where it could be accessed and **manipulated**, where new algorithms could be developed and old algorithms made more efficient. And this is a technically creative challenge, and it would change **the** perspective of people who worked on it. And then, we ’ d like to augment **the** automated **search** with human insight. We ’ d like to use **the** pattern recognition capability of **the** human eye to find faint, complex signals that our current algorithms miss. And, of course, we ’ d like to inspire and engage **the** next generation. We ’ d like to take **the** materials that we have built for education, and get them out to students everywhere, students that can ’ t come and visit us at **the** ATA. We ’ d like to tell our story better, and engage young people, and thereby change their perspective. I ’ m sorry Seth Godin, but over **the** millennia, we ’ ve seen where tribalism leads. We ’ ve seen what happens when we divide an already small **planet** into smaller **islands**. And, ultimately, we actually all belong to only one tribe, to Earthlings. And SETI is a mirror â a mirror that can show us ourselves from an extraordinary perspective, and can help to trivialize **the** differences among us. If SETI does nothing but change **the** perspective of humans on this **planet**, then it will be one of **the** most profound **endeavors** in history. So, in **the** opening days of 2009, a visionary president stood on **the** steps of **the** U. S. Capitol and said,”We cannot help but believe that **the** old hatreds shall someday pass, that **the** lines of tribe shall soon dissolve, that, as **the** world grows smaller, our common humanity shall reveal itself.”So, I look forward to working with **the** TED community to hear about your ideas about how to fulfill this wish, and in collaborating with you, hasten **the** day that that visionary statement can become a reality. Thank you.

Text Sample 32: POS Dim 1 – 2011 – Score 31.00 – 2011/t002439.txt

The oceans cover some 70 percent of our **planet**. And I think Arthur C. Clarke probably had it right when he said that perhaps we ought to call our **planet** Planet Ocean. And **the** oceans are hugely productive, as you can see by **the** satellite image of photosynthesis, **the** production of new life. In fact, **the** oceans produce half of **the** new life every day on Earth as well as about half **the** oxygen that we breathe. In addition to that, it harbors a lot of **the** biodiversity on Earth, and much of it we don ’ t know about. But I ’ ll tell you some of that today. That also doesn ’ t even get into **the** whole protein extraction that we do from **the** ocean. That ’ s about 10 percent of our global needs and 100 percent of some **island** nations. If you were to descend into **the** 95 percent of **the** biosphere that ’ s livable, it would quickly become pitch black, interrupted only by pinpoints of light from bioluminescent organisms. And if you turn **the** lights on, you might periodically see spectacular organisms swim by, because those are **the** denizens of **the** deep, **the** things that live in **the** deep ocean. And eventually, **the** deep **sea** floor would come into view. This type of **habitat** covers more of **the** Earth ’ s **surface** than all other **habitats** combined. And yet, we know more about **the surface** of **the** Moon and about Mars than we do about this **habitat**, despite **the** fact that we have yet to extract a gram of food, a breath of oxygen or a drop of water from those bodies. And so 10 years ago, an international program began called **the** Census of Marine Life, which set out to try and improve our understanding of life in **the** global oceans. It involved 17 different projects around **the** world. As you can see, these are **the** footprints of **the** different projects. And I hope you ’ ll appreciate **the** level of global coverage that it managed to achieve. It all began when two scientists, Fred Grassle and Jesse Ausubel, met in Woods Hole, Massachusetts where both were guests at **the** famed oceanographic institute. And Fred was lamenting **the** state of marine biodiversity and **the** fact that it was in trouble and nothing was being done about it. Well, from that discussion grew this program that involved

2, 700 scientists from more than 80 countries around **the** world who engaged in 540 ocean expeditions at a combined cost of 650 million dollars to study **the** distribution, diversity and abundance of life in **the** global ocean. And so what did we find? We found spectacular new species, **the** most beautiful and visually **stunning** things everywhere we looked — from **the** shoreline to **the** **abyss**, form microbes all **the** way up to **fish** and everything in between. And **the** limiting step here wasn ’ t **the** unknown diversity of life, but rather **the** taxonomic specialists who can identify and catalog these species that became **the** limiting step. They, in fact, are an endangered species themselves. There are actually four to five new species described everyday for **the** oceans. And as I say, it could be a much larger number. Now, I come from Newfoundland in Canada — It ’ s an **island** off **the** east coast of that **continent** — where we experienced one of **the** worst **fishing** disasters in human history. And so this photograph shows a small boy next to a codfish. It ’ s around 1900. Now, when I was a boy of about his age, I would go out **fishing** with my grandfather and we would catch **fish** about half that size. And I thought that was **the** norm, because I had never seen **fish** like this. If you were to go out there today, 20 years after this fishery collapsed, if you could catch a **fish**, which would be a bit of a challenge, it would be half that size still. So what we ’ re experiencing is something called shifting baselines. Our expectations of what **the** oceans can produce is something that we don ’ t really appreciate because we haven ’ t seen it in our lifetimes. Now most of us, and I would say me included, think that human exploitation of **the** oceans really only became very serious in **the** last 50 to, perhaps, 100 years or so. **The** census actually tried to look back in time, using every source of information they could get their hands on. And so anything from restaurant menus to monastery records to ships ’ logs to see what **the** oceans looked like. Because science data really goes back to, at best, World War II, for **the** most part. And so what they found, in fact, is that exploitation really began heavily with **the** Romans. And so at that time, of course, there was no refrigeration. So fishermen could only catch what they could either eat or sell that day. But **the** Romans developed salting. And with salting, it became possible to store **fish** and to transport it long distances. And so began industrial **fishing**. And so these are **the** sorts of extrapolations that we have of what sort of loss we ’ ve had **relative** to pre-human impacts on **the** ocean. They range from 65 to 98 percent for these major groups of organisms, as shown in **the** dark **blue** bars. Now for those species **the** we managed to leave alone, that we protect — for example, marine mammals in recent years and **sea** birds — there is some recovery. So it ’ s not all hopeless. But for **the** most part, we ’ ve gone from salting to exhausting. Now this other line of evidence is a really interesting one. It ’ s from trophy **fish** caught off **the** coast of Florida. And so this is a photograph from **the** 1950s. I want you to notice **the** scale on **the** **slide**, because when you see **the** same picture from **the** 1980s, we see **the fish** are much smaller and we ’ re also seeing a change in terms of **the** composition of those **fish**. By 2007, **the** catch was actually laughable in terms of **the** size for a trophy **fish**. But this is no laughing matter. **The** oceans have lost a lot of their productivity and we ’ re responsible for it. So what ’ s left? Actually quite a lot. There ’ s a lot of exciting things, and I ’ m going to tell you a little bit about them. And I want to start with a bit on technology, because, of course, this is a TED Conference and you want to hear something on technology. So one of **the** tools that we use to sample **the** deep ocean are remotely operated vehicles. So these are tethered vehicles we lower down to **the sea** floor where they ’ re our eyes and our hands for working on **the sea** bottom. So a couple of years ago, I was supposed to go on an oceanographic cruise and I couldn ’ t go because of a scheduling conflict. But through a satellite link I was able to sit at my study at home with my dog curled up at my feet, a cup of tea in my hand, and I could tell **the** pilot,"I want a sample right there."And that ' s exactly what **the** pilot did for me. That ' s **the** sort of technology that ' s available today that really wasn ' t available even a decade ago. So it allows us to sample these amazing **habitats** that are very far from **the surface** and very far from light. And so one of **the** tools that we can use to sample **the** oceans is acoustics, or sound waves. And **the** advantage of sound waves is that they actually pass well through water, unlike light. And so we can send out sound waves, they bounce off **objects** like **fish** and are reflected back. And so in this example, a census scientist took out two ships. One would send out sound waves that would bounce back. They would be received by a second ship, and that would give us very precise estimates, in this case, of 250 billion herring in a period of about a minute. And that ' s an area about **the** size of Manhattan Island. And to be able to do that is a tremendous fisheries tool, because knowing how many **fish** are there is really critical. We can also use satellite **tags** to track animals as they move through **the** oceans. And so for animals that come to **the surface** to breathe, such as this **elephant seal**, it ' s an opportunity to send data back to shore and tell us where exactly it is in **the** ocean. And so from that we can produce these tracks. For example, **the** dark **blue** shows you where **the elephant seal** moved in **the** north Pacific. Now I realize for those of you who are colorblind, this **slide** is not very helpful, but stick with me nonetheless. For animals that don ' t **surface**, we have something called pop-up **tags**, which collect data about light and what time **the** sun rises and sets. And then at some period of time it pops up to **the surface** and, again, relays that data back to shore. Because GPS doesn ' t work under water. That ' s why we need these tools. And so from this we ' re able to identify these **blue highways**, these hot spots in **the** ocean, that should be real priority areas for ocean conservation. Now one of **the** other things that you may think about is that, when you go to **the supermarket** and you buy things, they ' re scanned. And so there ' s a barcode on that product that tells **the computer** exactly what **the** product is. Geneticists have developed a similar tool called genetic barcoding. And what barcoding does is use a specific gene called CO1 that ' s consistent within a species, but varies among species. And so what that means is we can unambiguously identify which species are which even if they look similar to each other, but may be biologically quite different. Now one of **the** nicest examples I like to cite on this is **the** story of two young women, high school students in New York City, who worked with **the** census. They went out and collected **fish** from markets and from restaurants in New York City and they barcoded it. Well what they found was mislabeled **fish**. So for example, they found something which was sold as tuna, which is very valuable, was in fact tilapia, which is a much less valuable **fish**. They also found an endangered species sold as a common one. So barcoding allows us to know what we ' re working with and also what we ' re eating. **The** Ocean Biogeographic Information System is **the** database for all **the** census data. It ' s open access ; you can all go in and download data as you wish. And it contains all **the** data from **the** census plus other data sets that people were willing to contribute. And so what you can do with that is to plot **the** distribution of species and where they **occur** in **the** oceans. What I ' ve plotted up here is **the** data that we have on hand. This is where our sampling effort has concentrated. Now what you can see is we ' ve sampled **the** area in **the** North Atlantic, in **the** North Sea in particular, and also **the** east coast of North America fairly well. That ' s **the** warm colors which show a well-sampled region. **The** cold colors, **the blue** and **the** black, show areas where we have almost no data. So even after a 10-year census, there are large areas that still remain unexplored. Now there are a group of scientists living in Texas, working in **the** Gulf of Mexico who decided really as a labor of love to pull together all **the** knowledge they could about biodiversity in **the** Gulf of Mexico. And so they put this together, a list of all **the** species, where they ' re known to **occur**, and it really seemed like a very esoteric, scientific type of exercise. But then, of course, there was **the** Deep Horizon **oil spill**. So all of a sudden, this labor of love for no obvious economic reason has become a critical piece of information in terms of how that system is going to recover, how long it will take and how **the** lawsuits and **the** multi-billion-dollar discussions that are going to happen in **the** coming years are likely to be resolved. So what did we find? Well, I could stand here for hours, but, of course, I ' m not allowed to do that. But I will tell you some of my favorite discoveries from **the** census. So one of **the** things we discovered is where are **the** hot spots of diversity? Where do we find **the** most species of ocean life? And what we find if we plot up **the** well-known species is this sort of a distribution. And what we see is that for coastal **tags**, for those organisms that live near **the** shoreline, they ' re most diverse in **the** tropics. This is something we ' ve actually known for a while, so it ' s not a real breakthrough. What is really exciting though is that **the** oceanic **tags**, or **the** ones that live far from **the** coast, are actually more diverse at intermediate latitudes. This is **the** sort of data, again, that managers could use if they want to prioritize areas of **the** ocean that we need to conserve. You can do this on a global scale, but you can also do it on a regional scale. And that ' s why biodiversity data can be so valuable. Now while a lot of **the** species we discovered in **the** census are things that are small and hard to see, that certainly wasn ' t always **the** case. For example, while it ' s hard to believe that a three kilogram lobster could elude scientists, it did until a few years ago when South African fishermen requested an export permit and scientists realized that this was something new to science. Similarly this Golden V kelp collected in Alaska just below **the** low water mark is probably a new species. Even though it ' s three meters long, it actually, again, eluded science. Now this guy, this bigfin squid, is seven meters in length. But to be fair, it lives in **the** deep waters of **the** Mid- Atlantic Ridge, so it was a lot harder to find. But there ' s still potential for discovery of big and exciting things. This particular **shrimp**, we ' ve dubbed it **the** Jurassic **shrimp**, it ' s thought to have gone extinct 50 years ago — at least it was, until **the** census discovered it was living and doing just fine off **the** coast of Australia. And it shows that **the** ocean, because of its vastness, can hide secrets for a very long time. So, Steven Spielberg, eat your heart out. If we look at distributions, in fact distributions change dramatically. And so one of **the** records that we had was this sooty shearwater, which undergoes these spectacular migrations all **the** way from New Zealand all **the** way up to Alaska and back again in **search** of endless summer as they complete their life cycles. We also talked about **the** White Shark Cafe. This is a location in **the** Pacific where white shark converge. We don ' t know why they converge there, we simply don ' t know. That ' s a question for **the** future. One of **the** things that we ' re taught in high school is that all animals require oxygen in order to survive. Now this little critter, it ' s only about half a millimeter in size, not terribly charismatic. But it was only discovered in **the** early 1980s. But **the** really interesting thing about it is that, a few years ago, census scientists discovered that this guy can thrive in oxygen-poor sediments in **the** deep Mediterranean Sea. So now they know that, in fact, animals can live without oxygen, at least some of them, and that they can adapt to even **the** harshest of conditions. If you were to suck all **the** water out of **the** ocean, this is what you ' d be left behind with, and that ' s **the** biomass of life on **the sea** floor. Now what we see is huge biomass towards **the** poles and not much biomass in between. We found life in **the** extremes. And so there were new species that were found that live inside ice and help to support an ice-based food **web**. And we also found this spectacular yeti **crab** that lives near boiling hot hydrothermal vents at Easter Island. And this particular species really captured **the** public ' s attention. We also found **the** deepest vents known yet — 5, 000 meters — **the** hottest vents at 407 degrees Celsius — vents in **the** South Pacific and also in **the** Arctic where none had been found before. So even new environments are still within **the** domain of **the** discoverable. Now in terms of **the** unknowns, there are many. And I ' m just going to summarize just a few of them very quickly for you. First of all, we might ask, how many **fishes** in **the sea**? We actually know **the fishes** better than we do any other group in **the** ocean other than marine mammals. And so we can actually extrapolate based on rates of discovery how many more species we ' re likely to discover. And from that, we actually **calculate** that we know about 16, 500 marine species and there are probably another 1, 000 to 4, 000 left to go. So we ' ve done pretty well. We ' ve got about 75 percent of **the fish**, maybe as much as 90 percent. But **the fishes**, as I say, are **the** best known. So our level of knowledge is much less for other groups of organisms. Now this figure is actually based on a brand new paper that ' s going to come out in **the** journal PLoS **Biology**. And what is does is predict how many more species there are on land and in **the** ocean. And what they found is that they think that we know of about nine percent of **the** species in **the** ocean. That means 91 percent, even after **the** census, still remain to be discovered. And so that turns out to be about two million species once all is said and done. So we still have quite a lot of work to do in terms of unknowns. Now this bacterium is part of mats that are found off **the** coast of Chile. And these mats actually cover an area **the** size of Greece. And so this particular bacterium is actually visible to **the** naked eye. But you can imagine **the** biomass that represents. But **the** really intriguing thing about **the** microbes is just how diverse they are. A single drop of seawater could contain 160 different types of microbes. And **the** oceans themselves are thought potentially to contain as many as a billion different types. So that ' s really exciting. What are they all doing out there? We actually don ' t know. **The** most exciting thing, I would say, about this census is **the** role of global science. And so as we see in this image of light during **the** night, there are lots of areas of **the** Earth where human development is much greater and other areas where it ' s much less, but between them we see large dark areas of relatively unexplored ocean. **The** other point I ' d like to make about this is that this ocean ' s interconnected. Marine organisms do not care about international boundaries ; they move where they will. And so **the** importance then of global collaboration becomes all **the** more important. We ' ve lost a lot of paradise. For example, these tuna that were once so abundant in **the** North Sea are now effectively gone. There were trawls taken in **the** deep **sea** in **the** Mediterranean, which collected more garbage than they did animals. And that ' s **the** deep **sea**, that ' s **the** environment that we consider to be among **the** most pristine **left** on Earth. And there are a lot of other pressures. Ocean acidification is a really big issue that people are concerned with, as well as ocean warming, and **the** effects they ' re going to have on coral reefs. On **the** scale of decades, in our lifetimes, we ' re going to see a lot of damage to coral reefs. And I could spend **the** rest of my time, which is getting very limited, going through this litany of concerns about **the** ocean, but I want to end on a more positive note. And so **the** grand challenge then is to try and make sure that we preserve what ' s left, because there is still spectacular beauty. And **the** oceans are so productive, there ' s so much going on in there that ' s of relevance to humans that we really need to, even from a selfish perspective, try to do better than we have in **the** past. So we need to recognize those hot spots and do our best to protect them. When we look at pictures like this, they take our breath away, in addition to helping to give us breath by **the** oxygen that **the** oceans provide. Census scientists worked in **the** rain, they worked in **the** cold, they worked under water and they worked above water trying to illuminate **the** wondrous discovery, **the** still vast unknown, **the** spectacular adaptations that we see in ocean life. So whether you ’ re a yak herder living in **the** mountains of Chile, whether you ’ re a stockbroker in New York City or whether you ’ re a TEDster living in Edinburgh, **the** oceans matter. And as **the** oceans go so shall we. Thanks for listening.

Text Sample 33: POS Dim 1 – 2011 – Score 23.00 – 2011/t002559.txt
Each of you possesses **the** most powerful, dangerous and subversive trait that natural **selection** has ever **devised**. It ’ s a piece of neural audio technology for rewiring other people ’ s minds. I ’ m talking about your language, of course, because it allows you to implant a thought from your mind directly into someone else ’ s mind, and they can attempt to do **the** same to you, without either of you having to perform surgery. Instead, when you speak, you ’ re actually using a form of telemetry not so different from **the** remote control **device** for your television. It ’ s just that, whereas that **device** relies on **pulses** of infrared light, your language relies on **pulses**, discrete **pulses**, of sound. And just as you use **the** remote control **device** to alter **the** internal settings of your television to suit your mood, you use your language to alter **the** settings inside someone else ’ s brain to suit your interests. Languages are genes talking, getting things that they want. And just imagine **the** sense of wonder in a baby when it first discovers that, merely by uttering a sound, it can get **objects** to move across a room as if by magic, and maybe even into its mouth. Now language ’ s subversive power has been recognized throughout **the** ages in censorship, in books you can ’ t read, phrases you can ’ t use and words you can ’ t say. In fact, **the** Tower of Babel story in **the** Bible is a fable and warning about **the** power of language. According to that story, early humans developed **the** conceit that, by using their language to work together, they could build a tower that would take them all **the** way to heaven. Now God, angered at this attempt to usurp his power, destroyed **the** tower, and then to ensure that it would never be rebuilt, he scattered **the** people by giving them different languages — confused them by giving them different languages. And this leads to **the** wonderful irony that our languages exist to prevent us from communicating. Even today, we know that there are words we cannot use, phrases we cannot say, because if we do so, we might be accosted, jailed, or even killed. And all of this from a puff of air emanating from our mouths. Now all this fuss about a single one of our traits tells us there ’ s something worth explaining. And that is how and why did this remarkable trait **evolve**, and why did it **evolve** only in our species? Now it ’ s a little bit of a surprise that to get an answer to that question, we have to go to tool use in **the** chimpanzees. Now these chimpanzees are using tools, and we take that as a sign of their intelligence. But if they really were intelligent, why would they use a stick to extract termites from **the** ground rather than a shovel? And if they really were intelligent, why would they crack open **nuts** with a **rock**? Why wouldn ’ t they just go to a shop and buy a bag of **nuts** that somebody else had already cracked open for them? Why not? I mean, that ’ s what we do. Now **the** reason **the** chimpanzees don ’ t do that is that they lack what psychologists and anthropologists call social **learning**. They seem to lack **the** ability to learn from others by **copying** or imitating or simply watching. As a result, they can ’ t improve on others ’ ideas or learn from others ’ mistakes — benefit from others ’ wisdom. And so they just do **the** same thing over and

over and over again. In fact, we could go away for a million years and come back and these chimpanzees would be doing **the** same thing with **the** same sticks for **the** termites and **the** same **rocks** to crack open **the nuts**. Now this may sound arrogant, or even full of hubris. How do we know this? Because this is exactly what our ancestors, **the** Homo erectus, did. These upright apes **evolved** on **the** African savanna about two million years ago, and they made these splendid hand axes that fit wonderfully into your hands. But if we look at **the fossil** record, we see that they made **the** same hand axe over and over and over again for one million years. You can follow it through **the fossil** record. Now if we make some guesses about how long Homo erectus lived, what their generation time was, that ' s about 40, 000 generations of parents to offspring, and other individuals watching, in which that hand axe didn ' t change. It ' s not even clear that our very close genetic **relatives**, **the** Neanderthals, had social **learning**. Sure enough, their tools were more complicated than those of Homo erectus, but they too showed very little change over **the** 300, 000 years or so that those species, **the** Neanderthals, lived in Eurasia. **Okay**, so what this tells us is that, contrary to **the** old adage,"monkey see, monkey do,"**the** surprise really is that all of **the** other animals really cannot do that — at least not very much. And even this picture has **the** suspicious taint of being rigged about it — something from a Barnum & Bailey circus. But by comparison, we can learn. We can learn by watching other people and **copying** or imitating what they can do. We can then choose, from among a range of options, **the** best one. We can benefit from others ' ideas. We can build on their wisdom. And as a result, our ideas do accumulate, and our technology progresses. And this cumulative cultural adaptation, as anthropologists call this accumulation of ideas, is responsible for everything around you in your bustling and teeming everyday lives. I mean **the** world has changed out of all proportion to what we would recognize even 1, 000 or 2, 000 years ago. And all of this because of cumulative cultural adaptation. **The** chairs you ' re sitting in, **the** lights in this auditorium, my microphone, **the** iPads and iPods that you carry around with you — all are a result of cumulative cultural adaptation. Now to many commentators, cumulative cultural adaptation, or social **learning**, is job done, end of story. Our species can make stuff, therefore we prospered in a way that no other species has. In fact, we can even make **the**"stuff of life"— as I just said, all **the** stuff around us. But in fact, it turns out that some time around 200, 000 years ago, when our species first arose and acquired social **learning**, that this was really **the** beginning of our story, not **the** end of our story. Because our acquisition of social **learning** would create a social and **evolutionary** dilemma, **the** resolution of which, it ' s fair to say, would determine not only **the** future course of our psychology, but **the** future course of **the** entire world. And most importantly for this, it ' ll tell us why we have language. And **the** reason that dilemma arose is, it turns out, that social **learning** is visual theft. If I can learn by watching you, I can steal your best ideas, and I can benefit from your efforts, without having to put in **the** time and energy that you did into developing them. If I can watch which lure you use to catch a **fish**, or I can watch how you flake your hand axe to make it better, or if I follow you secretly to your mushroom patch, I can benefit from your knowledge and wisdom and skills, and maybe even catch that **fish** before you do. Social **learning** really is visual theft. And in any species that acquired it, it would behoove you to hide your best ideas, lest somebody steal them from you. And so some time around 200, 000 years ago, our species confronted this crisis. And we really had only two options for dealing with **the** conflicts that visual theft would bring. One of those options was that we could have retreated into small family groups. Because then **the** benefits of our ideas and knowledge would flow just to our **relatives**. Had we chosen this option, sometime around 200, 000 years ago, we would probably still be living like **the** Neanderthals were when we first entered Europe 40, 000 years ago. And this is because in small groups there are fewer ideas, there are fewer innovations. And small groups are more prone to accidents and bad luck. So if we ’ d chosen that path, our **evolutionary** path would have led into **the** forest — and been a short one indeed. **The** other option we could choose was to develop **the** systems of communication that would allow us to share ideas and to cooperate amongst others. Choosing this option would mean that a vastly greater fund of accumulated knowledge and wisdom would become available to any one individual than would ever arise from within an individual family or an individual person on their own. Well, we chose **the** second option, and language is **the** result. Language **evolved** to solve **the** crisis of visual theft. Language is a piece of social technology for enhancing **the** benefits of cooperation — for reaching agreements, for striking deals and for coordinating our activities. And you can see that, in a developing society that was beginning to acquire language, not having language would be a like a bird without **wings**. Just as **wings** open up this **sphere** of air for birds to exploit, language opened up **the sphere** of cooperation for humans to exploit. And we take this utterly for granted, because we ’ re a species that is so at home with language, but you have to realize that even **the** simplest acts of exchange that we engage in are utterly dependent upon language. And to see why, consider two scenarios from early in our **evolution**. Let ’ s imagine that you are really good at making arrowheads, but you ’ re hopeless at making **the** wooden shafts with **the** flight feathers attached. Two other people you know are very good at making **the** wooden shafts, but they ’ re hopeless at making **the** arrowheads. So what you do is — one of those people has not really acquired language yet. And let ’ s pretend **the** other one is good at language skills. So what you do one day is you take a pile of arrowheads, and you walk up to **the** one that can ’ t speak very well, and you put **the** arrowheads down in front of him, hoping that he ’ ll get **the** idea that you want to trade your arrowheads for finished arrows. But he looks at **the** pile of arrowheads, thinks they ’ re a gift, picks them up, smiles and walks off. Now you pursue this guy, gesticulating. A scuffle ensues and you get stabbed with one of your own arrowheads. **Okay**, now replay this scene now, and you ’ re approaching **the** one who has language. You put down your arrowheads and say,”I ’ d like to trade these arrowheads for finished arrows. I ’ ll split you 50 / 50.”**The** other one says,”Fine. Looks good to me. We ’ ll do that.”Now **the** job is done. Once we have language, we can put our ideas together and cooperate to have a prosperity that we couldn ’ t have before we acquired it. And this is why our species has prospered around **the** world while **the** rest of **the** animals sit behind bars in zoos, languishing. That ’ s why we build space shuttles and cathedrals while **the** rest of **the** world sticks sticks into **the** ground to extract termites. All right, if this view of language and its value in solving **the** crisis of visual theft is true, any species that acquires it should show an **explosion** of creativity and prosperity. And this is exactly what **the** archeological record shows. If you look at our ancestors, **the** Neanderthals and **the** Homo erectus, our immediate ancestors, they ’ re confined to small regions of **the** world. But when our species arose about 200, 000 years ago, sometime after that we quickly walked out of Africa and spread around **the** entire world, occupying nearly every **habitat** on Earth. Now whereas other species are confined to places that their genes adapt them to, with social **learning** and language, we could transform **the** environment to suit our needs. And so we prospered in a way that no other animal has. Language really is **the** most potent trait that has ever **evolved**. It is **the** most valuable trait we have for converting new lands and resources into more people and their genes that natural

selection has ever **devised**. Language really is **the** voice of our genes. Now having **evolved** language, though, we did something **peculiar**, even bizarre. As we spread out around **the** world, we developed thousands of different languages. Currently, there are about seven or 8, 000 different languages spoken on Earth. Now you might say, well, this is just natural. As we diverge, our languages are naturally going to diverge. But **the** real puzzle and irony is that **the** greatest density of different languages on Earth is found where people are most tightly packed together. If we go to **the island** of Papua New Guinea, we can find about 800 to 1, 000 distinct human languages, different human languages, spoken on that **island** alone. There are places on that **island** where you can encounter a new language every two or three miles. Now, incredible as this sounds, I once met a Papuan man, and I asked him if this could possibly be true. And he said to me,"Oh no. They ' re far closer together than that."And it ' s true ; there are places on that **island** where you can encounter a new language in under a mile. And this is also true of some remote oceanic **islands**. And so it seems that we use our language, not just to cooperate, but to draw rings around our cooperative groups and to establish identities, and perhaps to protect our knowledge and wisdom and skills from eavesdropping from outside. And we know this because when we study different language groups and associate them with their cultures, we see that different languages slow **the** flow of ideas between groups. They slow **the** flow of technologies. And they even slow **the** flow of genes. Now I can ' t speak for you, but it seems to be **the** case that we don ' t have sex with people we can ' t talk to. Now we have to counter that, though, against **the** evidence we ' ve heard that we might have had some rather distasteful genetic dalliances with **the** Neanderthals and **the** Denisovans. **Okay**, this tendency we have, this seemingly natural tendency we have, towards isolation, towards keeping to ourselves, crashes head first into our modern world. This remarkable image is not a map of **the** world. In fact, it ' s a map of Facebook friendship links. And when you plot those friendship links by their latitude and longitude, it literally draws a map of **the** world. Our modern world is communicating with itself and with each other more than it has at any time in its past. And that communication, that connectivity around **the** world, that globalization now raises a burden. Because these different languages impose a barrier, as we ' ve just seen, to **the** transfer of goods and ideas and technologies and wisdom. And they impose a barrier to cooperation. And nowhere do we see that more clearly than in **the** European Union, whose 27 member countries speak 23 official languages. **The** European Union is now spending over one billion euros annually translating among their 23 official languages. That ' s something on **the** order of 1. 45 billion U. S. dollars on translation costs alone. Now think of **the** absurdity of this situation. If 27 individuals from those 27 member states sat around table, speaking their 23 languages, some very simple mathematics will tell you that you need an army of 253 translators to anticipate all **the** pairwise possibilities. **The** European Union employs a permanent staff of about 2, 500 translators. And in 2007 alone — and I ' m sure there are more recent figures — something on **the** order of 1. 3 million pages were translated into English alone. And so if language really is **the** solution to **the** crisis of visual theft, if language really is **the** conduit of our cooperation, **the** technology that our species derived to promote **the** free flow and exchange of ideas, in our modern world, we confront a question. And that question is whether in this modern, globalized world we can really afford to have all these different languages. To put it this way, nature knows no other circumstance in which functionally equivalent traits coexist. One of them always drives **the** other extinct. And we see this in **the** inexorable march towards standardization. There are lots and lots of ways of measuring things

— weighing them and measuring their length — but **the** metric system is winning. There are lots and lots of ways of measuring time, but a really bizarre base 60 system known as hours and minutes and seconds is nearly universal around **the** world. There are many, many ways of imprinting CDs or DVDs, but those are all being standardized as well. And you can probably think of many, many more in your own everyday lives. And so our modern world now is confronting us with a dilemma. And it ' s **the** dilemma that this Chinese man faces, who ' s language is spoken by more people in **the** world than any other single language, and yet he is sitting at his blackboard, converting Chinese phrases into English language phrases. And what this does is it raises **the** possibility to us that in a world in which we want to promote cooperation and exchange, and in a world that might be dependent more than ever before on cooperation to maintain and enhance our levels of prosperity, his actions suggest to us it might be inevitable that we have to confront **the** idea that our destiny is to be one world with one language. Thank you. Matt Ridley : Mark, one question. Svante found that **the** FOXP2 gene, which seems to be associated with language, was also shared in **the** same form in Neanderthals as us. Do we have any idea how we could have defeated Neanderthals if they also had language? Mark Pagel : This is a very good question. So many of you will be familiar with **the** idea that there ' s this gene called FOXP2 that seems to be implicated in some ways in **the** fine motor control that ' s associated with language. **The** reason why I don ' t believe that tells us that **the** Neanderthals had language is — here ' s a simple analogy : Ferraris are cars that have engines. My car has an engine, but it ' s not a Ferrari. Now **the** simple answer then is that genes alone don ' t, all by themselves, determine **the** outcome of very complicated things like language. What we know about this FOXP2 and Neanderthals is that they may have had fine motor control of their mouths — who knows. But that doesn ' t tell us they necessarily had language. MR : Thank you very much indeed.

Text Sample 34: POS Dim 1 – 2011 – Score 20.00 – 2011/t002528.txt

I ' m a neuroscientist. And in neuroscience, we have to deal with many difficult questions about **the** brain. But I want to start with **the** easiest question and **the** question you really should have all asked yourselves at some point in your life, because it ' s a fundamental question if we want to understand brain function. And that is, why do we and other animals have brains? Not all species on our **planet** have brains, so if we want to know what **the** brain is for, let ' s think about why we **evolved** one. Now you may reason that we have one to perceive **the** world or to think, and that ' s completely wrong. If you think about this question for any length of time, it ' s blindingly obvious why we have a brain. We have a brain for one reason and one reason only, and that ' s to produce adaptable and complex movements. There is no other reason to have a brain. Think about it. Movement is **the** only way you have of affecting **the** world around you. Now that ' s not quite true. There ' s one other way, and that ' s through sweating. But apart from that, everything else goes through contractions of muscles. So think about communication — speech, gestures, writing, sign language — they ' re all mediated through contractions of your muscles. So it ' s really important to remember that sensory, memory and cognitive processes are all important, but they ' re only important to either drive or suppress future movements. There can be no **evolutionary** advantage to laying down memories of childhood or perceiving **the** color of a rose if it doesn ' t affect **the** way you ' re going to move later in life. Now for those who don ' t believe this argument, we have trees and grass on our **planet** without **the** brain, but **the** clinching evidence is this animal here — **the** humble **sea** squirt. Rudimentary animal, has a nervous system, swims around in **the** ocean in its juvenile life. And at some point of its life, it implants on a **rock**. And **the** first thing it does in implanting on that **rock**, which it never leaves, is to digest its own brain and nervous system for food. So once you don ' t need to move, you don ' t need **the** luxury of that brain. And this animal is often taken as an analogy to what happens at universities when professors get tenure, but that ' s a different subject. So I am a movement chauvinist. I believe movement is **the** most important function of **the** brain — don ' t let anyone tell you that it ' s not true. Now if movement is so important, how well are we doing understanding how **the** brain controls movement? And **the** answer is we ' re doing extremely poorly ; it ' s a very hard problem. But we can look at how well we ' re doing by thinking about how well we ' re doing building machines which can do what humans can do. Think about **the** game of chess. How well are we doing determining what piece to move where? If you pit Garry Kasparov here, when he ' s not in jail, against IBM ' s Deep Blue, well **the** answer is IBM ' s Deep Blue will occasionally win. And I think if IBM ' s Deep Blue played anyone in this room, it would win every time. That problem is solved. What about **the** problem of picking up a chess piece, dexterously **manipulating** it and putting it back down on **the** board? If you put a five **year-old** child ' s dexterity against **the** best robots of today, **the** answer is simple : **the** child wins easily. There ' s no competition at all. Now why is that top problem so easy and **the** bottom problem so hard? One reason is a very smart five **year-old** could tell you **the** algorithm for that top problem — look at all possible moves to **the** end of **the** game and choose **the** one that makes you win. So it ' s a very simple algorithm. Now of course there are other moves, but with vast **computers** we approximate and come close to **the** optimal solution. When it comes to being dexterous, it ' s not even clear what **the** algorithm is you have to solve to be dexterous. And we ' ll see you have to both perceive and act on **the** world, which has a lot of problems. But let me show you cutting-edge robotics. Now a lot of robotics is very impressive, but manipulation robotics is really just in **the** dark ages. So this is **the** end of a Ph. D. project from one of **the** best robotics institutes. And **the** student has trained this robot to pour this water into a glass. It ' s a hard problem because **the** water sloshes about, but it can do it. But it doesn ' t do it with anything like **the** agility of a human. Now if you want this robot to do a different task, that ' s another three-year Ph. D. program. There is no generalization at all from one task to another in robotics. Now we can compare this to cutting-edge human performance. So what I ' m going to show you is Emily Fox winning **the** world record for cup **stacking**. Now **the** Americans in **the** audience will know all about cup **stacking**. It ' s a high school sport where you have 12 cups you have to **stack** and unstack against **the** clock in a prescribed order. And this is her getting **the** world record in real time. And she ' s pretty happy. We have no idea what is going on inside her brain when she does that, and that ' s what we ' d like to know. So in my group, what we try to do is reverse engineer how humans control movement. And it sounds like an easy problem. You send a command down, it causes muscles to contract. Your arm or body moves, and you get sensory feedback from vision, from skin, from muscles and so on. **The** trouble is these signals are not **the** beautiful signals you want them to be. So one thing that makes controlling movement difficult is, for example, sensory feedback is extremely noisy. Now by noise, I do not mean sound. We use it in **the** engineering and neuroscience sense meaning a random noise corrupting a signal. So **the** old days before digital radio when you were tuning in your radio and you heard"crrcckkk"on **the** station you wanted to hear, that was **the** noise. But more generally, this noise is something that corrupts **the** signal. So for example, if you put your hand under a table and try to localize it with your other hand, you can be off by several centimeters due to **the** noise in sensory feedback. Similarly, when you put motor output on movement output, it ' s extremely noisy. Forget about trying to hit **the** bull ' s eye in darts, just aim for **the** same spot over and over again. You have a huge spread due to movement variability. And more than that, **the** outside world, or task, is both ambiguous and variable. **The** teapot could be full, it could be empty. It changes over time. So we work in a whole sensory movement task **soup** of noise. Now this noise is so great that society places a huge premium on those of us who can reduce **the** consequences of noise. So if you ' re lucky enough to be able to knock a small white ball into a hole several hundred yards away using a long metal stick, our society will be willing to reward you with hundreds of millions of dollars. Now what I want to convince you of is **the** brain also goes through a lot of effort to reduce **the** negative consequences of this sort of noise and variability. And to do that, I ' m going to tell you about a framework which is very popular in statistics and machine **learning** of **the** last 50 years called Bayesian decision theory. And it ' s more recently a unifying way to think about how **the** brain deals with uncertainty. And **the** fundamental idea is you want to make inferences and then take actions. So let ' s think about **the** inference. You want to generate beliefs about **the** world. So what are beliefs? Beliefs could be : where are my arms in space? Am I looking at a cat or a fox? But we ' re going to represent beliefs with **probabilities**. So we ' re going to represent a belief with a number between zero and one — zero meaning I don ' t believe it at all, one means I ' m absolutely certain. And numbers in between give you **the** gray levels of uncertainty. And **the** key idea to Bayesian inference is you have two sources of information from which to make your inference. You have data, and data in neuroscience is sensory input. So I have sensory input, which I can take in to make beliefs. But there ' s another source of information, and that ' s effectively prior knowledge. You accumulate knowledge throughout your life in memories. And **the** point about Bayesian decision theory is it gives you **the** mathematics of **the** optimal way to combine your prior knowledge with your sensory evidence to generate new beliefs. And I ' ve put **the** formula up there. I ' m not going to explain what that formula is, but it ' s very beautiful. And it has real beauty and real explanatory power. And what it really says, and what you want to estimate, is **the probability** of different beliefs given your sensory input. So let me give you an intuitive example. Imagine you ' re learning to play tennis and you want to decide where **the** ball is going to bounce as it comes over **the** net towards you. There are two sources of information Bayes ' rule tells you. There ' s sensory evidence — you can use visual information auditory information, and that might tell you it ' s going to land in that red spot. But you know that your senses are not perfect, and therefore there ' s some variability of where it ' s going to land shown by that cloud of red, representing numbers between 0. 5 and maybe 0. 1. That information is available in **the** current shot, but there ' s another source of information not available on **the** current shot, but only available by repeated experience in **the** game of tennis, and that ' s that **the** ball doesn ' t bounce with equal **probability** over **the** court during **the** match. If you ' re playing against a very good opponent, they may distribute it in that green area, which is **the** prior distribution, making it hard for you to return. Now both these sources of information carry important information. And what Bayes ' rule says is that I should multiply **the** numbers on **the** red by **the** numbers on **the** green to get **the** numbers of **the yellow**, which have **the** ellipses, and that ' s my belief. So it ' s **the** optimal way of combining information. Now I wouldn ' t tell you all this if it wasn ' t that a few years ago, we showed this is exactly what people do when they learn new movement skills. And what it means is we really are Bayesian inference machines. As we go around, we learn about statistics of **the** world and lay that down, but we also learn about how noisy our own sensory apparatus is, and then combine those in a real Bayesian way. Now a key part to **the** Bayesian is this part of **the** formula. And what this part really says is I have to predict **the probability** of different sensory feedbacks given my beliefs. So that really means I have to make predictions of **the** future. And I want to convince you **the** brain does make predictions of **the** sensory feedback it ’ s going to get. And moreover, it profoundly changes your perceptions by what you do. And to do that, I ’ ll tell you about how **the** brain deals with sensory input. So you send a command out, you get sensory feedback back, and that transformation is governed by **the** physics of your body and your sensory apparatus. But you can imagine looking inside **the** brain. And here ’ s inside **the** brain. You might have a little predictor, a neural simulator, of **the** physics of your body and your senses. So as you send a movement command down, you tap a **copy** of that off and run it into your neural simulator to anticipate **the** sensory consequences of your actions. So as I shake this ketchup bottle, I get some true sensory feedback as **the** function of time in **the** bottom row. And if I ’ ve got a good predictor, it predicts **the** same thing. Well why would I bother doing that? I ’ m going to get **the** same feedback anyway. Well there ’ s good reasons. Imagine, as I shake **the** ketchup bottle, someone very kindly comes up to me and taps it on **the** back for me. Now I get an extra source of sensory information due to that external act. So I get two sources. I get you tapping on it, and I get me shaking it, but from my senses ’ point of view, that is combined together into one source of information. Now there ’ s good reason to believe that you would want to be able to distinguish external events from internal events. Because external events are actually much more behaviorally relevant than feeling everything that ’ s going on inside my body. So one way to reconstruct that is to compare **the** prediction — which is only based on your movement commands — with **the** reality. Any discrepancy should hopefully be external. So as I go around **the** world, I ’ m making predictions of what I should get, subtracting them off. Everything left over is external to me. What evidence is there for this? Well there ’ s one very clear example where a sensation generated by myself feels very different then if generated by another person. And so we decided **the** most obvious place to start was with tickling. It ’ s been known for a long time, you can ’ t tickle yourself as well as other people can. But it hasn ’ t really been shown, it ’ s because you have a neural simulator, simulating your own body and subtracting off that sense. So we can bring **the** experiments of **the** 21st century by applying robotic technologies to this problem. And in effect, what we have is some sort of stick in one hand attached to a robot, and they ’ re going to move that back and forward. And then we ’ re going to track that with a **computer** and use it to control another robot, which is going to tickle their palm with another stick. And then we ’ re going to ask them to rate a bunch of things including ticklishness. I ’ ll show you just one part of our study. And here I ’ ve taken away **the** robots, but basically people move with their right arm sinusoidally back and forward. And we replay that to **the** other hand with a time delay. Either no time delay, in which case light would just tickle your palm, or with a time delay of two- tenths of three-tenths of a second. So **the** important point here is **the** right hand always does **the** same things — sinusoidal movement. **The** left hand always is **the** same and puts sinusoidal tickle. All we ’ re playing with is a tempo causality. And as we go from naught to 0. 1 second, it becomes more ticklish. As you go from 0. 1 to 0. 2, it becomes more ticklish at **the** end. And by 0. 2 of a second, it ’ s equivalently ticklish to **the** robot that just tickled you without you doing anything. So whatever is responsible for this cancellation is extremely tightly coupled with tempo causality. And based on this illustration, we really convinced ourselves in **the** field that **the** brain ’ s making precise predictions and subtracting them off from **the** sensations. Now I have to admit, these are **the** worst studies my lab has ever run. Because **the** tickle sensation on **the** palm comes and goes, you need large numbers of subjects with these stars making them significant. So we were looking for a much more objective way to assess this phenomena. And in **the** intervening years I had two daughters. And one thing you notice about children in backseats of cars on long journeys, they get into fights — which started with one of them doing something to **the** other, **the** other retaliating. It quickly escalates. And children tend to get into fights which escalate in terms of force. Now when I screamed at my children to stop, sometimes they would both say to me **the** other person hit them harder. Now I happen to know my children don ’ t lie, so I thought, as a neuroscientist, it was important how I could explain how they were telling inconsistent truths. And we hypothesize based on **the** tickling study that when one child hits another, they generate **the** movement command. They predict **the** sensory consequences and subtract it off. So they actually think they ’ ve hit **the** person less hard than they have — rather like **the** tickling. Whereas **the** passive recipient doesn ’ t make **the** prediction, feels **the** full blow. So if they retaliate with **the** same force, **the** first person will think it ’ s been escalated. So we decided to test this in **the** lab. Now we don ’ t work with children, we don ’ t work with hitting, but **the** concept is **identical**. We bring in two adults. We tell them they ’ re going to play a game. And so here ’ s player one and player two sitting opposite to each other. And **the** game is very simple. We started with a motor with a little lever, a little force transfuser. And we use this motor to apply force down to player one ’ s fingers for three seconds and then it stops. And that player ’ s been told, remember **the** experience of that force and use your other finger to apply **the** same force down to **the** other subject ’ s finger through a force transfuser — and they do that. And player two ’ s been told, remember **the** experience of that force. Use your other hand to apply **the** force back down. And so they take it in turns to apply **the** force they ’ ve just experienced back and forward. But critically, they ’ re briefed about **the** rules of **the** game in separate rooms. So they don ’ t know **the** rules **the** other person ’ s playing by. And what we ’ ve measured is **the** force as a function of terms. And if we look at what we start with, a quarter of a Newton there, a number of turns, perfect would be that red line. And what we see in all pairs of subjects is this — a 70 percent escalation in force on each go. So it really suggests, when you ’ re doing this — based on this study and others we ’ ve done — that **the** brain is canceling **the** sensory consequences and underestimating **the** force it ’ s producing. So it re-shows **the** brain makes predictions and fundamentally changes **the** precepts. So we ’ ve made inferences, we ’ ve done predictions, now we have to generate actions. And what Bayes ’ rule says is, given my beliefs, **the** action should in some sense be optimal. But we ’ ve got a problem. Tasks are symbolic — I want to **drink**, I want to dance — but **the** movement system has to contract 600 muscles in a particular sequence. And there ’ s a big gap between **the** task and **the** movement system. So it could be bridged in infinitely many different ways. So think about just a point to point movement. I could choose these two paths out of an infinite number of paths. Having chosen a particular path, I can hold my hand on that path as infinitely many different joint **configurations**. And I can hold my arm in a particular joint **configuration** either very stiff or very relaxed. So I have a huge amount of choice to make. Now it turns out, we are extremely stereotypical. We all move **the** same way pretty much. And so it turns out we ’ re so stereotypical, our brains have got dedicated neural circuitry to decode this stereotyping. So if I take some dots and set them in motion with biological motion, your brain ' s circuitry would understand instantly what ' s going on. Now this is a bunch of dots moving. You will know what this person is doing, whether happy, sad, old, young — a huge amount of information. If these dots were cars going on a racing circuit, you would have absolutely no idea what ' s going on. So why is it that we move **the** particular ways we do? Well let ' s think about what really happens. Maybe we don ' t all quite move **the** same way. Maybe there ' s variation in **the** population. And maybe those who move better than others have got more chance of getting their children into **the** next generation. So in **evolutionary** scales, movements get better. And perhaps in life, movements get better through learning. So what is it about a movement which is good or bad? Imagine I want to intercept this ball. Here are two possible paths to that ball. Well if I choose **the** left-hand path, I can work out **the** forces required in one of my muscles as a function of time. But there ' s noise added to this. So what I actually get, based on this lovely, smooth, desired force, is a very noisy version. So if I pick **the** same command through many times, I will get a different noisy version each time, because noise changes each time. So what I can show you here is how **the** variability of **the** movement will **evolve** if I choose that way. If I choose a different way of moving — on **the** right for example — then I ' ll have a different command, different noise, playing through a noisy system, very complicated. All we can be sure of is **the** variability will be different. If I move in this particular way, I end up with a smaller variability across many movements. So if I have to choose between those two, I would choose **the** right one because it ' s less variable. And **the** fundamental idea is you want to plan your movements so as to minimize **the** negative consequence of **the** noise. And one intuition to get is actually **the** amount of noise or variability I show here gets bigger as **the** force gets bigger. So you want to avoid big forces as one principle. So we ' ve shown that using this, we can explain a huge amount of data — that exactly people are going about their lives planning movements so as to minimize negative consequences of noise. So I hope I ' ve convinced you **the** brain is there and **evolved** to control movement. And it ' s an intellectual challenge to understand how we do that. But it ' s also relevant for disease and rehabilitation. There are many diseases which effect movement. And hopefully if we understand how we control movement, we can apply that to robotic technology. And finally, I want to remind you, when you see animals do what look like very simple tasks, **the** actual complexity of what is going on inside their brain is really quite dramatic. Thank you very much. Chris Anderson : Quick question for you, Dan. So you ' re a movement — — chauvinist. Does that mean that you think that **the** other things we think our brains are about — **the** dreaming, **the** yearning, **the** falling in love and all these things — are a kind of side show, an accident? DW : No, no, actually I think they ' re all important to drive **the** right movement behavior to get **reproduction** in **the** end. So I think people who study sensation or memory without realizing why you ' re laying down memories of childhood. **The** fact that we forget most of our childhood, for example, is probably fine, because it doesn ' t effect our movements later in life. You only need to store things which are really going to effect movement. CA : So you think that people thinking about **the** brain, and consciousness generally, could get real insight by saying, where does movement play in this game? DW : So people have found out for example that studying vision in **the** absence of realizing why you have vision is a mistake. You have to study vision with **the** realization of how **the** movement system is going to use vision. And it uses it very differently once you think about it that way. CA : Well that was quite fascinating. Thank you very much indeed.

Text Sample 35: POS Dim 1 – 1984 – Score 8.00 – 1984/t000297.txt

In this rather long sort of marathon presentation, I ’ ve tried to break it up into three parts : **the** first being a whole lot of examples on how it can be a little bit more pleasurable to deal with a **computer** and really address **the** qualities of **the** human interface. And these will be some simple design qualities and they will also be some qualities of, if you will, **the** intelligence of interaction. Then **the** second part will really just be examples of new technologies — new media falling very much into that mold. Again, I will go through them as fast as possible. And then **the** last one will be some examples I ’ ve been able to collect, which I think illustrate this at least as best I can, in **the** world of entertainment. People have this belief — and I share most of it — that we will be using **the** TV screens or their equivalents for electronic books of **the** future. But then you think,”My God! What a terrible image you get when you look at still pictures on TV.”Well, it doesn ’ t have to be terrible. And that is a **slide** taken from a TV set and it was pre- processed to be very sympathetic to **the** TV medium, and it absolutely looks beautiful. Well, what ’ s happened? How did people get into this mess? Where you are now, all of a sudden, sitting in front of personal **computers** and video text — teletext systems, and somewhat horrified by what you see on **the** screen? Well, you have to remember that TV was designed to be looked at eight times **the** distance of **the** diagonal. So you get a 13-inch, 19-inch, whatever, TV, and then you should multiply that by eight and that ’ s **the** distance you should sit away from **the** TV set. Now we ’ ve put people 18 **inches** in front of a TV, and all **the** artifacts that none of **the** original designers expected to be seen, all of a sudden, are staring you in **the** face : **the** shadow mask, **the** scan lines, all of that. And they can be treated very easily ; there are actually ways of getting rid of them, there are actually ways of just making absolutely beautiful pictures. I ’ m talking here a little bit about display technologies. Let me talk about how you might input information. And my favorite example is always fingers. I ’ m very interested in touch-sensitive displays. High-tech, high-touch. Isn ’ t that what some of you said? It ’ s certainly a very important medium for input, and a lot of people think that fingers are a very low- resolution sort of stylus for inputting to a display. In fact, they ’ re not : it ’ s really a very, very high-resolution input medium — you have to just do it twice, you have to touch **the** screen and then rotate your finger slightly — and you can move a cursor with great accuracy. And so when you see on **the** market these systems that have just a few light emitting diodes on **the** side and are very low resolution, it ’ s nice that they exist because it still is better than nothing. But it, in some sense, misses **the** point : namely, that fingers are a very, very high-resolution input medium. Now, what are some of **the** other advantages? Well, **the** one advantage is that you don ’ t have to pick them up, and people don ’ t realize how important that is — not having to pick up your fingers to use them. When you think for a second of **the** mouse on Macintosh — and I will not criticize **the** mouse too much — when you ’ re typing — what you have — you want to now put something — first of all, you ’ ve got to find **the** mouse. You have to probably stop. Maybe not come to a grinding halt, but you ’ ve got to sort of find that mouse. Then you find **the** mouse, and you ’ re going to have to wiggle it a little bit to see where **the** cursor is on **the** screen. And then when you finally see where it is, then you ’ ve got to move it to get **the** cursor over there, and then —”Bang”— you ’ ve got to hit a button or do whatever. That ’ s four separate steps versus typing and then touching and typing and just doing it all in one motion — or one-and-a-half, depending on how you want to count. Again, what I ’ m trying to do is just illustrate **the** kinds of problems that I think face **the** designers of new **computer** systems and entertainment systems and educational systems from **the** perspective of **the** quality of that interface. And another advantage, of course, of using fingers is you have 10 of them. And we have never known how to do this technically, so this **slide** is a fake **slide**. We never succeeded in using ten fingers, but there are certain things you can do, obviously, with more than one-finger input, which is rather fascinating. What we did stumble across was something... Again, which is typical of **the computer** field, is when you have a bug that you can ’ t get rid of you turn it into a feature. And maybe... maybe a mouse is a new kind of bug. But **the** bug in our case was in touch-sensitive displays : we wanted to be able to draw — you know, rub your finger across **the** screen to input continuous points — and there was just too much friction created between your finger and **the** glass — if glass was **the** substrate, which it usually is. So we found that that actually was a feature in **the** sense you could build a pressure-sensitive display. And when you touch it with your finger, you can actually, then, introduce all **the** forces on **the** face of that screen, and that actually has a certain amount of value. Let me see if I can load another disc and show you, quickly, an example. Now, imagine a screen, which is not only touch-sensitive now, it ’ s pressure-sensitive. And it ’ s pressure-sensitive to **the** forces both in **the** plane of **the** screen — X, Y, and Z at least in one direction ; we couldn ’ t figure out how to come in **the** other direction. But let me get rid of **the slide**, and let ’ s see if this comes on. OK. So there is **the** pressure-sensitive display in operation. **The** person ’ s just, if you will, pushing on **the** screen to make a curve. But this is **the** interesting part. I want to stop it for a second because **the** movie is very badly made. And **the** particular display was built about six years ago, and when we moved from one room to another room, a rather large person sat on it and it got destroyed. So all we have is this record. But imagine that screen having lots of **objects** on it and **the** person has touched an **object** — one of N — like he did there, and then pushed on it. Now, imagine a program where some of those **objects** are physically heavy and some are light : one is an anvil on a fuzzy rug and **the** other one is a ping-pong ball on a sheet of glass. And when you touch it, you have to really push very hard to move that anvil across **the** screen, and yet you touch **the** ping-pong ball very lightly and it just scoots across **the** screen. And what you can do — oops, I didn ’ t mean to do that — what you can do is actually feed back to **the** user **the** feeling of **the** physical properties. So again, they don ’ t have to be weight ; they could be a general trying to move troops, and he ’ s got to move an aircraft carrier versus a little boat. In fact, they funded it for that very reason. **The** whole notion, then, is one that at **the** interface there are physical properties in that transducer — in this case it ’ s pressure and touches — that allow you to present things to **the** user that you could never present before. So it ’ s not simply looking at **the** quality or, if you will, **the** luxury of that interface, but it ’ s actually looking at **the** idea of presenting things that previously couldn ’ t be presented before. I want to move on to another example, which is one of a different sort, where we ’ re trying to use **computer** and video disc technology now to come up with a new kind of book. Here, **the** idea is that you ’ re going to take this book, if you will, and it ’ s going to come alive. You ’ re going to sort of breathe life into it. We are so used to doing monologues. Filmmakers, for example, are **the** experts in monologue making : you make a film and it has a well-formed beginning, middle and end, and in some sense **the** art of it is that. And you then say,”There ’ s an opportunity for making conversational movies.”Well, what does that mean? And it sort of nibbles at **the** core of **the** whole profession and all **the** assumptions of that medium. So, book writing is **the** same thing. What I ’ ll show you very quickly is a new kind of book where it is mixed now with... all sorts of things live in there, but you have to keep a few things in mind. One is that this book knows about itself. Each frame of **the** movie has information about itself. So it knows, or at least there is computer-readable information in **the** medium itself. It ' s just not a static movie frame. That ' s one thing. **The** other is that you have to realize that it is a random access medium, and you can, in fact, branch and expand and elaborate and shrink. And here — again, my favorite example — is **the** cookbook, **the**"Larousse Gastronomique."And I think I use **the** example all too often, but it ' s a great one because there is a classic ending in that little encyclopedia-style cookbook that tells you how to do something like penguin, and you get to **the** end of **the** recipe and it says,"Cook until done."Now, that would be, if you will, **the** top green track, which doesn ' t mean too much. But you might have to elaborate for me or for somebody who isn ' t an expert, and say,"Cook at 380 degrees for 45 minutes."And then for a real beginner, you would go down even further and elaborate more — say,"Open **the** oven, preheat, wait for **the** light to go out, open **the** door, don ' t leave it open too long, put **the** penguin in and shut **the** door..."whatever. And that ' s a much more elaborate one than you dribble back. That ' s one kind of use of random access. And **the** other is where you want to explain **the** same thing in different ways. If you ' re in a classroom situation and somebody asks a question, **the** last thing you do is repeat what you just said. You try and think of a different way of saying **the** same thing, or if you know **the** particular student and that student ' s cognitive style, then you might say it in a way that you think would have a good impedance match with that student. There are all sorts of **techniques** you will use — and again, this is a different kind of branching. So, what I will show you is... it ' s a rather boring book, but I ' m afraid sometimes you have to do boring books because your sponsors aren ' t necessarily interested in fiction and entertainment. And this is a book on how to repair a transmission. Now, I don ' t even know what vintage **the** transmission is, but let me just show you very quickly some of it, and we ' ll move on. Narrator : And continue to get descriptions for each of these chapters. Nicholas Negroponte : Now, this is his table of contents. Just a picture of **the** transmission, and as you rub your finger across **the** transmission it highlights **the** various parts. Narrator : When I find a chapter that I want to see, I just touch **the** text and **the** system will format pages for me to read. **The** words or phrases that are lit up in red are glossary words, so I can get a different definition by just touching **the** word, and **the** definition appears, superimposed over **the** illustration. NN : This is about **the oil** pan, or **the oil** filter and all that. This is relatively important because it sets **the** page... Narrator : This is another example of a page with glossary words highlighted in red. I can get a definition of these words just by touching them, and **the** definition will appear in **the** illustration corner. I can get back to **the** illustration, but in this case it ' s not a single frame, but it ' s actually a movie of someone coming into **the** frame and doing **the** repair that ' s described in **the** text. **The** two-headed slider is a speed control that allows me to watch **the** movie at various speeds, in forward or reverse. And **the** movie is displayed as a full frame movie. I can go back to **the** beginning... and play **the** movie at full speed. Here ' s another step-by-step procedure, only in this case — NN : Okay, this movie is... Everybody ' s heard of sound-sync movies — this is text-sync movies, so as **the** movie plays, **the** text gets highlighted. We highlight **the** text as we go through **the** movie. Repairman :... Not too far out. Front poles, preferably. Don ' t loosen them too far. If you loosen them too far, you ' ll have a big mess. NN : I suspect that some of you might not even understand that language. OK. I ' m at **the** third and last part of this, which I said I would make an attempt to at least give you some examples that may be more directly related to **the** world of entertainment. And of course, good education has got to be good entertainment, so my first example will be drawn from a very recent experiment that we ’ ve been doing — in this case, in Senegal — where we have tried to use personal **computers** as a pedagogical medium. But not as teaching machines at all ; **the** whole notion is to use this as an instrument where there is a complete reversal of roles — **the** child is, if you will, **the** teacher and **the** machine is **the** student — and **the** art of **computer** programming is a vehicle that sort of approximates thinking about thinking. But teaching kids programming per se is utterly irrelevant. And there are just a few **slides** I want to go through, but there ’ s a story I ’ d like to tell. And that was when, before we did this in any developing countries — we ’ re doing it, in fact, in three developing countries right now : Pakistan, Colombia and Senegal — we did it in some pretty rough areas of New York City. And one child, whose name I ’ ve forgotten, was about seven or eight years old, absolutely considered mentally handicapped — couldn ’ t read, didn ’ t even make it in **the** lowest section of **the** school ’ s classes — and was pretty much not in school, though physically there. But did hang around **the**, quote,”**computer** room,”where there were quite a few **computers**, and learned this particular language called Logo — and learned it with great ease and found it a lot of fun, it was very interesting. And one day, by chance, some visitors from **the** NIE came by in their double-breasted suits looking at this setup, and none of **the** children who were normally there, except for this one child, were there. He was, and he said,”Let me show you how this works,”and they got an absolutely ingenuous, wonderful description of Logo. And **the** child was just zipping right through it, showing them all sorts of things until they asked him how to do something which he couldn ’ t explain and so he flipped through **the** manual, found **the** explanation and typed **the** command and got it to do what they asked. They were delighted, and by **the** time it was time to go see **the** principal, whom they ’ d actually come to see — not **the computer** room — they went upstairs and they said,”This is absolutely remarkable! That child was very articulate and showed us and even dealt with **the** things he couldn ’ t do automatically with that manual. It was just absolutely **fantastic**.”**The** principal said,”There ’ s a dreadful mistake, because that child can ’ t read. And you obviously have been hoodwinked or you ’ ve talked about somebody else.”And they all got up and they all went downstairs and **the** child was still there. And they did something very intelligent : they asked **the** child,”Can you read?”And **the** child said,”No, I can ’ t.”And then they said,”But wait a minute. You just looked through that manual and you found...”and he said,”Oh, but that ’ s not reading.”And so they said,”Well, what ’ s reading then?”He says,”Well, reading is this junk they give me in little books to read. It ’ s absolutely irrelevant, and I get nothing for it. But here, with a little bit of effort I get a lot of return.”And it really meant something to **the** child. **The** child read beautifully, it turned out, and was really very competent. So it actually meant something. And that story has many other anecdotes that are similar, but wow. **The** key to **the** future of **computers** in education is right there, and it is : when does it mean something to a child? There is a myth, and it truly is a myth : we believe — and I ’ m sure a lot of you believe in this room — that it is harder to read and write than it is to learn how to speak. And it ’ s not, but we think speech —”My God, little children pick it up somehow, and by **the** age of two they ’ re doing a mediocre job, and by three and four they ’ re speaking reasonably well. And yet you ’ ve got to go to school to learn how to read, and you have to sit in a classroom and somebody has to teach you. Hence, it must be harder.”Well, it ’ s not harder. What **the** truth is is that speaking has great value to a child ; **the** child can get a great deal by talking to you. Reading and writing is utterly useless. There is no reason for a child to read and write except blind faith, and that it ’ s going to help you. So what happens is you go to school and people say,”Just believe me, you ’ re going to like it. You ’ re going to like reading,”and just read and read. On **the** other hand, you give a kid — a three-year-old kid — a **computer** and they type a little command and — Poof! — something happens. And all of a sudden... You may not call that reading and writing, but a certain bit of typing and reading stuff on **the** screen has a huge payoff, and it ’ s a lot of fun. And in fact, it ’ s a powerful educational instrument. Well, in Senegal we found that this was **the** traditional classroom : 120 kids — three per desk — one teacher, a little bit of chalk. This student was one of our first students, and it ’ s **the** girl on **the** left leaning with her chalkboard, and she came... within two days — I want to show you **the** program she wrote, and remember her hairstyle. And that is **the** program she made. That ’ s what meant something to her, is doing **the** hair pattern, and actually did it within two days — an hour each day — and found it was, to her, absolutely **the** most meaningful piece... But rooted in that, little did she know how much knowledge she was acquiring about geometry and just math and logic and all **the** rest. And again, I could talk for three hours about this subject. I will come to my last example and then quit. And my last example — as some of my former colleagues, whom I see in **the** room, can imagine what it will be. Yes, it is. It ’ s our work — that was a while ago, and it still is my favorite project — of teleconferencing. And **the** reason it remains a favorite project is that we were asked to do a teleconferencing system where you had **the** following situation : you had five people at five different sites — they were known people — and you had to have these people in teleconference, such that each one was utterly convinced that **the** other four were physically present. Now, that is sufficiently zany that we would, obviously, jump to **the** bait, and we did. And **the** fact that we knew **the** people — we had to take a page out of **the** history of Walt Disney — we actually went so far as to build CRTs in **the** shapes of **the** people ’ s faces. So if I wanted to call my friend Peter Sprague on **the** phone, my secretary would get his head out and bring it and set it on **the** desk, and that would be **the** TV used for **the** occasion. And it ’ s uncanny : there ’ s no way I can explain to you **the** amount of eye contact you get with that physical face projected on a 3D CRT of that sort. **The** next thing that we had to do is to persuade them that there needed to be spatial correspondence, which is straightforward, but again, it ’ s something that didn ’ t fall naturally out of a telecommunications or computing style of thinking ; it was a very, if you will, architectural or spatial concept. And that was to recognize that when you sit around **the** table, **the** actual location of **the** people becomes rather important. And when somebody gets up, in fact, to go answer a phone or use a bathroom or something, **the** empty seat becomes, if you will, that person. And you point frequently to **the** empty seat and you say,”He or she wouldn ’ t agree,”and **the** empty chair is that person and **the** spatiality is crucial. So we said,”Well, these will be on round tables and **the** order around **the** table had to be **the** same, so that at my site, I would be, if you will, real and then at each other ’ s site you ’ d have these plastic heads. And **the** plastic heads, sometimes you want to project them. And there are a number of schemes, which I don ’ t want to dwell on, but this is **the** one that we finally used where we projected onto rear screen material that was molded in **the** face — literally in **the** face of **the** person. And I ’ ll show you one more **slide**, where this is actually made from something called a solid photograph and is **the** screen. Now, we track, on **the** person ’ s head, **the** head motions — so we transmit with a video **the** head positions — and so this head moves in about two axes. So if I, all of a sudden, turn to **the** person to my **left** and start talking to that person, then at **the** person to my right ’ s site, he ’ ll see these two plastic heads talking to each other. And then if that person interrupts, then those two heads may turn. And it really is reconstructing, quite accurately, teleconferencing.

America ’ s public energy conversation boils down to this question : Would you rather die of A) **oil** wars, or B) climate change, or C) nuclear holocaust, or D) all of **the** above? Oh, I missed one : or E) none of **the** above? That ’ s **the** one we ’ re not normally offered. What if we could make energy do our work without working our undoing? Could we have fuel without fear? Could we reinvent fire? You see, fire made us human ; **fossil** fuels made us modern. But now we need a new fire that makes us safe, secure, healthy and durable. Let ’ s see how. Four-fifths of **the** world ’ s energy still comes from burning each year four cubic miles of **the** rotted remains of primeval swamp goo. Those **fossil** fuels have built our civilization. They ’ ve created our wealth. They ’ ve enriched **the** lives of billions. But they also have rising costs to our security, economy, health and environment that are starting to erode, if not outweigh their benefits. So we need a new fire. And switching from **the** old fire to **the** new fire means changing two big stories about **oil** and electricity, each of which puts two- fifths of **the fossil carbon** in **the** air. But they ’ re really quite distinct. Less than one percent of our electricity is made from **oil** — although almost half is made from **coal**. Their uses are quite concentrated. Three-fourths of our **oil** fuel is **transportation**. Three-fourths of our electricity powers buildings. And **the** rest of both runs factories. So very efficient vehicles, buildings and factories save **oil** and **coal**, and also natural gas that can displace both of them. But today ’ s energy system is not just inefficient, it is also disconnected, aging, dirty and insecure. So it needs refurbishment. By 2050 though, it could become efficient, connected and distributed with elegantly frugal autos, factories and buildings all relying on a modern, secure and resilient electricity system. We can eliminate our addiction to **oil** and **coal** by 2050 and use **one-third** less natural gas while switching to efficient use and **renewable** supply. This could cost, by 2050, five trillion dollars less in net present value, that is expressed as a lump **sum** today, than business as usual — assuming that **carbon emissions** and all other hidden or external costs are worth zero — a conservatively low estimate. Yet this cheaper energy system could support 158 percent bigger U. S. economy all without needing **oil** or **coal**, or for that matter nuclear energy. Moreover, this transition needs no new inventions and no acts of Congress and no new federal taxes, mandate subsidies or laws and running Washington gridlock. Let me say that again. I ’ m going to tell you how to get **the** United States completely off **oil** and **coal**, five trillion dollars cheaper with no act of Congress led by business for profit. In other words, we ’ re going to use our most effective institutions — private enterprise co-evolving with civil society and sped by military innovation to go around our least effective institutions. And whether you care most about profits and jobs and competitive advantage or national security, or environmental stewardship and climate protection and public health, reinventing fire makes sense and makes money. General Eisenhower reputedly said that enlarging **the** boundaries of a tough problem makes it soluble by encompassing more options and more synergies. So in reinventing fire, we integrated all four sectors that use energy — **transportation**, buildings, industry and electricity — and we integrated four kinds of innovation, not just technology and policy, but also design and business strategy. Those combinations yield very much more than **the sum** of **the** parts, especially in creating deeply disruptive business opportunities. Oil costs our economy two billion dollars a day, plus another four billion dollars a day in hidden economic and military costs, raising its total cost to over a sixth of GDP. Our mobility fuel goes three-fifths to automobiles. So let ' s start by making autos **oil** free. **Two-thirds** of **the** energy it takes to move a typical car is caused by its weight. And every unit of energy you save at **the** wheels, by taking out weight or drag, saves seven units in **the** tank, because you don ' t have to waste six units getting **the** energy to **the** wheels. Unfortunately, over **the** past quarter century, epidemic obesity has made our two-ton steel cars gain weight twice as fast as we have. But today, ultralight, ultrastrong materials, like **carbon** fiber composites, can make dramatic weight savings snowball and can make cars simpler and cheaper to build. Lighter and more slippery autos need less force to move them, so their engines get smaller. Indeed, that sort of vehicle fitness then makes electric propulsion affordable because **the** batteries or fuel cells also get smaller and lighter and cheaper. So sticker prices will ultimately fall to about **the** same as today, while **the** driving cost, even from **the** start, is very much lower. So these innovations together can transform automakers from wringing tiny savings out of Victorian engine and seal-stamping technologies to **the** steeply falling costs of three linked innovations that strongly reenforce each other — namely ultralight materials, making them into structures and electric propulsion. **The** sales can grow and **the** prices fall even faster with temporary feebates, that is rebates for efficient new autos paid for by fees on inefficient ones. And just in **the** first two years **the** biggest of Europe ' s five feebate programs has tripled **the** speed of improving automotive efficiency. **The** resulting shift to electric autos is going to be as game-changing as shifting from typewriters to **the** gains in **computers**. Of course, **computers** and electronics are now America ' s biggest industry, while typewriter makers have vanished. So vehicle fitness opens a new automotive competitive strategy that can double **the oil** savings over **the** next 40 years, but then also make electrification affordable, and that displaces **the** rest of **the oil**. America could lead this next automotive revolution. Currently **the** leader is Germany. Last year, Volkswagen announced that by next year they ' ll be producing this **carbon** fiber plugin hybrid getting 230 miles a gallon. Also last year, BMW announced this **carbon** fiber electric car, they said that its **carbon** fiber is paid for by needing fewer batteries. And they said,"We do not intend to be a typewriter maker."Audi claimed it ' s going to beat them both by a year. Seven years ago, an even faster and cheaper American manufacturing technology was used to make this little **carbon** fiber test part, which doubles as a **carbon** cap. In one minute — and you can tell from **the** sound how immensely stiff and strong it is. Don ' t worry about dropping it, it ' s tougher than titanium. Tom Friedman actually whacked it as hard as he could with a sledgehammer without even scuffing it. But such manufacturing **techniques** can scale to automotive speed and cost with aerospace performance. They can save four-fifths of **the** capital needed to make autos. They can save lives because this stuff can absorb up to 12 times as much crash energy per **pound** as steel. If we made all of our autos this way, it would save **oil** equivalent to finding one and a half Saudi Arabias, or half an OPEC, by drilling in **the** Detroit formation, a very prospective play. And all those mega-barrels under Detroit cost an average of 18 **bucks** a barrel. They are all- American, carbon-free and inexhaustible. **The** same physics and **the** same business logic also apply to big vehicles. In **the** five years ending with 2010, Walmart saved 60 percent of **the** fuel per ton-mile in its giant fleet of heavy trucks through better logistics and design. But just **the** technological savings in heavy trucks can get to **two-thirds**. And combined with triple to quintuple efficiency **airplanes**, now on **the** drawing board, can save close to a trillion dollars. Also today ' s military revolution in energy efficiency is going to speed up all of these civilian advances in much **the** same way that military R&D has given us **the** Internet, **the** Global Positioning System and **the** jet engine and microchip industries. As we design and build vehicles better, we can also use them smarter by harnessing four powerful **techniques** for eliminating needless driving. Instead of just seeing **the** travel grow, we can use innovative pricing, charging for road infrastructure by **the** mile, not by **the** gallon. We can use some smart IT to enhance transit and enable car sharing and ride sharing. We can allow smart and lucrative growth models that help people already be near where they want to be, so they don ' t need to go somewhere else. And we can use smart IT to make traffic free-flowing. Together, those things can give us **the** same or better access with 46 to 84 percent less driving, saving another 0. 4 trillion dollars, plus 0. 3 trillion dollars from using trucks more productively. So 40 years hence, when you add it all up, a far more mobile U. S. economy can use no **oil**. Saving or displacing barrels for 25 **bucks** rather than buying them for over a hundred, adds up to a $4 trillion net saving counting all **the** hidden costs at zero. So to get mobility without **oil**, to phase out **the oil**, we can get efficient and then switch fuels. Those 125 to 240 mile-per-gallon-equivalent autos can use any mixture of hydrogen fuel cells, electricity and advanced biofuels. **The** trucks and planes can realistically use hydrogen or advanced biofuels. **The** trucks could even use natural gas. But no vehicles will need **oil**. And **the** most biofuel we might need, just three million barrels a day, can be made **two-thirds** from waste without displacing any cropland and without harming soil or climate. Our team speeds up these kinds of **oil** savings by what we call"institutional acupuncture."We figure out where **the** business logic is congested and not flowing properly, we stick little needles in it to get it flowing, working with partners like Ford and Walmart and **the** Pentagon. And **the** long transition is already well under way. In fact, three years ago mainstream analysts were starting to see peak **oil**, not in supply, but in demand. And Deutsche Bank even said world **oil** use could peak around 2016. In other words, **oil** is getting uncompetitive even at low prices before it becomes unavailable even at high prices. But **the** electrified vehicles don ' t need to burden **the** electricity grid. Rather, when smart autos exchange electricity and information through smart buildings with smart grids, they ' re adding to **the** grid valuable flexibility and storage that help **the** grid integrate varying solar and wind power. So **the** electrified autos make **the** auto and electricity problems easier to solve together than separately. And they also converge **the oil** story with our second big story, saving electricity and then making it differently. And those twin revolutions in electricity will bring to that sector more numerous and profound and diverse disruptions than any other sector, because we ' ve got 21st century technology and speed colliding head-on with 20th and 19th century institutions, rules and cultures. Changing how we make electricity gets easier if we need less of it. Most of it now is wasted and **the** technologies for saving it keep improving faster than we ' re installing them. So **the** unbought efficiency resource keeps getting ever bigger and cheaper. But as efficiency in buildings and industry starts to grow faster than **the** economy, America ' s electricity use could actually shrink, even with **the** little extra use required for those efficient electrified autos. And we can do this just by reasonably accelerating existing trends. Over **the** next 40 years, buildings, which use three-quarters of **the** electricity, can triple or quadruple their energy productivity, saving 1. 4 trillion dollars, net present value, with a 33 percent internal rate of return or in English, **the** savings are worth four times what they cost. And industry can accelerate too, doubling its energy productivity with a 21 percent internal rate of return. **The** key is a disruptive innovation that we call integrative design that often makes very big energy savings cost less than small or no savings. That is, it can give you expanding returns, not diminishing returns. That is how our 2010 retrofit is saving over two-fifths of **the** energy in **the** Empire State Building — remanufacturing those six and a half thousand windows on site into super windows that pass light, but reflect heat. plus better lights and office equipment and such cut **the** maximum cooling load by a third. And then renovating smaller chillers instead of adding bigger ones saved 17 million dollars of capital cost, which helped pay for **the** other improvements and reduce **the** payback to just three years. Integrative design can also increase energy savings in industry. Dow ' s billion-dollar efficiency investment has already returned nine billion dollars. But industry as a whole has another half-trillion dollars of energy still to save. For example, three-fifths of **the** world ' s electricity runs motors. Half of that runs pumps and fans. And those can all be made more efficient, and **the** motors that turn them can have their system efficiency roughly doubled by integrating 35 improvements, paying back in about a year. But first we ought to be capturing bigger, cheaper savings that are normally ignored and are not in **the textbooks**. For example, pumps, **the** biggest use of motors, move liquid through pipes. But a standard industrial pumping loop was redesigned to use at least 86 percent less energy, not by getting better pumps, but just by replacing long, thin, crooked pipes with **fat**, short, straight pipes. This is not about new technology, it ' s just rearranging our metal furniture. Of course, it also shrinks **the** pumping equipment and its capital costs. So what do such savings mean for **the** electricity that is three-fifths used in motors? Well, from **the coal** burned at **the** power plant through all these compounding losses, only a tenth of **the** fuel energy actually ends up coming out **the** pipe as flow. But now let ' s turn those compounding losses around **backwards**, and every unit of flow or friction that we save in **the** pipe saves 10 units of fuel cost, pollution and what Hunter Lovins calls"global weirding"back at **the** power plant. And of course, as you go back upstream, **the** components get smaller and therefore cheaper. Our team has lately found such snowballing energy savings in more than 30 billion dollars worth of industrial redesigns — everything from data centers and chip fabs to mines and refineries. Typically our retrofit designs save about 30 to 60 percent of **the** energy and pay back in a few years, while **the** new facility designs save 40 to 90-odd percent with generally lower capital cost. Now needing less electricity would ease and speed **the** shift to new sources of electricity, chiefly renewables. China leads their explosive growth and their plummeting cost. In fact, these solar power **module** costs have just fallen off **the** bottom of **the** chart. And Germany now has more solar workers than America has steel workers. Already in about 20 states private installers will come put those cheap solar cells on your roof with no money down and beat your utility bill. Such unregulated products could ultimately add up to a virtual utility that bypasses your electric company just as your cellphone bypassed your wireline phone company. And this sort of thing gives utility executives **the** heebee-jeebees and it gives venture capitalists sweet dreams. Renewables are no longer a fringe activity. For each of **the** past four years half of **the** world ' s new generating capacity has been **renewable**, mainly lately in developing countries. In 2010, renewables other than big hydro, particularly wind and solar cells, got 151 billion dollars of private investment, and they actually surpassed **the** total installed capacity of nuclear power in **the** world by adding 60 billion watts in that one year. That happens to be **the** same amount of solar cell capacity that **the** world can now make every year — a number that goes up 60 or 70 percent a year. In contrast, **the** net additions of nuclear capacity and **coal** capacity and **the** orders behind those keep fading because they cost too much and they have too much financial risk. In fact in this country, no new nuclear power plant has been able to raise any private construction capital, despite seven years of 100-plus percent subsidies. So how else could we replace **the** coal-fired power plants? Well efficiency and gas can displace them all at just below their operating cost and, combined with renewables, can displace them more than 23 times at less than their replacement cost. But we only need to replace them once. We ’ re often told though that only **coal** and nuclear plants can keep **the** lights on, because they ’ re 24 / 7, whereas wind and solar power are variable, and hence supposedly unreliable. Actually no generator is 24 / 7. They all break. And when a big plant goes down, you lose a thousand megawatts in milliseconds, often for weeks or months, often without warning. That is exactly why we ’ ve designed **the** grid to back up failed plants with working plants. And in exactly **the** same way, **the** grid can handle wind and solar power ’ s forecastable variations. Hourly simulations show that largely or wholly **renewable** grids can deliver highly reliable power when they ’ re forecasted, integrated and diversified by both type and location. And that ’ s true both for continental areas like **the** U. S. or Europe and for smaller areas embedded within a larger grid. That is how, for example, four German states in 2010 were 43 to 52 percent wind powered. Portugal was 45 percent **renewable** powered, Denmark 36. And it ’ s how all of Europe can shift to **renewable** electricity. In America, our aging, dirty and insecure power system has to be replaced anyway by 2050. And whatever we replace it with is going to cost about **the** same, about six trillion dollars at present value — whether we buy more of what we ’ ve got or new nuclear and so- called clean **coal**, or renewables that are more or less centralized. But those four futures at **the** same cost differ profoundly in their risks, around national security, fuel, water, finance, technology, climate and health. For example, our over-centralized grid is very vulnerable to cascading and potentially economy-shattering blackouts caused by bad space weather or other natural disasters or a **terrorist** attack. But that blackout risk **disappears**, and all of **the** other risks are best managed, with distributed renewables organized into local micro-grids that normally interconnect, but can stand alone at need. That is, they can disconnect fractally and then reconnect seamlessly. That approach is exactly what **the** Pentagon is adopting for its own power supply. They think they need that ; how about **the** rest of us that they ’ re defending? We want our stuff to work too. At about **the** same cost as business as usual, this would maximize national security, customer choice, entrepreneurial opportunity and innovation. Together, efficient use and diverse dispersed **renewable** supply are starting to transform **the** whole electricity sector. Traditionally utilities build a lot of giant **coal** and nuclear plants and a bunch of big gas plants and maybe a little bit of efficiency renewables. And those utilities were rewarded, as they still are in 34 states, for selling you more electricity. However, especially where regulators are now instead rewarding cutting your bills, **the** investments are shifting radically toward efficiency, demand response, cogeneration, renewables and ways to knit them all together reliably with less transmission and little or no bulk electricity storage. So our energy future is not fate, but choice, and that choice is very flexible. In 1976, for example, government and industry insisted that **the** amount of energy needed to make a dollar of GDP could never go down. And I heretically suggested it could go down several-fold. Well that ’ s what ’ s actually happened so far. It ’ s fallen by half. But with today ’ s much better technologies, more mature delivery channels and integrative design, we can do far more and even cheaper. So to solve **the** energy problem, we just needed to enlarge it. And **the** results may at first seem incredible, but as Marshall McLuhan said,”Only puny secrets need protection. Big discoveries are protected by public incredulity.”Now combine **the** electricity and **oil** revolutions, both driven by modern efficiency, and you get **the** really big story : reinventing fire, where business enabled and sped by smart policies in mindful markets can lead **the** United States completely off **oil** and **coal** by 2050, saving 5 trillion dollars, growing **the** economy 2. 6-fold, strengthening out national security, oh, and by **the** way, by getting rid of **the oil** and **coal**, reducing **the fossil carbon emissions** by 82 to 86 percent. Now if you like any of those outcomes, you can support reinventing fire without needing to like all of them and without needing to agree about which of them is most important. So focusing on outcomes, not motives, can turn gridlock and conflict into a unifying solution to America ' s energy challenge. This also turns out to be **the** best way to cope with global challenges — climate change, nuclear proliferation, energy insecurity, energy poverty — all of which make us less safe. Now our team at RMI helps smart companies to get unstuck and speed this journey via six sectoral initiatives, with some more hatching. Of course there ' s still a lot of old thinking out there too. Former **oil** man Maurice Strong said,"Not all **the fossils** are in **the** fuel."But as Edgar Woolard, who used to chair Dupont, reminds us,"Companies hampered by old thinking won ' t be a problem because,"he said,"they simply won ' t be around long-term."I ' ve described not just a once-in-a-civilization business opportunity, but one of **the** most profound transitions in **the** history of our species. We humans are inventing a new fire, not dug from below, but flowing from above ; not scarce, but bountiful ; not local, but everywhere ; not transient, but permanent ; not costly, but free. And but for a little transitional tail of natural gas and a bit of biofuel grown in ways that sustain and endure, this new fire is flameless. Efficiently used, it really can do our work without working our undoing. Each of you owns a piece of that $5 trillion prize. And our new book"Reinventing Fire"describes how you can capture it. So with **the** conversation just begun at ReinventingFire. com, let me invite you each to engage with us and with each other, with everyone around you, to help make **the** world richer, fairer, cooler and safer by together reinventing fire. Thank you.

The job of uncovering **the** global food waste scandal started for me when I was 15 years old. I bought some pigs. I was living in Sussex. And I started to feed them in **the** most traditional and environmentally **friendly** way. I went to my school kitchen, and I said,"Give me **the** scraps that my school friends have turned their noses up at."I went to **the** local baker and took their stale bread. I went to **the** local greengrocer, and I went to a farmer who was throwing away potatoes because they were **the** wrong shape or size for **supermarkets**. This was great. My pigs turned that food waste into delicious pork. I sold that pork to my school friends ' parents, and I made a good **pocket** money addition to my teenage allowance. But I noticed that most of **the** food that I was giving my pigs was in fact fit for human **consumption**, and that I was only scratching **the surface**, and that right **the** way up **the** food supply chain, in **supermarkets**, greengrocers, bakers, in our homes, in factories and farms, we were hemorrhaging out food. Supermarkets didn ' t even want to talk to me about how much food they were wasting. I ' d been round **the** back. I ' d seen bins full of food being locked and then trucked off to landfill sites, and I thought, surely there is something more sensible to do with food than waste it. One morning, when I was feeding my pigs, I noticed a particularly tasty-looking sun-dried tomato loaf that used to crop up from time to time. I grabbed hold of it, sat down, and ate my breakfast with my pigs. That was **the** first act of what I later learned to call freeganism, really an exhibition of **the** injustice of food waste, and **the** provision of **the** solution to food waste, which is simply to sit down and eat food, rather than throwing it away. That became, as it were, a way of confronting large businesses in **the** business of wasting food, and exposing, most importantly, to **the** public, that when we ’ re talking about food being thrown away, we ’ re not talking about rotten stuff, we ’ re not talking about stuff that ’ s beyond **the** pale. We ’ re talking about good, fresh food that is being wasted on a colossal scale. Eventually, I set about writing my book, really to demonstrate **the** extent of this problem on a global scale. What this shows is a nation-by-nation breakdown of **the** likely level of food waste in each country in **the** world. Unfortunately, empirical data, good, hard stats, don ’ t exist, and therefore to prove my point, I first of all had to find some proxy way of uncovering how much food was being wasted. So I took **the** food supply of every single country and I compared it to what was actually likely to be being consumed in each country. That ’ s based on diet intake surveys, it ’ s based on levels of obesity, it ’ s based on a range of factors that gives you an approximate guess as to how much food is actually going into people ’ s mouths. That black line in **the** middle of that table is **the** likely level of **consumption** with an allowance for certain levels of inevitable waste. There will always be waste. I ’ m not that unrealistic that I think we can live in a waste-free world. But that black line shows what a food supply should be in a country if they allow for a good, stable, secure, nutritional diet for every person in that country. Any dot above that line, and you ’ ll quickly notice that that includes most countries in **the** world, represents unnecessary surplus, and is likely to reflect levels of waste in each country. As a country gets richer, it invests more and more in getting more and more surplus into its shops and restaurants, and as you can see, most European and North American countries fall between 150 and 200 percent of **the** nutritional requirements of their populations. So a country like America has twice as much food on its shop shelves and in its restaurants than is actually required to feed **the** American people. But **the** thing that really struck me, when I plotted all this data, and it was a lot of numbers, was that you can see how it levels off. Countries rapidly shoot towards that 150 mark, and then they level off, and they don ’ t really go on rising as you might expect. So I decided to unpack that data a little bit further to see if that was true or false. And that ’ s what I came up with. If you include not just **the** food that ends up in shops and restaurants, but also **the** food that people feed to livestock, **the** maize, **the** soy, **the** wheat, that humans could eat but choose to fatten livestock instead to produce increasing amounts of meat and dairy products, what you find is that most rich countries have between three and four times **the** amount of food that their population needs to feed itself. A country like America has four times **the** amount of food that it needs. When people talk about **the** need to increase global food production to feed those nine billion people that are expected on **the planet** by 2050, I always think of these graphs. **The** fact is, we have an enormous buffer in rich countries between ourselves and hunger. We ’ ve never had such gargantuan surpluses before. In many ways, this is a great success story of human civilization, of **the** agricultural surpluses that we set out to achieve 12, 000 years ago. It is a success story. It has been a success story. But what we have to recognize now is that we are reaching **the** ecological limits that our **planet** can bear, and when we chop down forests, as we are every day, to grow more and more food, when we extract water from depleting water reserves, when we emit **fossil** fuel **emissions** in **the** quest to grow more and more food, and then we throw away so much of it, we have to think about what we can start saving. And yesterday, I went to one of **the** local **supermarkets** that I often visit to inspect, if you like, what they ’ re throwing away. I found quite a few packets of biscuits amongst all **the** fruit and vegetables and everything else that was in there. And I thought, well this could serve as a symbol for today. So I want you to imagine that these nine biscuits that I found in **the** bin represent **the** global food supply, **okay**? We start out with nine. That ’ s what ’ s in fields around **the** world every single year. **The** first biscuit we ’ re going to lose before we even leave **the** farm. That ’ s a problem primarily associated with developing work **agriculture**, whether it ’ s a lack of infrastructure, refrigeration, pasteurization, grain stores, even basic fruit crates, which means that food goes to waste before it even leaves **the** fields. **The** next three biscuits are **the** foods that we decide to feed to livestock, **the** maize, **the** wheat and **the** soya. Unfortunately, our beasts are inefficient animals, and they turn **two-thirds** of that into feces and heat, so we ’ ve lost those two, and we ’ ve only kept this one in meat and dairy products. Two more we ’ re going to throw away directly into bins. This is what most of us think of when we think of food waste, what ends up in **the** garbage, what ends up in **supermarket** bins, what ends up in restaurant bins. We ’ ve lost another two, and we ’ ve left ourselves with just four biscuits to feed on. That is not a superlatively efficient use of global resources, especially when you think of **the** billion hungry people that exist already in **the** world. Having gone through **the** data, I then needed to demonstrate where that food ends up. Where does it end up? We ’ re used to seeing **the** stuff on our **plates**, but what about all **the** stuff that goes missing in between? **Supermarkets** are an easy place to start. This is **the** result of my hobby, which is unofficial bin inspections. Strange you might think, but if we could rely on corporations to tell us what they were doing in **the** back of their stores, we wouldn ’ t need to go sneaking around **the** back, opening up bins and having a look at what ’ s inside. But this is what you can see more or less on every street corner in Britain, in Europe, in North America. It represents a colossal waste of food, but what I discovered whilst I was writing my book was that this very evident abundance of waste was actually **the** tip of **the** iceberg. When you start going up **the** supply chain, you find where **the** real food waste is happening on a gargantuan scale. Can I have a show of hands if you have a loaf of sliced bread in your house? Who lives in a household where that crust — that slice at **the** first and last end of each loaf — who lives in a household where it does get eaten? **Okay**, most people, not everyone, but most people, and this is, I ’ m glad to say, what I see across **the** world, and yet has anyone seen a **supermarket** or sandwich shop anywhere in **the** world that serves sandwiches with crusts on it? I certainly haven ’ t. So I kept on thinking, where do those crusts go? This is **the** answer, unfortunately : 13, 000 slices of fresh bread coming out of this one single factory every single day, day-fresh bread. In **the** same year that I visited this factory, I went to Pakistan, where people in 2008 were going hungry as a result of a squeeze on global food supplies. We contribute to that squeeze by depositing food in bins here in Britain and elsewhere in **the** world. We take food off **the** market shelves that hungry people depend on. Go one step up, and you get to farmers, who throw away sometimes a third or even more of their harvest because of cosmetic standards. This farmer, for example, has invested 16, 000 **pounds** in growing spinach, not one leaf of which he harvested, because there was a little bit of grass growing in amongst it. Potatoes that are cosmetically imperfect, all going for pigs. Parsnips that are too small for **supermarket** specifications, tomatoes in Tenerife, oranges in Florida, bananas in Ecuador, where I visited last year, all being **discarded**. This is one day ’ s waste from one banana plantation in Ecuador. All being **discarded**, perfectly edible, because they ’ re **the** wrong shape or size. If we do that to fruit and vegetables, you bet we can do it to animals too. Liver, lungs, heads, tails, kidneys, testicles, all of these things which are traditional, delicious and nutritious parts of our gastronomy go to waste. Offal **consumption** has halved in Britain and America in **the** last 30 years. As a result, this stuff gets fed to dogs at best, or is incinerated. This man, in Kashgar, Xinjiang province, in Western China, is serving up his national dish. It ’ s called sheep ’ s organs. It ’ s delicious, it ’ s nutritious, and as I learned when I went to Kashgar, it symbolizes their taboo against food waste. I was sitting in a roadside cafe. A chef came to talk to me, I finished my bowl, and halfway through **the** conversation, he stopped talking and he started frowning into my bowl. I thought,”My goodness, what taboo have I broken? How have I insulted my host?”He pointed at three grains of rice at **the** bottom of my bowl, and he said,”Clean.”I thought,”My God, you know, I go around **the** world telling people to stop wasting food. This guy has thrashed me at my own game.”But it gave me faith. It gave me faith that we, **the** people, do have **the** power to stop this tragic waste of resources if we regard it as socially unacceptable to waste food on a colossal scale, if we make noise about it, tell corporations about it, tell governments we want to see an end to food waste, we do have **the** power to bring about that change. **Fish**, 40 to 60 percent of European **fish** are **discarded** at **sea**, they don ’ t even get landed. In our homes, we ’ ve lost touch with food. This is an experiment I did on three lettuces. Who keeps lettuces in their fridge? Most people. **The** one on **the left** was kept in a fridge for 10 days. **The** one in **the** middle, on my kitchen table. Not much difference. **The** one on **the** right I treated like cut flowers. It ’ s a living organism, cut **the** slice off, stuck it in a vase of water, it was all right for another two weeks after this. Some food waste, as I said at **the** beginning, will inevitably arise, so **the** question is, what is **the** best thing to do with it? I answered that question when I was 15. In fact, humans answered that question 6, 000 years ago : We domesticated pigs to turn food waste back into food. And yet, in Europe, that practice has become illegal since 2001 as a result of **the** foot-and-mouth outbreak. It ’ s unscientific. It ’ s unnecessary. If you cook food for pigs, just as if you cook food for humans, it is **rendered** safe. It ’ s also a massive saving of resources. At **the** moment, Europe depends on importing millions of tons of soy from South America, where its production contributes to global warming, to deforestation, to biodiversity loss, to feed livestock here in Europe. At **the** same time we throw away millions of tons of food waste which we could and should be feeding them. If we did that, and fed it to pigs, we would save that amount of **carbon**. If we feed our food waste which is **the** current government favorite way of getting rid of food waste, to anaerobic digestion, which turns food waste into gas to produce electricity, you save a paltry 448 kilograms of **carbon** dioxide per ton of food waste. It ’ s much better to feed it to pigs. We knew that during **the** war. A silver lining : It has kicked off globally, **the** quest to tackle food waste. Feeding **the** 5, 000 is an event I first organized in 2009. We fed 5, 000 people all on food that otherwise would have been wasted. Since then, it ’ s happened again in London, it ’ s happening internationally, and across **the** country. It ’ s a way of organizations coming together to celebrate food, to say **the** best thing to do with food is to eat and **enjoy** it, and to stop wasting it. For **the** sake of **the planet** we live on, for **the** sake of our children, for **the** sake of all **the** other organisms that share our **planet** with us, we are a terrestrial animal, and we depend on our land for food. At **the** moment, we are trashing our land to grow food that no one eats. Stop wasting food. Thank you very much.

All right. So, like all good stories, this starts a long, long time ago when there was basically nothing. So here is a complete picture of **the universe** about

14-odd billion years ago. All energy is concentrated into a single point of energy. For some reason it explodes, and you begin to get these things. So you ’ re now about 14 billion years into this. And these things expand and expand and expand into these giant galaxies, and you get trillions of them. And within these galaxies you get these enormous dust clouds. And I want you to pay particular attention to **the** three little prongs in **the** center of this picture. If you take a close-up of those, they look like this. And what you ’ re looking at is columns of dust where there ’ s so much dust — by **the** way, **the** scale of this is a trillion vertical miles — and what ’ s happening is there ’ s so much dust, it comes together and it fuses and ignites a thermonuclear reaction. And so what you ’ re watching is **the** birth of stars. These are stars being born out of here. When enough stars come out, they create a galaxy. This one happens to be a particularly important galaxy, because you are here. And as you take a close-up of this galaxy, you find a relatively normal, not particularly interesting star. By **the** way, you ’ re now about **two-thirds** of **the** way into this story. So this star doesn ’ t even appear until about **two-thirds** of **the** way into this story. And then what happens is there ’ s enough dust left over that it doesn ’ t ignite into a star, it becomes a **planet**. And this is about a little over four billion years ago. And soon thereafter there ’ s enough material left over that you get a primordial **soup**, and that creates life. And life starts to expand and expand and expand, until it goes kaput. Now **the** really strange thing is life goes kaput, not once, not twice, but five times. So almost all life on Earth is **wiped** out about five times. And as you ’ re thinking about that, what happens is you get more and more complexity, more and more stuff to build new things with. And we don ’ t appear until about 99. 96 percent of **the** time into this story, just to put ourselves and our ancestors in perspective. So within that context, there ’ s two theories of **the** case as to why we ’ re all here. **The** first theory of **the** case is that ’ s all she wrote. Under that theory, we are **the** be-all and end-all of all creation. And **the** reason for trillions of galaxies, sextillions of **planets**, is to create something that looks like that and something that looks like that. And that ’ s **the** purpose of **the universe** ; and then it flat-lines, it doesn ’ t get any better. **The** only question you might want to ask yourself is, could that be just mildly arrogant? And if it is — and particularly given **the** fact that we came very close to extinction. There were only about 2, 000 of our species left. A few more weeks without rain, we would have never seen any of these. So maybe you have to think about a second theory if **the** first one isn ’ t good enough. Second theory is : Could we upgrade? Well, why would one ask a question like that? Because there have been at least 29 upgrades so far of humanoids. So it turns out that we have upgraded. We ’ ve upgraded time and again and again. And it turns out that we keep discovering upgrades. We found this one last year. We found another one last month. And as you ’ re thinking about this, you might also ask **the** question : So why a single human species? Wouldn ’ t it be really odd if you went to Africa and Asia and Antarctica and found exactly **the** same bird — particularly given that we co-existed at **the** same time with at least eight other versions of humanoid at **the** same time on this **planet**? So **the** normal state of affairs is not to have just a Homo sapiens ; **the** normal state of affairs is to have various versions of humans walking around. And if that is **the** normal state of affairs, then you might ask yourself, all right, so if we want to create something else, how big does a mutation have to be? Well Svante Paabo has **the** answer. **The** difference between humans and Neanderthal is 0. 004 percent of gene code. That ’ s how big **the** difference is one species to another. This explains most contemporary political debates. But as you ’ re thinking about this, one of **the** interesting things is how small these mutations are and where they take place. Difference human / Neanderthal is sperm and testis, smell and skin. And those are **the** specific genes that differ from one to **the** other. So very small changes can have a big impact. And as you ' re thinking about this, we ' re continuing to mutate. So about 10, 000 years ago by **the** Black Sea, we had one mutation in one gene which led to **blue** eyes. And this is continuing and continuing and continuing. And as it continues, one of **the** things that ' s going to happen this year is we ' re going to discover **the** first 10, 000 human **genomes**, because it ' s gotten cheap enough to do **the** gene sequencing. And when we find these, we may find differences. And by **the** way, this is not a debate that we ' re ready for, because we have really misused **the** science in this. In **the** 1920s, we thought there were major differences between people. That was partly based on Francis Galton ' s work. He was Darwin ' s cousin. But **the** U. S., **the** Carnegie Institute, Stanford, American Neurological Association took this really far. That got exported and was really misused. In fact, it led to some absolutely horrendous treatment of human beings. So since **the** 1940s, we ' ve been saying there are no differences, we ' re all **identical**. We ' re going to know at year end if that is true. And as we think about that, we ' re actually beginning to find things like, do you have an ACE gene? Why would that matter? Because nobody ' s ever climbed an 8, 000-meter peak without oxygen that doesn ' t have an ACE gene. And if you want to get more specific, how about a 577R genotype? Well it turns out that every male Olympic power athelete ever tested carries at least one of these variants. If that is true, it leads to some very complicated questions for **the** London Olympics. Three options : Do you want **the** Olympics to be a showcase for really hardworking mutants? Option number two : Why don ' t we play it like **golf** or sailing? Because you have one and you don ' t have one, I ' ll give you a tenth of a second head start. Version number three : Because this is a naturally **occurring** gene and you ' ve got it and you didn ' t pick **the** right parents, you get **the** right to upgrade. Three different options. If these differences are **the** difference between an Olympic medal and a non-Olympic medal. And it turns out that as we discover these things, we human beings really like to change how we look, how we act, what our bodies do. And we had about 10. 2 million plastic surgeries in **the** United States, except that with **the** technologies that are coming online today, today ' s corrections, deletions, augmentations and enhancements are going to seem like child ' s play. You already saw **the** work by Tony Atala on TED, but this ability to start filling things like inkjet cartridges with cells are allowing us to print skin, organs and a whole series of other body parts. And as these technologies go forward, you keep seeing this, you keep seeing this, you keep seeing things — 2000, human **genome** sequence — and it seems like nothing ' s happening, until it does. And we may just be in some of these weeks. And as you ' re thinking about these two guys sequencing a human **genome** in 2000 and **the** Public Project sequencing **the** human **genome** in 2000, then you don ' t hear a lot, until you hear about an experiment last year in China, where they take skin cells from this mouse, put four chemicals on it, turn those skin cells into stem cells, let **the** stem cells grow and create a full **copy** of that mouse. That ' s a big deal. Because in essence what it means is you can take a cell, which is a pluripotent stem cell, which is like a skier at **the** top of a mountain, and those two skiers become two pluripotent stem cells, four, eight, 16, and then it gets so crowded after 16 divisions that those cells have to differentiate. So they go down one side of **the** mountain, they go down another. And as they pick that, these become bone, and then they pick another road and these become platelets, and these become macrophages, and these become T cells. But it ' s really hard, once you ski down, to get back up. Unless, of course, if you have a ski lift. And what those four chemicals do is they take any cell and take it way back up **the** mountain so it can become any body part. And as you think of that, what it means is potentially you can rebuild a full **copy** of any organism out of any one of its cells. That turns out to be a big deal because now you can take, not just mouse cells, but you can human skin cells and turn them into human stem cells. And then what they did in October is they took skin cells, turned them into stem cells and began to turn them into liver cells. So in theory, you could grow any organ from any one of your cells. Here ' s a second experiment : If you could photocopy your body, maybe you also want to take your mind. And one of **the** things you saw at TED about a year and a half ago was this guy. And he gave a wonderful technical talk. He ' s a professor at MIT. But in essence what he said is you can take retroviruses, which get inside brain cells of mice. You can **tag** them with proteins that light up when you light them. And you can map **the exact** pathways when a mouse sees, feels, touches, remembers, loves. And then you can take a fiber optic cable and light up some of **the** same things. And by **the** way, as you do this, you can image it in two colors, which means you can download this information as binary code directly into a **computer**. So what ' s **the** bottom line on that? Well it ' s not completely inconceivable that someday you ' ll be able to download your own memories, maybe into a new body. And maybe you can upload other people ' s memories as well. And this might have just one or two small ethical, political, moral implications. Just a thought. Here ' s **the** kind of questions that are becoming interesting questions for philosophers, for governing people, for economists, for scientists. Because these technologies are moving really quickly. And as you think about it, let me close with an example of **the** brain. **The** first place where you would expect to see enormous **evolutionary** pressure today, both because of **the** inputs, which are becoming massive, and because of **the** plasticity of **the** organ, is **the** brain. Do we have any evidence that that is happening? Well let ' s take a look at something like autism incidence per thousand. Here ' s what it looks like in 2000. Here ' s what it looks like in 2002, 2006, 2008. Here ' s **the** increase in less than a decade. And we still don ' t know why this is happening. What we do know is, potentially, **the** brain is reacting in a hyperactive, hyper-plastic way, and creating individuals that are like this. And this is only one of **the** conditions that ' s out there. You ' ve also got people with who are extraordinarily smart, people who can remember everything they ' ve seen in their lives, people who ' ve got synesthesia, people who ' ve got schizophrenia. You ' ve got all kinds of stuff going on out there, and we still don ' t understand how and why this is happening. But one question you might want to ask is, are we seeing a rapid **evolution** of **the** brain and of how we process data? Because when you think of how much data ' s coming into our brains, we ' re trying to take in as much data in a day as people used to take in in a lifetime. And as you ' re thinking about this, there ' s four theories as to why this might be going on, plus a whole series of others. I don ' t have a good answer. There really needs to be more research on this. One option is **the** fast food fetish. There ' s beginning to be some evidence that obesity and diet have something to do with gene modifications, which may or may not have an impact on how **the** brain of an infant works. A second option is **the** sexy **geek** option. These conditions are highly rare. But what ' s beginning to happen is because these **geeks** are all getting together, because they are highly qualified for **computer** programming and it is highly remunerated, as well as other very detail-oriented tasks, that they are concentrating geographically and finding like-minded **mates**. So this is **the** assortative mating hypothesis of these genes reinforcing one another in these structures. **The** third, is this too much information? We ' re trying to process so much stuff that some people get synesthetic and just have huge pipes that remember everything. Other people get hyper-sensitive to **the** amount of information. Other people react with various psychological conditions or reactions to this information. Or maybe it ’ s chemicals. But when you see an increase of that order of magnitude in a condition, either you ’ re not measuring it right or there ’ s something going on very quickly, and it may be **evolution** in real time. Here ’ s **the** bottom line. What I think we are doing is we ’ re transitioning as a species. And I didn ’ t think this when Steve Gullans and I started writing together. I think we ’ re transitioning into Homo evolutis that, for better or worse, is not just a hominid that ’ s conscious of his or her environment, it ’ s a hominid that ’ s beginning to directly and deliberately control **the evolution** of its own species, of bacteria, of plants, of animals. And I think that ’ s such an order of magnitude change that your grandkids or your great-grandkids may be a species very different from you. Thank you very much.

Text Sample 39: POS Dim 1 – 2015 – Score 23.00 – 2015/t001481.txt
So I ’ ve had **the** great privilege of traveling to some incredible places, photographing these distant landscapes and remote cultures all over **the** world. I love my job. But people think it ’ s this string of epiphanies and sunrises and rainbows, when in reality, it looks more something like this. This is my office. We can ’ t afford **the** fanciest places to stay at night, so we tend to sleep a lot outdoors. As long as we can stay dry, that ’ s a bonus. We also can ’ t afford **the** fanciest restaurants. So we tend to eat whatever ’ s on **the** local menu. And if you ’ re in **the** Ecuadorian Pramo, you ’ re going to eat a large rodent called a cuy. But what makes our experiences perhaps a little bit different and a little more unique than that of **the** average person is that we have this gnawing thing in **the** back of our mind that even in our darkest moments, and those times of despair, we think,”Hey, there might be an image to be made here, there might be a story to be told.”And why is storytelling important? Well, it helps us to connect with our cultural and our natural heritage. And in **the** Southeast, there ’ s an alarming disconnect between **the** public and **the** natural areas that allow us to be here in **the** first place. We ’ re visual creatures, so we use what we see to teach us what we know. Now **the** majority of us aren ’ t going to willingly go way down to a swamp. So how can we still expect those same people to then advocate on behalf of their protection? We can ’ t. So my job, then, is to use photography as a communication tool, to help bridge **the** gap between **the** science and **the** aesthetics, to get people talking, to get them thinking, and to hopefully, ultimately, get them caring. I started doing this 15 years ago right here in Gainesville, right here in my backyard. And I fell in love with adventure and discovery, going to explore all these different places that were just minutes from my front doorstep. There are a lot of beautiful places to find. Despite all these years that have passed, I still see **the** world through **the** eyes of a child and I try to incorporate that sense of wonderment and that sense of curiosity into my photography as often as I can. And we ’ re pretty lucky because here in **the** South, we ’ re still blessed with a relatively blank canvas that we can fill with **the** most fanciful adventures and incredible experiences. It ’ s just a matter of how far our imagination will take us. See, a lot of people look at this and they say,”Oh yeah, wow, that ’ s a pretty tree.”But I don ’ t just see a tree — I look at this and I see opportunity. I see an entire weekend. Because when I was a kid, these were **the** types of images that got me off **the** sofa and dared me to explore, dared me to go find **the** woods and put my head **underwater** and see what we have. And folks, I ’ ve been photographing all over **the** world and I promise you, what we have here in **the** South, what we have in **the** Sunshine State, rivals anything else that I ’ ve seen. But yet our tourism industry is busy promoting all **the** wrong things. Before most kids are 12, they ’ ll have

been to Disney World more times than they ’ ve been in a canoe or camping under a starry sky. And I have nothing against Disney or Mickey ; I used to go there, too. But they ’ re missing out on those fundamental connections that create a real sense of pride and ownership for **the** place that they call home. And this is compounded by **the** issue that **the** landscapes that define our natural heritage and fuel our aquifer for our drinking water have been deemed as scary and dangerous and spooky. When our ancestors first came here, they warned,”Stay out of these areas, they ’ re haunted. They ’ re full of evil spirits and ghosts.”I don ’ t know where they came up with that idea. But it ’ s actually led to a very real disconnect, a very real negative mentality that has kept **the** public disinterested, silent, and ultimately, our environment at risk. We ’ re a state that ’ s surrounded and defined by water, and yet for centuries, swamps and wetlands have been regarded as these obstacles to overcome. And so we ’ ve treated them as these second-class ecosystems, because they have very little monetary value and of course, they ’ re known to harbor alligators and snakes — which, I ’ ll admit, these aren ’ t **the** most cuddly of ambassadors. So it became assumed, then, that **the** only good swamp was a drained swamp. And in fact, draining a swamp to make way for **agriculture** and development was considered **the** very essence of conservation not too long ago. But now we ’ re backpedaling, because **the** more we come to learn about these sodden landscapes, **the** more secrets we ’ re starting to **unlock** about interspecies relationships and **the** connectivity of **habitats**, watersheds and flyways. Take this bird, for example : this is **the** prothonotary warbler. I love this bird because it ’ s a swamp bird, through and through, a swamp bird. They nest and they **mate** and they breed in these old-growth swamps in these flooded forests. And so after **the spring**, after they raise their young, they then fly thousand of miles over **the** Gulf of Mexico into Central and South America. And then after **the** winter, **the spring** rolls around and they come back. They fly thousands of miles over **the** Gulf of Mexico. And where do they go? Where do they land? Right back in **the** same tree. That ’ s **nuts**. This is a bird **the** size of a tennis ball — I mean, that ’ s crazy! I used a GPS to get here today, and this is my hometown. It ’ s crazy. So what happens, then, when this bird flies over **the** Gulf of Mexico into Central America for **the** winter and then **the spring** rolls around and it flies back, and it comes back to this : a freshly sodded **golf** course? This is a narrative that ’ s all too commonly unraveling here in this state. And this is a natural process that ’ s **occurred** for thousands of years and we ’ re just now learning about it. So you can imagine all else we have to learn about these landscapes if we just preserve them first. Now despite all this rich life that abounds in these swamps, they still have a bad name. Many people feel uncomfortable with **the** idea of wading into Florida ’ s blackwater. I can understand that. But what I loved about growing up in **the** Sunshine State is that for so many of us, we live with this latent but very palpable fear that when we put our toes into **the** water, there might be something much more ancient and much more adapted than we are. Knowing that you ’ re not top dog is a welcomed discomfort, I think. How often in this modern and urban and digital age do you actually get **the** chance to feel vulnerable, or consider that **the** world may not have been made for just us? So for **the** last decade, I began seeking out these areas where **the** concrete yields to forest and **the** pines turn to cypress, and I viewed all these mosquitoes and reptiles, all these discomforts, as affirmations that I ’ d found true wilderness, and I embrace them wholly. Now as a conservation photographer obsessed with blackwater, it ’ s only fitting that I ’ d eventually end up in **the** most **famous** swamp of all : **the** Everglades. Growing up here in North Central Florida, it always had these enchanted names, places like Loxahatchee and Fakahatchee, Corkscrew, Big

Cypress. I started what turned into a five-year project to hopefully reintroduce **the** Everglades in a new light, in a more inspired light. But I knew this would be a tall order, because here you have an area that ' s roughly a third **the** size **the** state of Florida, it ' s huge. And when I say Everglades, most people are like,"Oh, yeah, **the** national park."But **the** Everglades is not just a park ; it ' s an entire watershed, starting with **the** Kissimmee chain of lakes in **the** north, and then as **the** rains would fall in **the** summer, these downpours would flow into Lake Okeechobee, and Lake Okeechobee would fill up and it would overflow its banks and **spill** southward, ever slowly, with **the** topography, and get into **the** river of grass, **the** Sawgrass Prairies, before meting into **the** cypress slews, until going further south into **the** mangrove swamps, and then finally — finally — reaching Florida Bay, **the** emerald gem of **the** Everglades, **the** great estuary, **the** 850 square-mile estuary. So sure, **the** national park is **the** southern end of this system, but all **the** things that make it unique are these inputs that come in, **the** fresh water that starts 100 miles north. So no manner of these political or invisible boundaries protect **the** park from polluted water or insufficient water. And unfortunately, that ' s precisely what we ' ve done. Over **the** last 60 years, we have drained, we have dammed, we have dredged **the** Everglades to where now only one third of **the** water that used to reach **the bay** now reaches **the bay** today. So this story is not all sunshine and rainbows, unfortunately. For better or for worse, **the** story of **the** Everglades is intrinsically tied to **the** peaks and **the** valleys of mankind ' s relationship with **the** natural world. But I ' ll show you these beautiful pictures, because it gets you on board. And while I have your attention, I can tell you **the** real story. It ' s that we ' re taking this, and we ' re trading it for this, at an alarming rate. And what ' s lost on so many people is **the sheer** scale of which we ' re discussing. Because **the** Everglades is not just responsible for **the** drinking water for 7 million Floridians ; today it also provides **the** agricultural fields for **the** year-round tomatoes and oranges for over 300 million Americans. And it ' s that same seasonal **pulse** of water in **the** summer that built **the** river of grass 6, 000 years ago. Ironically, today, it ' s also responsible for **the** over half a million acres of **the** endless river of sugarcane. These are **the** same fields that are responsible for dumping exceedingly high levels of fertilizers into **the** watershed, forever changing **the** system. But in order for you to not just understand how this system works, but to also get personally connected to it, I decided to break **the** story down into several different narratives. And I wanted that story to start in Lake Okeechobee, **the** beating heart of **the** Everglade system. And to do that, I picked an ambassador, an iconic species. This is **the** Everglade snail kite. It ' s a great bird, and they used to nest in **the** thousands, thousands in **the** northern Everglades. And then they ' ve gone down to about 400 nesting pairs today. And why is that? Well, it ' s because they eat one source of food, an apple snail, about **the** size of a ping-pong ball, an aquatic gastropod. So as we started damming up **the** Everglades, as we started diking Lake Okeechobee and draining **the** wetlands, we lost **the habitat** for **the** snail. And thus, **the** population of **the** kites declined. And so, I wanted a photo that would not only communicate this relationship between wetland, snail and bird, but I also wanted a photo that would communicate how incredible this relationship was, and how very important it is that they ' ve come to depend on each other, this healthy wetland and this bird. And to do that, I brainstormed this idea. I started sketching out these plans to make a photo, and I sent it to **the** wildlife biologist down in Okeechobee — this is an endangered bird, so it takes special permission to do. So I built this submerged platform that would hold snails just right under **the** water. And I spent months planning this crazy idea. And I took this platform down to Lake Okeechobee and I spent over a week in **the** water, wading waist-deep, 9-hour shifts from dawn until dusk, to get one image that I thought might communicate this. And here ’ s **the** day that it finally worked : [Video : After setting up **the** platform, I look off and I see a kite coming over **the** cattails. And I see him scanning and **searching**. And he gets right over **the** trap, and I see that he ’ s seen it. And he beelines, he goes straight for **the** trap. And in that moment, all those months of planning, waiting, all **the** sunburn, mosquito **bites** — suddenly, they ’ re all worth it. Oh my gosh, I can ’ t believe it!] You can believe how excited I was when that happened. But what **the** idea was, is that for someone who ’ s never seen this bird and has no reason to care about it, these photos, these new perspectives, will help shed a little new light on just one species that makes this watershed so incredible, so valuable, so important. Now, I know I can ’ t come here to Gainesville and talk to you about animals in **the** Everglades without talking about gators. I love gators, I grew up loving gators. My parents always said I had an unhealthy relationship with gators. But what I like about them is, they ’ re like **the** freshwater equivalent of sharks. They ’ re feared, they ’ re hated, and they are tragically misunderstood. Because these are a unique species, they ’ re not just apex predators. In **the** Everglades, they are **the** very architects of **the** Everglades, because as **the** water drops down in **the** winter during **the** dry season, they start excavating these holes called gator holes. And they do this because as **the** water drops down, they ’ ll be able to stay **wet** and they ’ ll be able to forage. And now this isn ’ t just affecting them, other animals also depend on this relationship, so they become a keystone species as well. So how do you make an apex predator, an ancient reptile, at once look like it dominates **the** system, but at **the** same time, look vulnerable? Well, you wade into a pit of about 120 of them, then you hope that you ’ ve made **the** right decision. I still have all my fingers, it ’ s cool. But I understand, I know I ’ m not going to rally you guys, I ’ m not going to rally **the** troops to”Save **the** Everglades for **the** gators!”It won ’ t happen because they ’ re so ubiquitous, we see them now, they ’ re one of **the** great conservation success stories of **the** US. But there is one species in **the** Everglades that no matter who you are, you can ’ t help but love, too, and that ’ s **the** roseate spoonbill. These birds are great, but they ’ ve had a really tough time in **the** Everglades, because they started out with thousands of nesting pairs in Florida Bay, and at **the** turn of **the** 20th century, they got down to two — two nesting pairs. And why? That ’ s because women thought they looked better on their hats then they did flying in **the** sky. Then we banned **the** plume trade, and their numbers started rebounding. And as their numbers started rebounding, scientists began to pay attention, they started studying these birds. And what they found out is that these birds ’ behavior is intrinsically tied to **the** annual draw-down cycle of water in **the** Everglades, **the** thing that defines **the** Everglades watershed. What they found out is that these birds started nesting in **the** winter as **the** water drew down, because they ’ re tactile feeders, so they have to touch whatever they eat. And so they wait for these concentrated pools of **fish** to be able to feed enough to feed their young. So these birds became **the** very icon of **the** Everglades — an indicator species of **the** overall health of **the** system. And just as their numbers were rebounding in **the** mid-20th century — shooting up to 900, 1, 000, 1, 100, 1, 200 — just as that started happening, we started draining **the** southern Everglades. And we stopped **two-thirds** of that water from moving south. And it had drastic consequences. And just as those numbers started reaching their peak, unfortunately, today, **the** real spoonbill story, **the** real photo of what it looks like is more something like this. And we ’ re down to less than 70 nesting pairs in Florida Bay today, because we ’ ve disrupted **the** system so much. So all these different organizations are shouting, they ’ re screaming,”**The** Everglades is fragile! It ’ s fragile!”It is not. It is resilient.

Because despite all we ’ ve taken, despite all we ’ ve done and we ’ ve drained and we ’ ve dammed and we ’ ve dredged it, pieces of it are still here, waiting to be put back together. And this is what I ’ ve loved about South Florida, that in one place, you have this unstoppable force of mankind meeting **the** immovable **object** of tropical nature. And it ’ s at this new frontier that we are forced with a new appraisal. What is wilderness worth? What is **the** value of biodiversity, or our drinking water? And fortunately, after decades of debate, we ’ re finally starting to act on those questions. We ’ re slowly **undertaking** these projects to bring more freshwater back to **the bay**. But it ’ s up to us as citizens, as residents, as stewards to hold our elected officials to their promises. What can you do to help? It ’ s so easy. Just get outside, get out there. Take your friends out, take your kids out, take your family out. Hire a **fishing** guide. Show **the** state that protecting wilderness not only makes ecological sense, but economic sense as well. It ’ s a lot of fun, just do it — put your feet in **the** water. **The** swamp will change you, I promise. Over **the** years, we ’ ve been so generous with these other landscapes around **the** country, cloaking them with this American pride, places that we now consider to define us : Grand Canyon, Yosemite, Yellowstone. And we use these parks and these natural areas as beacons and as cultural compasses. And sadly, **the** Everglades is very commonly left out of that conversation. But I believe it ’ s every bit as iconic and emblematic of who we are as a country as any of these other wildernesses. It ’ s just a different kind of wild. But I ’ m encouraged, because maybe we ’ re finally starting to come around, because what was once deemed this swampy wasteland, today is a World Heritage site. It ’ s a wetland of international importance. And we ’ ve come a long way in **the** last 60 years. And as **the** world ’ s largest and most ambitious wetland restoration project, **the** international spotlight is on us in **the** Sunshine State. Because if we can heal this system, it ’ s going to become an icon for wetland restoration all over **the** world. But it ’ s up to us to decide which legacy we want to attach our flag to. They say that **the** Everglades is our greatest test. If we pass it, we get to keep **the planet**. I love that quote, because it ’ s a challenge, it ’ s a prod. Can we do it? Will we do it? We have to, we must. But **the** Everglades is not just a test. It ’ s also a gift, and ultimately, our responsibility. Thank you.

Well, you know, sometimes **the** most important things come in **the** smallest packages. I am going to try to convince you, in **the** 15 minutes I have, that microbes have a lot to say about questions such as,”Are we alone?”and they can tell us more about not only life in our solar system but also maybe beyond, and this is why I am tracking them down in **the** most impossible places on Earth, in extreme environments where conditions are really pushing them to **the** brink of survival. Actually, sometimes me too, when I ’ m trying to follow them too close. But here ’ s **the** thing : We are **the** only advanced civilization in **the** solar system, but that doesn ’ t mean that there is no microbial life nearby. In fact, **the planets** and moons you see here could host life — all of them — and we know that, and it ’ s a strong possibility. And if we were going to find life on those moons and **planets**, then we would answer questions such as, are we alone in **the** solar system? Where are we coming from? Do we have family in **the** neighborhood? Is there life beyond our solar system? And we can ask all those questions because there has been a revolution in our understanding of what a habitable **planet** is, and today, a habitable **planet** is a **planet** that has a zone where water can stay stable, but to me this is a **horizontal** definition of habitability, because it involves a distance to a star, but there is another **dimension** to habitability, and this is a vertical **dimension**. Think of it as conditions in **the** subsurface of a **planet** where you are very far away from a sun, but you still have water, energy, nutrients, which for some of them means food, and a protection. And when you look at **the** Earth, very far away from any sunlight, deep in **the** ocean, you have life thriving and it uses only **chemistry** for life processes. So when you think of it at that point, all walls collapse. You have no limitations, basically. And if you have been looking at **the** headlines lately, then you will see that we have discovered a subsurface ocean on Europa, on Ganymede, on Enceladus, on Titan, and now we are finding a geyser and hot **springs** on Enceladus, Our solar system is turning into a giant spa. For anybody who has gone to a spa knows how much microbes like that, right? So at that point, think also about Mars. There is no life possible at **the surface** of Mars today, but it might still be hiding **underground**. So, we have been making progress in our understanding of habitability, but we also have been making progress in our understanding of what **the** signatures of life are on Earth. And you can have what we call **organic** molecules, and these are **the** bricks of life, and you can have **fossils**, and you can minerals, biominerals, which is due to **the** reaction between bacteria and **rocks**, and of course you can have gases in **the** atmosphere. And when you look at those tiny green algae on **the** right of **the slide** here, they are **the** direct descendants of those who have been pumping oxygen a billion years ago in **the** atmosphere of **the** Earth. When they did that, they poisoned 90 percent of **the** life at **the surface** of **the** Earth, but they are **the** reason why you are breathing this air today. But as much as our understanding grows of all of these things, there is one question we still cannot answer, and this is, where are we coming from? And you know, it ’ s getting worse, because we won ’ t be able to find **the** physical evidence of where we are coming from on this **planet**, and **the** reason being is that anything that is older than four billion years is gone. All record is gone, erased by **plate** tectonics and erosion. This is what I call **the** Earth ’ s biological horizon. Beyond this horizon we don ’ t know where we are coming from. So is everything lost? Well, maybe not. And we might be able to find evidence of our own origin in **the** most unlikely place, and this place in Mars. How is this possible? Well clearly at **the** beginning of **the** solar system, Mars and **the** Earth were bombarded by giant **asteroids** and comets, and there were ejecta from these impacts all over **the** place. Earth and Mars kept throwing **rocks** at each other for a very long time. Pieces of **rocks** landed on **the** Earth. Pieces of **the** Earth landed on Mars. So clearly, those two **planets** may have been seeded by **the** same material. So yeah, maybe Granddady is sitting there on **the surface** and waiting for us. But that also means that we can go to Mars and try to find traces of our own origin. Mars may hold that secret for us. This is why Mars is so special to us. But for that to happen, Mars needed to be habitable at **the** time when conditions were right. So was Mars habitable? We have a number of missions telling us exactly **the** same thing today. At **the** time when life appeared on **the** Earth, Mars did have an ocean, it had volcanoes, it had lakes, and it had deltas like **the** beautiful picture you see here. This picture was sent by **the** Curiosity rover only a few weeks ago. It shows **the** remnants of a delta, and this picture tells us something : water was abundant and stayed founting at **the surface** for a very long time. This is good news for life. Life **chemistry** takes a long time to actually happen. So this is extremely good news, but does that mean that if we go there, life will be easy to find on Mars? Not necessarily. Here ’ s what happened : At **the** time when life exploded at **the surface** of **the** Earth, then everything went south for Mars, literally. **The** atmosphere was stripped away by solar winds, Mars lost its magnetosphere, and then cosmic rays and U. V. bombarded **the surface** and water escaped to space and went **underground**. So if we want to be able to understand, if we want to be able to find those traces of **the** signatures of life at **the surface** of Mars, if they are there, we need to understand what was **the** impact of each of these events on **the** preservation of its record. Only then will we be able to know where those signatures are hiding, and only then will we be able to send our rover to **the** right places where we can sample those **rocks** that may be telling us something really important about who we are, or, if not, maybe telling us that somewhere, independently, life has appeared on another **planet**. So to do that, it ' s easy. You only need to go back 3. 5 billion years ago in **the** past of a **planet**. We just need a time machine. Easy, right? Well, actually, it is. Look around you — that ' s **planet** Earth. This is our time machine. Geologists are using it to go back in **the** past of our own **planet**. I am using it a little bit differently. I use **planet** Earth to go in very extreme environments where conditions were similar to those of Mars at **the** time when **the** climate changed, and there I ' m trying to understand what happened. What are **the** signatures of life? What is left? How are we going to find it? So for one moment now I ' m going to take you with me on a trip into that time machine. And now, what you see here, we are at 4, 500 meters in **the** Andes, but in fact we are less than a billion years after **the** Earth and Mars formed. **The** Earth and Mars will have looked pretty much exactly like that — volcanoes everywhere, evaporating lakes everywhere, minerals, hot **springs**, and then you see those mounds on **the** shore of those lakes? Those are built by **the** descendants of **the** first organisms that gave us **the** first **fossil** on Earth. But if we want to understand what ' s going on, we need to go a little further. And **the** other thing about those sites is that exactly like on Mars three and a half billion years ago, **the** climate is changing very fast, and water and ice are **disappearing**. But we need to go back to that time when everything changed on Mars, and to do that, we need to go higher. Why is that? Because when you go higher, **the** atmosphere is getting thinner, it ' s getting more unstable, **the** temperature is getting cooler, and you have a lot more U. V. radiation. Basically, you are getting to those conditions on Mars when everything changed. So I was not promising anything about a leisurely trip on **the** time machine. You are not going to be sitting in that time machine. You have to haul 1, 000 **pounds** of equipment to **the** summit of this 20, 000-foot volcano in **the** Andes here. That ' s about 6, 000 meters. And you also have to sleep on 42-degree **slopes** and really hope that there won ' t be any **earthquake** that night. But when we get to **the** summit, we actually find **the** lake we came for. At this **altitude**, this lake is experiencing exactly **the** same conditions as those on Mars three and a half billion years ago. And now we have to change our voyage into an inner voyage inside that lake, and to do that, we have to remove our mountain gear and actually don suits and go for it. But at **the** time we enter that lake, at **the** very moment we enter that lake, we are stepping back three and a half billion years in **the** past of another **planet**, and then we are going to get **the** answer came for. Life is everywhere, absolutely everywhere. Everything you see in this picture is a living organism. Maybe not so **the** diver, but everything else. But this picture is very deceiving. Life is abundant in those lakes, but like in many places on Earth right now and due to climate change, there is a huge loss in biodiversity. In **the** samples that we took back home, 36 percent of **the** bacteria in those lakes were composed of three species, and those three species are **the** ones that have survived so far. Here ' s another lake, right next to **the** first one. **The** red color you see here is not due to minerals. It ' s actually due to **the** presence of a tiny algae. In this region, **the** U. V. radiation is really nasty. Anywhere on Earth, 11 is considered to be extreme. During U. V. storms there, **the** U. V. Index reaches 43. SPF 30 is not going to do anything to you over there, and **the** water is so transparent in those lakes that **the** algae has nowhere to hide, really, and so they are developing their own sunscreen, and this is **the** red color you see. But they can adapt only so far, and then when all **the** water is gone from **the surface**, microbes have only one solution **left** : They go **underground**. And those microbes, **the rocks** you see in that **slide** here, well, they are actually living inside **rocks** and they are using **the** protection of **the** translucence of **the rocks** to get **the** good part of **the** U. V. and **discard the** part that could actually damage their DNA. And this is why we are taking our rover to train them to **search** for life on Mars in these areas, because if there was life on Mars three and a half billion years ago, it had to use **the** same strategy to actually protect itself. Now, it is pretty obvious that going to extreme environments is helping us very much for **the** exploration of Mars and to prepare missions. So far, it has helped us to understand **the** geology of Mars. It has helped to understand **the** past climate of Mars and its **evolution**, but also its habitability potential. Our most recent rover on Mars has discovered traces of **organics**. Yeah, there are **organics** at **the surface** of Mars. And it also discovered traces of methane. And we don ’ t know yet if **the** methane in question is really from geology or **biology**. Regardless, what we know is that because of **the** discovery, **the** hypothesis that there is still life present on Mars today remains a viable one. So by now, I think I have convinced you that Mars is very special to us, but it would be a mistake to think that Mars is **the** only place in **the** solar system that is interesting to find potential microbial life. And **the** reason is because Mars and **the** Earth could have a common root to their tree of life, but when you go beyond Mars, it ’ s not that easy. Celestial mechanics is not making it so easy for an exchange of material between **planets**, and so if we were to discover life on those **planets**, it would be different from us. It would be a different type of life. But in **the** end, it might be just us, it might be us and Mars, or it can be many trees of life in **the** solar system. I don ’ t know **the** answer yet, but I can tell you something : No matter what **the** result is, no matter what that magic number is, it is going to give us a standard by which we are going to be able to measure **the** life potential, abundance and diversity beyond our own solar system. And this can be achieved by our generation. This can be our legacy, but only if we dare to explore. Now, finally, if somebody tells you that looking for alien microbes is not cool because you cannot have a philosophical conversation with them, let me show you why and how you can tell them they ’ re wrong. Well, **organic** material is going to tell you about environment, about complexity and about diversity. DNA, or any information carrier, is going to tell you about adaptation, about **evolution**, about survival, about planetary changes and about **the** transfer of information. All together, they are telling us what started as a microbial pathway, and why what started as a microbial pathway sometimes ends up as a civilization or sometimes ends up as a dead end. Look at **the** solar system, and look at **the** Earth. On Earth, there are many intelligent species, but only one has achieved technology. Right here in **the** journey of our own solar system, there is a very, very powerful message that says here ’ s how we should look for alien life, small and big. So yeah, microbes are talking and we are listening, and they are taking us, one **planet** at a time and one moon at a time, towards their big brothers out there. And they are telling us about diversity, they are telling us about abundance of life, and they are telling us how this life has survived thus far to reach civilization, intelligence, technology and, indeed, philosophy. Thank you.

Text Sample 41: POS Dim 1 – 2015 – Score 20.00 – 2015/t001601.txt

I ’ d like to take you on **the** epic quest of **the** Rosetta spacecraft. To escort and land **the** probe on a comet, this has been my passion for **the** past two years. In order to do that, I need to explain to you something about **the** origin of **the** solar system. When we go back four and a half billion years, there was a cloud of gas and dust. In **the** center of this cloud, our sun formed and ignited. Along with that, what we now know as **planets**, comets and **asteroids** formed. What then happened, according to theory, is that when **the** Earth had cooled down a bit after its formation, comets massively impacted **the** Earth and delivered water to Earth. They probably also delivered complex **organic** material to Earth, and that may have bootstrapped **the** emergence of life. You can compare this to having to solve a 250-piece puzzle and not a 2, 000-piece puzzle. Afterwards, **the** big **planets** like Jupiter and Saturn, they were not in their place where they are now, and they interacted gravitationally, and they swept **the** whole interior of **the** solar system clean, and what we now know as comets ended up in something called **the** Kuiper Belt, which is a belt of **objects** beyond **the** orbit of Neptune. And sometimes these **objects** run into each other, and they gravitationally deflect, and then **the** gravity of Jupiter pulls them back into **the** solar system. And they then become **the** comets as we see them in **the** sky. **The** important thing here to note is that in **the** meantime, **the** four and a half billion years, these comets have been sitting on **the** outside of **the** solar system, and haven ’ t changed — deep, frozen versions of our solar system. In **the** sky, they look like this. We know them for their tails. There are actually two tails. One is a dust tail, which is blown away by **the** solar wind. **The** other one is an ion tail, which is charged particles, and they follow **the** magnetic field in **the** solar system. There ’ s **the** coma, and then there is **the** nucleus, which here is too small to see, and you have to remember that in **the** case of Rosetta, **the** spacecraft is in that center pixel. We are only 20, 30, 40 kilometers away from **the** comet. So what ’ s important to remember? Comets contain **the** original material from which our solar system was formed, so they ’ re ideal to study **the** components that were present at **the** time when Earth, and life, started. Comets are also suspected of having brought **the** elements which may have bootstrapped life. In 1983, ESA set up its long-term Horizon 2000 program, which contained one cornerstone, which would be a mission to a comet. In parallel, a small mission to a comet, what you see here, Giotto, was launched, and in 1986, flew by **the** comet of Halley with an armada of other spacecraft. From **the** results of that mission, it became immediately clear that comets were ideal bodies to study to understand our solar system. And thus, **the** Rosetta mission was approved in 1993, and originally it was supposed to be launched in 2003, but a problem arose with an Ariane rocket. However, our P. R. department, in its enthusiasm, had already made 1, 000 Delft **Blue plates** with **the** name of **the** wrong comets. So I ’ ve never had to buy any china since. That ’ s **the** positive part. Once **the** whole problem was solved, we left Earth in 2004 to **the** newly selected comet, Churyumov-Gerasimenko. This comet had to be specially selected because A, you have to be able to get to it, and B, it shouldn ’ t have been in **the** solar system too long. This particular comet has been in **the** solar system since 1959. That ’ s **the** first time when it was deflected by Jupiter, and it got close enough to **the** sun to start changing. So it ’ s a very fresh comet. Rosetta made a few historic firsts. It ’ s **the** first satellite to orbit a comet, and to escort it throughout its whole tour through **the** solar system — closest approach to **the** sun, as we will see in August, and then away again to **the** exterior. It ’ s **the** first ever landing on a comet. We actually orbit **the** comet using something which is not normally done with spacecraft. Normally, you look at **the** sky and you know where you point and where you are. In this case, that ’ s not enough. We navigated by looking at landmarks on **the** comet. We recognized features — boulders, craters — and that ' s how we know where we are respective to **the** comet. And, of course, it ' s **the** first satellite to go beyond **the** orbit of Jupiter on solar cells. Now, this sounds more heroic than it actually is, because **the** technology to use radio isotope thermal generators wasn ' t available in Europe at that time, so there was no choice. But these solar **arrays** are big. This is one **wing**, and these are not specially selected small people. They ' re just like you and me. We have two of these **wings**, 65 square meters. Now later on, of course, when we got to **the** comet, you find out that 65 square meters of sail close to a body which is outgassing is not always a very handy choice. Now, how did we get to **the** comet? Because we had to go there for **the** Rosetta scientific objectives very far away — four times **the** distance of **the** Earth to **the** sun — and also at a much higher velocity than we could achieve with fuel, because we ' d have to take six times as much fuel as **the** whole spacecraft weighed. So what do you do? You use gravitational flybys, slingshots, where you pass by a **planet** at very low **altitude**, a few thousand kilometers, and then you get **the** velocity of that **planet** around **the** sun for free. We did that a few times. We did Earth, we did Mars, we did twice Earth again, and we also flew by two **asteroids**, Lutetia and Steins. Then in 2011, we got so far from **the** sun that if **the** spacecraft got into trouble, we couldn ' t actually save **the** spacecraft anymore, so we went into hibernation. Everything was switched off except for one clock. Here you see in white **the** trajectory, and **the** way this works. You see that from **the** circle where we started, **the** white line, actually you get more and more and more elliptical, and then finally we approached **the** comet in May 2014, and we had to start doing **the** rendezvous maneuvers. On **the** way there, we flew by Earth and we took a few pictures to test our cameras. This is **the** moon rising over Earth, and this is what we now call a selfie, which at that time, by **the** way, that word didn ' t exist. It ' s at Mars. It was taken by **the** CIVA camera. That ' s one of **the** cameras on **the** lander, and it just looks under **the** solar **arrays**, and you see **the planet** Mars and **the** solar **array** in **the** distance. Now, when we got out of hibernation in January 2014, we started arriving at a distance of two million kilometers from **the** comet in May. However, **the** velocity **the** spacecraft had was much too fast. We were going 2, 800 kilometers an hour faster than **the** comet, so we had to **brake**. We had to do eight maneuvers, and you see here, some of them were really big. We had to **brake the** first one by a few hundred kilometers per hour, and actually, **the** duration of that was seven hours, and it used 218 kilos of fuel, and those were seven nerve-wracking hours, because in 2007, there was a leak in **the** system of **the** propulsion of Rosetta, and we had to close off a branch, so **the** system was actually operating at a pressure which it was never designed or qualified for. Then we got in **the** vicinity of **the** comet, and these were **the** first pictures we saw. **The** true comet rotation period is 12 and a half hours, so this is accelerated, but you will understand that our flight dynamics engineers thought, this is not going to be an easy thing to land on. We had hoped for some kind of spud-like thing where you could easily land. But we had one hope : maybe it was smooth. No. That didn ' t work either. So at that point in time, it was clearly unavoidable : we had to map this body in all **the** detail you could get, because we had to find an area which is 500 meters in **diameter** and flat. Why 500 meters? That ' s **the** error we have on landing **the** probe. So we went through this process, and we mapped **the** comet. We used a **technique** called photoclinometry. You use shadows thrown by **the** sun. What you see here is a **rock** sitting on **the surface** of **the** comet, and **the** sun shines from above. From **the** shadow, we, with our brain, can immediately determine roughly what **the** shape of that **rock** is. You can program that in a **computer**, you then cover **the** whole comet, and you can map **the** comet. For that, we flew special trajectories starting in August. First, a **triangle** of 100 kilometers on a side at 100 kilometers ’ distance, and we repeated **the** whole thing at 50 kilometers. At that time, we had seen **the** comet at all kinds of angles, and we could use this **technique** to map **the** whole thing. Now, this led to a **selection** of landing sites. This whole process we had to do, to go from **the** mapping of **the** comet to actually finding **the** final landing site, was 60 days. We didn ’ t have more. To give you an idea, **the** average Mars mission takes hundreds of scientists for years to meet about where shall we go? We had 60 days, and that was it. We finally selected **the** final landing site and **the** commands were prepared for Rosetta to launch Philae. **The** way this works is that Rosetta has to be at **the** right point in space, and aiming towards **the** comet, because **the** lander is passive. **The** lander is then pushed out and moves towards **the** comet. Rosetta had to turn around to get its cameras to actually look at Philae while it was departing and to be able to communicate with it. Now, **the** landing duration of **the** whole trajectory was seven hours. Now do a simple calculation : if **the** velocity of Rosetta is off by one centimeter per second, seven hours is 25, 000 seconds. That means 252 meters wrong on **the** comet. So we had to know **the** velocity of Rosetta much better than one centimeter per second, and its location in space better than 100 meters at 500 million kilometers from Earth. That ’ s no mean feat. Let me quickly take you through some of **the** science and **the** instruments. I won ’ t bore you with all **the** details of all **the** instruments, but it ’ s got everything. We can sniff gas, we can measure dust particles, **the** shape of them, **the** composition, there are magnetometers, everything. This is one of **the** results from an instrument which measures gas density at **the** position of Rosetta, so it ’ s gas which has left **the** comet. **The** bottom graph is September of last year. There is a long-term variation, which in itself is not surprising, but you see **the** sharp peaks. This is a comet day. You can see **the** effect of **the** sun on **the** evaporation of gas and **the** fact that **the** comet is rotating. So there is one spot, apparently, where there is a lot of stuff coming from, it gets heated in **the** Sun, and then cools down on **the** back side. And we can see **the** density variations of this. These are **the** gases and **the organic** compounds that we already have measured. You will see it ’ s an impressive list, and there is much, much, much more to come, because there are more measurements. Actually, there is a conference going on in Houston at **the** moment where many of these results are presented. Also, we measured dust particles. Now, for you, this will not look very impressive, but **the** scientists were thrilled when they saw this. Two dust particles : **the** right one they call Boris, and they shot it with tantalum in order to be able to analyze it. Now, we found sodium and magnesium. What this tells you is this is **the** concentration of these two materials at **the** time **the** solar system was formed, so we learned things about which materials were there when **the planet** was made. Of course, one of **the** important elements is **the** imaging. This is one of **the** cameras of Rosetta, **the** OSIRIS camera, and this actually was **the** cover of Science magazine on January 23 of this year. Nobody had expected this body to look like this. Boulders, **rocks** — if anything, it looks more like **the** Half Dome in Yosemite than anything else. We also saw things like this : dunes, and what look to be, on **the** righthand side, wind-blown shadows. Now we know these from Mars, but this comet doesn ’ t have an atmosphere, so it ’ s a bit difficult to create a wind-blown shadow. It may be local outgassing, stuff which goes up and comes back. We don ’ t know, so there is a lot to investigate. Here, you see **the** same image twice. On **the** left-hand side, you see in **the** middle a pit. On **the right-hand** side, if you carefully look, there are three jets coming out of **the** bottom of that pit. So this is **the** activity of **the** comet. Apparently, at **the** bottom of these pits is where **the** active regions are, and where **the** material evaporates into space. There is a very intriguing crack in **the** neck of **the** comet. You see it on **the right-hand** side. It ’ s a kilometer long, and it ’ s two and a half meters wide. Some people suggest that actually, when we get close to **the** sun, **the** comet may split in two, and then we ’ ll have to choose, which comet do we go for? **The** lander — again, lots of instruments, mostly comparable except for **the** things which hammer in **the** ground and drill, etc. But much **the** same as Rosetta, and that is because you want to compare what you find in space with what you find on **the** comet. These are called ground truth measurements. These are **the** landing descent images that were taken by **the** OSIRIS camera. You see **the** lander getting further and further away from Rosetta. On **the** top right, you see an image taken at 60 meters by **the** lander, 60 meters above **the surface** of **the** comet. **The** boulder there is some 10 meters. So this is one of **the** last images we took before we landed on **the** comet. Here, you see **the** whole sequence again, but from a different perspective, and you see three blown-ups from **the** bottom-left to **the** middle of **the** lander traveling over **the surface** of **the** comet. Then, at **the** top, there is a before and an after image of **the** landing. **The** only problem with **the** after image is, there is no lander. But if you carefully look at **the right-hand** side of this image, we saw **the** lander still there, but it had bounced. It had departed again. Now, on a bit of a comical note here is that originally Rosetta was designed to have a lander which would bounce. That was **discarded** because it was way too expensive. Now, we forgot, but **the** lander knew. During **the** first bounce, in **the** magnetometers, you see here **the** data from them, from **the** three axes, x, y and z. Halfway through, you see a red line. At that red line, there is a change. What happened, apparently, is during **the** first bounce, somewhere, we hit **the** edge of a crater with one of **the** legs of **the** lander, and **the** rotation velocity of **the** lander changed. So we ’ ve been rather lucky that we are where we are. This is one of **the** iconic images of Rosetta. It ’ s a man-made **object**, a leg of **the** lander, standing on a comet. This, for me, is one of **the** very best images of space science I have ever seen. One of **the** things we still have to do is to actually find **the** lander. **The blue** area here is where we know it must be. We haven ’ t been able to find it yet, but **the search** is continuing, as are our efforts to start getting **the** lander to work again. We listen every day, and we hope that between now and somewhere in April, **the** lander will wake up again. **The** findings of what we found on **the** comet : This thing would float in water. It ’ s half **the** density of water. So it looks like a very big **rock**, but it ’ s not. **The** activity increase we saw in June, July, August last year was a four-fold activity increase. By **the** time we will be at **the** sun, there will be 100 kilos a second leaving this comet : gas, dust, whatever. That ’ s 100 million kilos a day. Then, finally, **the** landing day. I will never forget — absolute madness, 250 TV crews in Germany. **The** BBC was interviewing me, and another TV crew who was following me all day were filming me being interviewed, and it went on like that for **the** whole day. **The** Discovery Channel crew actually caught me when leaving **the** control room, and they asked **the** right question, and man, I got into tears, and I still feel this. For a month and a half, I couldn ’ t think about landing day without crying, and I still have **the** emotion in me. With this image of **the** comet, I would like to leave you. Thank you.

Text Sample 42: POS Dim 1 – 2013 – Score 23.00 – 2013/t002142.txt

Now, extinction is a different kind of death. It ’ s bigger. We didn ’ t really realize that until 1914, when **the** last passenger pigeon, a female named Martha, died at **the** Cincinnati zoo. This had been **the** most abundant bird in **the** world that ’ d been in North America for six million years. Suddenly it wasn ’ t here at all. Flocks that were a mile wide and 400 miles long used to darken **the** sun. Aldo Leopold said this was a biological storm, a feathered tempest. And indeed it was a keystone species that enriched **the** entire **eastern** deciduous forest, from **the** Mississippi to **the** Atlantic, from Canada down to **the** Gulf. But it went from five billion birds to zero in just a couple decades. What happened? Well, commercial hunting happened. These birds were hunted for meat that was sold by **the** ton, and it was easy to do because when those big flocks came down to **the** ground, they were so dense that hundreds of hunters and netters could show up and slaughter them by **the** tens of thousands. It was **the** cheapest source of protein in America. By **the** end of **the** century, there was nothing left but these beautiful skins in museum specimen drawers. There ’ s an upside to **the** story. This made people realize that **the** same thing was about to happen to **the** American bison, and so these birds saved **the** buffalos. But a lot of other animals weren ’ t saved. **The** Carolina parakeet was a parrot that lit up backyards everywhere. It was hunted to death for its feathers. There was a bird that people liked on **the** East Coast called **the** heath hen. It was loved. They tried to protect it. It died anyway. A local newspaper spelled out,”There is no survivor, there is no future, there is no life to be recreated in this form ever again.”There ’ s a sense of deep tragedy that goes with these things, and it happened to lots of birds that people loved. It happened to lots of mammals. Another keystone species is a **famous** animal called **the** European aurochs. There was sort of a movie made about it recently. And **the** aurochs was like **the** bison. This was an animal that basically kept **the** forest mixed with grasslands across **the** entire Europe and Asian **continent**, from Spain to Korea. **The** documentation of this animal goes back to **the** Lascaux cave paintings. **The** extinctions still go on. There ’ s an ibex in Spain called **the** bucardo. It went extinct in 2000. There was a marvelous animal, a marsupial wolf called **the** thylacine in Tasmania, south of Australia, called **the** Tasmanian **tiger**. It was hunted until there were just a few **left** to die in zoos. A little bit of film was shot. Sorrow, anger, mourning. Don ’ t mourn. Organize. What if you could find out that, using **the** DNA in museum specimens, **fossils** maybe up to 200, 000 years old could be used to bring species back, what would you do? Where would you start? Well, you ’ d start by finding out if **the** biotech is really there. I started with my wife, Ryan Phelan, who ran a biotech business called DNA Direct, and through her, one of her colleagues, George Church, one of **the** leading genetic engineers who turned out to be also obsessed with passenger pigeons and a lot of confidence that methodologies he was working on might actually do **the** deed. So he and Ryan organized and hosted a meeting at **the** Wyss Institute in Harvard bringing together specialists on passenger pigeons, conservation ornithologists, bioethicists, and fortunately passenger pigeon DNA had already been sequenced by a molecular biologist named Beth Shapiro. All she needed from those specimens at **the** Smithsonian was a little bit of toe pad tissue, because down in there is what is called ancient DNA. It ’ s DNA which is pretty badly fragmented, but with good **techniques** now, you can basically reassemble **the** whole **genome**. Then **the** question is, can you reassemble, with that **genome**, **the** whole bird? George Church thinks you can. So in his book,”Regenesis,”which I recommend, he has a chapter on **the** science of bringing back extinct species, and he has a machine called **the** Multiplex Automated **Genome** Engineering machine. It ’ s kind of like an **evolution** machine. You try combinations of genes that you write at **the** cell level and then in organs on a chip, and **the** ones that win, that you can then put into a living organism. It ’ ll work. **The** precision of this, one of George ’ s **famous** unreadable **slides**, nevertheless points out that there ’ s a level of precision here right down to **the** individual base pair. **The** passenger pigeon has 1. 3 billion base pairs in its **genome**. So what you ' re getting is **the** capability now of replacing one gene with another variation of that gene. It ' s called an allele. Well that ' s what happens in normal hybridization anyway. So this is a form of synthetic hybridization of **the genome** of an extinct species with **the genome** of its closest living **relative**. Now along **the** way, George points out that his technology, **the** technology of synthetic **biology**, is currently accelerating at four times **the** rate of Moore ' s Law. It ' s been doing that since 2005, and it ' s likely to continue. **Okay**, **the** closest living **relative** of **the** passenger pigeon is **the** band-tailed pigeon. They ' re abundant. There ' s some around here. Genetically, **the** band- tailed pigeon already is mostly living passenger pigeon. There ' s just some bits that are band-tailed pigeon. If you replace those bits with passenger pigeon bits, you ' ve got **the** extinct bird back, cooing at you. Now, there ' s work to do. You have to figure out exactly what genes matter. So there ' s genes for **the** short tail in **the** band-tailed pigeon, genes for **the** long tail in **the** passenger pigeon, and so on with **the** red eye, peach-colored breast, flocking, and so on. Add them all up and **the** result won ' t be perfect. But it should be be perfect enough, because nature doesn ' t do perfect either. So this meeting in Boston led to three things. First off, Ryan and I decided to create a nonprofit called Revive and Restore that would push de-extinction generally and try to have it go in a responsible way, and we would push ahead with **the** passenger pigeon. Another direct result was a young grad student named Ben Novak, who had been obsessed with passenger pigeons since he was 14 and had also learned how to work with ancient DNA, himself sequenced **the** passenger pigeon, using money from his family and friends. We hired him full-time. Now, this photograph I took of him last year at **the** Smithsonian, he ' s looking down at Martha, **the** last passenger pigeon alive. So if he ' s successful, she won ' t be **the** last. **The** third result of **the** Boston meeting was **the** realization that there are scientists all over **the** world working on various forms of de-extinction, but they ' d never met each other. And National Geographic got interested because National Geographic has **the** theory that **the** last century, discovery was basically finding things, and in this century, discovery is basically making things. De-extinction falls in that category. So they hosted and funded this meeting. And 35 scientists, they were conservation biologists and molecular biologists, basically meeting to see if they had work to do together. Some of these conservation biologists are pretty radical. There ' s three of them who are not just re-creating ancient species, they ' re recreating extinct ecosystems in northern Siberia, in **the** Netherlands, and in Hawaii. Henri, from **the** Netherlands, with a Dutch last name I won ' t try to pronounce, is working on **the** aurochs. **The** aurochs is **the** ancestor of all domestic cattle, and so basically its **genome** is alive, it ' s just unevenly distributed. So what they ' re doing is working with seven breeds of primitive, hardy-looking cattle like that Maremmana primitivo on **the** top there to rebuild, over time, with selective back-breeding, **the** aurochs. Now, re-wilding is moving faster in Korea than it is in America, and so **the** plan is, with these re-wilded areas all over Europe, they will introduce **the** aurochs to do its old job, its old ecological role, of clearing **the** somewhat barren, closed-canopy forest so that it has these biodiverse meadows in it. Another amazing story came from Alberto Fernndez-Arias. Alberto worked with **the** bucardo in Spain. **The** last bucardo was a female named Celia who was still alive, but then they captured her, they got a little bit of tissue from her ear, they cryopreserved it in liquid nitrogen, released her back into **the** wild, but a few months later, she was found dead under a fallen tree. They took **the** DNA from that ear, they planted it as a **cloned** egg in a goat, **the** pregnancy came to term, and a live baby bucardo was born. It was **the** first de-extinction in history. It was short-lived. Sometimes interspecies clones have respiration problems. This one had a malformed lung and died after 10 minutes, but Alberto was confident that **cloning** has moved along well since then, and this will move ahead, and eventually there will be a population of bucardos back in **the** mountains in northern Spain. Cryopreservation pioneer of great depth is Oliver Ryder. At **the** San Diego zoo, his frozen zoo has collected **the** tissues from over 1, 000 species over **the** last 35 years. Now, when it ’ s frozen that deep, minus 196 degrees Celsius, **the** cells are intact and **the** DNA is intact. They ’ re basically viable cells, so someone like Bob Lanza at Advanced Cell Technology took some of that tissue from an endangered animal called **the** Javan banteng, put it in a cow, **the** cow went to term, and what was born was a live, healthy baby Javan banteng, who thrived and is still alive. **The** most exciting thing for Bob Lanza is **the** ability now to take any kind of cell with induced pluripotent stem cells and turn it into germ cells, like sperm and eggs. So now we go to Mike McGrew who is a scientist at Roslin Institute in Scotland, and Mike ’ s doing miracles with birds. So he ’ ll take, say, falcon skin cells, fibroblast, turn it into induced pluripotent stem cells. Since it ’ s so pluripotent, it can become germ plasm. He then has a way to put **the** germ plasm into **the** embryo of a chicken egg so that that chicken will have, basically, **the** gonads of a falcon. You get a male and a female each of those, and out of them comes falcons. Real falcons out of slightly doctored chickens. Ben Novak was **the** youngest scientist at **the** meeting. He showed how all of this can be put together. **The** sequence of events : he ’ ll put together **the genomes** of **the** band-tailed pigeon and **the** passenger pigeon, he ’ ll take **the techniques** of George Church and get passenger pigeon DNA, **the techniques** of Robert Lanza and Michael McGrew, get that DNA into chicken gonads, and out of **the** chicken gonads get passenger pigeon eggs, squabs, and now you ’ re getting a population of passenger pigeons. It does raise **the** question of, they ’ re not going to have passenger pigeon parents to teach them how to be a passenger pigeon. So what do you do about that? Well birds are pretty hard-wired, as it happens, so most of that is already in their DNA, but to **supplement** it, part of Ben ’ s idea is to use homing pigeons to help train **the** young passenger pigeons how to flock and how to find their way to their old nesting grounds and **feeding** grounds. There were some conservationists, really **famous** conservationists like Stanley Temple, who is one of **the** founders of conservation **biology**, and Kate Jones from **the** IUCN, which does **the** Red List. They ’ re excited about all this, but they ’ re also concerned that it might be competitive with **the** extremely important efforts to protect endangered species that are still alive, that haven ’ t gone extinct yet. You see, you want to work on protecting **the** animals out there. You want to work on getting **the** market for ivory in Asia down so you ’ re not using 25, 000 **elephants** a year. But at **the** same time, conservation biologists are realizing that bad news bums people out. And so **the** Red List is really important, keep track of what ’ s endangered and critically endangered, and so on. But they ’ re about to create what they call a Green List, and **the** Green List will have species that are doing fine, thank you, species that were endangered, like **the** bald eagle, but they ’ re much better off now, thanks to everybody ’ s good work, and protected areas around **the** world that are very, very well managed. So basically, they ’ re **learning** how to build on good news. And they see reviving extinct species as **the** kind of good news you might be able to build on. Here ’ s a couple related examples. Captive breeding will be a major part of bringing back these species. **The** California condor was down to 22 birds in 1987. Everybody thought is was finished. Thanks to captive breeding at **the** San Diego Zoo, there ’ s 405 of them now, 226 are out in **the** wild. That technology will be used on de-extincted animals. Another success story is **the** mountain gorilla in Central Africa. In 1981, Dian Fossey was sure they were going extinct. There were just 254 **left**. Now there are 880. They ' re increasing in population by three percent a year. **The** secret is, they have an eco-tourism program, which is absolutely brilliant. So this photograph was taken last month by Ryan with an iPhone. That ' s how comfortable these wild gorillas are with visitors. Another interesting project, though it ' s going to need some help, is **the** northern white rhinoceros. There ' s no breeding pairs left. But this is **the** kind of thing that a wide variety of DNA for this animal is available in **the** frozen zoo. A bit of **cloning**, you can get them back. So where do we go from here? These have been private meetings so far. I think it ' s time for **the** subject to go public. What do people think about it? You know, do you want extinct species back? Do you want extinct species back? Tinker Bell is going to come fluttering down. It is a Tinker Bell moment, because what are people excited about with this? What are they concerned about? We ' re also going to push ahead with **the** passenger pigeon. So Ben Novak, even as we speak, is joining **the** group that Beth Shapiro has at UC Santa Cruz. They ' re going to work on **the genomes** of **the** passenger pigeon and **the** band-tailed pigeon. As that data matures, they ' ll send it to George Church, who will work his magic, get passenger pigeon DNA out of that. We ' ll get help from Bob Lanza and Mike McGrew to get that into germ plasm that can go into chickens that can produce passenger pigeon squabs that can be raised by band-tailed pigeon parents, and then from then on, it ' s passenger pigeons all **the** way, maybe for **the** next six million years. You can do **the** same thing, as **the** costs come down, for **the** Carolina parakeet, for **the** great auk, for **the** heath hen, for **the** ivory- billed woodpecker, for **the** Eskimo curlew, for **the** Caribbean **monk seal**, for **the** woolly mammoth. Because **the** fact is, humans have made a huge hole in nature in **the** last 10, 000 years. We have **the** ability now, and maybe **the** moral obligation, to repair some of **the** damage. Most of that we ' ll do by expanding and protecting wildlands, by expanding and protecting **the** populations of endangered species. But some species that we killed off totally we could consider bringing back to a world that misses them. Thank you. Chris Anderson : Thank you. I ' ve got a question. So, this is an emotional topic. Some people stand. I suspect there are some people out there sitting, kind of asking tormented questions, almost, about, well, wait, wait, wait, wait, wait, wait a minute, there ' s something wrong with mankind interfering in nature in this way. There ' s going to be unintended consequences. You ' re going to uncork some sort of Pandora ' s box of who-knows-what. Do they have a point? Stewart Brand : Well, **the** earlier point is we interfered in a big way by making these animals go extinct, and many of them were keystone species, and we changed **the** whole ecosystem they were in by letting them go. Now, there ' s **the** shifting baseline problem, which is, so when these things come back, they might replace some birds that are there that people really know and love. I think that ' s, you know, part of how it ' ll work. This is a long, slow process — One of **the** things I like about it, it ' s multi-generation. We will get woolly mammoths back. CA : Well it feels like both **the** conversation and **the** potential here are pretty thrilling. Thank you so much for presenting. SB : Thank you. CA : Thank you.

Text Sample 43: POS Dim 1 – 2013 – Score 21.00 – 2013/t001929.txt

Technology can change our understanding of nature. Take for example **the** case of **lions**. For centuries, it ' s been said that female **lions** do all of **the** hunting out in **the** open savanna, and male **lions** do nothing until it ' s time for dinner. You ’ ve heard this too, I can tell. Well recently, I led an airborne mapping campaign in **the** Kruger National Park in South Africa. Our colleagues put GPS tracking collars on male and female **lions**, and we mapped their hunting behavior from **the** air. **The** lower **left** shows a **lion** sizing up a herd of impala for a kill, and **the** right shows what I call **the lion** viewshed. That ’ s how far **the lion** can see in all directions until his or her view is obstructed by vegetation. And what we found is that male **lions** are not **the** lazy hunters we thought them to be. They just use a different strategy. Whereas **the** female **lions** hunt out in **the** open savanna over long distances, usually during **the** day, male **lions** use an ambush strategy in dense vegetation, and often at night. This video shows **the** actual hunting viewsheds of male **lions** on **the left** and females on **the** right. Red and darker colors show more dense vegetation, and **the** white are wide open spaces. And this is **the** viewshed right literally at **the** eye level of hunting male and female **lions**. All of a sudden, you get a very clear understanding of **the** very spooky conditions under which male **lions** do their hunting. I bring up this example to begin, because it emphasizes how little we know about nature. There ’ s been a huge amount of work done so far to try to slow down our losses of tropical forests, and we are losing our forests at a rapid rate, as shown in red on **the slide**. I find it ironic that we ’ re doing so much, yet these areas are fairly unknown to science. So how can we save what we don ’ t understand? Now I ’ m a global ecologist and an Earth explorer with a background in physics and **chemistry** and **biology** and a lot of other boring subjects, but above all, I ’ m obsessed with what we don ’ t know about our **planet**. So I created this, **the** Carnegie Airborne Observatory, or CAO. It may look like a plane with a fancy paint job, but I packed it with over 1, 000 kilos of high-tech sensors, **computers**, and a very motivated staff of Earth scientists and pilots. Two of our instruments are very unique : one is called an imaging spectrometer that can actually measure **the** chemical composition of plants as we fly over them. Another one is a set of lasers, very high-powered lasers, that fire out of **the** bottom of **the** plane, sweeping across **the** ecosystem and measuring it at nearly 500, 000 times per second in high-resolution 3D. Here ’ s an image of **the** Golden Gate Bridge in San Francisco, not far from where I live. Although we flew straight over this bridge, we imaged it in 3D, captured its color in just a few seconds. But **the** real power of **the** CAO is its ability to capture **the** actual building blocks of ecosystems. This is a small town in **the** Amazon, imaged with **the** CAO. We can slice through our data and see, for example, **the** 3D structure of **the** vegetation and **the** buildings, or we can use **the** chemical information to actually figure out how fast **the** plants are growing as we fly over them. **The** hottest pinks are **the** fastest-growing plants. And we can see biodiversity in ways that you never could have imagined. This is what a rainforest might look like as you fly over it in a hot air balloon. This is how we see a rainforest, in kaleidoscopic color that tells us that there are many species living with one another. But you have to remember that these trees are literally bigger than **whales**, and what that means is that they ’ re impossible to understand just by walking on **the** ground below them. So our imagery is 3D, it ’ s chemical, it ’ s biological, and this tells us not only **the** species that are living in **the** canopy, but it tells us a lot of information about **the** rest of **the** species that occupy **the** rainforest. Now I created **the** CAO in order to answer questions that have proven extremely challenging to answer from any other vantage point, such as from **the** ground, or from satellite sensors. I want to share three of those questions with you today. **The** first questions is, how do we manage our **carbon** reserves in tropical forests? Tropical forests contain a huge amount of **carbon** in **the** trees, and we need to keep that **carbon** in those forests if we ’ re going to avoid any further global warming. Unfortunately, global **carbon emissions** from deforestation now equals **the** global **transportation** sector. That ' s all ships, **airplanes**, trains and automobiles combined. So it ' s understandable that policy negotiators have been working hard to reduce deforestation, but they ' re doing it on landscapes that are hardly known to science. If you don ' t know where **the carbon** is exactly, in detail, how can you know what you ' re losing? Basically, we need a high-tech accounting system. With our system, we ' re able to see **the carbon** stocks of tropical forests in utter detail. **The** red shows, obviously, closed- canopy tropical forest, and then you see **the** cookie cutting, or **the** cutting of **the** forest in **yellows** and greens. It ' s like cutting a cake except this cake is about **whale** deep. And yet, we can zoom in and see **the** forest and **the** trees at **the** same time. And what ' s amazing is, even though we flew very high above this forest, later on in analysis, we can go in and actually experience **the** treetrops, leaf by leaf, branch by branch, just as **the** other species that live in this forest experience it along with **the** trees themselves. We ' ve been using **the** technology to explore and to actually put out **the** first **carbon** geographies in high resolution in faraway places like **the** Amazon Basin and not-so-faraway places like **the** United States and Central America. What I ' m going to do is I ' m going to take you on a high-resolution, first-time tour of **the carbon** landscapes of Peru and then Panama. **The** colors are going to be going from red to **blue**. Red is extremely high **carbon** stocks, your largest cathedral forests you can imagine, and **blue** are very low **carbon** stocks. And let me tell you, Peru alone is an amazing place, totally unknown in terms of its **carbon** geography until today. We can fly to this area in northern Peru and see super high **carbon** stocks in red, and **the** Amazon River and floodplain cutting right through it. We can go to an area of utter devastation caused by deforestation in **blue**, and **the** virus of deforestation spreading out in orange. We can also fly to **the** southern Andes to see **the** tree line and see exactly how **the carbon** geography ends as we go up into **the** mountain system. And we can go to **the** biggest swamp in **the** western Amazon. It ' s a watery dreamworld akin to Jim Cameron ' s"Avatar."We can go to one of **the** smallest tropical countries, Panama, and see also a huge range of **carbon** variation, from high in red to low in **blue**. Unfortunately, most of **the carbon** is lost in **the** lowlands, but what you see that ' s left, in terms of high **carbon** stocks in greens and reds, is **the** stuff that ' s up in **the** mountains. One interesting exception to this is right in **the** middle of your screen. You ' re seeing **the** buffer zone around **the** Panama Canal. That ' s in **the** reds and **yellows**. **The** canal authorities are using force to protect their watershed and global commerce. This kind of **carbon** mapping has transformed conservation and resource policy development. It ' s really advancing our ability to save forests and to curb climate change. My second question : How do we prepare for climate change in a place like **the** Amazon rainforest? Let me tell you, I spend a lot of time in these places, and we ' re seeing **the** climate changing already. Temperatures are increasing, and what ' s really happening is we ' re getting a lot of **droughts**, recurring **droughts**. **The** 2010 mega-drought is shown here with red showing an area about **the** size of Western Europe. **The** Amazon was so dry in 2010 that even **the** main stem of **the** Amazon river itself dried up partially, as you see in **the** photo in **the** lower portion of **the slide**. What we found is that in very remote areas, these **droughts** are having a big negative impact on tropical forests. For example, these are all of **the** dead trees in red that suffered mortality following **the** 2010 **drought**. This area happens to be on **the** border of Peru and Brazil, totally unexplored, almost totally unknown scientifically. So what we think, as Earth scientists, is species are going to have to migrate with climate change from **the** east in Brazil all **the** way west into **the** Andes and up into **the** mountains in order to minimize their exposure to climate change. One of **the** problems with this is that humans are taking apart **the** western Amazon as we speak. Look at this 100-square-kilometer gash in **the** forest created by gold miners. You see **the** forest in green in 3D, and you see **the** effects of gold mining down below **the** soil **surface**. Species have nowhere to migrate in a system like this, obviously. If you haven ' t been to **the** Amazon, you should go. It ' s an amazing experience every time, no matter where you go. You ' re going to probably see it this way, on a river. But what happens is a lot of times **the** rivers hide what ' s really going on back in **the** forest itself. We flew over this same river, imaged **the** system in 3D. **The** forest is on **the left**. And then we can digitally remove **the** forest and see what ' s going on below **the** canopy. And in this case, we found gold mining activity, all of it illegal, set back away from **the** river ' s edge, as you ' ll see in those strange pockmarks coming up on your screen on **the** right. Don ' t worry, we ' re working with **the** authorities to deal with this and many, many other problems in **the** region. So in order to put together a conservation plan for these unique, important corridors like **the** western Amazon and **the** Andes Amazon corridor, we have to start making geographically explicit plans now. How do we do that if we don ' t know **the** geography of biodiversity in **the** region, if it ' s so unknown to science? So what we ' ve been doing is using **the** laser-guided spectroscopy from **the** CAO to map for **the** first time **the** biodiversity of **the** Amazon rainforest. Here you see actual data showing different species in different colors. Reds are one type of species, **blues** are another, and greens are yet another. And when we take this together and scale up to **the** regional level, we get a completely new geography of biodiversity unknown prior to this work. This tells us where **the** big biodiversity changes **occur** from **habitat** to **habitat**, and that ' s really important because it tells us a lot about where species may migrate to and migrate from as **the** climate shifts. And this is **the** pivotal information that ' s needed by decision makers to develop protected areas in **the** context of their regional development plans. And third and final question is, how do we manage biodiversity on a **planet** of protected ecosystems? **The** example I started out with about **lions** hunting, that was a study we did behind **the** fence line of a protected area in South Africa. And **the** truth is, much of Africa ' s nature is going to persist into **the** future in protected areas like I show in **blue** on **the** screen. This puts incredible pressure and responsibility on park management. They need to do and make decisions that will benefit all of **the** species that they ' re protecting. Some of their decisions have really big impacts. For example, how much and where to use fire as a management tool? Or, how to deal with a large species like **elephants**, which may, if their populations get too large, have a negative impact on **the** ecosystem and on other species. And let me tell you, these types of dynamics really play out on **the** landscape. In **the** foreground is an area with lots of fire and lots of **elephants** : wide open savanna in **blue**, and just a few trees. As we cross this fence line, now we ' re getting into an area that has had protection from fire and zero **elephants** : dense vegetation, a radically different ecosystem. And in a place like Kruger, **the** soaring **elephant** densities are a real problem. I know it ' s a sensitive issue for many of you, and there are no easy answers with this. But what ' s good is that **the** technology we ' ve developed and we ' re working with in South Africa, for example, is allowing us to map every single tree in **the** savanna, and then through repeat flights we ' re able to see which trees are being pushed over by **elephants**, in **the** red as you see on **the** screen, and how much that ' s happening in different types of landscapes in **the** savanna. That ' s giving park managers a very first opportunity to use tactical management strategies that are more nuanced and don ' t lead to those extremes that I just showed you. So really, **the** way we ' re looking at protected areas nowadays is to think of it as tending to a circle of life, where we have fire management, **elephant** management, those impacts on **the** structure of **the** ecosystem, and then those impacts affecting everything from insects up to apex predators like **lions**. Going forward, I plan to greatly expand **the** airborne observatory. I ’ m hoping to actually put **the** technology into orbit so we can manage **the** entire **planet** with technologies like this. Until then, you ’ re going to find me flying in some remote place that you ’ ve never heard of. I just want to end by saying that technology is absolutely critical to managing our **planet**, but even more important is **the** understanding and wisdom to apply it. Thank you.

When I was a young man, I spent six years of wild adventure in **the** tropics working as an investigative journalist in some of **the** most bewitching parts of **the** world. I was as reckless and foolish as only young men can be. This is why wars get fought. But I also felt more alive than I ’ ve ever done since. And when I came home, I found **the** scope of my existence gradually diminishing until loading **the** dishwasher seemed like an interesting challenge. And I found myself sort of scratching at **the** walls of life, as if I was trying to find a way out into a wider space beyond. I was, I believe, ecologically bored. Now, we **evolved** in rather more challenging times than these, in a world of horns and tusks and fangs and claws. And we still possess **the** fear and **the** courage and **the** aggression required to navigate those times. But in our comfortable, safe, crowded lands, we have few opportunities to exercise them without harming other people. And this was **the** sort of constraint that I found myself bumping up against. To conquer uncertainty, to know what comes next, that ’ s almost been **the** dominant aim of industrialized societies, and having got there, or almost got there, we have just encountered a new set of unmet needs. We ’ ve privileged safety over experience and we ’ ve gained a lot in doing so, but I think we ’ ve lost something too. Now, I don ’ t romanticize **evolutionary** time. I ’ m already beyond **the** lifespan of most hunter-gatherers, and **the** outcome of a mortal combat between me myopically stumbling around with a stone-tipped spear and an enraged giant aurochs isn ’ t very hard to predict. Nor was it authenticity that I was looking for. I don ’ t find that a useful or even intelligible concept. I just wanted a richer and rawer life than I ’ ve been able to lead in Britain, or, indeed, that we can lead in most parts of **the** industrialized world. And it was only when I stumbled across an unfamiliar word that I began to understand what I was looking for. And as soon as I found that word, I realized that I wanted to devote much of **the** rest of my life to it. **The** word is”rewilding,”and even though rewilding is a young word, it already has several definitions. But there are two in particular that fascinate me. **The** first one is **the** mass restoration of ecosystems. One of **the** most exciting scientific findings of **the** past half century has been **the** discovery of widespread trophic cascades. A trophic cascade is an ecological process which starts at **the** top of **the** food chain and tumbles all **the** way down to **the** bottom, and **the** classic example is what happened in **the** Yellowstone National Park in **the** United States when wolves were reintroduced in 1995. Now, we all know that wolves kill various species of animals, but perhaps we ’ re slightly less aware that they give life to many others. It sounds strange, but just follow me for a while. Before **the** wolves turned up, they ’ d been absent for 70 years. **The** numbers of deer, because there was nothing to hunt them, had built up and built up in **the** Yellowstone Park, and despite efforts by humans to control them, they ’ d managed to reduce much of **the** vegetation there to almost nothing, they ’ d just grazed it away. But as soon as **the** wolves arrived, even though they were few in number, they started to have **the** most remarkable effects. First, of course, they killed some of **the** deer, but that wasn ' t **the** major thing. Much more significantly, they radically changed **the** behavior of **the** deer. **The** deer started avoiding certain parts of **the** park, **the** places where they could be trapped most easily, particularly **the** valleys and **the** gorges, and immediately those places started to regenerate. In some areas, **the** height of **the** trees quintupled in just six years. Bare valley sides quickly became forests of aspen and willow and cottonwood. And as soon as that happened, **the** birds started moving in. **The** number of songbirds, of migratory birds, started to increase greatly. **The** number of beavers started to increase, because beavers like to eat **the** trees. And beavers, like wolves, are ecosystem engineers. They create niches for other species. And **the** dams they built in **the** rivers provided **habitats** for otters and muskrats and ducks and **fish** and reptiles and amphibians. **The** wolves killed coyotes, and as a result of that, **the** number of rabbits and mice began to rise, which meant more hawks, more weasels, more foxes, more badgers. Ravens and bald eagles came down to feed on **the** carrion that **the** wolves had left. Bears fed on it too, and their population began to rise as well, partly also because there were more berries growing on **the** regenerating shrubs, and **the** bears reinforced **the** impact of **the** wolves by killing some of **the** calves of **the** deer. But here ' s where it gets really interesting. **The** wolves changed **the** behavior of **the** rivers. They began to meander less. There was less erosion. **The** channels narrowed. More pools formed, more riffle sections, all of which were great for wildlife **habitats**. **The** rivers changed in response to **the** wolves, and **the** reason was that **the** regenerating forests stabilized **the** banks so that they collapsed less often, so that **the** rivers became more fixed in their course. Similarly, by driving **the** deer out of some places and **the** vegetation recovering on **the** valley sides, there was less soil erosion, because **the** vegetation stabilized that as well. So **the** wolves, small in number, transformed not just **the** ecosystem of **the** Yellowstone National Park, this huge area of land, but also its physical geography. **Whales** in **the** southern oceans have similarly wide-ranging effects. One of **the** many post-rational excuses made by **the** Japanese government for killing **whales** is that they said,"Well, **the** number of **fish** and krill will rise and then there ' ll be more for people to eat."Well, it ' s a stupid excuse, but it sort of kind of makes sense, doesn ' t it, because you ' d think that **whales** eat huge amounts of **fish** and krill, so obviously take **the whales** away, there ' ll be more **fish** and krill. But **the** opposite happened. You take **the whales** away, and **the** number of krill collapses. Why would that possibly have happened? Well, it now turns out that **the whales** are crucial to sustaining that entire ecosystem, and one of **the** reasons for this is that they often feed at depth and then they come up to **the surface** and produce what biologists politely call large fecal plumes, huge **explosions** of poop right across **the surface** waters, up in **the** photic zone, where there ' s enough light to allow photosynthesis to take place, and those great plumes of fertilizer stimulate **the** growth of phytoplankton, **the** plant plankton at **the** bottom of **the** food chain, which stimulate **the** growth of zooplankton, which feed **the fish** and **the** krill and all **the** rest of it. **The** other thing that **whales** do is that, as they ' re plunging up and down through **the** water column, they ' re kicking **the** phytoplankton back up towards **the surface** where it can continue to survive and reproduce. And interestingly, well, we know that plant plankton in **the** oceans absorb **carbon** from **the** atmosphere — **the** more plant plankton there are, **the** more **carbon** they absorb — and eventually they filter down into **the abyss** and remove that **carbon** from **the** atmospheric system. Well, it seems that when **whales** were at their historic populations, they were probably responsible for sequestering some tens of millions of tons of **carbon** every year from **the** atmosphere. And when you look at it like that, you think, wait a minute, here are **the** wolves changing **the** physical geography of **the** Yellowstone National Park. Here are **the whales** changing **the** composition of **the** atmosphere. You begin to see that possibly, **the** evidence supporting James Lovelock ' s Gaia hypothesis, which conceives of **the** world as a coherent, self-regulating organism, is beginning, at **the** ecosystem level, to accumulate. Trophic cascades tell us that **the** natural world is even more fascinating and complex than we thought it was. They tell us that when you take away **the** large animals, you are left with a radically different ecosystem to one which retains its large animals. And they make, in my view, a powerful case for **the** reintroduction of missing species. Rewilding, to me, means bringing back some of **the** missing plants and animals. It means taking down **the** fences, it means blocking **the** drainage ditches, it means preventing commercial **fishing** in some large areas of **sea**, but otherwise stepping back. It has no view as to what a right ecosystem or a right assemblage of species looks like. It doesn ' t try to produce a heath or a meadow or a rain forest or a kelp garden or a coral reef. It lets nature decide, and nature, by and large, is pretty good at deciding. Now, I mentioned that there are two definitions of rewilding that interest me. **The** other one is **the** rewilding of human life. And I don ' t see this as an alternative to civilization. I believe we can **enjoy the** benefits of advanced technology, as we ' re doing now, but at **the** same time, if we choose, have access to a richer and wilder life of adventure when we want to because there would be wonderful, rewilded **habitats**. And **the** opportunities for this are developing more rapidly than you might think possible. There ' s one estimate which suggests that in **the** United States, two thirds of **the** land which was once forested and then cleared has become reforested as loggers and farmers have retreated, particularly from **the eastern** half of **the** country. There ' s another one which suggests that 30 million hectares of land in Europe, an area **the** size of Poland, will be vacated by farmers between 2000 and 2030. Now, faced with opportunities like that, does it not seem a little unambitious to be thinking only of bringing back wolves, lynx, bears, beavers, bison, boar, moose, and all **the** other species which are already beginning to move quite rapidly across Europe? Perhaps we should also start thinking about **the** return of some of our lost megafauna. What megafauna, you say? Well, every **continent** had one, apart from Antarctica. When Trafalgar Square in London was excavated, **the** river gravels there were found to be stuffed with **the** bones of hippopotamus, rhinos, **elephants**, hyenas, **lions**. Yes, ladies and gentlemen, there were **lions** in Trafalgar Square long before Nelson ' s Column was built. All these species lived here in **the** last interglacial period, when temperatures were pretty similar to our own. It ' s not climate, largely, which has got rid of **the** world ' s megafaunas. It ' s pressure from **the** human population hunting and destroying their **habitats** which has done so. And even so, you can still see **the** shadows of these great beasts in our current ecosystems. Why is it that so many deciduous trees are able to sprout from whatever point **the** trunk is broken? Why is it that they can withstand **the** loss of so much of their bark? Why do understory trees, which are subject to lower **sheer** forces from **the** wind and have to carry less weight than **the** big canopy trees, why are they so much tougher and harder to break than **the** canopy trees are? **Elephants**. They are elephant-adapted. In Europe, for example, they **evolved** to resist **the** straight-tusked **elephant**, elephas antiquus, which was a great beast. It was related to **the** Asian **elephant**, but it was a temperate animal, a temperate forest creature. It was a lot bigger than **the** Asian **elephant**. But why is it that some of our common shrubs have spines which seem to be over- engineered to resist browsing by deer? Perhaps because they **evolved** to resist browsing by rhinoceros. Isn ’ t it an amazing thought that every time you wander into a park or down an avenue or through a leafy street, you can see **the** shadows of these great beasts? Paleoecology, **the** study of past ecosystems, crucial to an understanding of our own, feels like a portal through which you may pass into an enchanted kingdom. And if we really are looking at areas of land of **the** sort of sizes I ’ ve been talking about becoming available, why not reintroduce some of our lost megafauna, or at least species closely related to those which have become extinct everywhere? Why shouldn ’ t all of us have a Serengeti on our doorsteps? And perhaps this is **the** most important thing that rewilding offers us, **the** most important thing that ’ s missing from our lives : hope. In motivating people to love and defend **the** natural world, an ounce of hope is worth a ton of despair. **The** story rewilding tells us is that ecological change need not always proceed in one direction. It offers us **the** hope that our silent **spring** could be replaced by a raucous summer. Thank you.

Text Sample 45: POS Dim 1 – 2014 – Score 25.00 – 2014/t001657.txt

On June 12, 2014, precisely at 3:33 in a balmy winter afternoon in SĂŁo Paulo, Brazil, a typical South American winter afternoon, this kid, this young man that you see celebrating here like he had scored a goal, Juliano Pinto, 29 years old, accomplished a magnificent deed. Despite being paralyzed and not having any sensation from mid-chest to **the** tip of his toes as **the** result of a car crash six years ago that killed his brother and produced a complete spinal cord lesion that left Juliano in a wheelchair, Juliano rose to **the** occasion, and on this day did something that pretty much everybody that saw him in **the** six years deemed impossible. Juliano Pinto delivered **the** opening kick of **the** 2014 Brazilian World Soccer Cup here just by thinking. He could not move his body, but he could imagine **the** movements needed to kick a ball. He was an athlete before **the** lesion. He ’ s a para-athlete right now. He ’ s going to be in **the** Paralympic Games, I hope, in a couple years. But what **the** spinal cord lesion did not rob from Juliano was his ability to dream. And dream he did that afternoon, for a stadium of about 75, 000 people and an audience of close to a billion watching on TV. And that kick crowned, basically, 30 years of basic research studying how **the** brain, how this amazing **universe** that we have between our ears that is only comparable to **universe** that we have above our head because it has about 100 billion elements talking to each other through **electrical** brainstorms, what Juliano accomplished took 30 years to imagine in laboratories and about 15 years to plan. When John Chapin and I, 15 years ago, proposed in a paper that we would build something that we called a brain-machine interface, meaning connecting a brain to **devices** so that animals and humans could just move these **devices**, no matter how far they are from their own bodies, just by imagining what they want to do, our colleagues told us that we actually needed professional help, of **the** psychiatry variety. And despite that, a Scot and a Brazilian persevered, because that ’ s how we were raised in our respective countries, and for 12, 15 years, we made demonstration after demonstration suggesting that this was possible. And a brain-machine interface is not rocket science, it ’ s just brain research. It ’ s nothing but using sensors to read **the** **electrical** brainstorms that a brain is producing to generate **the** motor commands that have to be downloaded to **the** spinal cord, so we projected sensors that can read hundreds and now thousands of these brain cells simultaneously, and extract from these **electrical** signals **the** motor planning that **the** brain is generating to actually make us move into space. And by doing that, we converted these signals into digital commands that any mechanical, electronic, or even a virtual **device** can understand so that **the** subject can imagine what he, she or it wants to make move, and **the device** obeys that brain command. By sensorizing these **devices** with lots of different types of sensors, as you are going to see in a moment, we actually sent messages back to **the** brain to confirm that that voluntary motor will was being enacted, no matter where â next to **the** subject, next door, or across **the planet**. And as this message gave feedback back to **the** brain, **the** brain realized its goal : to make us move. So this is just one experiment that we published a few years ago, where a monkey, without moving its body, learned to control **the** movements of an avatar arm, a virtual arm that doesn ’ t exist. What you ’ re listening to is **the** sound of **the** brain of this monkey as it explores three different visually **identical spheres** in virtual space. And to get a reward, a drop of orange juice that monkeys love, this animal has to **detect**, select one of these **objects** by touching, not by seeing it, by touching it, because every time this virtual hand touches one of **the objects**, an **electrical pulse** goes back to **the** brain of **the** animal describing **the** fine texture of **the surface** of this **object**, so **the** animal can judge what is **the** correct **object** that he has to grab, and if he does that, he gets a reward without moving a muscle. **The** perfect Brazilian lunch : not moving a muscle and getting your orange juice. So as we saw this happening, we actually came and proposed **the** idea that we had published 15 years ago. We reenacted this paper. We got it out of **the** drawers, and we proposed that perhaps we could get a human being that is paralyzed to actually use **the** brain-machine interface to regain mobility. **The** idea was that if you suffered â and that can happen to any one of us. Let me tell you, it ’ s very sudden. It ’ s a millisecond of a collision, a car accident that transforms your life completely. If you have a complete lesion of **the** spinal cord, you cannot move because your brainstorms cannot reach your muscles. However, your brainstorms continue to be generated in your head. Paraplegic, quadriplegic patients dream about moving every night. They have that inside their head. **The** problem is how to get that code out of it and make **the** movement be created again. So what we proposed was, let ’ s create a new body. Let ’ s create a robotic vest. And that ’ s exactly why Juliano could kick that ball just by thinking, because he was wearing **the** first brain-controlled robotic vest that can be used by paraplegic, quadriplegic patients to move and to regain feedback. That was **the** original idea, 15 years ago. What I ’ m going to show you is how 156 people from 25 countries all over **the** five **continents** of this beautiful Earth, dropped their lives, dropped their **patents**, dropped their dogs, wives, kids, school, jobs, and congregated to come to Brazil for 18 months to actually get this done. Because a couple years after Brazil was awarded **the** World Cup, we heard that **the** Brazilian government wanted to do something meaningful in **the** opening ceremony in **the** country that reinvented and perfected soccer until we met **the** Germans, of course. But that ’ s a different talk, and a different neuroscientist needs to talk about that. But what Brazil wanted to do is to showcase a completely different country, a country that values science and technology, and can give a gift to millions, 25 million people around **the** world that cannot move any longer because of a spinal cord injury. Well, we went to **the** Brazilian government and to FIFA and proposed, well, let ’ s have **the** kickoff of **the** 2014 World Cup be given by a Brazilian paraplegic using a brain- controlled exoskeleton that allows him to kick **the** ball and to feel **the** contact of **the** ball. They looked at us, thought that we were completely **nuts**, and said,”Okay, let ’ s try.”We had 18 months to do everything from zero, from scratch. We had no exoskeleton, we had no patients, we had nothing done. These people came all together and in 18 months, we got eight patients in a routine of training and basically built from nothing this guy, that we call Bra-Santos Dumont 1. **The** first brain-controlled exoskeleton to be built was named after **the** most **famous** Brazilian scientist ever, Alberto Santos Dumont, who, on October 19, 1901, created and flew himself **the** first controlled airship on air in Paris for a million people to see. Sorry, my American friends, I live in North Carolina, but it was two years before **the** Wright Brothers flew on **the** coast of North Carolina. Flight control is Brazilian. So we went together with these guys and we basically put this exoskeleton together, 15 degrees of freedom, hydraulic machine that can be commanded by brain signals recorded by a non-invasive technology called electroencephalography that can basically allow **the** patient to imagine **the** movements and send his commands to **the** controls, **the** motors, and get it done. This exoskeleton was covered with an **artificial** skin invented by Gordon Cheng, one of my greatest friends, in Munich, to allow sensation from **the** joints moving and **the** foot touching **the** ground to be delivered back to **the** patient through a vest, a shirt. It is a smart shirt with micro-vibrating elements that basically delivers **the** feedback and fools **the** patient ’ s brain by creating a sensation that it is not a machine that is carrying him, but it is he who is walking again. So we got this going, and what you ’ ll see here is **the** first time one of our patients, Bruno, actually walked. And he takes a few seconds because we are setting everything, and you are going to see a **blue** light cutting in front of **the** helmet because Bruno is going to imagine **the** movement that needs to be performed, **the computer** is going to analyze it, Bruno is going to certify it, and when it is certified, **the device** starts moving under **the** command of Bruno ’ s brain. And he just got it right, and now he starts walking. After nine years without being able to move, he is walking by himself. And more than that â â more than just walking, he is feeling **the** ground, and if **the** speed of **the** exo goes up, he tells us that he is walking again on **the** sand of Santos, **the** beach resort where he used to go before he had **the** accident. That ’ s why **the** brain is creating a new sensation in Bruno ’ s head. So he walks, and at **the** end of **the** walk â I am running out of time already â he says,”You know, guys, I need to borrow this thing from you when I get married, because I wanted to walk to **the** priest and see my bride and actually be there by myself. Of course, he will have it whenever he wants. And this is what we wanted to show during **the** World Cup, and couldn ’ t, because for some mysterious reason, FIFA cut its broadcast in half. What you are going to see very quickly is Juliano Pinto in **the** exo doing **the** kick a few minutes before we went to **the** pitch and did **the** real thing in front of **the** entire crowd, and **the** lights you are going to see just describe **the** operation. Basically, **the blue** lights pulsating indicate that **the** exo is ready to go. It can receive thoughts and it can deliver feedback, and when Juliano makes **the** decision to kick **the** ball, you are going to see two streams of green and **yellow** light coming from **the** helmet and going to **the** legs, representing **the** mental commands that were taken by **the** exo to actually make that happen. And in basically 13 seconds, Juliano actually did. You can see **the** commands. He gets ready, **the** ball is set, and he kicks. And **the** most amazing thing is, 10 seconds after he did that, and looked at us on **the** pitch, he told us, celebrating as you saw,”I felt **the** ball.”And that ’ s priceless. So where is this going to go? I have two minutes to tell you that it ’ s going to **the** limits of your imagination. Brain-actuating technology is here. This is **the** latest : We just published this a year ago, **the** first brain-to-brain interface that allows two animals to exchange mental messages so that one animal that sees something coming from **the** environment can send a mental SMS, a torpedo, a neurophysiological torpedo, to **the** second animal, and **the** second animal performs **the** act that he needed to perform without ever knowing what **the** environment was sending as a message, because **the** message came from **the** first animal ’ s brain. So this is **the** first demo. I ’ m going to be very quick because I want to show you **the** latest. But what you see here is **the** first rat getting informed by a light that is going to show up on **the left** of **the** cage that he has to press **the** left cage to basically get a reward. He goes there and does it. And **the** same time, he is sending a mental message to **the** second rat that didn ’ t see any light, and **the** second rat, in 70 percent of **the** times is going to press **the** left lever and get a reward without ever experiencing **the** light in **the** retina. Well, we took this to a little higher limit by getting monkeys to collaborate mentally in a brain net, basically to donate their brain activity and combine them to move **the** virtual arm that I showed you before, and what you see here is **the** first time **the** two monkeys combine their brains, synchronize their brains perfectly to get this virtual arm to move. One monkey is controlling **the** x **dimension**, **the** other monkey is controlling **the** y **dimension**. But it gets a little more interesting when you get three monkeys in there and you ask one monkey to control x and y, **the** other monkey to control y and z, and **the** third one to control x and z, and you make them all play **the** game together, moving **the** arm in 3D into a target to get **the famous** Brazilian orange juice. And they actually do. **The** black dot is **the** average of all these brains working in parallel, in real time. That is **the** definition of a biological **computer**, interacting by brain activity and achieving a motor goal. Where is this going? We have no idea. We ’ re just scientists. We are paid to be children, to basically go to **the** edge and discover what is out there. But one thing I know : One day, in a few decades, when our grandchildren **surf the** Net just by thinking, or a mother donates her eyesight to an autistic kid who cannot see, or somebody speaks because of a brain-to-brain bypass, some of you will remember that it all started on a winter afternoon in a Brazilian soccer field with an impossible kick. Thank you. Thank you. Bruno Giussani : Miguel, thank you for sticking to your time. I actually would have given you a couple more minutes, because there are a couple of points we want to develop, and, of course, clearly it seems that we need connected brains to figure out where this is going. So let ’ s connect all this together. So if I ’ m understanding correctly, one of **the** monkeys is actually getting a signal and **the** other monkey is reacting to that signal just because **the** first one is receiving it and transmitting **the** neurological impulse. Miguel Nicolelis : No, it ’ s a little different. No monkey knows of **the** existence of **the** other two monkeys. They are getting a visual feedback in 2D, but **the** task they have to accomplish is 3D. They have to move an arm in three **dimensions**. But each monkey is only getting **the** two **dimensions** on **the** video screen that **the** monkey controls. And to get that thing done, you need at least two monkeys to synchronize their brains, but **the** ideal is three. So what we found out is that when one monkey starts slacking down, **the** other two monkeys enhance their performance to get **the** guy to come back, so this adjusts dynamically, but **the** global synchrony remains **the** same. Now, if you flip without telling **the** monkey **the dimensions** that each brain has to control, like this guy is controlling x and y, but he should be controlling now y and z, instantaneously, that animal ’ s brain forgets about **the** old **dimensions** and it starts concentrating on **the** new **dimensions**. So what I need to say is that no Turing machine, no **computer** can predict what a brain net will do. So we will absorb technology as part of us. Technology will never absorb us. It ’ s simply impossible. BG : How many times have you tested this? And how many times have you succeeded versus failed? MN : Oh, tens of times. With **the** three monkeys? Oh, several times. I wouldn ’ t be able to talk about this here unless I had done it a few times. And I forgot to mention, because of time, that just three weeks ago, a European group just demonstrated **the** first man-to-man brain-to-brain connection. BG : And how does that play? MN : There was one bit of information â big ideas start in a humble way â but basically **the** brain activity of one subject was transmitted to a second **ob-**

ject, all non-invasive technology. So **the** first subject got a message, like our rats, a visual message, and transmitted it to **the** second subject. **The** second subject received a magnetic **pulse** in **the** visual cortex, or a different **pulse**, two different **pulses**. In one **pulse**, **the** subject saw something. On **the** other **pulse**, he saw something different. And he was able to verbally indicate what was **the** message **the** first subject was sending through **the** Internet across **continents**. Moderator : Wow. **Okay**, that ’ s where we are going. That ’ s **the** next TED Talk at **the** next conference. Miguel Nicolelis, thank you. MN : Thank you, Bruno. Thank you.

What ’ s **the** scariest thing you ’ ve ever done? Or another way to say it is, what ’ s **the** most dangerous thing that you ’ ve ever done? And why did you do it? I know what **the** most dangerous thing is that I ’ ve ever done because NASA does **the** math. You look back to **the** first five shuttle launches, **the** odds of a catastrophic event during **the** first five shuttle launches was one in nine. And even when I first flew in **the** shuttle back in 1995, 74 shuttle flight, **the** odds were still now that we look back about one in 38 or so — one in 35, one in 40. Not great odds, so it ’ s a really interesting day when you wake up at **the** Kennedy Space Center and you ’ re going to go to space that day because you realize by **the** end of **the** day you ’ re either going to be floating effortlessly, gloriously in space, or you ’ ll be dead. You go into, at **the** Kennedy Space Center, **the** suit-up room, **the** same room that our childhood heroes got dressed in, that Neil Armstrong and Buzz Aldrin got suited in to go ride **the** Apollo rocket to **the** moon. And I got my pressure suit built around me and rode down outside in **the** van heading out to **the** launchpad — in **the** Astro van — heading out to **the** launchpad, and as you come around **the** corner at **the** Kennedy Space Center, it ’ s normally predawn, and in **the** distance, lit up by **the** huge xenon lights, is your spaceship — **the** vehicle that is going to take you off **the planet**. **The** crew is sitting in **the** Astro van sort of hushed, almost holding hands, looking at that as it gets bigger and bigger. We ride **the** elevator up and we crawl in, on your hands and knees into **the** spaceship, one at a time, and you worm your way up into your chair and plunk yourself down on your back. And **the** hatch is closed, and suddenly, what has been a lifetime of both dreams and denial is becoming real, something that I dreamed about, in fact, that I chose to do when I was nine years old, is now suddenly within not too many minutes of actually happening. In **the** astronaut business — **the** shuttle is a very complicated vehicle ; it ’ s **the** most complicated flying machine ever built. And in **the** astronaut business, we have a saying, which is, there is no problem so bad that you can ’ t make it worse. And so you ’ re very conscious in **the** cockpit ; you ’ re thinking about all of **the** things that you might have to do, all **the** switches and all **the** wickets you have to go through. And as **the** time gets closer and closer, this excitement is building. And then about three and a half minutes before launch, **the** huge nozzles on **the** back, like **the** size of big church bells, swing back and forth and **the** mass of them is such that it sways **the** whole vehicle, like **the** vehicle is alive underneath you, like an **elephant** getting up off its knees or something. And then about 30 seconds before launch, **the** vehicle is completely alive — it is ready to go — **the** APUs are running, **the computers** are all self-contained, it ’ s ready to leave **the planet**. And 15 seconds before launch, this happens : Voice : 12, 11, 10, nine, eight, seven, six — — start, two, one, booster ignition, and liftoff of **the** space shuttle Discovery, returning to **the** space station, paving **the** way... Chris Hadfield : It is incredibly

powerful to be on board one of these things. You are in **the** grip of something that is vastly more powerful than yourself. It ’ s shaking you so hard you can ’ t focus on **the** instruments in front of you. It ’ s like you ’ re in **the** jaws of some enormous dog and there ’ s a foot in **the** small of your back pushing you into space, accelerating wildly straight up, shouldering your way through **the** air, and you ’ re in a very complex place — paying attention, watching **the** vehicle go through each one of its wickets with a steadily increasing smile on your face. After two minutes, those solid rockets explode off and then you just have **the** liquid engines, **the** hydrogen and oxygen, and it ’ s as if you ’ re in a dragster with your foot to **the** floor and accelerating like you ’ ve never accelerated. You get lighter and lighter, **the** force gets on us heavier and heavier. It feels like someone ’ s pouring cement on you or something. Until finally, after about eight minutes and 40 seconds or so, we are finally at exactly **the** right **altitude**, exactly **the** right speed, **the** right direction, **the** engine shut off, and we ’ re weightless. And we ’ re alive. It ’ s an amazing experience. But why would we take that risk? Why would you do something that dangerous? In my case **the** answer is fairly straightforward. I was inspired as a youngster that this was what I wanted to do. I watched **the** first people walk on **the** moon and to me, it was just an obvious thing — I want to somehow turn myself into that. But **the** real question is, how do you deal with **the** danger of it and **the** fear that comes from it? How do you deal with fear versus danger? And having **the** goal in mind, thinking about where it might lead, directed me to a life of looking at all of **the** small details to allow this to become possible, to be able to launch and go help build a space station where you are on board a million-pound creation that ’ s going around **the** world at five miles a second, eight kilometers a second, around **the** world 16 times a day, with experiments on board that are teaching us what **the** substance of **the universe** is made of and running 200 experiments inside. But maybe even more importantly, allowing us to see **the** world in a way that is impossible through any other means, to be able to look down and have — if your jaw could drop, it would — **the** jaw-dropping gorgeousness of **the** turning orb like a self-propelled art gallery of **fantastic**, constantly changing beauty that is **the** world itself. And you see, because of **the** speed, a sunrise or a sunset every 45 minutes for half a year. And **the** most magnificent part of all that is to go outside on a spacewalk. You are in a one-person spaceship that is your spacesuit, and you ’ re going through space with **the** world. It ’ s an entirely different perspective, you ’ re not looking up at **the universe**, you and **the** Earth are going through **the universe** together. And you ’ re holding on with one hand, looking at **the** world turn beside you. It ’ s roaring silently with color and texture as it pours by mesmerizingly next to you. And if you can tear your eyes away from that and you look under your arm down at **the** rest of everything, it ’ s unfathomable blackness, with a texture you feel like you could stick your hand into. and you are holding on with one hand, one link to **the** other seven billion people. And I was outside on my first spacewalk when my **left** eye went blind, and I didn ’ t know why. Suddenly my **left** eye slammed shut in great pain and I couldn ’ t figure out why my eye wasn ’ t working. I was thinking, what do I do next? I thought, well maybe that ’ s why we have two eyes, so I kept working. But unfortunately, without gravity, tears don ’ t fall. So you just get a bigger and bigger ball of whatever that is mixed with your tears on your eye until eventually, **the** ball becomes so big that **the surface** tension takes it across **the** bridge of your nose like a tiny little waterfall and goes”goosh”into your other eye, and now I was completely blind outside **the** spaceship. So what ’ s **the** scariest thing you ’ ve ever done? Maybe it ’ s **spiders**. A lot of people are afraid of **spiders**. I think you should be afraid of **spiders** — **spiders** are creepy and they ’ ve got long, hairy legs, and

spiders like this one, **the** brown recluse — it ’ s horrible. If a brown recluse **bites** you, you end with one of these horrible, big necrotic things on your leg and there might be one right now sitting on **the** chair behind you, in fact. And how do you know? And so a **spider** lands on you, and you go through this great, spasmy attack because **spiders** are scary. But then you could say, well is there a brown recluse sitting on **the** chair beside me or not? I don ’ t know. Are there brown recluses here? So if you actually do **the** research, you find out that in **the** world there are about 50, 000 different types of **spiders**, and there are about two dozen that are venomous out of 50, 000. And if you ’ re in Canada, because of **the** cold winters here in B. C., there ’ s about 720, 730 different types of **spiders** and there ’ s one — one — that is venomous, and its venom isn ’ t even fatal, it ’ s just kind of like a nasty sting. And that **spider** — not only that, but that **spider** has beautiful markings on it, it ’ s like”I ’ m dangerous. I got a big radiation symbol on my back, it ’ s **the** black widow.”So, if you ’ re even slightly careful you can avoid running into **the** one **spider** — and it lives close **the** ground, you ’ re walking along, you are never going to go through a **spider web** where a black widow **bites** you. **Spider webs** like this, it doesn ’ t build those, it builds them down in **the** corners. And its a black widow because **the** female **spider** eats **the** male ; it doesn ’ t care about you. So in fact, **the** next time you walk into a spiderweb, you don ’ t need to panic and go with your caveman reaction. **The** danger is entirely different than **the** fear. How do you get around it, though? How do you change your behavior? Well, next time you see a spiderweb, have a good look, make sure it ’ s not a black widow **spider**, and then walk into it. And then you see another spiderweb and walk into that one. It ’ s just a little bit of fluffy stuff. It ’ s not a big deal. And **the spider** that may come out is no more threat to you than a lady bug or a butterfly. And then I guarantee you if you walk through 100 spiderwebs you will have changed your fundamental human behavior, your caveman reaction, and you will now be able to walk in **the** park in **the** morning and not worry about that spiderweb — or into your grandma ’ s attic or whatever, into your own basement. And you can apply this to anything. If you ’ re outside on a spacewalk and you ’ re blinded, your natural reaction would be to panic, I think. It would make you nervous and worried. But we had considered all **the** venom, and we had practiced with a whole variety of different spiderwebs. We knew everything there is to know about **the** spacesuit and we trained **underwater** thousands of times. And we don ’ t just practice things going right, we practice things going wrong all **the** time, so that you are constantly walking through those spiderwebs. And not just **underwater**, but also in virtual reality labs with **the** helmet and **the** gloves so you feel like it ’ s realistic. So when you finally actually get outside on a spacewalk, it feels much different than it would if you just went out first time. And even if you ’ re blinded, your natural, panicky reaction doesn ’ t happen. Instead you kind of look around and go,”Okay, I can ’ t see, but I can hear, I can talk, Scott Parazynski is out here with me. He could come over and help me.”We actually practiced incapacitated crew rescue, so he could float me like a blimp and stuff me into **the** airlock if he had to. I could find my own way back. It ’ s not nearly as big a deal. And actually, if you keep on crying for a while, whatever that gunk was that ’ s in your eye starts to dilute and you can start to see again, and Houston, if you negotiate with them, they will let you then keep working. We finished everything on **the** spacewalk and when we came back inside, Jeff got some cotton batting and took **the** crusty stuff around my eyes, and it turned out it was just **the** anti-fog, sort of a mixture of **oil** and soap, that got in my eye. And now we use Johnson ’ s No More Tears, which we probably should ’ ve been using right from **the** very beginning. But **the** key to that is by looking at **the** difference between perceived danger and actual danger, where is **the** real risk? What is **the** real thing that you should be afraid of? Not just a generic fear of bad things happening. You can fundamentally change your reaction to things so that it allows you to go places and see things and do things that otherwise would be completely denied to you... where you could see **the** hardpan south of **the** Sahara, or you can see New York City in a way that is almost dreamlike, or **the** unconscious gingham of Eastern Europe fields or **the** Great Lakes as a **collection** of small puddles. You can see **the** fault lines of San Francisco and **the** way **the** water pours out under **the** bridge, just entirely different than any other way that you could have if you had not found a way to conquer your fear. You see a beauty that otherwise never would have happened. It ’ s time to come home at **the** end. This is our spaceship, **the** Soyuz, that little one. Three of us climb in, and then this spaceship detaches from **the** station and falls into **the** atmosphere. These two parts here actually melt, we jettison them and they burn up in **the** atmosphere. **The** only part that survives is **the** little **bullet** that we ’ re riding in, and it falls into **the** atmosphere, and in essence you are riding a meteorite home, and riding meteorites is scary, and it ought to be. But instead of riding into **the** atmosphere just screaming, like you would if suddenly you found yourself riding a meteorite back to Earth — — instead, 20 years previously we had started studying Russian, and then once you learn Russian, then we learned orbital mechanics in Russian, and then we learned vehicle control theory, and then we got into **the** simulator and practiced over and over and over again. And in fact, you can fly this meteorite and steer it and land in about a 15-kilometer circle anywhere on **the** Earth. So in fact, when our crew was coming back into **the** atmosphere inside **the** Soyuz, we weren ’ t screaming, we were laughing ; it was fun. And when **the** great big parachute opened, we knew that if it didn ’ t open there ’ s a second parachute, and it runs on a nice little clockwork mechanism. So we came back, we came thundering back to Earth and this is what it looked like to land in a Soyuz, in Kazakhstan. Reporter : And you can see one of those **search** and recovery helicopters, once again that helicopter part of dozen such Russian Mi- 8 helicopters. Touchdown — 3:14 and 48 seconds, a. m. Central Time. CH : And you roll to a stop as if someone threw your spaceship at **the** ground and it tumbles end over end, but you ’ re ready for it you ’ re in a custom-built seat, you know how **the** shock absorber works. And then eventually **the** Russians reach in, drag you out, plunk you into a chair, and you can now look back at what was an incredible experience. You have taken **the** dreams of that nine-year-old boy, which were impossible and dauntingly scary, dauntingly **terrifying**, and put them into practice, and figured out a way to reprogram yourself, to change your primal fear so that it allowed you to come back with a set of experiences and a level of inspiration for other people that never could have been possible otherwise. Just to finish, they asked me to play that guitar. I know this song, and it ’ s really a tribute to **the** genius of David Bowie himself, but it ’ s also, I think, a reflection of **the** fact that we are not machines exploring **the universe**, we are people, and we ’ re taking that ability to adapt and that ability to understand and **the** ability to take our own self-perception into a new place. — This is Major Tom to ground control — — I ’ ve left forevermore — — And I ’ m floating in a most **peculiar** way — — And **the** stars look very different today — — For here am I floating in **the** tin can — — A last glimpse of **the** world — — Planet Earth is **blue** and there ’ s so much left to do — Fear not. That ’ s very nice of you. Thank you very much. Thank you.

Text Sample 47: POS Dim 1 – 2014 – Score 18.00 – 2014/t001794.txt

Every day we face issues like climate change or **the** safety of vaccines where we have to answer questions whose answers rely heavily on scientific information. Scientists tell us that **the** world is warming. Scientists tell us that vaccines are safe. But how do we know if they are right? Why should be believe **the** science? **The** fact is, many of us actually don ’ t believe **the** science. Public opinion polls consistently show that significant proportions of **the** American people don ’ t believe **the** climate is warming due to human activities, don ’ t think that there is **evolution** by natural **selection**, and aren ’ t persuaded by **the** safety of vaccines. So why should we believe **the** science? Well, scientists don ’ t like talking about science as a matter of belief. In fact, they would contrast science with faith, and they would say belief is **the** domain of faith. And faith is a separate thing apart and distinct from science. Indeed they would say religion is based on faith or maybe **the** calculus of Pascal ’ s wager. Blaise Pascal was a 17th-century mathematician who tried to bring scientific reasoning to **the** question of whether or not he should believe in God, and his wager went like this : Well, if God doesn ’ t exist but I decide to believe in him nothing much is really lost. Maybe a few hours on Sunday. But if he does exist and I don ’ t believe in him, then I ’ m in deep trouble. And so Pascal said, we ’ d better believe in God. Or as one of my college professors said,”He clutched for **the** handrail of faith.”He made that leap of faith leaving science and rationalism behind. Now **the** fact is though, for most of us, most scientific claims are a leap of faith. We can ’ t really judge scientific claims for ourselves in most cases. And indeed this is actually true for most scientists as well outside of their own specialties. So if you think about it, a geologist can ’ t tell you whether a vaccine is safe. Most chemists are not experts in **evolutionary** theory. A physicist cannot tell you, despite **the** claims of some of them, whether or not tobacco causes cancer. So, if even scientists themselves have to make a leap of faith outside their own fields, then why do they accept **the** claims of other scientists? Why do they believe each other ’ s claims? And should we believe those claims? So what I ’ d like to argue is yes, we should, but not for **the** reason that most of us think. Most of us were taught in school that **the** reason we should believe in science is because of **the** scientific method. We were taught that scientists follow a method and that this method guarantees **the** truth of their claims. **The** method that most of us were taught in school, we can call it **the textbook** method, is **the** hypothetical deductive method. According to **the** standard model, **the textbook** model, scientists develop hypotheses, they deduce **the** consequences of those hypotheses, and then they go out into **the** world and they say,”Okay, well are those consequences true?”Can we observe them taking place in **the** natural world? And if they are true, then **the** scientists say,”Great, we know **the** hypothesis is correct.”So there are many **famous** examples in **the** history of science of scientists doing exactly this. One of **the** most **famous** examples comes from **the** work of Albert Einstein. When Einstein developed **the** theory of general relativity, one of **the** consequences of his theory was that space-time wasn ’ t just an empty void but that it actually had a fabric. And that that fabric was bent in **the** presence of massive **objects** like **the** sun. So if this theory were true then it meant that light as it passed **the** sun should actually be bent around it. That was a pretty startling prediction and it took a few years before scientists were able to test it but they did test it in 1919, and lo and behold it turned out to be true. Starlight actually does bend as it travels around **the** sun. This was a huge confirmation of **the** theory. It was considered proof of **the** truth of this radical new idea, and it was written up in many newspapers around **the** globe. Now, sometimes this theory or this model is referred to as **the** deductive- nomological model, mainly because academics like to make things complicated. But also because in **the** ideal case, it ’ s about laws. So nomological means having to do with laws. And in **the** ideal case, **the** hypothesis isn ' t just an idea : ideally, it is a law of nature. Why does it matter that it is a law of nature? Because if it is a law, it can ' t be broken. If it ' s a law then it will always be true in all times and all places no matter what **the** circumstances are. And all of you know of at least one example of a **famous** law : Einstein ' s **famous** equation, E=MC2, which tells us what **the** relationship is between energy and mass. And that relationship is true no matter what. Now, it turns out, though, that there are several problems with this model. **The** main problem is that it ' s wrong. It ' s just not true. And I ' m going to talk about three reasons why it ' s wrong. So **the** first reason is a logical reason. It ' s **the** problem of **the** fallacy of affirming **the** consequent. So that ' s another fancy, academic way of saying that false theories can make true predictions. So just because **the** prediction comes true doesn ' t actually logically prove that **the** theory is correct. And I have a good example of that too, again from **the** history of science. This is a picture of **the** Ptolemaic **universe** with **the** Earth at **the** center of **the universe** and **the** sun and **the planets** going around it. **The** Ptolemaic model was believed by many very smart people for many centuries. Well, why? Well **the** answer is because it made lots of predictions that came true. **The** Ptolemaic system enabled astronomers to make accurate predictions of **the** motions of **the planet**, in fact more accurate predictions at first than **the** Copernican theory which we now would say is true. So that ' s one problem with **the textbook** model. A second problem is a practical problem, and it ' s **the** problem of auxiliary hypotheses. Auxiliary hypotheses are assumptions that scientists are making that they may or may not even be aware that they ' re making. So an important example of this comes from **the** Copernican model, which ultimately replaced **the** Ptolemaic system. So when Nicolaus Copernicus said, actually **the** Earth is not **the** center of **the universe**, **the** sun is **the** center of **the** solar system, **the** Earth moves around **the** sun. Scientists said, well **okay**, Nicolaus, if that ' s true we ought to be able to **detect the** motion of **the** Earth around **the** sun. And so this **slide** here illustrates a concept known as stellar parallax. And astronomers said, if **the** Earth is moving and we look at a prominent star, let ' s say, Sirius — well I know I ' m in Manhattan so you guys can ' t see **the** stars, but imagine you ' re out in **the** country, imagine you chose that rural life — and we look at a star in December, we see that star against **the** backdrop of distant stars. If we now make **the** same observation six months later when **the** Earth has moved to this position in June, we look at that same star and we see it against a different backdrop. That difference, that angular difference, is **the** stellar parallax. So this is a prediction that **the** Copernican model makes. Astronomers looked for **the** stellar parallax and they found nothing, nothing at all. And many people argued that this proved that **the** Copernican model was false. So what happened? Well, in hindsight we can say that astronomers were making two auxiliary hypotheses, both of which we would now say were incorrect. **The** first was an assumption about **the** size of **the** Earth ' s orbit. Astronomers were assuming that **the** Earth ' s orbit was large **relative** to **the** distance to **the** stars. Today we would draw **the** picture more like this, this comes from NASA, and you see **the** Earth ' s orbit is actually quite small. In fact, it ' s actually much smaller even than shown here. **The** stellar parallax therefore, is very small and actually very hard to **detect**. And that leads to **the** second reason why **the** prediction didn ' t work, because scientists were also assuming that **the** telescopes they had were sensitive enough to **detect the** parallax. And that turned out not to be true. It wasn ' t until **the** 19th century that scientists were able to **detect the** stellar parallax. So, there ' s a third problem as well. **The** third problem is simply a factual problem, that a lot of science doesn ' t fit **the textbook** model. A lot of science isn ’ t deductive at all, it ’ s actually inductive. And by that we mean that scientists don ’ t necessarily start with theories and hypotheses, often they just start with observations of stuff going on in **the** world. And **the** most **famous** example of that is one of **the** most **famous** scientists who ever lived, Charles Darwin. When Darwin went out as a young man on **the** voyage of **the** Beagle, he didn ’ t have a hypothesis, he didn ’ t have a theory. He just knew that he wanted to have a career as a scientist and he started to collect data. Mainly he knew that he hated medicine because **the** sight of **blood** made him sick so he had to have an alternative career path. So he started collecting data. And he collected many things, including his **famous** finches. When he collected these finches, he threw them in a bag and he had no idea what they meant. Many years later back in London, Darwin looked at his data again and began to develop an explanation, and that explanation was **the** theory of natural **selection**. Besides inductive science, scientists also often participate in modeling. One of **the** things scientists want to do in life is to explain **the** causes of things. And how do we do that? Well, one way you can do it is to build a model that tests an idea. So this is a picture of Henry Cadell, who was a Scottish geologist in **the** 19th century. You can tell he ’ s Scottish because he ’ s wearing a deerstalker cap and Wellington boots. And Cadell wanted to answer **the** question, how are mountains formed? And one of **the** things he had observed is that if you look at mountains like **the** Appalachians, you often find that **the rocks** in them are folded, and they ’ re folded in a particular way, which suggested to him that they were actually being compressed from **the** side. And this idea would later play a major role in discussions of continental drift. So he built this model, this crazy contraption with levers and wood, and here ’ s his wheelbarrow, buckets, a big sledgehammer. I don ’ t know why he ’ s got **the** Wellington boots. Maybe it ’ s going to rain. And he created this physical model in order to demonstrate that you could, in fact, create patterns in **rocks**, or at least, in this case, in mud, that looked a lot like mountains if you compressed them from **the** side. So it was an argument about **the** cause of mountains. Nowadays, most scientists prefer to work inside, so they don ’ t build physical models so much as to make **computer** simulations. But a **computer** simulation is a kind of a model. It ’ s a model that ’ s made with mathematics, and like **the** physical models of **the** 19th century, it ’ s very important for thinking about causes. So one of **the** big questions to do with climate change, we have tremendous amounts of evidence that **the** Earth is warming up. This **slide** here, **the** black line shows **the** measurements that scientists have taken for **the** last 150 years showing that **the** Earth ’ s temperature has steadily increased, and you can see in particular that in **the** last 50 years there ’ s been this dramatic increase of nearly one degree centigrade, or almost two degrees Fahrenheit. So what, though, is driving that change? How can we know what ’ s causing **the** observed warming? Well, scientists can model it using a **computer** simulation. So this diagram illustrates a **computer** simulation that has looked at all **the** different factors that we know can influence **the** Earth ’ s climate, so sulfate particles from air pollution, volcanic dust from volcanic eruptions, changes in solar radiation, and, of course, **greenhouse** gases. And they asked **the** question, what set of variables put into a model will reproduce what we actually see in real life? So here is **the** real life in black. Here ’ s **the** model in this light gray, and **the** answer is a model that includes, it ’ s **the** answer E on that SAT, all of **the** above. **The** only way you can reproduce **the** observed temperature measurements is with all of these things put together, including **greenhouse** gases, and in particular you can see that **the** increase in **greenhouse** gases tracks this very dramatic increase in temperature over **the** last 50 years. And so this is why climate scientists say it ’ s not just that we know that climate change is happening, we know that **greenhouse** gases are a major part of **the** reason why. So now because there all these different things that scientists do, **the** philosopher Paul Feyerabend famously said,"**The** only principle in science that doesn ' t inhibit progress is : anything goes."Now this quotation has often been taken out of context, because Feyerabend was not actually saying that in science anything goes. What he was saying was, actually **the** full quotation is,"If you press me to say what is **the** method of science, I would have to say : anything goes."What he was trying to say is that scientists do a lot of different things. Scientists are creative. But then this pushes **the** question back : If scientists don ' t use a single method, then how do they decide what ' s right and what ' s wrong? And who judges? And **the** answer is, scientists judge, and they judge by judging evidence. Scientists collect evidence in many different ways, but however they collect it, they have to subject it to scrutiny. And this led **the** sociologist Robert Merton to focus on this question of how scientists scrutinize data and evidence, and he said they do it in a way he called"organized skepticism."And by that he meant it ' s organized because they do it collectively, they do it as a group, and skepticism, because they do it from a position of distrust. That is to say, **the** burden of proof is on **the** person with a novel claim. And in this sense, science is intrinsically conservative. It ' s quite hard to persuade **the** scientific community to say,"Yes, we know something, this is true."So despite **the** popularity of **the** concept of paradigm shifts, what we find is that actually, really major changes in scientific thinking are relatively rare in **the** history of science. So finally that brings us to one more idea : If scientists judge evidence collectively, this has led historians to focus on **the** question of consensus, and to say that at **the** end of **the** day, what science is, what scientific knowledge is, is **the** consensus of **the** scientific experts who through this process of organized scrutiny, collective scrutiny, have judged **the** evidence and come to a conclusion about it, either yea or nay. So we can think of scientific knowledge as a consensus of experts. We can also think of science as being a kind of a jury, except it ' s a very special kind of jury. It ' s not a jury of your peers, it ' s a jury of **geeks**. It ' s a jury of men and women with Ph. D. s, and unlike a conventional jury, which has only two choices, guilty or not guilty, **the** scientific jury actually has a number of choices. Scientists can say yes, something ' s true. Scientists can say no, it ' s false. Or, they can say, well it might be true but we need to work more and collect more evidence. Or, they can say it might be true, but we don ' t know how to answer **the** question and we ' re going to put it aside and maybe we ' ll come back to it later. That ' s what scientists call"intractable."But this leads us to one final problem : If science is what scientists say it is, then isn ' t that just an appeal to authority? And weren ' t we all taught in school that **the** appeal to authority is a logical fallacy? Well, here ' s **the** paradox of modern science, **the** paradox of **the** conclusion I think historians and philosophers and sociologists have come to, that actually science is **the** appeal to authority, but it ' s not **the** authority of **the** individual, no matter how smart that individual is, like Plato or Socrates or Einstein. It ' s **the** authority of **the** collective community. You can think of it is a kind of wisdom of **the** crowd, but a very special kind of crowd. Science does appeal to authority, but it ' s not based on any individual, no matter how smart that individual may be. It ' s based on **the** collective wisdom, **the** collective knowledge, **the** collective work, of all of **the** scientists who have worked on a particular problem. Scientists have a kind of culture of collective distrust, this"show me"culture, illustrated by this nice woman here showing her colleagues her evidence. Of course, these people don ' t really look like scientists, because they ' re much too happy. **Okay**, so that brings me to my final point. Most of us get up in **the** morning. Most of us trust our cars. Well, see, now I ' m thinking, I ' m in Manhattan, this is a bad analogy, but most Americans who don ’ t live in Manhattan get up in **the** morning and get in their cars and turn on that ignition, and their cars work, and they work incredibly well. **The** modern automobile hardly ever breaks down. So why is that? Why do cars work so well? It ’ s not because of **the** genius of Henry Ford or Karl Benz or even Elon Musk. It ’ s because **the** modern automobile is **the** product of more than 100 years of work by hundreds and thousands and tens of thousands of people. **The** modern automobile is **the** product of **the** collected work and wisdom and experience of every man and woman who has ever worked on a car, and **the** reliability of **the** technology is **the** result of that accumulated effort. We benefit not just from **the** genius of Benz and Ford and Musk but from **the** collective intelligence and hard work of all of **the** people who have worked on **the** modern car. And **the** same is true of science, only science is even older. Our basis for trust in science is actually **the** same as our basis in trust in technology, and **the** same as our basis for trust in anything, namely, experience. But it shouldn ’ t be blind trust any more than we would have blind trust in anything. Our trust in science, like science itself, should be based on evidence, and that means that scientists have to become better communicators. They have to explain to us not just what they know but how they know it, and it means that we have to become better listeners. Thank you very much.

Text Sample 48: POS Dim 1 – 2024 – Score 20.00 – 2024/t003227.txt

Chris Anderson : Demis, so good to have you here. Demis Hassabis : It ’ s **fantastic** to be here, thanks, Chris. Now, you told Time Magazine,”I want to understand **the** big questions, **the** really big ones that you normally go into philosophy or physics if you ’ re interested in them. I thought building AI would be **the** fastest route to answer some of those questions.”Why did you think that? DH : Well, I guess when I was a kid, my favorite subject was physics, and I was interested in all **the** big questions, fundamental nature of reality, what is consciousness, you know, all **the** big ones. And usually you go into physics, if you ’ re interested in that. But I read a lot of **the** great physicists, some of my all-time scientific heroes like Feynman and so on. And I realized, in **the** last, sort of 20, 30 years, we haven ’ t made much progress in understanding some of these fundamental laws. So I thought, why not build **the** ultimate tool to help us, which is **artificial** intelligence. And at **the** same time, we could also maybe better understand ourselves and **the** brain better, by doing that too. So not only was it incredible tool, it was also useful for some of **the** big questions itself. CA : Super interesting. So obviously AI can do so many things, but I think for this conversation, I ’ d love to focus in on this **theme** of what it might do to **unlock the** really big questions, **the** giant scientific breakthroughs, because it ’ s been such a **theme** driving you and your company. DH : So I mean, one of **the** big things AI can do, and I ’ ve always thought about, is we ’ re getting, you know, even back 20, 30 years ago, **the** beginning of **the** internet era and **computer** era, **the** amount of data that was being produced and also scientific data, just too much for **the** human mind to comprehend in many cases. And I think one of **the** uses of AI is to find patterns and insights in huge amounts of data and then **surface** that to **the** human scientists to make sense of and make new hypotheses and conjectures. So it seems to me very compatible with **the** scientific method. CA : Right. But game play has played a huge role in your own journey in figuring this thing out. Who is this young lad on **the left** there? Who is that? DH : So that was me, I think I must have been about around nine years old. I ’ m captaining **the** England Under 11 team, and we ’ re playing in a Four Nations tournament, that ’ s why we ’ re all in red. I think we ’ re playing France, Scotland and Wales, I think it was. CA : That is so weird, because that happened to me too. In my dreams. And it wasn ’ t just chess, you loved all kinds of games. DH : I loved all kinds of games, yeah. CA : And when you launched DeepMind, pretty quickly, you started having it tackle game play. Why? DH : Well, look, I mean, games actually got me into AI in **the** first place because while we were doing things like, we used to go on training camps with **the** England team and so on. And actually back then, I guess it was in **the** mid ’ 80s, we would use **the** very early chess **computers**, if you remember them, to train against, as well as playing against each other. And they were big lumps of plastic, you know, physical boards that you used to, some of you remember, used to actually press **the** squares down and there were LED lights, came on. And I remember actually, not just thinking about **the** chess, I was actually just fascinated by **the** fact that this lump of plastic, someone had programmed it to be smart and actually play chess to a really high standard. And I was just amazed by that. And that got me thinking about thinking. And how does **the** brain come up with these thought processes, these ideas, and then maybe how we could mimic that with **computers**. So yeah, it ’ s been a whole **theme** for my whole life, really. CA : But you raised all this money to launch DeepMind, and pretty soon you were using it to do, for example, this. I mean, this is an odd use of it. What was going on here? DH : Well, we started off with games at **the** beginning of DeepMind. This was back in 2010, so this is from about 10 years ago, it was our first big breakthrough. Because we started off with classic Atari games from **the** 1970s, **the** simplest kind of **computer** games there are out there. And one of **the** reasons we used games is they ’ re very convenient to test out your ideas and your algorithms. They ’ re really fast to test. And also, as your systems get more powerful, you can choose harder and harder games. And this was actually **the** first time ever that our machine surprised us, **the** first of many times, which, it figured out in this game called Breakout, that you could send **the** ball round **the** back of **the** wall, and actually, it would be much safer way to knock out all **the** tiles of **the** wall. It ’ s a classic Atari game there. And that was our first real aha moment. CA : So this thing was not programmed to have any strategy. It was just told, try and figure out a way of winning. You just move **the** bat at **the** bottom and see if you can find a way of winning. DH : It was a real revolution at **the** time. So this was in 2012, 2013 where we coined these terms”deep reinforcement **learning**.”And **the** key thing about them is that those systems were learning directly from **the** pixels, **the** raw pixels on **the** screen, but they weren ’ t being told anything else. So they were being told, maximize **the** score, here are **the** pixels on **the** screen, 30, 000 pixels. **The** system has to make sense on its own from first principles what ’ s going on, what it ’ s controlling, how to get points. And that ’ s **the** other nice thing about using games to begin with. They have clear objectives, to win, to get scores. So you can kind of measure very easily that your systems are improving. CA : But there was a direct line from that to this moment a few years later, where country of South Korea and many other parts of Asia and in fact **the** world went crazy over – over what? DH : Yeah, so this was **the** pinnacle of – this is in 2016 – **the** pinnacle of our games-playing work, where, so we ’ d done Atari, we ’ d done some more complicated games. And then we reached **the** pinnacle, which was **the** game of Go, which is what they play in Asia instead of chess, but it ’ s actually more complex than chess. And **the** actual brute force algorithms that were used to kind of crack chess were not possible with Go because it ’ s a much more pattern-based game, much more intuitive game. So even though Deep Blue beat Garry Kasparov in **the** ’ 90s, it took another 20 years for our program, AlphaGo, to beat **the** world champion at

Go. And we always thought, myself and **the** people working on this project for many years, if you could build a system that could beat **the** world champion at Go, it would have had to have done something very interesting. And in this case, what we did with AlphaGo, is it basically learned for itself, by playing millions and millions of games against itself, ideas about Go, **the** right strategies. And in fact invented its own new strategies that **the** Go world had never seen before, even though we ’ ve played Go for more than, you know, 2, 000 years, it ’ s **the** oldest board game in existence. So, you know, it was pretty astounding. Not only did it win **the** match, it also came up with brand new strategies. CA : And you continued this with a new strategy of not even really teaching it anything about Go, but just setting up systems that just from first principles would play so that they could teach themselves from scratch, Go or chess. Talk about AlphaZero and **the** amazing thing that happened in chess then. DH : So following this, we started with AlphaGo by giving it all of **the** human games that are being played on **the** internet. So it started that as a basic starting point for its knowledge. And then we wanted to see what would happen if we started from scratch, from literally random play. So this is what AlphaZero was. That ’ s why it ’ s **the** zero in **the** name, because it started with zero prior knowledge And **the** reason we did that is because then we would build a system that was more general. So AlphaGo could only play Go, but AlphaZero could play any two-player game, and it did it by playing initially randomly and then slowly, incrementally improving. Well, not very slowly, actually, within **the** course of 24 hours, going from random to better than world-champion level. CA : And so this is so amazing to me. So I ’ m more familiar with chess than with Go. And for decades, thousands and thousands of AI experts worked on building incredible chess **computers**. Eventually, they got better than humans. You had a moment a few years ago, where in nine hours, AlphaZero taught itself to play chess better than any of those systems ever did. Talk about that. DH : It was a pretty incredible moment, actually. So we set it going on chess. And as you said, there ’ s this rich history of chess and AI where there are these expert systems that have been programmed with these chess ideas, chess algorithms. And you have this amazing, you know, I remember this day very clearly, where you sort of sit down with **the** system starting off random, you know, in **the** morning, you go for a cup of coffee, you come back. I can still just about beat it by lunchtime, maybe just about. And then you let it go for another four hours. And by dinner, it ’ s **the** greatest chess-playing entity that ’ s ever existed. And, you know, it ’ s quite amazing, like, looking at that live on something that you know well, you know, like chess, and you ’ re expert in and actually just seeing that in front of your eyes. And then you extrapolate to what it could then do in science or something else, which of course, games were only a means to an end. They were never **the** end in themselves. They were just **the** training ground for our ideas and to make quick progress in a matter of, you know, less than five years actually went from Atari to Go. CA : I mean, this is why people are in awe of AI and also kind of terrified by it. I mean, it ’ s not just incremental improvement. **The** fact that in a few hours you can achieve what millions of humans over centuries have not been able to achieve. That gives you pause for thought. DH : It does, I mean, it ’ s a hugely powerful technology. It ’ s going to be incredibly transformative. And we have to be very thoughtful about how we use that capability. CA : So talk about this use of it because this is again, this is another extension of **the** work you ’ ve done, where now you ’ re turning it to something incredibly useful for **the** world. What are all **the** letters on **the left**, and what ’ s on **the** right? DH : This was always my aim with AI from a kid, which is to use it to accelerate scientific discovery. And actually, ever since doing my undergrad at Cambridge, I had this problem in mind one day for AI, it ’ s called

the protein-folding problem. And it ' s kind of like a 50-year grand challenge in **biology**. And it ' s very simple to explain. Proteins are essential to life. They ' re **the** building blocks of life. Everything in your body depends on proteins. A protein is sort of described by its amino acid sequence, which you can think of as roughly **the** genetic sequence describing **the** protein, so that are **the** letters. CA : And each of those letters represents in itself a complex molecule? DH : That ' s right, each of those letters is an amino acid. And you can think of them as a kind of string of beads there at **the** bottom, left, right? But in nature, in your body or in an animal, this string, a sequence, turns into this beautiful shape on **the** right. That ' s **the** protein. Those letters describe that shape. And that ' s what it looks like in nature. And **the** important thing about that 3D structure is **the** 3D structure of **the** protein goes a long way to telling you what its function is in **the** body, what it does. And so **the** protein-folding problem is : Can you directly predict **the** 3D structure just from **the** amino acid sequence? So literally if you give **the** machine, **the** AI system, **the** letters on **the left**, can it produce **the** 3D structure on **the** right? And that ' s what AlphaFold does, our program does. CA : It ' s not **calculating** it from **the** letters, it ' s looking at patterns of other folded proteins that are known about and somehow learning from those patterns that this may be **the** way to do this? DH : So when we started this project, actually straight after AlphaGo, I thought we were ready. Once we ' d cracked Go, I felt we were finally ready after, you know, almost 20 years of working on this stuff to actually tackle some scientific problems, including protein folding. And what we start with is painstakingly, over **the** last 40-plus years, experimental biologists have pieced together around 150, 000 protein structures using very complicated, you know, X-ray crystallography **techniques** and other complicated experimental **techniques**. And **the** rule of thumb is that it takes one PhD student their whole PhD, so four or five years, to uncover one structure. But there are 200 million proteins known to nature. So you could just, you know, take forever to do that. And so we managed to actually fold, using AlphaFold, in one year, all those 200 million proteins known to science. So that ' s a billion years of PhD time saved. CA : So it ' s amazing to me just how reliably it works. I mean, this shows, you know, here ' s **the** model and you do **the** experiment. And sure enough, **the** protein turns out **the** same way. Times 200 million. DH : And **the** more deeply you go into proteins, you just start appreciating how exquisite they are. I mean, look at how beautiful these proteins are. And each of these things do a special function in nature. And they ' re almost like works of art. And it ' s still astounds me today that AlphaFold can predict, **the** green is **the** ground truth, and **the blue** is **the** prediction, how well it can predict, is to within **the width** of an atom on average, is how accurate **the** prediction is, which is what is needed for biologists to use it, and for drug design and for disease understanding, which is what AlphaFold **unlocks**. CA : You made a surprising decision, which was to give away **the** actual results of your 200 million proteins. DH : We open-sourced AlphaFold and gave everything away on a huge database with our wonderful colleagues, **the** European Bioinformatics Institute. CA : I mean, you ' re part of Google. Was there a phone call saying,"Uh, Demis, what did you just do?"DH : You know, I ' m lucky we have very supportive, Google ' s really supportive of science and understand **the** benefits this can bring to **the** world. And, you know, **the** argument here was that we could only ever have even scratched **the surface** of **the** potential of what we could do with this. This, you know, maybe like a millionth of what **the** scientific community is doing with it. There ' s over a million and a half biologists around **the** world have used AlphaFold and its predictions. We think that ' s almost every biologist in **the** world is making use of this now, every pharma company. So we ' ll never know probably what **the** full impact of it all is. CA : But you ’ re continuing this work in a new company that ’ s spinning out of Google called Isomorph. DH : Isomorphic. CA : Isomorphic. Give us just a sense of **the** vision there. What ’ s **the** vision? DH : AlphaFold is a sort of fundamental **biology** tool. Like, what are these 3D structures, and then what might they do in nature? And then if you, you know, **the** reason I thought about this and was so excited about this, is that this is **the** beginnings of understanding disease and also maybe helpful for designing drugs. So if you know **the** shape of **the** protein, and then you can kind of figure out which part of **the surface** of **the** protein you ’ re going to target with your drug compound. And Isomorphic is extending this work we did in AlphaFold into **the chemistry** space, where we can design chemical compounds that will bind exactly to **the** right spot on **the** protein and also, importantly, to nothing else in **the** body. So it doesn ’ t have any side effects and it ’ s not toxic and so on. And we ’ re building many other AI models, sort of sister models to AlphaFold to help predict, make predictions in **chemistry** space. CA : So we can expect to see some pretty dramatic health medicine breakthroughs in **the** coming few years. DH : I think we ’ ll be able to get down drug discovery from years to maybe months. CA : OK. Demis, I ’ d like to change direction a bit. Our mutual friend, Liv Boeree, gave a talk last year at TEDAI that she called **the**”Moloch Trap.”**The** Moloch Trap is a situation where organizations, companies in a competitive situation can be driven to do things that no individual running those companies would by themselves do. I was really struck by this talk, and it ’ s felt, as a sort of layperson observer, that **the** Moloch Trap has been shockingly in effect in **the** last couple of years. So here you are with DeepMind, sort of pursuing these amazing medical breakthroughs and scientific breakthroughs, and then suddenly, kind of out of left field, OpenAI with Microsoft releases ChatGPT. And **the** world goes crazy and suddenly goes,”Holy crap, AI is...”you know, everyone can use it. And there ’ s a sort of, it felt like **the** Moloch Trap in action. I think Microsoft CEO Satya Nadella actually said,”Google is **the** 800-pound gorilla in **the search** space. We wanted to make Google dance.”How...? And it did, Google did dance. There was a dramatic response. Your role was changed, you took over **the** whole Google AI effort. Products were rushed out. You know, Gemini, some part amazing, part embarrassing. I ’ m not going to ask you about Gemini because you ’ ve addressed it elsewhere. But it feels like this was **the** Moloch Trap happening, that you and others were pushed to do stuff that you wouldn ’ t have done without this sort of catalyzing competitive thing. Meta did something similar as well. They rushed out an **open-source** version of AI, which is arguably a reckless act in itself. This seems **terrifying** to me. Is it **terrifying**? DH : Look, it ’ s a complicated topic, of course. And, first of all, I mean, there are many things to say about it. First of all, we were working on many large language models. And in fact, obviously, Google research actually invented Transformers, as you know, which was **the** architecture that allowed all this to be possible, five, six years ago. And so we had many large models internally. **The** thing was, I think what **the** ChatGPT moment did that changed was, and fair play to them to do that, was they demonstrated, I think somewhat surprisingly to themselves as well, that **the** public were ready to, you know, **the** general public were ready to embrace these systems and actually find value in these systems. Impressive though they are, I guess, when we ’ re working on these systems, mostly you ’ re focusing on **the** flaws and **the** things they don ’ t do and hallucinations and things you ’ re all familiar with now. We ’ re thinking, you know, would anyone really find that useful given that it does this and that? And we would want them to improve those things first, before putting them out. But interestingly, it turned out that even with those flaws, many tens of millions of people still find them very useful. And so that was an interesting update on maybe **the** convergence of products and **the** science that actually, all of these amazing things we ' ve been doing in **the** lab, so to speak, are actually ready for prime time for general use, beyond **the** rarefied world of science. And I think that ' s pretty exciting in many ways. CA : So at **the** moment, we ' ve got this exciting **array** of products which we ' re all **enjoying**. And, you know, all this generative AI stuff is amazing. But let ' s roll **the** clock forward a bit. Microsoft and OpenAI are reported to be building or investing like 100 billion dollars into an absolute monster database supercomputer that can offer compute at orders of magnitude more than anything we have today. It takes like five gigawatts of energy to drive this, it ' s estimated. That ' s **the** energy of New York City to drive a data center. So we ' re pumping all this energy into this giant, vast brain. Google, I presume is going to match this type of investment, right? DH : Well, I mean, we don ' t talk about our specific numbers, but you know, I think we ' re investing more than that over time. So, and that ' s one of **the** reasons we teamed up with Google back in 2014, is kind of we knew that in order to get to AGI, we would need a lot of compute. And that ' s what ' s transpired. And Google, you know, had and still has **the** most **computers**. CA : So Earth is building these giant **computers** that are going to basically, these giant brains, that are going to power so much of **the** future economy. And it ' s all by companies that are in competition with each other. How will we avoid **the** situation where someone is getting a lead, someone else has got 100 billion dollars invested in their thing. Isn ' t someone going to go,"Wait a sec. If we used reinforcement learning here to maybe have **the** AI tweak its own code and rewrite itself and make it so [powerful], we might be able to catch up in nine hours over **the** weekend with what they ' re doing. Roll **the** dice, dammit, we have no choice. Otherwise we ' re going to lose a fortune for our shareholders."How are we going to avoid that? DH : Yeah, well, we must avoid that, of course, clearly. And my view is that as we get closer to AGI, we need to collaborate more. And **the** good news is that most of **the** scientists involved in these labs know each other very well. And we talk to each other a lot at conferences and other things. And this technology is still relatively nascent. So probably it ' s OK what ' s happening at **the** moment. But as we get closer to AGI, I think as a society, we need to start thinking about **the** types of architectures that get built. So I ' m very optimistic, of course, that ' s why I spent my whole life working on AI and working towards AGI. But I suspect there are many ways to build **the** architecture safely, robustly, reliably and in an understandable way. And I think there are almost certainly going to be ways of building architectures that are unsafe or risky in some form. So I see a sort of, a kind of bottleneck that we have to get humanity through, which is building safe architectures as **the** first types of AGI systems. And then after that, we can have a sort of, a flourishing of many different types of systems that are perhaps sharded off those safe architectures that ideally have some mathematical guarantees or at least some practical guarantees around what they do. CA : Do governments have an essential role here to define what a level playing field looks like and what is absolutely taboo? DH : Yeah, I think it ' s not just about – actually I think government and civil society and academia and all parts of society have a critical role to play here to shape, along with industry labs, what that should look like as we get closer to AGI and **the** cooperation needed and **the** collaboration needed, to prevent that kind of runaway race dynamic happening. CA : OK, well, it sounds like you remain optimistic. What ' s this image here? DH : That ' s one of my favorite images, actually. I call it, like, **the** tree of all knowledge. So, you know, we ' ve been talking a lot about science, and a lot of science can be boiled down to if you imagine all **the** knowledge that exists in **the** world as a tree of knowledge, and then maybe what we know today as a civilization is some, you know, small subset of that. And I see AI as this tool that allows us, as scientists, to explore, potentially, **the** entire tree one day. And we have this idea of root node problems that, like AlphaFold, **the** protein-folding problem, where if you could crack them, it **unlocks** an entire new branch of discovery or new research. And that ' s what we try and focus on at DeepMind and Google DeepMind to crack those. And if we get this right, then I think we could be, you know, in this incredible new era of radical abundance, curing all diseases, spreading consciousness to **the** stars. You know, maximum human flourishing. CA : We ' re out of time, but what ' s **the** last example of like, in your dreams, this dream question that you think there is a shot that in your lifetime AI might take us to? DH : I mean, once AGI is built, what I ' d like to use it for is to try and use it to understand **the** fundamental nature of reality. So do experiments at **the** Planck scale. You know, **the** smallest possible scale, theoretical scale, which is almost like **the** resolution of reality. CA : You know, I was brought up religious. And in **the** Bible, there ' s a story about **the** tree of knowledge that doesn ' t work out very well. Is there any scenario where we discover knowledge that **the universe** says,"Humans, you may not know that."DH : Potentially. I mean, there might be some unknowable things. But I think scientific method is **the** greatest sort of invention humans have ever come up with. You know, **the** enlightenment and scientific discovery. That ' s what ' s built this incredible modern civilization around us and all **the** tools that we use. So I think it ' s **the** best **technique** we have for understanding **the** enormity of **the universe** around us. CA : Well, Demis, you ' ve already changed **the** world. I think probably everyone here will be cheering you on in your efforts to ensure that we continue to accelerate in **the** right direction. DH : Thank you. CA : Demis Hassabis.

Text Sample 49: POS Dim 1 – 2024 – Score 19.00 – 2024/t003234.txt

I want to tell you what I see coming. I ' ve been lucky enough to be working on AI for almost 15 years now. Back when I started, to describe it as fringe would be an understatement. Researchers would say,"No, no, we ' re only working on machine **learning**."Because working on AI was seen as way too out there. In 2010, just **the** very mention of **the** phrase"AGI,"**artificial** general intelligence, would get you some seriously strange looks and even a cold shoulder."You ' re actually building AGI?"people would say."Isn ' t that something out of science fiction?"People thought it was 50 years away or 100 years away, if it was even possible at all. Talk of AI was, I guess, kind of embarrassing. People generally thought we were weird. And I guess in some ways we kind of were. It wasn ' t long, though, before AI started beating humans at a whole range of tasks that people previously thought were way out of reach. Understanding images, translating languages, transcribing speech, playing Go and chess and even diagnosing diseases. People started waking up to **the** fact that AI was going to have an enormous impact, and they were rightly asking technologists like me some pretty tough questions. Is it true that AI is going to solve **the** climate crisis? Will it make personalized education available to everyone? Does it mean we ' ll all get universal basic income and we won ' t have to work anymore? Should I be afraid? What does it mean for weapons and war? And of course, will China win? Are we in a race? Are we headed for a mass misinformation apocalypse? All good questions. But it was actually a simpler and much more kind of fundamental question that left me puzzled. One that actually gets to **the** very heart of my work every day. One morning over breakfast, my six-year-old nephew Caspian was playing with Pi, **the** AI I created at my last company, Inflection. With a mouthful of scrambled eggs, he looked at me plain in **the** face and said,”But Mustafa, what is an AI anyway?”He ’ s such a sincere and curious and optimistic little guy. He ’ d been talking to Pi about how cool it would be if one day in **the** future, he could visit dinosaurs at **the** zoo. And how he could make infinite amounts of chocolate at home. And why Pi couldn ’ t yet play I Spy.”Well,”I said,”it ’ s a clever piece of software that ’ s read most of **the** text on **the** open internet, and it can talk to you about anything you want.””Right. So like a person then?”I was stumped. Genuinely left scratching my head. All my boring stock answers came rushing through my mind.”No, but AI is just another general-purpose technology, like printing or steam.”It will be a tool that will augment us and make us smarter and more productive. And when it gets better over time, it ’ ll be like an all-knowing oracle that will help us solve grand scientific challenges.”You know, all of these responses started to feel, I guess, a little bit defensive. And actually better suited to a policy seminar than breakfast with a no-nonsense six-year-old.”Why am I hesitating?”I thought to myself. You know, let ’ s be honest. My nephew was asking me a simple question that those of us in AI just don ’ t confront often enough. What is it that we are actually creating? What does it mean to make something totally new, fundamentally different to any invention that we have known before? It is clear that we are at an inflection point in **the** history of humanity. On our current trajectory, we ’ re headed towards **the** emergence of something that we are all struggling to describe, and yet we cannot control what we don ’ t understand. And so **the** metaphors, **the** mental models, **the** names, these all matter if we ’ re to get **the** most out of AI whilst limiting its potential downsides. As someone who embraces **the** possibilities of this technology, but who ’ s also always cared deeply about its ethics, we should, I think, be able to easily describe what it is we are building. And that includes **the** six-year-olds. So it ’ s in that spirit that I offer up today **the** following metaphor for helping us to try to grapple with what this moment really is. I think AI should best be understood as something like a new digital species. Now, don ’ t take this too literally, but I predict that we ’ ll come to see them as digital companions, new partners in **the** journeys of all our lives. Whether you think we ’ re on a 10-, 20- or 30-year path here, this is, in my view, **the** most accurate and most fundamentally honest way of describing what ’ s actually coming. And above all, it enables everybody to prepare for and shape what comes next. Now I totally get, this is a strong claim, and I ’ m going to explain to everyone as best I can why I ’ m making it. But first, let me just try to set **the** context. From **the** very first microscopic organisms, life on Earth stretches back billions of years. Over that time, life **evolved** and diversified. Then a few million years ago, something began to shift. After countless cycles of growth and adaptation, one of life ’ s branches began using tools, and that branch grew into us. We went on to produce a mesmerizing variety of tools, at first slowly and then with astonishing speed, we went from stone axes and fire to language, writing and eventually industrial technologies. One invention unleashed a thousand more. And in time, we became homo technologicus. Around 80 years ago, another new branch of technology began. With **the** invention of **computers**, we quickly jumped from **the** first mainframes and transistors to today ’ s **smartphones** and virtual-reality headsets. Information, knowledge, communication, computation. In this revolution, creation has exploded like never before. And now a new wave is upon us. **Artificial** intelligence. These waves of history are clearly speeding up, as each one is amplified and accelerated by **the** last. And if you look back, it ’ s clear that we are in **the** fastest and most consequential wave ever. **The** journeys of humanity and technology are now deeply intertwined. In just 18 months, over a billion people have used large language models. We ’ ve witnessed one landmark event after another.

Just a few years ago, people said that AI would never be creative. And yet AI now feels like an endless river of creativity, making poetry and images and music and video that stretch **the** imagination. People said it would never be empathetic. And yet today, millions of people **enjoy** meaningful conversations with AIs, talking about their hopes and dreams and helping them work through difficult emotional challenges. AIs can now drive cars, manage energy grids and even invent new molecules. Just a few years ago, each of these was impossible. And all of this is turbocharged by spiraling exponentials of data and computation. Last year, Inflection 2. 5, our last model, used five billion times more computation than **the** DeepMind AI that beat **the** old-school Atari games just over 10 years ago. That ' s nine orders of magnitude more computation. 10x per year, every year for almost a decade. Over **the** same time, **the** size of these models has grown from first tens of millions of parameters to then billions of parameters, and very soon, tens of trillions of parameters. If someone did nothing but read 24 hours a day for their entire life, they ' d consume eight billion words. And of course, that ' s a lot of words. But today, **the** most advanced AIs consume more than eight trillion words in a single month of training. And all of this is set to continue. **The** long arc of technological history is now in an extraordinary new phase. So what does this mean in practice? Well, just as **the** internet gave us **the** browser and **the smartphone** gave us apps, **the** cloud-based supercomputer is ushering in a new era of ubiquitous AIs. Everything will soon be represented by a conversational interface. Or, to put it another way, a personal AI. And these AIs will be infinitely knowledgeable, and soon they ' ll be factually accurate and reliable. They ' ll have near-perfect IQ. They ' ll also have exceptional EQ. They ' ll be kind, supportive, empathetic. These elements on their own would be transformational. Just imagine if everybody had a personalized tutor in their **pocket** and access to low-cost medical advice. A lawyer and a doctor, a business strategist and coach – all in your **pocket** 24 hours a day. But things really start to change when they develop what I call AQ, their"actions quotient."This is their ability to actually get stuff done in **the** digital and physical world. And before long, it won ' t just be people that have AIs. Strange as it may sound, every organization, from small business to nonprofit to national government, each will have their own. Every town, building and **object** will be represented by a unique interactive persona. And these won ' t just be mechanistic assistants. They ' ll be companions, confidants, colleagues, friends and partners, as varied and unique as we all are. At this point, AIs will convincingly imitate humans at most tasks. And we ' ll feel this at **the** most intimate of scales. An AI organizing a community get-together for an elderly neighbor. A sympathetic expert helping you make sense of a difficult diagnosis. But we ' ll also feel it at **the** largest scales. Accelerating scientific discovery, autonomous cars on **the** roads, drones in **the** skies. They ' ll both order **the** takeout and run **the** power station. They ' ll interact with us and, of course, with each other. They ' ll speak every language, take in every pattern of sensor data, sights, sounds, streams and streams of information, far surpassing what any one of us could consume in a thousand lifetimes. So what is this? What are these AIs? If we are to prioritize safety above all else, to ensure that this new wave always serves and amplifies humanity, then we need to find **the** right metaphors for what this might become. For years, we in **the** AI community, and I specifically, have had a tendency to refer to this as just tools. But that doesn ' t really capture what ' s actually happening here. AIs are clearly more dynamic, more ambiguous, more integrated and more emergent than mere tools, which are entirely subject to human control. So to contain this wave, to put human agency at its center and to mitigate **the** inevitable unintended consequences that are likely to arise, we should start to think about them as we might a new kind of digital species. Now it ' s just an analogy, it ' s not a literal description, and it ' s not perfect. For a start, they clearly aren ' t biological in any traditional sense, but just pause for a moment and really think about what they already do. They communicate in our languages. They see what we see. They consume unimaginably large amounts of information. They have memory. They have personality. They have creativity. They can even reason to some extent and formulate rudimentary plans. They can act autonomously if we allow them. And they do all this at levels of sophistication that is far beyond anything that we ' ve ever known from a mere tool. And so saying AI is mainly about **the** math or **the** code is like saying we humans are mainly about **carbon** and water. It ' s true, but it completely misses **the** point. And yes, I get it, this is a super arresting thought but I honestly think this frame helps sharpen our focus on **the** critical issues. What are **the** risks? What are **the** boundaries that we need to impose? What kind of AI do we want to build or allow to be built? This is a story that ' s still unfolding. Nothing should be accepted as a given. We all must choose what we create. What AIs we bring into **the** world, or not. These are **the** questions for all of us here today, and all of us alive at this moment. For me, **the** benefits of this technology are stunningly obvious, and they inspire my life ' s work every single day. But quite frankly, they ' ll speak for themselves. Over **the** years, I ' ve never shied away from highlighting risks and talking about downsides. Thinking in this way helps us focus on **the** huge challenges that lie ahead for all of us. But let ' s be clear. There is no path to progress where we leave technology behind. **The** prize for all of civilization is immense. We need solutions in health care and education, to our climate crisis. And if AI delivers just a **fraction** of its potential, **the** next decade is going to be **the** most productive in human history. Here ' s another way to think about it. In **the** past, **unlocking** economic growth often came with huge downsides. **The** economy expanded as people discovered new **continents** and opened up new frontiers. But they colonized populations at **the** same time. We built factories, but they were grim and dangerous places to work. We struck **oil**, but we **polluted the planet**. Now because we are still designing and building AI, we have **the** potential and opportunity to do it better, radically better. And today, we ' re not discovering a new **continent** and plundering its resources. We ' re building one from scratch. Sometimes people say that data or chips are **the** 21st century ' s new **oil**, but that ' s totally **the** wrong image. AI is to **the** mind what nuclear **fusion** is to energy. Limitless, abundant, world-changing. And AI really is different, and that means we have to think about it creatively and honestly. We have to push our analogies and our metaphors to **the** very limits to be able to grapple with what ' s coming. Because this is not just another invention. AI is itself an infinite inventor. And yes, this is exciting and promising and concerning and intriguing all at once. To be quite honest, it ' s pretty surreal. But step back, see it on **the** long view of glacial time, and these really are **the** very most appropriate metaphors that we have today. Since **the** beginning of life on Earth, we ' ve been **evolving**, changing and then creating everything around us in our human world today. And AI isn ' t something outside of this story. In fact, it ' s **the** very opposite. It ' s **the** whole of everything that we have created, distilled down into something that we can all interact with and benefit from. It ' s a reflection of humanity across time, and in this sense, it isn ' t a new species at all. This is where **the** metaphors end. Here ' s what I ' ll tell Caspian next time he asks. AI isn ' t separate. AI isn ' t even in some senses, new. AI is us. It ' s all of us. And this is perhaps **the** most promising and vital thing of all that even a six-year-old can get a sense for. As we build out AI, we can and must reflect all that is good, all that we love, all that is special about humanity : our empathy, our kindness, our curiosity and our creativity. This, I would argue, is **the** greatest challenge of **the** 21st century, but also **the** most wonderful, inspiring and hopeful opportunity for all of us. Thank you. Chris Anderson : Thank you Mustafa. It ’ s an amazing vision and a super powerful metaphor. You ’ re in an amazing position right now. I mean, you were connected at **the** hip to **the** amazing work happening at OpenAI. You ’ re going to have resources made available, there are reports of these giant new data centers, 100 billion dollars invested and so forth. And a new species can emerge from it. I mean, in your book, you did, as well as painting an incredible optimistic vision, you were super eloquent on **the** dangers of AI. And I ’ m just curious, from **the** view that you have now, what is it that most keeps you up at night? Mustafa Suleyman : I think **the** great risk is that we get stuck in what I call **the** pessimism aversion trap. You know, we have to have **the** courage to confront **the** potential of dark scenarios in order to get **the** most out of all **the** benefits that we see. So **the** good news is that if you look at **the** last two or three years, there have been very, very few downsides, right? It ’ s very hard to say explicitly what harm an LLM has caused. But that doesn ’ t mean that that ’ s what **the** trajectory is going to be over **the** next 10 years. So I think if you pay attention to a few specific capabilities, take for example, autonomy. Autonomy is very obviously a threshold over which we increase risk in our society. And it ’ s something that we should step towards very, very closely. **The** other would be something like recursive self-improvement. If you allow **the** model to independently self-improve, update its own code, explore an environment without oversight, and, you know, without a human in control to change how it operates, that would obviously be more dangerous. But I think that we ’ re still some way away from that. I think it ’ s still a good five to 10 years before we have to really confront that. But it ’ s time to start talking about it now. CA : A digital species, unlike any biological species, can replicate not in nine months, but in nine nanoseconds, and produce an indefinite number of **copies** of itself, all of which have more power than we have in many ways. I mean, **the** possibility for unintended consequences seems pretty immense. And isn ’ t it true that if a problem happens, it could happen in an hour? MS : No. That is really not true. I think there ’ s no evidence to suggest that. And I think that, you know, that ’ s often referred to as **the**”intelligence **explosion**.”And I think it is a theoretical, hypothetical maybe that we ’ re all kind of curious to explore, but there ’ s no evidence that we ’ re anywhere near anything like that. And I think it ’ s very important that we choose our words super carefully. Because you ’ re right, that ’ s one of **the** weaknesses of **the** species framing, that we will design **the** capability for self-replication into it if people choose to do that. And I would actually argue that we should not, that would be one of **the** dangerous capabilities that we should step back from, right? So there ’ s no chance that this will”emerge”accidentally. I really think that ’ s a very low **probability**. It will happen if engineers deliberately design those capabilities in. And if they don ’ t take enough efforts to deliberately design them out. And so this is **the** point of being explicit and transparent about trying to introduce safety by design very early on. CA : Thank you, your vision of humanity injecting into this new thing **the** best parts of ourselves, avoiding all those weird, biological, freaky, horrible tendencies that we can have in certain circumstances, I mean, that is a very inspiring vision. And thank you so much for coming here and sharing it at TED. Thank you, good luck.

Text Sample 50: POS Dim 1 – 2024 – Score 18.00 – 2024/t003168.txt

When I look up at **the** sky at night, I see 100 billion stars of **the** Milky Way galaxy. They look like lights in cabins of a giant spaceship, **The** Milky Way, sailing through space. And I wonder if there are other passengers in those cabins. There are 100 billion of them, comparable to **the** number of people who ever lived on Earth. It would be arrogant to think otherwise, that we are alone, that we are unique and special, especially if you read **the** news every day. We are not **the** pinnacle of creation. There is room for improvement. I ' m just a curious farm boy, and I wonder about **the** world around me. And I hate to behave like **the** adults in **the** room, because they often pretend to know more than we actually know. And that bothered me since I was a young kid. And so I decided to become a scientist and answer **the** questions based on evidence, not based on prejudice, not based on **the** politics of getting **the** largest number of likes on social media. I don ' t have a footprint on social media. I **enjoy** nature. Whatever it brings to our doorstep is welcome. So let ' s just look around. And for 70 years, we ' ve been **searching** for radio signals. This is equivalent to staying at home and waiting for a phone call that may never come because nobody cares that we are lonely. It may also be that others are addicted to digital screens and they live in a virtual reality, as we are at this point in time. A much better approach is to check if there is any **object** in our backyard that may have arrived from a neighbor ' s yard. Like a tennis ball, that may tell us that **the** neighbor plays tennis. And we haven ' t really checked until **the** last decade. **The** first **object** to have been reported by astronomers that came from outside **the** solar system looked really weird. It was discovered by a telescope in Hawaii. When it passed close to Earth, it was **the** size of a football field. What you see behind me is **the** artist ' s depiction. It looked really weird because as it was tumbling every eight hours, **the** amount of sunlight reflected from it changed by a factor of ten, which meant that it has a very extreme shape, most likely flat, like a pancake. And moreover, it exhibited a push away from **the** sun by some mysterious force because there was no evaporation, no cometary tail around it, no dust, no gas. So **the** question was, what is pushing it? And I suggested that maybe it ' s **the** reflection of sunlight, but for that, **the object** had to be very thin, like a sail. And that meant that it was not produced naturally. Maybe it ' s a **surface** layer, maybe it ' s space trash, like a plastic bag tumbling in **the** wind. And so we go back 70 years to a question that Enrico Fermi, **the** physicist, asked at Los Alamos,"Where is everybody?"Well, this is a question that single people often ask. But if you stay at home – You will not find anyone. You have to go to dating sites. At **the** very least, you need to look through your windows for other people. And he didn ' t seek **the** evidence. He was just asking **the** question and kept repeating it. And if we don ' t look for evidence, we will not find anything. It ' s a self-fulfilling prophecy. It ' s a way to maintain our ignorance. And science is better than politics. We can find **the** evidence if we allocate **the** funds for it. This is a real image, what you see behind me, it ' s **the** Tesla Roadster car that was put as a dummy payload on **the** Falcon Heavy launch of 2018. It ' s now moving in an elliptical orbit around **the** Sun, and perhaps in 20 million years, it will collide with Earth. And if it will do so unexpectedly, some of my colleagues would argue"This is a **rock** of a type that we ' ve never seen before."We cannot see it with our best telescopes because it ' s too small. It doesn ' t reflect enough sunlight. ' Oumuamua was **the** size of a football field, big enough for us to see. And so **the** next Copernican revolution would be that we are not at **the** intellectual center of **the universe**. Not only that we are not at **the** physical center of **the universe**, but actually, you know, we arrive to **the** play relatively late. We are not at **the** center of stage. **The** play is not about us. We should be modest. We keep thinking that it ' s about us, but it ' s not. And we better find other actors that will tell us what **the** play is about. And people often say extraordinary claims require extraordinary evidence, but they are not seeking **the** evidence. Actually, extraordinary evidence requires extraordinary funding. Elon Musk argued recently,"I don ' t see any aliens."But new scientific knowledge does not fall into our lap. We had to invest 10 billion dollars in **the** Large Hadron Collider in order to find **the** Higgs boson. We had to invest 10 billion dollars in **the** Webb telescope in order to find **the** first generation of galaxies. This is **the** way science is done. You need to put **the** effort in order to find something new. And only over **the** past decade, we discovered **objects** that came from outside **the** solar system. **The** first one was actually a decade ago. It was a meteor, an **object** half a meter in size that collided with Earth and burned up in **the** atmosphere. It was spotted by US government satellites. **The** fireball that it generated released a few percent of **the** Hiroshima atomic bomb energy, and it was moving too fast to be bound to **the** Sun ' s gravity. And so we **concluded** it ' s interstellar. It came from outside **the** solar system. Could it be a Voyager-like meteor? Imagine our own spacecraft colliding with a **planet** like Earth. In **the** future, it would appear as a meteor of unusual material strength and unusual speed, which are exactly **the** properties of this meteor from 2014. And then ' Oumuamua was discovered in 2017, and finally a comet appeared, also from interstellar space, was moving too fast. And so my colleagues argued,"Well, this one looks familiar. Doesn ' t it convince you that **the** others are natural in origin? **Rocks** of a type that we ' ve never seen before?"And I say, if I go down **the** street and I see a weird person, and after that I see a normal person, it doesn ' t make **the** weird person normal. Now **the** US – Director of National intelligence – Avril Haines delivered three reports to **the** US Congress, talking about unidentified anomalous phenomena. **The** good news is **the** sky is not classified. We don ' t need to wait for **the** US government to tell us what lies outside **the** solar system. Their day job is national security. My day job is figuring out what lies beyond **the** solar system. And **the** sky is not classified. We can answer **the** question ourselves. So I ' m leading **the** Galileo project. We built an observatory at Harvard University that monitors **the** sky 24 / 7, looking for **objects** that are not familiar, not birds, balloons, drones, **airplanes**, satellites. So far, we monitored half a million **objects**. Haven ' t found anything unusual yet, but we keep looking and we are using machine-learning software to figure out what we are looking at. But **the** most exciting **endeavor** that I was involved in is an expedition to **the** Pacific Ocean near Papua New Guinea, to look for **the** materials from this meteor that I described before. And **the** US Space Command issued a letter to NASA confirming at **the** 99. 999 percent that this **object** indeed originated from outside **the** solar system. Based on its high speed, it was moving faster than 95 percent of all stars in **the** vicinity of **the** Sun. It exploded in **the** lower atmosphere, about 90 kilometers away from Manus Island in Papua New Guinea, and that meant that **the object** had material strength tougher than even **iron** meteorites. And so I led an expedition in June 2023. You can see **the** team on **the** ship that was fittingly called Silver Star, and we used **the** sled with magnets on both sides to **search** for droplets left over from **the explosion** of this meteor. And at **the** bottom left you see **the** filming crew of Netflix. They are preparing a documentary about this research, and **the** director asked me,"Avi, it looks like you are running,"because I was jogging at sunrise, as I often do on land for a few miles. And he said,"Are you running away from something or towards something?"And I said,"Both. I ' m running away from some of my colleagues who have strong opinions without seeking evidence, and I ' m running towards a higher intelligence in interstellar space."Now we used this sled and collected magnetic particles from **the** ocean floor about a mile deep. And then I brought them to my colleagues at Harvard University. They look like metallic **spheres**, very distinct from **the** background of sand in which they were collected. And my colleague at Harvard, Stein Jacobsen, is a world-renowned geochemist. He used **the** electron microprobe, a mass spectrometer, in his laboratory. **The** person on **the** other side of me in this picture is a summer intern, Sophie Bergstrom, who found most of our molten droplets. And so I called her **the** spheral hunter. And most of our spherules were actually of a type familiar from **the** solar system, but about 10 percent of them looked unusual, and they had a chemical composition very different from solar system materials. They had abundances of elements like beryllium, lanthanum, uranium, that are up to a factor of 1, 000 more than found in solar system materials. They were not from **the** Earth, not from **the** moon, not from Mars, not from **asteroids**. And so now **the** question arises, was this a **rock** from another star? And of course, one possibility is that there was a natural process that produced it. For example, most stars are **dwarf** stars, 10 percent of **the** mass of **the** sun, and they are 100 times denser than **the** sun. And so if you bring a **planet** like **the** Earth close to them, they spaghettify **the planet**, make a stream of **rocks** that could be ejected at a speed similar to that of this meteor. But it ' s also possible that this **object** was of **artificial** origin, in which case, if we look for bigger pieces of **the object**, we might find a gadget with buttons on it. And I asked students in my class,"If we find such a gadget, should we press a button?"Now, some of my critics argued, maybe it ' s **coal** ash. So we looked at 55 elements from **the** periodic table and found that **the** abundances of elements are very different from **coal** ash. So it ' s not **coal** ash. Others argued,"Maybe it was not a meteor, maybe it was a truck."Well, **the** data came from US government satellites. We actually based our **search** region on **the** Department of Defense coordinates, and we went 26 times back and forth, **searching** that region. So **the** next expedition, hopefully within **the** year, will **search** for bigger pieces of **the object**, maybe even **the** core of **the object**, because that could have a huge impact on humanity. We all know **the** biblical story about Moses, who looked at **the** bush that was burning without being consumed, with religious awe, and that gave Moses **the** sense that there is a superhuman entity, God, out there. Now, Friedrich Nietzsche in 1882 argued,"God is dead."And that gave rise to **the** modern period of science and technology, where humans have this hubris, they lack modesty. Nobody is smarter than us, we are at **the** top of **the** food chain. Maybe AI will do a little better. But AI is just a digital mirror. It reflects our faults. It ' s nothing better than us. It ' s not a digital species. It ' s just us. And if we find a partner out there, of course, that will give a new meaning to our existence. And it ' s a whole different ball game. Something from another star has nothing to do with us. And we better be ready for that. Not look at **the** mirror and imagine something like it, as science fiction stories do. Now **the** good news is, next year, **the** Rubin Observatory in Chile will survey **the** southern sky every four days with a camera that is **the** size of a person, 3. 2 billion pixels, a thousand times more than your cell phone camera. And so if we find more **objects** like ' Oumuamua, it might give us a sense of modesty. We might bring back this sense of awe that Moses had. Except in this time, it will be based on something that was delivered from interstellar space, from a neighbor. And that is quite promising, actually, because it may change our priorities. Instead of spending four trillion dollars a year on military budgets, killing each other for territories on this **rock**, **the** tiny **rock**, left over from **the** formation of **the** sun, we might realize that there is a smarter kid on **the** block, and that kid may provide a better role model than our politicians. And if we allocate four trillion dollars a year to space exploration, we could send a CubeSat towards every star in **the** Milky Way galaxy, hundreds of billions of them, within one century. And it gets better than that, because if we find a superhuman intelligence out there... We might learn new physics. **The** first question I would ask is,"What happened before **the** Big Bang?"And they might have quantum gravity engineers that are capable of creating a baby **universe** in **the** laboratory. And this job of creating a new **universe** can be perfected. And that would help us actually, given that there is a lot of room for improvement in **the** world that we inhabit. Thank you. Chris Anderson : Thank you, Avi. I ' m here like a visitor from another **planet**, because we ' re out of time. But also just to ask you one yes or no question, OK? If you had to put money on it, in **the** next ten years, what do you think – is it likely that we will discover convincing evidence that persuades a critical mass of your colleagues that there is someone out there. And I just want a yes or no. Avi Loeb : Yes. CA : Yes! Avi Loeb!

Text Sample 51: POS Dim 1 – 2016 – Score 23.00 – 2016/t001399.txt

I was excited to be a part of **the**"Dream"**theme**, and then I found out I ' m leading off **the**"Nightmare?"section of it. And certainly there are things about **the** climate crisis that qualify. And I have some bad news, but I have a lot more good news. I ' m going to propose three questions and **the** answer to **the** first one necessarily involves a little bad news. But — hang on, because **the** answers to **the** second and third questions really are very positive. So **the** first question is,"Do we really have to change?"And of course, **the** Apollo Mission, among other things changed **the** environmental movement, really launched **the** modern environmental movement. 18 months after this Earthrise picture was first seen on earth, **the** first Earth Day was organized. And we learned a lot about ourselves looking back at our **planet** from space. And one of **the** things that we learned confirmed what **the** scientists have long told us. One of **the** most essential facts about **the** climate crisis has to do with **the** sky. As this picture illustrates, **the** sky is not **the** vast and limitless expanse that appears when we look up from **the** ground. It is a very thin shell of atmosphere surrounding **the planet**. That right now is **the** open sewer for our industrial civilization as it ' s currently organized. We are spewing 110 million tons of heat-trapping global warming pollution into it every 24 hours, free of charge, go ahead. And there are many sources of **the greenhouse** gases, I ' m certainly not going to go through them all. I ' m going to focus on **the** main one, but **agriculture** is involved, diet is involved, population is involved. Management of forests, **transportation**, **the** oceans, **the** melting of **the** permafrost. But I ' m going to focus on **the** heart of **the** problem, which is **the** fact that we still rely on dirty, carbon-based fuels for 85 percent of all **the** energy that our world burns every year. And you can see from this image that after World War II, **the emission** rates started really accelerating. And **the** accumulated amount of man- made, global warming pollution that is up in **the** atmosphere now traps as much extra heat energy as would be released by 400, 000 Hiroshima-class atomic bombs exploding every 24 hours, 365 days a year. Fact-checked over and over again, conservative, it ' s **the** truth. Now it ' s a big **planet**, but — that is a lot of energy, particularly when you multiply it 400, 000 times per day. And all that extra heat energy is heating up **the** atmosphere, **the** whole earth system. Let ' s look at **the** atmosphere. This is a depiction of what we used to think of as **the** normal distribution of temperatures. **The** white represents normal temperature days ; 1951-1980 are arbitrarily chosen. **The blue** are cooler than average days, **the** red are warmer than average days. But **the** entire curve has moved to **the** right in **the** 1980s. And you ' ll see in **the** lower **right-hand** corner **the** appearance of statistically significant numbers of extremely hot days. In **the** 90s, **the** curve shifted further. And in **the** last 10 years, you see **the** extremely hot days are now more numerous than **the** cooler than average days.

In fact, they are 150 times more common on **the surface** of **the** earth than they were just 30 years ago. So we ' re having record-breaking temperatures. Fourteen of **the** 15 of **the** hottest years ever measured with instruments have been in this young century. **The** hottest of all was last year. Last month was **the** 371st month in a row warmer than **the** 20th-century average. And for **the** first time, not only **the** warmest January, but for **the** first time, it was more than two degrees Fahrenheit warmer than **the** average. These higher temperatures are having an effect on animals, plants, people, ecosystems. But on a global basis, 93 percent of all **the** extra heat energy is trapped in **the** oceans. And **the** scientists can measure **the** heat buildup much more precisely now at all depths : deep, mid-ocean, **the** first few hundred meters. And this, too, is accelerating. It goes back more than a century. And more than half of **the** increase has been in **the** last 19 years. This has consequences. **The** first order of consequence : **the** ocean-based storms get stronger. Super Typhoon Haiyan went over areas of **the** Pacific five and a half degrees Fahrenheit warmer than normal before it slammed into Tacloban, as **the** most destructive storm ever to make landfall. Pope Francis, who has made such a difference to this whole issue, visited Tacloban right after that. Superstorm Sandy went over areas of **the** Atlantic nine degrees warmer than normal before slamming into New York and New Jersey. **The** second order of consequences are affecting all of us right now. **The** warmer oceans are evaporating much more water vapor into **the** skies. Average humidity worldwide has gone up four percent. And it creates these atmospheric rivers. **The** Brazilian scientists call them"flying rivers."And they funnel all of that extra water vapor over **the** land where storm conditions trigger these massive record-breaking downpours. This is from Montana. Take a look at this storm last August. As it moves over Tucson, Arizona. It literally splashes off **the** city. These downpours are really unusual. Last July in Houston, Texas, it rained for two days, 162 billion gallons. That represents more than two days of **the** full flow of Niagara Falls in **the** middle of **the** city, which was, of course, paralyzed. These record downpours are creating historic floods and mudslides. This one is from Chile last year. And you ' ll see that warehouse going by. There are **oil** tankers cars going by. This is from Spain last September, you could call this **the** running of **the** cars and trucks, I guess. Every night on **the** TV news now is like a nature hike through **the** Book of Revelation. I mean, really. **The** insurance industry has certainly noticed, **the** losses have been mounting up. They ' re not under any illusions about what ' s happening. And **the** causality requires a moment of discussion. We ' re used to thinking of linear cause and linear effect — one cause, one effect. This is systemic causation. As **the** great Kevin Trenberth says,"All storms are different now. There ' s so much extra energy in **the** atmosphere, there ' s so much extra water vapor. Every storm is different now."So, **the** same extra heat pulls **the** soil moisture out of **the** ground and causes these deeper, longer, more pervasive **droughts** and many of them are underway right now. It dries out **the** vegetation and causes more fires in **the** western part of North America. There ' s certainly been evidence of that, a lot of them. More lightning, as **the** heat energy builds up, there ' s a considerable amount of additional lightning also. These climate-related disasters also have geopolitical consequences and create instability. **The** climate-related historic **drought** that started in Syria in 2006 destroyed 60 percent of **the** farms in Syria, killed 80 percent of **the** livestock, and drove 1. 5 million climate refugees into **the** cities of Syria, where they collided with another 1. 5 million refugees from **the** Iraq War. And along with other factors, that opened **the** gates of Hell that people are trying to close now. **The** US Defense Department has long warned of consequences from **the** climate crisis, including refugees, food and water shortages and pandemic disease. Right now we ’ re seeing microbial diseases from **the** tropics spread to **the** higher latitudes ; **the transportation** revolution has had a lot to do with this. But **the** changing conditions change **the** latitudes and **the** areas where these microbial diseases can become endemic and change **the** range of **the** vectors, like mosquitoes and ticks that carry them. **The** Zika epidemic now — we ’ re better positioned in North America because it ’ s still a little too cool and we have a better public health system. But when women in some regions of South and Central America are advised not to get pregnant for two years — that ’ s something new, that ought to get our attention. **The** Lancet, one of **the** two greatest medical journals in **the** world, last summer labeled this a medical emergency now. And there are many factors because of it. This is also connected to **the** extinction crisis. We ’ re in danger of losing 50 percent of all **the** living species on earth by **the** end of this century. And already, land-based plants and animals are now moving towards **the** poles at an average rate of 15 feet per day. Speaking of **the** North Pole, last December 29, **the** same storm that caused historic flooding in **the** American Midwest, raised temperatures at **the** North Pole 50 degrees Fahrenheit warmer than normal, causing **the** thawing of **the** North Pole in **the** middle of **the** long, dark, winter, polar night. And when **the** land- based ice of **the** Arctic melts, it raises **sea** level. Paul Nicklen ’ s beautiful photograph from Svalbard illustrates this. It ’ s more dangerous coming off Greenland and particularly, Antarctica. **The** 10 largest risk cities for sea-level rise by population are mostly in South and Southeast Asia. When you measure it by assets at risk, number one is Miami : three and a half trillion dollars at risk. Number three : New York and Newark. I was in Miami last fall during **the** supermoon, one of **the** highest high-tide days. And there were **fish** from **the** ocean swimming in some of **the** streets of Miami Beach and Fort Lauderdale and Del Rey. And this happens regularly during **the** highest- tide tides now. Not with rain — they call it”sunny-day flooding.”It comes up through **the** storm sewers. And **the** Mayor of Miami speaks for many when he says it is long past time this can be viewed through a partisan lens. This is a crisis that ’ s getting worse day by day. We have to move beyond partisanship. And I want to take a moment to honor these House Republicans — who had **the** courage last fall to step out and take a political risk, by telling **the** truth about **the** climate crisis. So **the** cost of **the** climate crisis is mounting up, there are many of these aspects I haven ’ t even mentioned. It ’ s an enormous burden. I ’ ll mention just one more, because **the** World Economic Forum last month in Davos, after their annual survey of 750 economists, said **the** climate crisis is now **the** number one risk to **the** global economy. So you get central bankers like Mark Carney, **the** head of **the** UK Central Bank, saying **the** vast majority of **the carbon** reserves are unburnable. Subprime **carbon**. I ’ m not going to remind you what happened with subprime mortgages, but it ’ s **the** same thing. If you look at all of **the carbon** fuels that were burned since **the** beginning of **the** industrial revolution, this is **the** quantity burned in **the** last 16 years. Here are all **the** ones that are proven and left on **the** books, 28 trillion dollars. **The** International Energy Agency says only this amount can be burned. So **the** rest, 22 trillion dollars — unburnable. Risk to **the** global economy. That ’ s why divestment movement makes practical sense and is not just a moral imperative. So **the** answer to **the** first question,”Must we change?”is yes, we have to change. Second question,”Can we change?”This is **the** exciting news! **The** best projections in **the** world 16 years ago were that by 2010, **the** world would be able to install 30 gigawatts of wind capacity. We beat that mark by 14 and a half times over. We see an exponential curve for wind installations now. We see **the** cost coming down dramatically. Some countries — take Germany, an industrial powerhouse with a climate not that different from Vancouver ’ s, by **the** way — one day last December, got 81 percent of all its energy from **renewable** resources, mainly solar and wind. A lot of countries are getting more than half on an average basis. More good news : energy storage, from batteries particularly, is now beginning to take off because **the** cost has been coming down very dramatically to solve **the** intermittency problem. With solar, **the** news is even more exciting! **The** best projections 14 years ago were that we would install one gigawatt per year by 2010. When 2010 came around, we beat that mark by 17 times over. Last year, we beat it by 58 times over. This year, we ' re on track to beat it 68 times over. We ' re going to win this. We are going to prevail. **The** exponential curve on solar is even steeper and more dramatic. When I came to this stage 10 years ago, this is where it was. We have seen a revolutionary breakthrough in **the** emergence of these exponential curves. And **the** cost has come down 10 percent per year for 30 years. And it ' s continuing to come down. Now, **the** business community has certainly noticed this, because it ' s crossing **the** grid parity point. Cheaper solar penetration rates are beginning to rise. Grid parity is understood as that line, that threshold, below which **renewable** electricity is cheaper than electricity from burning **fossil** fuels. That threshold is a little bit like **the** difference between 32 degrees Fahrenheit and 33 degrees Fahrenheit, or zero and one Celsius. It ' s a difference of more than one degree, it ' s **the** difference between ice and water. And it ' s **the** difference between markets that are frozen up, and liquid flows of capital into new opportunities for investment. This is **the** biggest new business opportunity in **the** history of **the** world, and **two-thirds** of it is in **the** private sector. We are seeing an **explosion** of new investment. Starting in 2010, investments globally in **renewable** electricity generation surpassed **fossils**. **The** gap has been growing ever since. **The** projections for **the** future are even more dramatic, even though **fossil** energy is now still subsidized at a rate 40 times larger than renewables. And by **the** way, if you add **the** projections for nuclear on here, particularly if you assume that **the** work many are doing to try to break through to safer and more acceptable, more affordable forms of nuclear, this could change even more dramatically. So is there any precedent for such a rapid adoption of a new technology? Well, there are many, but let ' s look at cell phones. In 1980, AT&T, then Ma Bell, commissioned McKinsey to do a global market survey of those clunky new mobile phones that appeared then."How many can we sell by **the** year 2000?"they asked. McKinsey came back and said,"900, 000."And sure enough, when **the** year 2000 arrived, they did sell 900, 000 — in **the** first three days. And for **the** balance of **the** year, they sold 120 times more. And now there are more cell connections than there are people in **the** world. So, why were they not only wrong, but way wrong? I ' ve asked that question myself,"Why?"And I think **the** answer is in three parts. First, **the** cost came down much faster than anybody expected, even as **the** quality went up. And low-income countries, places that did not have a landline grid — they leap-frogged to **the** new technology. **The** big expansion has been in **the** developing counties. So what about **the** electricity grids in **the** developing world? Well, not so hot. And in many areas, they don ' t exist. There are more people without any electricity at all in India than **the** entire population of **the** United States of America. So now we ' re getting this : solar panels on grass huts and new business models that make it affordable. Muhammad Yunus financed this one in Bangladesh with micro- credit. This is a village market. Bangladesh is now **the** fastest-deploying country in **the** world : two systems per minute on average, night and day. And we have all we need : enough energy from **the** Sun comes to **the** earth every hour to supply **the** full world ' s energy needs for an entire year. It ' s actually a little bit less than an hour. So **the** answer to **the** second question,"Can we change?"is clearly"Yes."And it ' s an ever-firmer"yes."Last question,”Will we change?”Paris really was a breakthrough, some of **the** provisions are binding and **the** regular reviews will matter a lot. But nations aren ’ t waiting, they ’ re going ahead. China has already announced that starting next year, they ’ re adopting a nationwide cap and trade system. They will likely link up with **the** European Union. **The** United States has already been changing. All of these **coal** plants were proposed in **the** next 10 years and canceled. All of these existing **coal** plants were retired. All of these **coal** plants have had their retirement announced. All of them — canceled. We are moving forward. Last year — if you look at all of **the** investment in new electricity generation in **the** United States, almost three-quarters was from **renewable** energy, mostly wind and solar. We are solving this crisis. **The** only question is : how long will it take to get there? So, it matters that a lot of people are organizing to insist on this change. Almost 400, 000 people marched in New York City before **the** UN special session on this. Many thousands, tens of thousands, marched in cities around **the** world. And so, I am extremely optimistic. As I said before, we are going to win this. I ’ ll finish with this story. When I was 13 years old, I heard that proposal by President Kennedy to land a person on **the** Moon and bring him back safely in 10 years. And I heard adults of that day and time say,”That ’ s reckless, expensive, may well fail.”But eight years and two months later, in **the** moment that Neil Armstrong set foot on **the** Moon, there was great cheer that went up in NASA ’ s mission control in Houston. Here ’ s a little-known fact about that : **the** average age of **the** systems engineers, **the** controllers in **the** room that day, was 26, which means, among other things, their age, when they heard that challenge, was 18. We now have a moral challenge that is in **the** tradition of others that we have faced. One of **the** greatest poets of **the** last century in **the** US, Wallace Stevens, wrote a line that has stayed with me :”After **the** final ’ no, ’ there comes a ’ yes, ’ and on that ’ yes ’, **the** future world depends.”When **the** abolitionists started their movement, they met with no after no after no. And then came a yes. **The** Women ’ s Suffrage and Women ’ s Rights Movement met endless no ’ s, until finally, there was a yes. **The** Civil Rights Movement, **the** movement against apartheid, and more recently, **the** movement for gay and lesbian rights here in **the** United States and elsewhere. After **the** final”no”comes a”yes.”When any great moral challenge is ultimately resolved into a binary choice between what is right and what is wrong, **the** outcome is fore-ordained because of who we are as human beings. Ninety-nine percent of us, that is where we are now and it is why we ’ re going to win this. We have everything we need. Some still doubt that we have **the** will to act, but I say **the** will to act is itself a **renewable** resource. Thank you very much. Chris Anderson : You ’ ve got this incredible combination of skills. You ’ ve got this scientist mind that can understand **the** full range of issues, and **the** ability to turn it into **the** most vivid language. No one else can do that, that ’ s why you led this thing. It was amazing to see it 10 years ago, it was amazing to see it now. Al Gore : Well, you ’ re nice to say that, Chris. But honestly, I have a lot of really good friends in **the** scientific community who are incredibly patient and who will sit there and explain this stuff to me over and over and over again until I can get it into simple enough language that I can understand it. And that ’ s **the** key to trying to communicate. CA : So, your talk. First part : **terrifying**, second part : incredibly hopeful. How do we know that all those graphs, all that progress, is enough to solve what you showed in **the** first part? AG : I think that **the** crossing — you know, I ’ ve only been in **the** business world for 15 years. But one of **the** things I ’ ve learned is that apparently it matters if a new product or service is more expensive than **the** incumbent, or cheaper than. Turns out, it makes a difference if it ’ s cheaper than. And when it crosses that line, then a lot of things really change. We are regularly surprised by these developments. **The** late Rudi Dornbusch, **the** great economist said,”Things take longer to happen then you think they will, and then they happen much faster than you thought they could.”I really think that ’ s where we are. Some people are using **the** phrase”**The** Solar Singularity”now, meaning when it gets below **the** grid parity, unsubsidized in most places, then it ’ s **the** default choice. Now, in one of **the** presentations yesterday, **the** jitney thing, there is an effort to use regulations to slow this down. And I just don ’ t think it ’ s going to work. There ’ s a woman in Atlanta, Debbie Dooley, who ’ s **the** Chairman of **the** Atlanta Tea Party. They enlisted her in this effort to put a tax on solar panels and regulations. And she had just put solar panels on her roof and she didn ’ t understand **the** request. And so she went and formed an alliance with **the** Sierra Club and they formed a new organization called **the** Green Tea Party. And they defeated **the** proposal. So, finally, **the** answer to your question is, this sounds a little corny and maybe it ’ s a clich, but 10 years ago — and Christiana referred to this — there are people in this audience who played an incredibly significant role in generating those exponential curves. And it didn ’ t work out economically for some of them, but it kick-started this global revolution. And what people in this audience do now with **the** knowledge that we are going to win this. But it matters a lot how fast we win it. CA : Al Gore, that was incredibly powerful. If this turns out to be **the** year, that **the** partisan thing changes, as you said, it ’ s no longer a partisan issue, but you bring along people from **the** other side together, backed by science, backed by these kinds of investment opportunities, backed by reason that you win **the** day — boy, that ’ s really exciting. Thank you so much. AG : Thank you so much for bringing me back to TED. Thank you!

Text Sample 52: POS Dim 1 – 2016 – Score 21.00 – 2016/t001203.txt

Here ’ s a question that matters. [Is it ethical to **evolve the** human body?] Because we ’ re beginning to get all **the** tools together to **evolve** ourselves. And we can **evolve** bacteria and we can **evolve** plants and we can **evolve** animals, and we ’ re now reaching a point where we really have to ask, is it really ethical and do we want to **evolve** human beings? And as you ’ re thinking about that, let me talk about that in **the** context of prosthetics, prosthetics past, present, future. So this is **the iron** hand that belonged to one of **the** German counts. Loved to fight, lost his arm in one of these battles. No problem, he just made a suit of armor, put it on, perfect prosthetic. That ’ s where **the** concept of ruling with an **iron** fist comes from. And of course these prosthetics have been getting more and more useful, more and more modern. You can hold soft-boiled eggs. You can have all types of controls, and as you ’ re thinking about that, there are wonderful people like Hugh Herr who have been building absolutely extraordinary prosthetics. So **the** wonderful Aimee Mullins will go out and say, how tall do I want to be tonight? Or Hugh will say what type of cliff do I want to climb? Or does somebody want to run a marathon, or does somebody want to ballroom dance? And as you adapt these things, **the** interesting thing about prosthetics is they ’ ve been coming inside **the** body. So these external prosthetics have now become **artificial** knees. They ’ ve become **artificial** hips. And then they ’ ve **evolved** further to become not just nice to have but essential to have. So when you ’ re talking about a heart pacemaker as a prosthetic, you ’ re talking about something that isn ’ t just,”I ’ m missing my leg,”it ’ s,”if I don ’ t have this, I can die.”And at that point, a prosthetic becomes a symbiotic relationship with **the** human body. And four of **the** smartest people that I ’ ve ever met — Ed Boyden, Hugh Herr, Joe Jacobson, Bob Lander — are working on a Center for Extreme Bionics. And **the** interesting thing of what you ’ re seeing here is these prosthetics now get integrated into **the** bone. They get integrated into **the** skin. They get integrated into **the** muscle. And one of **the** other sides of Ed is he ’ s been thinking about how to connect **the** brain using light or other mechanisms directly to things like these prosthetics. And if you can do that, then you can begin changing fundamental aspects of humanity. So how quickly you react to something depends on **the diameter** of a nerve. And of course, if you have nerves that are external or prosthetic, say with light or liquid metal, then you can increase that **diameter** and you could even increase it theoretically to **the** point where, as long as you could see **the** muzzle flash, you could step out of **the** way of a **bullet**. Those are **the** order of magnitude of changes you ’ re talking about. This is a fourth sort of level of prosthetics. These are Phonak hearing aids, and **the** reason why these are so interesting is because they cross **the** threshold from where prosthetics are something for somebody who is”disabled”and they become something that somebody who is”normal”might want to actually have, because what this prosthetic does, which is really interesting, is not only does it help you hear, you can focus your hearing, so it can hear **the** conversation going on over there. You can have superhearing. You can have hearing in 360 degrees. You can have white noise. You can record, and oh, by **the** way, they also put a phone into this. So this functions as your hearing aid and also as your phone. And at that point, somebody might actually want to have a prosthetic voluntarily. All of these thousands of loosely connected little pieces are coming together, and it ’ s about time we ask **the** question, how do we want to **evolve** human beings over **the** next century or two? And for that we turn to a great philosopher who was a very smart man despite being a Yankee fan. And Yogi Berra used to say, of course, that it ’ s very tough to make predictions, especially about **the** future. So instead of making a prediction about **the** future to begin with, let ’ s take what ’ s happening in **the** present with people like Tony Atala, who is redesigning 30-some-odd organs. And maybe **the** ultimate prosthetic isn ’ t having something external, titanium. Maybe **the** ultimate prosthetic is take your own gene code, remake your own body parts, because that ’ s a whole lot more effective than any kind of a prosthetic. But while you ’ re at it, then you can take **the** work of Craig Venter and Ham Smith. And one of **the** things that we ’ ve been doing is trying to figure out how to reprogram cells. And if you can reprogram a cell, then you can change **the** cells in those organs. So if you can change **the** cells in those organs, maybe you make those organs more radiation-resistant. Maybe you make them absorb more oxygen. Maybe you make them more efficient to filter out stuff that you don ’ t want in your body. And over **the** last few weeks, George Church has been in **the** news a lot because he ’ s been talking about taking one of these programmable cells and inserting an entire human **genome** into that cell. And once you can insert an entire human **genome** into a cell, then you begin to ask **the** question, would you want to enhance any of that **genome**? Do you want to enhance a human body? How would you want to enhance a human body? Where is it ethical to enhance a human body and where is it not ethical to enhance a human body? And all of a sudden, what we ’ re doing is we ’ ve got this multidimensional chess board where we can change human genetics by using viruses to attack things like AIDS, or we can change **the** gene code through gene therapy to do away with some hereditary diseases, or we can change **the** environment, and change **the** expression of those genes in **the** epigenome and pass that on to **the** next generations. And all of a sudden, it ’ s not just one little bit, it ’ s all these **stacked** little bits that allow you to take little portions of it until all **the** portions coming together lead you to something that ’ s very different. And a lot of people are very scared by this stuff. And it does sound scary, and there are risks to this stuff. So why in **the** world would you ever want to do this stuff? Why would we really want to alter **the** human body in a fundamental way? **The** answer lies in part with Lord Rees, astronomer royal of Great Britain. And one of his favorite sayings is **the universe** is 100 percent malevolent. So what does that mean? It means if you take any one of your bodies at random, drop it anywhere in **the universe**, drop it in space, you die. Drop it on **the** Sun, you die. Drop it on **the surface** of Mercury, you die. Drop it near a supernova, you die. But fortunately, it ’ s only about 80 percent effective. So as a great physicist once said, there ’ s these little upstream eddies of **biology** that create order in this rapid torrent of entropy. So as **the universe** dissipates energy, there ’ s these upstream eddies that create biological order. Now, **the** problem with eddies is, they tend to **disappear**. They shift. They move in rivers. And because of that, when an eddy shifts, when **the** Earth becomes a snowball, when **the** Earth becomes very hot, when **the** Earth gets hit by an **asteroid**, when you have supervolcanoes, when you have solar flares, when you have potentially extinction-level events like **the** next election — then all of a sudden, you can have periodic extinctions. And by **the** way, that ’ s happened five times on Earth, and therefore it is very likely that **the** human species on Earth is going to go extinct someday. Not next week, not next month, maybe in November, but maybe 10, 000 years after that. As you ’ re thinking of **the** consequence of that, if you believe that extinctions are common and natural and normal and **occur** periodically, it becomes a moral imperative to diversify our species. And it becomes a moral imperative because it ’ s going to be really hard to live on Mars if we don ’ t fundamentally modify **the** human body. Right? You go from one cell, mom and dad coming together to make one cell, in a cascade to 10 trillion cells. We don ’ t know, if you change **the** gravity substantially, if **the** same thing will happen to create your body. We do know that if you expose our bodies as they currently are to a lot of radiation, we will die. So as you ’ re thinking of that, you have to really redesign things just to get to Mars. Forget about **the** moons of Neptune or Jupiter. And to borrow from Nikolai Kardashev, let ’ s think about life in a series of scales. So Life One civilization is a civilization that begins to alter his or her looks. And we ’ ve been doing that for thousands of years. You ’ ve got tummy tucks and you ’ ve got this and you ’ ve got that. You alter your looks, and I ’ m told that not all of those alterations take place for medical reasons. Seems odd. A Life Two civilization is a different civilization. A Life Two civilization alters fundamental aspects of **the** body. So you put human growth **hormone** in, **the** person grows taller, or you put x in and **the** person gets **fatter** or loses metabolism or does a whole series of things, but you ’ re altering **the** functions in a fundamental way. To become an intrasolar civilization, we ’ re going to have to create a Life Three civilization, and that looks very different from what we ’ ve got here. Maybe you splice in Deinococcus radiodurans so that **the** cells can resplice after a lot of exposure to radiation. Maybe you breathe by having oxygen flow through your **blood** instead of through your lungs. But you ’ re talking about really radical redesigns, and one of **the** interesting things that ’ s happened in **the** last decade is we ’ ve discovered a whole lot of **planets** out there. And some of them may be Earth-like. **The** problem is, if we ever want to get to these **planets**, **the** fastest human **objects** — Juno and Voyager and **the** rest of this stuff — take tens of thousands of years to get from here to **the** nearest solar system. So if you want to start exploring beaches somewhere else, or you want to see two-sun sunsets, then you ’ re talking about something that is very different, because you have to change **the** timescale and **the** body of humans in ways which may be absolutely unrecognizable. And that ’ s a Life Four civilization. Now, we can ’ t even begin to imagine what that might look like, but we ’ re beginning to get glimpses of instruments that might take us even that far. And let me give you two examples. So this is **the** wonderful Floyd Romesberg, and one of **the** things that Floyd ' s been doing is he ' s been playing with **the** basic **chemistry** of life. So all life on this **planet** is made in ATCGs, **the** four letters of DNA. All bacteria, all plants, all animals, all humans, all cows, everything else. And what Floyd did is he changed out two of those base pairs, so it ' s ATXY. And that means that you now have a parallel system to make life, to make babies, to reproduce, to **evolve**, that doesn ' t **mate** with most things on Earth or in fact maybe with nothing on Earth. Maybe you make plants that are immune to all bacteria. Maybe you make plants that are immune to all viruses. But why is that so interesting? It means that we are not a unique solution. It means you can create alternate **chemistries** to us that could be **chemistries** adaptable to a very different **planet** that could create life and heredity. **The** second experiment, or **the** other implication of this experiment, is that all of you, all life is based on 20 amino acids. If you don ' t substitute two amino acids, if you don ' t say ATXY, if you say ATCG + XY, then you go from 20 building blocks to 172, and all of a sudden you ' ve got 172 building blocks of amino acids to build life-forms in very different shapes. **The** second experiment to think about is a really weird experiment that ' s been taking place in China. So this guy has been transplanting hundreds of mouse heads. Right? And why is that an interesting experiment? Well, think of **the** first heart transplants. One of **the** things they used to do is they used to bring in **the** wife or **the** daughter of **the** donor so **the** donee could tell **the** doctors,"Do you recognize this person? Do you love this person? Do you feel anything for this person?"We laugh about that today. We laugh because we know **the** heart is a muscle, but for hundreds of thousands of years, or tens of thousands of years,"I gave her my heart. She took my heart. She broke my heart."We thought this was emotion and we thought maybe emotions were transplanted with **the** heart. Nope. So how about **the** brain? Two possible outcomes to this experiment. If you can get a mouse that is functional, then you can see, is **the** new brain a blank slate? And boy, does that have implications. Second option : **the** new mouse recognizes Minnie Mouse. **The** new mouse remembers what it ' s afraid of, remembers how to navigate **the** maze, and if that is true, then you can transplant memory and consciousness. And then **the** really interesting question is, if you can transplant this, is **the** only input-output mechanism this down here? Or could you transplant that consciousness into something that would be very different, that would last in space, that would last tens of thousands of years, that would be a completely redesigned body that could hold consciousness for a long, long period of time? And let ' s come back to **the** first question : Why would you ever want to do that? Well, I ' ll tell you why. Because this is **the** ultimate selfie. This is taken from six billion miles away, and that ' s Earth. And that ' s all of us. And if that little thing goes, all of humanity goes. And **the** reason you want to alter **the** human body is because you eventually want a picture that says, that ' s us, and that ' s us, and that ' s us, because that ' s **the** way humanity survives long-term extinction. And that ' s **the** reason why it turns out it ' s actually unethical not to **evolve the** human body even though it can be scary, even though it can be challenging, but it ' s what ' s going to allow us to explore, live and get to places we can ' t even dream of today, but which our great-great-great-great-grandchildren might someday. Thank you very much.

In 1956, a documentary by Jacques Cousteau won both **the** Palme d ' Or and

an Oscar award. This film was called,”Le Monde Du Silence,”or,”**The** Silent World.”**The** premise of **the** title was that **the underwater** world was a quiet world. We now know, 60 years later, that **the underwater** world is anything but silent. Although **the** sounds are inaudible above water depending on where you are and **the** time of year, **the underwater** soundscape can be as noisy as any jungle or rainforest. Invertebrates like snapping **shrimp**, **fish** and marine mammals all use sound. They use sound to study their **habitat**, to keep in communication with each other, to navigate, to **detect** predators and prey. They also use sound by listening to know something about their environment. Take, for an example, **the** Arctic. It ’ s considered a vast, inhospitable place, sometimes described as a desert, because it is so cold and so remote and ice- covered for much of **the** year. And despite this, there is no place on Earth that I would rather be than **the** Arctic, especially as days lengthen and **spring** comes. To me, **the** Arctic really embodies this disconnect between what we see on **the surface** and what ’ s going on **underwater**. You can look out across **the** ice — all white and **blue** and cold — and see nothing. But if you could hear **underwater**, **the** sounds you would hear would at first amaze and then delight you. And while your eyes are seeing nothing for kilometers but ice, your ears are telling you that out there are bowhead and beluga **whales**, walrus and bearded **seals**. **The** ice, too, makes sounds. It screeches and cracks and pops and groans, as it collides and rubs when temperature or currents or winds change. And under 100 percent **sea** ice in **the** dead of winter, bowhead **whales** are singing. And you would never expect that, because we humans, we tend to be very visual animals. For most of us, but not all, our sense of sight is how we navigate our world. For marine mammals that live **underwater**, where chemical cues and light transmit poorly, sound is **the** sense by which they see. And sound transmits very well **underwater**, much better than it does in air, so signals can be heard over great distances. In **the** Arctic, this is especially important, because not only do Arctic marine mammals have to hear each other, but they also have to listen for cues in **the** environment that might indicate heavy ice ahead or open water. Remember, although they spend most of their lives **underwater**, they are mammals, and so they have to **surface** to breathe. So they might listen for thin ice or no ice, or listen for echoes off nearby ice. Arctic marine mammals live in a rich and varied **underwater** soundscape. In **the spring**, it can be a cacophony of sound. But when **the** ice is frozen solid, and there are no big temperature shifts or current changes, **the underwater** Arctic has some of **the** lowest ambient noise levels of **the** world ’ s oceans. But this is changing. This is primarily due to a decrease in seasonal **sea** ice, which is a direct result of human **greenhouse** gas **emissions**. We are, in effect, with climate change, conducting a completely uncontrolled experiment with our **planet**. Over **the** past 30 years, areas of **the** Arctic have seen decreases in seasonal **sea** ice from anywhere from six weeks to four months. This decrease in **sea** ice is sometimes referred to as an increase in **the** open water season. That is **the** time of year when **the** Arctic is navigable to vessels. And not only is **the** extent of ice changing, but **the** age and **the width** of ice is, too. Now, you may well have heard that a decrease in seasonal **sea** ice is causing a loss of **habitat** for animals that rely on **sea** ice, such as ice **seals**, or walrus, or polar bears. Decreasing **sea** ice is also causing increased erosion along coastal villages, and changing prey availability for marine birds and mammals. Climate change and decreases in **sea** ice are also altering **the underwater** soundscape of **the** Arctic. What do I mean by soundscape? Those of us who eavesdrop on **the** oceans for a living use instruments called hydrophones, which are **underwater** microphones, and we record ambient noise — **the** noise all around us. And **the** soundscape describes **the** different contributors to this noise field. What we are hearing on our hydrophones are **the** very real sounds of climate change. We are hearing these changes from three fronts : from **the** air, from **the** water and from land. First : air. Wind on water creates waves. These waves make bubbles ; **the** bubbles break, and when they do, they make noise. And this noise is like a hiss or a static in **the** background. In **the** Arctic, when it ’ s ice-covered, most of **the** noise from wind doesn ’ t make it into **the** water column, because **the** ice acts as a buffer between **the** atmosphere and **the** water. This is one of **the** reasons that **the** Arctic can have very low ambient noise levels. But with decreases in seasonal **sea** ice, not only is **the** Arctic now open to this wave noise, but **the** number of storms and **the** intensity of storms in **the** Arctic has been increasing. All of this is raising noise levels in a previously quiet ocean. Second : water. With less seasonal **sea** ice, subarctic species are moving north, and taking advantage of **the** new **habitat** that is created by more open water. Now, Arctic **whales**, like this bowhead, they have no dorsal **fin**, because they have **evolved** to live and swim in ice-covered waters, and having something sticking off of your back is not very conducive to migrating through ice, and may, in fact, be excluding animals from **the** ice. But now, everywhere we ’ ve listened, we ’ re hearing **the** sounds of **fin whales** and humpback **whales** and killer **whales**, further and further north, and later and later in **the** season. We are hearing, in essence, an invasion of **the** Arctic by subarctic species. And we don ’ t know what this means. Will there be competition for food between Arctic and subarctic animals? Might these subarctic species introduce diseases or parasites into **the** Arctic? And what are **the** new sounds that they are producing doing to **the** soundscape **underwater**? And third : land. And by land... I mean people. More open water means increased human use of **the** Arctic. Just this past summer, a massive cruise ship made its way through **the** Northwest Passage — **the** once-mythical route between Europe and **the** Pacific. Decreases in **sea** ice have allowed humans to occupy **the** Arctic more often. It has allowed increases in **oil** and gas exploration and extraction, **the** potential for commercial **shipping**, as well as increased tourism. And we now know that ship noise increases levels of stress **hormones** in **whales** and can disrupt feeding behavior. Air guns, which produce loud, low-frequency”whoomps”every 10 to 20 seconds, changed **the** swimming and vocal behavior of **whales**. And all of these sound sources are decreasing **the** acoustic space over which Arctic marine mammals can communicate. Now, Arctic marine mammals are used to very high levels of noise at certain times of **the** year. But this is primarily from other animals or from **sea** ice, and these are **the** sounds with which they ’ ve **evolved**, and these are sounds that are vital to their very survival. These new sounds are loud and they ’ re alien. They might impact **the** environment in ways that we think we understand, but also in ways that we don ’ t. Remember, sound is **the** most important sense for these animals. And not only is **the** physical **habitat** of **the** Arctic changing rapidly, but **the** acoustic **habitat** is, too. It ’ s as if we ’ ve plucked these animals up from **the** quiet countryside and dropped them into a big city in **the** middle of rush hour. And they can ’ t escape it. So what can we do now? We can ’ t decrease wind speeds or keep subarctic animals from migrating north, but we can work on local solutions to reducing human- caused **underwater** noise. One of these solutions is to slow down ships that traverse **the** Arctic, because a slower ship is a quieter ship. We can restrict access in seasons and regions that are important for **mating** or feeding or migrating. We can get smarter about quieting ships and find better ways to explore **the** ocean bottom. And **the** good news is, there are people working on this right now. But ultimately, we humans have to do **the** hard work of reversing or at **the** very least decelerating human-caused atmospheric changes. So, let ’ s return to this idea of a silent world **underwater**. It ’ s entirely possible that many of

the whales swimming in **the** Arctic today, especially long- lived species like **the** bowhead **whale** that **the** Inuits say can live two human lives — it ’ s possible that these **whales** were alive in 1956, when Jacques Cousteau made his film. And in retrospect, considering all **the** noise we are creating in **the** oceans today, perhaps it really was”**The** Silent World.”Thank you.

Text Sample 54: POS Dim 1 – 2017 – Score 34.00 – 2017/t000900.txt
Chris Anderson : OK, Stewart, in **the** ’ 60s, you â I think it was ’ 68 â you founded this magazine. Stewart Brand : Bravo! It ’ s **the** original one. That ’ s hard to find. CA : Right. Issue One, right? SB : Mm hmm. CA : Why did that make so much impact? SB : Counterculture was **the** main event that I was part of at **the** time, and it was made up of hippies and New Left. That was sort of my contemporaries, **the** people I was just slightly older than. And my mode is to look at where **the** interesting flow is and then look in **the** other direction. CA : SB : Partly, I was trained to do that as an army officer, but partly, it ’ s just a cheap heuristic to find originalities : don ’ t look where everybody else is looking, look **the** opposite way. So **the** deal with counterculture is, **the** hippies were very romantic and kind of against technology, except very good LSD from Sandoz, and **the** New Left was against technology because they thought it was a power **device**. **Computers** were : do not spindle, fold, or mutilate. Fight that. And so, **the** Whole Earth Catalog was kind of a counter-counterculture thing in **the** sense that I bought Buckminster Fuller ’ s idea that tools of are of **the** essence. Science and engineers basically define **the** world in interesting ways. If all **the** politicians **disappeared** one week, it would be... a nuisance. But if all **the** scientists and engineers **disappeared** one week, it would be way more than a nuisance. CA : We still believe that, I think. SB : So focus on that. And then **the** New Left was talking about power to **the** people. And people like Steve Jobs and Steve Wozniak cut that and just said, power to people, tools that actually work. And so, where Fuller was saying don ’ t try to change human nature, people have been trying for a long time and it does not even bend, but you can change tools very easily. So **the** efficient thing to do if you want to make **the** world better is not try to make people behave differently like **the** New Left was, but just give them tools that go in **the** right direction. That was **the** Whole Earth Catalog. CA : And Stewart, **the** central image â this is one of **the** first images, **the** first time people had seen Earth from outer space. That had an impact, too. SB : It was kind of a chance that in **the spring** of ’ 66, thanks to an LSD experience on a rooftop in San Francisco, I got thinking about, again, something that Fuller talked about, that a lot of people assume that **the** Earth is flat and kind of infinite in terms of its resources, but once you really grasp that it ’ s a **sphere** and that there ’ s only so much of it, then you start husbanding your resources and thinking about it as a finite system.”Spaceship Earth”was his metaphor. And I wanted that to be **the** case, but on LSD I was getting higher and higher on my hundred micrograms on **the** roof of San Francisco, and noticed that **the** downtown buildings which were right in front of me were not all parallel, they were sort of fanned out like this. And that ’ s because they are on a curved **surface**. And if I were even higher, I would see that even more clearly, higher than that, more clearly still, higher enough, and it would close, and you would get **the** circle of Earth from space. And I thought, you know, we ’ ve been in space for 10 years â at that time, this is ’ 66 â and **the** cameras had never looked back. They ’ d always been looking out or looking at just parts of **the** Earth. And so I said, why haven ’ t we seen a photograph of **the** whole Earth yet? And it went around and NASA got it and senators, secretaries got it,

and various people in **the** Politburo got it, and it went around and around. And within two and a half years, about **the** time **the** Whole Earth Catalog came out, these images started to appear, and indeed, they did transform everything. And my idea of hacking civilization is that you try to do something lazy and ingenious and just sort of trick **the** situation. So all of these photographs that you see â and then **the** march for science last week, they were carrying these Whole Earth banners and so on â I did that with no work. I sold those buttons for 25 cents apiece. So, you know, tweaking **the** system is, I think, not only **the** most efficient way to make **the** system go in interesting ways, but in some ways, **the** safest way, because when you try to horse **the** whole system around in a big way, you can get into big horsing-around problems, but if you tweak it, it will adjust to **the** tweak. CA : So since then, among many other things, you ' ve been regarded as a leading voice in **the** environmental movement, but you are also a counterculturalist, and recently, you ' ve been taking on a lot of, well, you ' ve been declaring what a lot of environmentalists almost believe are heresies. I kind of want to explore a couple of those. I mean, tell me about this image here. SB : Ha-ha! That ' s a National Geographic image of what is called **the** mammoth steppe, what **the** far north, **the** sub-Arctic and Arctic region, used to look like. In fact, **the** whole world used to look like that. What we find in South Africa and **the** Serengeti now, lots of big animals, was **the** case in this part of Canada, throughout **the** US, throughout Eurasia, throughout **the** world. This was **the** norm and can be again. So in a sense, my long-term goal at this point is to not only bring back those animals and **the** grassland they made, which could be a climate stabilization system over **the** long run, but even **the** mammoths there in **the** background that are part of **the** story. And I think that ' s probably a 200- year goal. Maybe in 100, by **the** end of this century, we should be able to dial down **the** extinction rate to sort of what it ' s been in **the** background. Bringing back this amount of bio-abundance will take longer, but it ' s worth doing. CA : We ' ll come back to **the** mammoths, but explain how we should think of extinctions. Obviously, one of **the** huge concerns right now is that extinction is happening at a faster rate than ever in history. That ' s **the** meme that ' s out there. How should we think of it? SB : **The** story that ' s out there is that we ' re in **the** middle of **the** Sixth Extinction or maybe in **the** beginning of **the** Sixth Extinction. Because we ' re in **the** de-extinction business, **the** preventing-extinction business with Revive & Restore, we started looking at what ' s actually going on with extinction. And it turns out, there ' s a very confused set of data out there which gets oversimplified into **the** narrative of we ' re becoming... Here are five mass extinctions that are indicated by **the** **yellow triangles**, and we ' re now next. **The** last one there on **the** far right was **the** meteor that struck 66 million years ago and did in **the** dinosaurs. And **the** story is, we ' re **the** next meteor. Well, here ' s **the** deal. I wound up researching this for a paper I wrote, that a mass extinction is when 75 percent of all **the** species in **the** world go extinct. Well, there ' s on **the** order of five-and-a-half-million species, of which we ' ve identified one and a half million. Another 14, 000 are being identified every year. There ' s a lot of **biology** going on out there. Since 1500, about 500 species have gone extinct, and you ' ll see **the** term"mass extinction"kind of used in strange ways. So there was, about a year and a half ago, a front-page story by Carl Zimmer in **the** New York Times,"Mass Extinction in **the** Oceans, Broad Studies Show."And then you read into **the** article, and it mentions that since 1500, 15 species â one, five â have gone extinct in **the** oceans, and, oh, by **the** way, none in **the** last 50 years. And you read further into **the** story, and it ' s saying, **the** horrifying thing that ' s going on is that **the** fisheries are so overfishing **the** wild **fishes**, that it is taking down **the fish** populations in **the** oceans by 38 percent. That ' s **the** serious thing. None of those species are probably going to go extinct. So you ' ve just put, that headline writer put a panic button on **the** top of **the** story. It ' s clickbait kind of stuff, but it ' s basically saying,"Oh my God, start panicking, we ' re going to lose all **the** species in **the** oceans."Nothing like that is in prospect. And in fact, what I then started looking into in a little more detail, **the** Red List shows about 23, 000 species that are considered threatened at one level or another, coming from **the** International Union for **the** Conservation of Nature, **the** IUCN. And Nature Magazine had a piece surveying **the** loss of wildlife, and it said,"If all of those 23, 000 went extinct in **the** next century or so, and that rate of extinction carried on for more centuries and millennia, then we might be at **the** beginning of a sixth extinction. So **the** exaggeration is way out of hand. But environmentalists always exaggerate. That ' s a problem. CA : I mean, they probably feel a moral responsibility to, because they care so much about **the** thing that they are looking at, and unless you bang **the drum** for it, maybe no one listens. SB : Every time somebody says moral this or moral that â""moral hazard,""precautionary principle"â these are terms that are used to basically say no to things. CA : So **the** problem isn ' t so much **fish** extinction, animal extinction, it ' s **fish** flourishing, animal flourishing, that we ' re crowding them to some extent? SB : Yeah, and I think we are crowding, and there is losses going on. **The** major losses are caused by **agriculture**, and so anything that improves **agriculture** and basically makes it more condensed, more highly productive, including GMOs, please, but even if you want to do vertical farms in town, including inside farms, all **the** things that have been learned about how to grow pot in basements, is now being applied to growing vegetables inside containers â that ' s great, that ' s all good stuff, because land sparing is **the** main thing we can do for nature. People moving to cities is good. Making **agriculture** less of a destruction of **the** landscape is good. CA : There people talking about bringing back species, rewilding... Well, first of all, rewilding species : What ' s **the** story with these guys? SB : Ha-ha! Wolves. Europe, connecting to **the** previous point, we ' re now at probably peak farmland, and, by **the** way, in terms of population, we are already at peak children being alive. Henceforth, there will be fewer and fewer children. We are in **the** last doubling of human population, and it will get to nine, maybe nine and a half billion, and then start not just leveling off, but probably going down. Likewise, farmland has now peaked, and one of **the** ways that plays out in Europe is there ' s a lot of abandoned farmland now, which immediately reforests. They don ' t do wildlife corridors in Europe. They don ' t need to, because so many of these farms are connected that they ' ve made reforested wildlife corridors, that **the** wolves are coming back, in this case, to Spain. They ' ve gotten all **the** way to **the** Netherlands. There ' s bears coming back. There ' s lynx coming back. There ' s **the** European jackal. I had no idea such a thing existed. They ' re coming back from Italy to **the** rest of Europe. And unlike here, these are all predators, which is kind of interesting. They are being welcomed by Europeans. They ' ve been missed. CA : And counterintuitively, when you bring back **the** predators, it actually increases rather than reduces **the** diversity of **the** underlying ecosystem often. SB : Yeah, generally predators and large animals â large animals and large animals with sharp teeth and claws â are turning out to be highly important for a really rich ecosystem. CA : Which maybe brings us to this rather more dramatic rewilding project that you ' ve got yourself involved in. Why would someone want to bring back these **terrifying** woolly mammoths? SB : Hmm. Asian **elephants** are **the** closest **relative** to **the** woolly mammoth, and they ' re about **the** same size, genetically very close. They diverged quite recently in **evolutionary** history. **The** Asian **elephants** are closer to woolly mammoths than they are to African **elephants**, but they ' re close enough to African **elephants** that they have successfully hybridized. So we ’ re working with George Church at Harvard, who has already moved **the** genes for four major traits from **the** now well-preserved, well-studied **genome** of **the** woolly mammoth, thanks to so-called”ancient DNA analysis.”And in **the** lab, he has moved those genes into living Asian **elephant** cell lines, where they ’ re taking up their proper place thanks to CRISPR. I mean, they ’ re not shooting **the** genes in like you did with genetic engineering. Now with CRISPR you ’ re editing, basically, one allele, and replacing it in **the** place of another allele. So you ’ re now getting basically Asian **elephant** germline cells that are effectively in terms of **the** traits that you ’ re going for to be comfortable in **the** Arctic, you ’ re getting them in there. So we go through **the** process of getting that through a surrogate mother, an Asian **elephant** mother. You can get a proxy, as it ’ s being called by conservation biologists, of **the** woolly mammoth, that is effectively a hairy, curly-trunked, Asian **elephant** that is perfectly comfortable in **the** sub-Arctic. Now, it ’ s **the** case, so many people say,”Well, how are you going to get them there? And Asian **elephants**, they don ’ t like snow, right?”Well, it turns out, they do like snow. There ’ s some in an Ontario zoo that have made snowballs bigger than people. They just love â you know, with a trunk, you can start a little thing, roll it and make it bigger. And then people say,”Yeah, but it ’ s 22 months of gestation. This kind of cross-species **cloning** is tricky business, anyway. Are you going to lose some of **the** surrogate Asian **elephant** mothers?”And then George Church says,”That ’ s all right. We ’ ll do an **artificial** uterus and grow them that way.”Then people say,”Yeah, next century, maybe,”except **the** news came out this week in Nature that there ’ s now an **artificial** uterus in which they ’ ve grown a lamb to four weeks. That ’ s halfway through its gestation period. So this stuff is moving right along. CA : But why should we want a world where â Picture a world where there are thousands of these things thundering across Siberia. Is that a better world? SB : Potentially. It ’ s â There ’ s three groups, basically, working on **the** woolly mammoth seriously : Revive & Restore, we ’ re kind of in **the** middle ; George Church and **the** group at Harvard that are doing **the** genetics in **the** lab ; and then there ’ s an amazing old scientist named Zimov who works in northern Siberia, and his son Nikita, who has bought into **the** system, and they are, Sergey and Nikita Zimov have been, for 25 years, creating what they call”Pleistocene Park,”which is a place in a really tough part of Siberia that is pure tundra. And **the** research that ’ s been done shows that there ’ s probably one one-hundredth of **the** animals on **the** landscape there that there used to be. Like that earlier image, we saw lots of animals. Now there ’ s almost none. **The** tundra is mostly moss, and then there ’ s **the** boreal forest. And that ’ s **the** way it is, folks. There ’ s just a few animals there. So they brought in a lot of grazing animals : musk ox, Yakutian horses, they ’ re bringing in some bison, they ’ re bringing in some more now, and put them in at **the** density that they used to be. And grasslands are made by grazers. So these animals are there, grazing away, and they ’ re doing a couple of things. First of all, they ’ re turning **the** tundra, **the** moss, back into grassland. Grassland fixes **carbon**. Tundra, in a warming world, is thawing and releasing a lot of **carbon** dioxide and also methane. So already in their little 25 square miles, they ’ re doing a climate stabilization thing. Part of that story, though, is that **the** boreal forest is very absorbent to sunlight, even in **the** winter when snow is on **the** ground. And **the** way **the** mammoth steppe, which used to wrap all **the** way around **the** North Pole â there ’ s a lot of landmass around **the** North Pole â that was all this grassland. And **the** steppe was magnificent, probably one of **the** most productive biomes in **the** world, **the** biggest biome in **the** world. **The** forest part of it, right now, Sergey Zimov and Nikita go out with this old military tank they got for nothing, and they knock down **the** trees. And that ’ s a bore, and it ’ s tiresome, and as Sergey says,”... and they make no dung!”which, by **the** way, these big animals do, including mammoths. So mammoths become what conservation biologists call an umbrella species. It ’ s an exciting animal â pandas in China or wherever â that **the** excitement that goes on of making life good for that animal is making a **habitat**, an ecosystem, which is good for a whole lot of creatures and plants, and it ideally gets to **the** point of being self-managing, where **the** conservation biologists can back off and say,”All we have to do is keep out **the** destructive invasives, and this thing can just cook.”CA : So there ’ s many other species that you ’ re dreaming of de-extincting at some point, but I think what I ’ d actually like to move on to is this idea you talked about how mammoths might help green Siberia in a sense, or at least, I ’ m not talking about tropical rainforest, but this question of greening **the planet** you ’ ve thought about a lot. And **the** traditional story is that deforestation is one of **the** most awful curses of modern times, and that it ’ s a huge contributor to climate change. And then you went and sent me this graph here, or this map. What is this map? SB : Global greening. **The** thing to do with any narrative that you get from headlines and from short news stories is to look for what else is going on, and look for what Marc Andreessen calls”narrative violation.”So **the** narrative â and Al Gore is master of putting it out there â is that there ’ s this civilization-threatening climate change coming on very rapidly. We have to cease all extra production of **greenhouse** gases, especially CO2, as soon as possible, otherwise, we ’ re in deep, deep trouble. All of that is true, but it ’ s not **the** whole story, and **the** whole story is more interesting than these fragmentary stories. Plants love CO2. What plants are made of is CO2 plus water via sunshine. And so in many **greenhouses**, industrialized **greenhouses**, they add CO2 because **the** plants turn that into plant matter. So **the** studies have been done with satellites and other things, and what you ’ re seeing here is a graph of, over **the** last 33 years or so, there ’ s 14 percent more leaf action going on. There ’ s that much more biomass. There ’ s that much more what ecologists call”primary production.”There ’ s that much more life happening, thanks to climate change, thanks to all of our goddam **coal** plants. So â whoa, what ’ s going on here? By **the** way, crop production goes up with this. This is a partial counter to **the** increase of CO2, because there ’ s that much more plant that is sucking it down into plant matter. Some of that then decays and goes right back up, but some of it is going down into roots and going into **the** soil and staying there. So these counter things are part of what you need to bear in mind, and **the** deeper story is that thinking about and dealing with and engineering climate is a pretty complex process. It ’ s like medicine. You ’ re always, again, tweaking around with **the** system to see what makes an improvement. Then you do more of that, see it ’ s still getting better, then â oop! â that ’ s enough, back off half a turn. CA : But might some people say,”Not all green is created equal.”Possibly what we ’ re doing is trading off **the** magnificence of **the** rainforest and all that diversity for, I don ’ t know, green pond scum or grass or something like that. SB : In this particular study, it turns out every form of plant is increasing. Now, what ’ s interestingly left out of this study is what **the** hell is going on in **the** oceans. Primary production in **the** oceans, **the** biota of **the** oceans, mostly microbial, what they ’ re up to is probably **the** most important thing. They ’ re **the** ones that create **the** atmosphere that we ’ re happily breathing, and they ’ re not part of this study. This is one of **the** things James Lovelock has been insisting ; basically, our knowledge of **the** oceans, especially of ocean life, is fundamentally vapor, in this sense. So we ’ re in **the** process of finding out by inadvertent bad geoengineering of too much CO2 in **the** atmosphere, finding out, what is **the** ocean doing with that?

Well, **the** ocean, with **the** extra heat, is swelling up. That ’ s most of where we ’ re getting **the sea** level rise, and there ’ s a lot more coming with more global warming. We ’ re getting terrible harm to some of **the** coral reefs, like off of Australia. **The** great reef there is just a lot of bleaching from overheating. And this is why I and Danny Hillis, in our previous session on **the** main stage, was saying,”Look, geoengineering is worth experimenting with enough to see that it works, to see if we can buy time in **the** warming aspect of all of this, tweak **the** system with small but usable research, and then see if we should do more than tweak. CA : OK, so this is what we ’ re going to talk about for **the** last few minutes here because it ’ s such an important discussion. First of all, this book was just published by Yuval Harari. He ’ s basically saying **the** next **evolution** of humans is to become as gods. I think he â SB : Now, you ’ ve talked to him. And you ’ ve probably finished **the** book. I haven ’ t finished it yet. Where does he come out on â CA : I mean, it ’ s a pretty radical view. He thinks that we will completely remake ourselves using data, using bioengineering, to become completely new creatures that have, kind of, superpowers, and that there will be huge inequality. But we ’ re about to write a very radical, brand-new chapter of history. That ’ s what he believes. SB : Is he nervous about that? I forget. CA : He ’ s nervous about it, but I think he also likes provoking people. SB : Are you nervous about that? CA : I ’ m nervous about that. But, you know, with so much at TED, I ’ m excited and nervous. And **the** optimist in me is trying hard to lean towards”This is awesome and really exciting,”while **the** sort of responsible part of me is saying,”But, uh, maybe we should be a little bit careful as to how we think of it.”SB : That ’ s your secret sauce, isn ’ t it, for TED? Staying nervous and excited. CA : It ’ s also **the** recipe for being a little bit schizophrenic. But he didn ’ t quote you. What I thought was an astonishing statement that you made right back in **the** original Whole Earth Catalog, you ended it with this powerful phrase :”We are as gods, and might as well get good at it.”And then more recently, you ’ ve upgraded that statement. I want you talk about this philosophy. SB : Well, one of **the** things I ’ m **learning** is that documentation is better than memory â by far. And one of **the** things I ’ ve learned from somebody â I actually got on Twitter. It changed my life â it hasn ’ t forgiven me yet! And I took ownership of this phrase when somebody quoted it, and somebody else said,”Oh by **the** way, that isn ’ t what you originally wrote in that first 1968 Whole Earth Catalog. You wrote, ’ We are as gods and might as well get used to it. ’”I ’ d forgotten that entirely. **The** stories â these goddam stories â **the** stories we tell ourselves become lies over time. So, documentation helps cut through that. It did move on to”We are as gods and might as well get good at it,”and that was **the** Whole Earth Catalog. By **the** time I was doing a book called”Whole Earth Discipline : An Ecopragmatist Manifesto,”and in light of climate change, basically saying that we are as gods and have to get good at it. CA : We are as gods and have to get good at it. So talk about that, because **the** psychological reaction from so many people as soon as you talk about geoengineering is that **the** last thing they believe is that humans should be gods â some of them for religious reasons, but most just for humility reasons, that **the** systems are too complex, we should not be dabbling that way. SB : Well, this is **the** Greek narrative about hubris. And once you start getting really sure of yourself, you wind up sleeping with your mother. CA : I did not expect you would say that. SB : That ’ s **the** Oedipus story. Hubris is a really important cautionary tale to always have at hand. One of **the** guidelines I ’ ve kept for myself is : every day I ask myself how many things I am dead wrong about. And I ’ m a scientist by training and getting to work with scientists these days, which is pure joy. Science is organized skepticism. So you ’ re always insisting that even when something looks pretty good, you maintain a full set of not only suspicions about whether it ’ s as good as it looks, but : What else is going on? So this”What else is going?”on query, I think, is how you get away from fake news. It ’ s not necessarily real news, but it ’ s welcomely more complex news that you ’ re trying to take on. CA : But coming back to **the** application of this just for **the** environment : it seems like **the** philosophy of this is that, whether we like it or not, we are already dominating so many aspects of what happens on **planets**, and we ’ re doing it unintentionally, so we really should start doing it intentionally. What would it look like to start getting good at being a god? How should we start doing that? Are there small-scale experiments or systems we can nudge and play with? How on earth do we think about it? SB : **The** mentor that sort of freed me from total allegiance to Buckminster Fuller was Gregory Bateson. And Gregory Bateson was an epistemologist and anthropologist and biologist and psychologist and many other things, and he looked at how systems basically look at themselves. And that is, I think, part of how you want to always be looking at things. And what I like about David Keith ’ s approach to geoengineering is you don ’ t just haul off and do it. David Keith ’ s approach â and this is what Danny Hillis was talking about earlier â is that you do it really, really incrementally, you do some stuff to tweak **the** system, see how it responds, that tells you something about **the** system. That ’ s responding to **the** fact that people say, quite rightly,”What are we talking about here? We don ’ t understand how **the** climate system works. You can ’ t engineer a system you don ’ t understand.”And David says,”Well, that certainly applies to **the** human body, and yet medicine goes ahead, and we ’ re kind of glad that it has.”**The** way you engineer a system that is so large and complex that you can ’ t completely understand it is you tweak it, and this is kind of an anti-hubristic approach. This is : try a little bit here, back **the** hell off if it ’ s an issue, expand it if it seems to go OK, meanwhile, have other paths going forward. This is **the** whole argument for diversity and dialogue and all these other things and **the** things we were hearing about earlier with Sebastian [Thrun]. So **the** non-hubristic approach is looking for social license, which is a terminology that I think is a good one, of including society enough in these interesting, problematic, deep issues that they get to have a pretty good idea and have people that they trust paying close attention to **the** sequence of experiments as it ’ s going forward, **the** public dialogue as it ’ s going forward â which is more public than ever, which is **fantastic** â and you feel your way, you just ooze your way along, and this is **the** muddle-through approach that has worked pretty well so far. **The** reason that Sebastian and I are optimistic is we read people like Steven Pinker,”**The** Better Angels of Our Nature,”and so far, so good. Now, that can always change, but you can build a lot on that sense of : things are capable of getting better, figure out **the** tools that made that happen and apply those further. That ’ s **the** story. CA : Stewart, I think on that optimistic note, we ’ re actually going to wrap up. I am in awe of how you always are willing to challenge yourself and other people. I feel like this recipe for never allowing yourself to be too certain is so powerful. I want to learn it more for myself, and it ’ s been very insightful and inspiring, actually, listening to you today. Stewart Brand, thank you so much. SB : Thank you.

Text Sample 55: POS Dim 1 – 2017 – Score 26.00 – 2017/t001083.txt

Chris Anderson : Elon, hey, welcome back to TED. It ’ s great to have you here. Elon Musk : Thanks for having me. CA : So, in **the** next half hour or so, we ’ re going to spend some time exploring your vision for what an exciting future might look like, which I guess makes **the** first question a little ironic : Why are you boring? EM : Yeah. I ask myself that frequently. We ’ re trying to dig a hole under LA, and this is to create **the** beginning of what will hopefully be a 3D network of tunnels to alleviate congestion. So right now, one of **the** most soul-destroying things is traffic. It affects people in every part of **the** world. It takes away so much of your life. It ’ s horrible. It ’ s particularly horrible in LA. CA : I think you ’ ve brought with you **the** first visualization that ’ s been shown of this. Can I show this? EM : Yeah, absolutely. So this is **the** first time — Just to show what we ’ re talking about. So a couple of key things that are important in having a 3D tunnel network. First of all, you have to be able to integrate **the** entrance and exit of **the** tunnel seamlessly into **the** fabric of **the** city. So by having an elevator, sort of a car skate, that ’ s on an elevator, you can integrate **the** entrance and exits to **the** tunnel network just by using two parking spaces. And then **the** car gets on a skate. There ’ s no speed limit here, so we ’ re designing this to be able to operate at 200 kilometers an hour. CA : How much? EM : 200 kilometers an hour, or about 130 miles per hour. So you should be able to get from, say, Westwood to LAX in six minutes — five, six minutes. CA : So possibly, initially done, it ’ s like on a sort of toll road-type basis. EM : Yeah. CA : Which, I guess, alleviates some traffic from **the surface** streets as well. EM : So, I don ’ t know if people noticed it in **the** video, but there ’ s no real limit to how many levels of tunnel you can have. You can go much further deep than you can go up. **The** deepest mines are much deeper than **the** tallest buildings are tall, so you can alleviate any arbitrary level of urban congestion with a 3D tunnel network. This is a very important point. So a key rebuttal to **the** tunnels is that if you add one layer of tunnels, that will simply alleviate congestion, it will get used up, and then you ’ ll be back where you started, back with congestion. But you can go to any arbitrary number of tunnels, any number of levels. CA : But people — seen traditionally, it ’ s incredibly expensive to dig, and that would block this idea. EM : Yeah. Well, they ’ re right. To give you an example, **the** LA subway extension, which is — I think it ’ s a two-and-a-half mile extension that was just completed for two billion dollars. So it ’ s roughly a billion dollars a mile to do **the** subway extension in LA. And this is not **the** highest utility subway in **the** world. So yeah, it ’ s quite difficult to dig tunnels normally. I think we need to have at least a tenfold improvement in **the** cost per mile of tunneling. CA : And how could you achieve that? EM : Actually, if you just do two things, you can get to approximately an order of magnitude improvement, and I think you can go beyond that. So **the** first thing to do is to cut **the** tunnel **diameter** by a factor of two or more. So a single road lane tunnel according to regulations has to be 26 feet, maybe 28 feet in **diameter** to allow for crashes and emergency vehicles and sufficient ventilation for combustion engine cars. But if you shrink that **diameter** to what we ’ re attempting, which is 12 feet, which is plenty to get an electric skate through, you drop **the diameter** by a factor of two and **the** cross-sectional area by a factor of four, and **the** tunneling cost scales with **the** cross-sectional area. So that ’ s roughly a half-order of magnitude improvement right there. Then tunneling machines currently tunnel for half **the** time, then they stop, and then **the** rest of **the** time is putting in reinforcements for **the** tunnel wall. So if you design **the** machine instead to do continuous tunneling and reinforcing, that will give you a factor of two improvement. Combine that and that ’ s a factor of eight. Also these machines are far from being at their power or thermal limits, so you can jack up **the** power to **the** machine substantially. I think you can get at least a factor of two, maybe a factor of four or five improvement on top of that. So I think there ’ s a fairly straightforward series of steps to get somewhere in excess of an order of magnitude improvement in **the** cost per mile, and our target actually is — we ’ ve got a pet snail called Gary, this is from Gary **the** snail from”South Park,”I mean, sorry,”SpongeBob SquarePants.”So Gary is capable of — currently he ’ s capable of going 14 times faster than a tunnel-boring machine. CA : You want to beat Gary. EM : We want to beat Gary. He ’ s not a patient little fellow, and that will be victory. Victory is beating **the** snail. CA : But a lot of people imagining, dreaming about future cities, they imagine that actually **the** solution is flying cars, drones, etc. You go aboveground. Why isn ’ t that a better solution? You save all that tunneling cost. EM : Right. I ’ m in favor of flying things. Obviously, I do rockets, so I like things that fly. This is not some inherent bias against flying things, but there is a challenge with flying cars in that they ’ ll be quite noisy, **the** wind force generated will be very high. Let ’ s just say that if something ’ s flying over your head, a whole bunch of flying cars going all over **the** place, that is not an anxiety-reducing situation. You don ’ t think to yourself,”Well, I feel better about today.”You ’ re thinking,”Did they service their hubcap, or is it going to come off and guillotine me?”Things like that. CA : So you ’ ve got this vision of future cities with these rich, 3D networks of tunnels underneath. Is there a tie-in here with Hyperloop? Could you apply these tunnels to use for this Hyperloop idea you released a few years ago. EM : Yeah, so we ’ ve been sort of puttering around with **the** Hyperloop stuff for a while. We built a Hyperloop test track adjacent to SpaceX, just for a student competition, to encourage innovative ideas in transport. And it actually ends up being **the** biggest vacuum chamber in **the** world after **the** Large Hadron Collider, by volume. So it was quite fun to do that, but it was kind of a hobby thing, and then we think we might — so we ’ ve built a little pusher car to push **the** student pods, but we ’ re going to try seeing how fast we can make **the** pusher go if it ’ s not pushing something. So we ’ re cautiously optimistic we ’ ll be able to be faster than **the** world ’ s fastest **bullet** train even in a. 8-mile stretch. CA : Whoa. Good **brakes**. EM : Yeah, I mean, it ’ s — yeah. It ’ s either going to smash into tiny pieces or go quite fast. CA : But you can picture, then, a Hyperloop in a tunnel running quite long distances. EM : Exactly. And looking at tunneling technology, it turns out that in order to make a tunnel, you have to — In order to **seal** against **the** water table, you ’ ve got to typically design a tunnel wall to be good to about five or six atmospheres. So to go to vacuum is only one atmosphere, or near-vacuum. So actually, it sort of turns out that automatically, if you build a tunnel that is good enough to resist **the** water table, it is automatically capable of holding vacuum. CA : Huh. EM : So, yeah. CA : And so you could actually picture, what kind of length tunnel is in Elon ’ s future to running Hyperloop? EM : I think there ’ s no real length limit. You could dig as much as you want. I think if you were to do something like a DC-to-New York Hyperloop, I think you ’ d probably want to go **underground the** entire way because it ’ s a high- density area. You ’ re going under a lot of buildings and houses, and if you go deep enough, you cannot **detect the** tunnel. Sometimes people think, well, it ’ s going to be pretty annoying to have a tunnel dug under my house. Like, if that tunnel is dug more than about three or four tunnel **diameters** beneath your house, you will not be able to **detect** it being dug at all. In fact, if you ’ re able to **detect the** tunnel being dug, whatever **device** you are using, you can get a lot of money for that **device** from **the** Israeli military, who is trying to **detect** tunnels from Hamas, and from **the** US Customs and Border patrol that try and **detect** drug tunnels. So **the** reality is that earth is incredibly good at absorbing vibrations, and once **the** tunnel depth is below a certain level, it is undetectable. Maybe if you have a very sensitive seismic instrument, you might be able to **detect** it. CA : So you ’ ve started a new company to do this called **The** Boring Company. Very nice. Very funny. EM : What ’ s funny about that? CA : How much of your time is this? EM : It ’ s maybe... two or three percent. CA : You ’ ve called it a hobby. This is what an Elon Musk hobby looks like. EM : I mean, it really is, like — This is basically interns and people doing it part time. We bought some second-hand machinery. It ' s kind of puttering along, but it ' s making good progress, so — CA : So an even bigger part of your time is being spent on electrifying cars and transport through Tesla. Is one of **the** motivations for **the** tunneling project **the** realization that actually, in a world where cars are electric and where they ' re self-driving, there may end up being more cars on **the** roads on any given hour than there are now? EM : Yeah, exactly. A lot of people think that when you make cars autonomous, they ' ll be able to go faster and that will alleviate congestion. And to some degree that will be true, but once you have shared autonomy where it ' s much cheaper to go by car and you can go point to point, **the** affordability of going in a car will be better than that of a bus. Like, it will cost less than a bus **ticket**. So **the** amount of driving that will **occur** will be much greater with shared autonomy, and actually traffic will get far worse. CA : You started Tesla with **the** goal of persuading **the** world that electrification was **the** future of cars, and a few years ago, people were laughing at you. Now, not so much. EM : OK. I don ' t know. I don ' t know. CA : But isn ' t it true that pretty much every auto manufacturer has announced serious electrification plans for **the** short- to medium-term future? EM : Yeah. Yeah. I think almost every automaker has some electric vehicle program. They vary in seriousness. Some are very serious about transitioning entirely to electric, and some are just dabbling in it. And some, amazingly, are still pursuing fuel cells, but I think that won ' t last much longer. CA : But isn ' t there a sense, though, Elon, where you can now just declare victory and say, you know,"We did it."Let **the** world electrify, and you go on and focus on other stuff? EM : Yeah. I intend to stay with Tesla as far into **the** future as I can imagine, and there are a lot of exciting things that we have coming. Obviously **the** Model 3 is coming soon. We ' ll be **unveiling the** Tesla Semi truck. CA : OK, we ' re going to come to this. So Model 3, it ' s supposed to be coming in July-ish. EM : Yeah, it ' s looking quite good for starting production in July. CA : Wow. One of **the** things that people are so excited about is **the** fact that it ' s got autopilot. And you put out this video a while back showing what that technology would look like. EM : Yeah. CA : There ' s obviously autopilot in Model S right now. What are we seeing here? EM : Yeah, so this is using only cameras and GPS. So there ' s no LIDAR or radar being used here. This is just using passive optical, which is essentially what a person uses. **The** whole road system is meant to be navigated with passive optical, or cameras, and so once you solve cameras or vision, then autonomy is solved. If you don ' t solve vision, it ' s not solved. So that ' s why our focus is so heavily on having a vision neural net that ' s very effective for road conditions. CA : Right. Many other people are going **the** LIDAR route. You want cameras plus radar is most of it. EM : You can absolutely be superhuman with just cameras. Like, you can probably do it ten times better than humans would, just cameras. CA : So **the** new cars being sold right now have eight cameras in them. They can ' t yet do what that showed. When will they be able to? EM : I think we ' re still on track for being able to go cross-country from LA to New York by **the** end of **the** year, fully autonomous. CA : OK, so by **the** end of **the** year, you ' re saying, someone ' s going to sit in a Tesla without touching **the** steering wheel, tap in"New York,"off it goes. EM : Yeah. CA : Won ' t ever have to touch **the** wheel — by **the** end of 2017. EM : Yeah. Essentially, November or December of this year, we should be able to go all **the** way from a parking lot in California to a parking lot in New York, no controls touched at any point during **the** entire journey. CA : Amazing. But part of that is possible because you ' ve already got a fleet of Teslas driving all these roads. You ' re accumulating a huge amount of data of that national road system. EM

: Yes, but **the** thing that will be interesting is that I ' m actually fairly confident it will be able to do that route even if you change **the** route dynamically. So, it ' s fairly easy — If you say I ' m going to be really good at one specific route, that ' s one thing, but it should be able to go, really be very good, certainly once you enter a **highway**, to go anywhere on **the highway** system in a given country. So it ' s not sort of limited to LA to New York. We could change it and make it Seattle-Florida, that day, in real time. So you were going from LA to New York. Now go from LA to Toronto. CA : So leaving aside regulation for a second, in terms of **the** technology alone, **the** time when someone will be able to buy one of your cars and literally just take **the** hands off **the** wheel and go to sleep and wake up and find that they ' ve arrived, how far away is that, to do that safely? EM : I think that ' s about two years. So **the** real trick of it is not how do you make it work say 99. 9 percent of **the** time, because, like, if a car crashes one in a thousand times, then you ' re probably still not going to be comfortable falling asleep. You shouldn ' t be, certainly. It ' s never going to be perfect. No system is going to be perfect, but if you say it ' s perhaps — **the** car is unlikely to crash in a hundred lifetimes, or a thousand lifetimes, then people are like, OK, wow, if I were to live a thousand lives, I would still most likely never experience a crash, then that ' s probably OK. CA : To sleep. I guess **the** big concern of yours is that people may actually get seduced too early to think that this is safe, and that you ' ll have some horrible incident happen that puts things back. EM : Well, I think that **the** autonomy system is likely to at least mitigate **the** crash, except in rare circumstances. **The** thing to appreciate about vehicle safety is this is probabilistic. I mean, there ' s some chance that any time a human driver gets in a car, that they will have an accident that is their fault. It ' s never zero. So really **the** key threshold for autonomy is how much better does autonomy need to be than a person before you can rely on it? CA : But once you get literally safe hands-off driving, **the** power to disrupt **the** whole industry seems massive, because at that point you ' ve spoken of people being able to buy a car, drops you off at work, and then you let it go and provide a sort of Uber-like service to other people, earn you money, maybe even cover **the** cost of your lease of that car, so you can kind of get a car for free. Is that really likely? EM : Yeah. Absolutely this is what will happen. So there will be a shared autonomy fleet where you buy your car and you can choose to use that car exclusively, you could choose to have it be used only by friends and family, only by other drivers who are rated five star, you can choose to share it sometimes but not other times. That ' s 100 percent what will **occur**. It ' s just a question of when. CA : Wow. So you mentioned **the** Semi and I think you ' re planning to announce this in September, but I ' m curious whether there ' s anything you could show us today? EM : I will show you a teaser shot of **the** truck. It ' s alive. CA : OK. EM : That ' s definitely a case where we want to be cautious about **the** autonomy features. Yeah. CA : We can ' t see that much of it, but it doesn ' t look like just a little **friendly** neighborhood truck. It looks kind of badass. What sort of semi is this? EM : So this is a heavy duty, long-range semitruck. So it ' s **the** highest weight capability and with long range. So essentially it ' s meant to alleviate **the** heavy-duty trucking loads. And this is something which people do not today think is possible. They think **the** truck doesn ' t have enough power or it doesn ' t have enough range, and then with **the** Tesla Semi we want to show that no, an electric truck actually can out-torque any diesel semi. And if you had a tug- of-war competition, **the** Tesla Semi will tug **the** diesel semi uphill. CA : That ' s pretty cool. And short term, these aren ' t driverless. These are going to be trucks that truck drivers want to drive. EM : Yes. So what will be really fun about this is you have a flat torque RPM curve with an electric motor, whereas with a diesel motor or any kind of internal combustion engine car, you ’ ve got a torque RPM curve that looks like a hill. So this will be a very spry truck. You can drive this around like a sports car. There ’ s no gears. It ’ s, like, single speed. CA : There ’ s a great movie to be made here somewhere. I don ’ t know what it is and I don ’ t know that it ends well, but it ’ s a great movie. EM : It ’ s quite bizarre test-driving. When I was driving **the** test prototype for **the** first truck. It ’ s really weird, because you ’ re driving around and you ’ re just so nimble, and you ’ re in this giant truck. CA : Wait, you ’ ve already driven a prototype? EM : Yeah, I drove it around **the** parking lot, and I was like, this is crazy. CA : Wow. This is no vaporware. EM : It ’ s just like, driving this giant truck and making these mad maneuvers. CA : This is cool. OK, from a really badass picture to a kind of less badass picture. This is just a cute house from”Desperate Housewives”or something. What on earth is going on here? EM : Well, this illustrates **the** picture of **the** future that I think is how things will **evolve**. You ’ ve got an electric car in **the** driveway. If you look in between **the** electric car and **the** house, there are actually three Powerwalls **stacked** up against **the** side of **the** house, and then that house roof is a solar roof. So that ’ s an actual solar glass roof. CA : OK. EM : That ’ s a picture of a real — well, admittedly, it ’ s a real fake house. That ’ s a real fake house. CA : So these roof tiles, some of them have in them basically solar power, **the** ability to — EM : Yeah. Solar glass tiles where you can adjust **the** texture and **the** color to a very fine-grained level, and then there ’ s sort of microlouvers in **the** glass, such that when you ’ re looking at **the** roof from street level or close to street level, all **the** tiles look **the** same whether there is a solar cell behind it or not. So you have an even color from **the** ground level. If you were to look at it from a helicopter, you would be actually able to look through and see that some of **the** glass tiles have a solar cell behind them and some do not. You can ’ t tell from street level. CA : You put them in **the** ones that are likely to see a lot of sun, and that makes these roofs super affordable, right? They ’ re not that much more expensive than just tiling **the** roof. EM : Yeah. We ’ re very confident that **the** cost of **the** roof plus **the** cost of electricity — A solar glass roof will be less than **the** cost of a normal roof plus **the** cost of electricity. So in other words, this will be economically a no-brainer, we think it will look great, and it will last — We thought about having **the** warranty be infinity, but then people thought, well, that might sound like were just talking rubbish, but actually this is toughened glass. Well after **the** house has collapsed and there ’ s nothing there, **the** glass tiles will still be there. CA : I mean, this is cool. So you ’ re rolling this out in a couple week ’ s time, I think, with four different roofing types. EM : Yeah, we ’ re starting off with two, two initially, and **the** second two will be introduced early next year. CA : And what ’ s **the** scale of ambition here? How many houses do you believe could end up having this type of roofing? EM : I think eventually almost all houses will have a solar roof. **The** thing is to consider **the** time scale here to be probably on **the** order of 40 or 50 years. So on average, a roof is replaced every 20 to 25 years. But you don ’ t start replacing all roofs immediately. But eventually, if you say were to fast- forward to say 15 years from now, it will be unusual to have a roof that does not have solar. CA : Is there a mental model thing that people don ’ t get here that because of **the** shift in **the** cost, **the** economics of solar power, most houses actually have enough sunlight on their roof pretty much to power all of their needs. If you could capture **the** power, it could pretty much power all their needs. You could go off-grid, kind of. EM : It depends on where you are and what **the** house size is **relative** to **the** roof area, but it ’ s a fair statement to say that most houses in **the** US have enough roof area to power all **the** needs of **the** house. CA : So **the** key to **the** economics of **the** cars, **the** Semi, of these houses is **the** falling price of lithium-ion batteries, which you ’ ve made a huge bet on as Tesla. In many ways, that ' s almost **the** core competency. And you ' ve decided that to really, like, own that competency, you just have to build **the** world ' s largest manufacturing plant to double **the** world ' s supply of lithium-ion batteries, with this guy. What is this? EM : Yeah, so that ' s **the** Gigafactory, progress so far on **the** Gigafactory. Eventually, you can sort of roughly see that there ' s sort of a diamond shape overall, and when it ' s fully done, it ' ll look like a giant diamond, or that ' s **the** idea behind it, and it ' s aligned on true north. It ' s a small detail. CA : And capable of producing, eventually, like a hundred gigawatt hours of batteries a year. EM : A hundred gigawatt hours. We think probably more, but yeah. CA : And they ' re actually being produced right now. EM : They ' re in production already. CA : You guys put out this video. I mean, is that speeded up? EM : That ' s **the** slowed down version. CA : How fast does it actually go? EM : Well, when it ' s running at full speed, you can ' t actually see **the** cells without a strobe light. It ' s just blur. CA : One of your core ideas, Elon, about what makes an exciting future is a future where we no longer feel guilty about energy. Help us picture this. How many Gigafactories, if you like, does it take to get us there? EM : It ' s about a hundred, roughly. It ' s not 10, it ' s not a thousand. Most likely a hundred. CA : See, I find this amazing. You can picture what it would take to move **the** world off this vast **fossil** fuel thing. It ' s like you ' re building one, it costs five billion dollars, or whatever, five to 10 billion dollars. Like, it ' s kind of cool that you can picture that project. And you ' re planning to do, at Tesla — announce another two this year. EM : I think we ' ll announce locations for somewhere between two and four Gigafactories later this year. Yeah, probably four. CA : Whoa. No more teasing from you for here? Like — where, **continent**? You can say no. EM : We need to address a global market. CA : OK. This is cool. I think we should talk for — Actually, global market. I ' m going to ask you one question about politics, only one. I ' m kind of sick of politics, but I do want to ask you this. You ' re on a body now giving advice to a guy — EM : Who? CA : Who has said he doesn ' t really believe in climate change, and there ' s a lot of people out there who think you shouldn ' t be doing that. They ' d like you to walk away from that. What would you say to them? EM : Well, I think that first of all, I ' m just on two advisory councils where **the** format consists of going around **the** room and asking people ' s opinion on things, and so there ' s like a meeting every month or two. That ' s **the sum** total of my contribution. But I think to **the** degree that there are people in **the** room who are arguing in favor of doing something about climate change, or social issues, I ' ve used **the** meetings I ' ve had thus far to argue in favor of immigration and in favor of climate change. And if I hadn ' t done that, that wasn ' t on **the** agenda before. So maybe nothing will happen, but at least **the** words were said. CA : OK. So let ' s talk SpaceX and Mars. Last time you were here, you spoke about what seemed like a kind of incredibly ambitious dream to develop rockets that were actually reusable. And you ' ve only gone and done it. EM : Finally. It took a long time. CA : Talk us through this. What are we looking at here? EM : So this is one of our rocket boosters coming back from very high and fast in space. So just delivered **the** upper stage at high velocity. I think this might have been at sort of Mach 7 or so, delivery of **the** upper stage. CA : So that was a sped-up — EM : That was **the** slowed down version. CA : I thought that was **the** sped-up version. But I mean, that ' s amazing, and several of these failed before you finally figured out how to do it, but now you ' ve done this, what, five or six times? EM : We ' re at eight or nine. CA : And for **the** first time, you ' ve actually reflown one of **the** rockets that landed. EM : Yeah, so we landed **the** rocket booster and then prepped it for flight again and flew it again, so it ' s **the** first reflight of an orbital booster where that reflight is relevant. So it ’ s important to appreciate that reusability is only relevant if it is rapid and complete. So like an aircraft or a car, **the** reusability is rapid and complete. You do not send your aircraft to Boeing in- between flights. CA : Right. So this is allowing you to dream of this really ambitious idea of sending many, many, many people to Mars in, what, 10 or 20 years time, I guess. EM : Yeah. CA : And you ’ ve designed this outrageous rocket to do it. Help us understand **the** scale of this thing. EM : Well, visually you can see that ’ s a person. Yeah, and that ’ s **the** vehicle. CA : So if that was a skyscraper, that ’ s like, did I read that, a 40-story skyscraper? EM : Probably a little more, yeah. **The** thrust level of this is really — This **configuration** is about four times **the** thrust of **the** Saturn V moon rocket. CA : Four times **the** thrust of **the** biggest rocket humanity ever created before. EM : Yeah. Yeah. CA : As one does. EM : Yeah. In units of 747, a 747 is only about a quarter of a million **pounds** of thrust, so for every 10 million **pounds** of thrust, there ’ s 40 747s. So this would be **the** thrust equivalent of 120 747s, with all engines blazing. CA : And so even with a machine designed to escape Earth ’ s gravity, I think you told me last time this thing could actually take a fully loaded 747, people, cargo, everything, into orbit. EM : Exactly. This can take a fully loaded 747 with maximum fuel, maximum passengers, maximum cargo on **the** 747 — this can take it as cargo. CA : So based on this, you presented recently this Interplanetary Transport System which is visualized this way. This is a scene you picture in, what, 30 years time? 20 years time? People walking into this rocket. EM : I ’ m hopeful it ’ s sort of an eight- to 10-year time frame. Aspirationally, that ’ s our target. Our internal targets are more aggressive, but I think — CA : OK. EM : While vehicle seems quite large and is large by comparison with other rockets, I think **the** future spacecraft will make this look like a rowboat. **The** future spaceships will be truly enormous. CA : Why, Elon? Why do we need to build a city on Mars with a million people on it in your lifetime, which I think is kind of what you ’ ve said you ’ d love to do? EM : I think it ’ s important to have a future that is inspiring and appealing. I just think there have to be reasons that you get up in **the** morning and you want to live. Like, why do you want to live? What ’ s **the** point? What inspires you? What do you love about **the** future? And if we ’ re not out there, if **the** future does not include being out there among **the** stars and being a multiplanet species, I find that it ’ s incredibly depressing if that ’ s not **the** future that we ’ re going to have. CA : People want to position this as an either or, that there are so many desperate things happening on **the planet** now from climate to poverty to, you know, you pick your issue. And this feels like a distraction. You shouldn ’ t be thinking about this. You should be solving what ’ s here and now. And to be fair, you ’ ve done a fair old bit to actually do that with your work on sustainable energy. But why not just do that? EM : I think there ’ s — I look at **the** future from **the** standpoint of **probabilities**. It ’ s like a branching stream of **probabilities**, and there are actions that we can take that affect those **probabilities** or that accelerate one thing or slow down another thing. I may introduce something new to **the** **probability** stream. Sustainable energy will happen no matter what. If there was no Tesla, if Tesla never existed, it would have to happen out of necessity. It ’ s tautological. If you don ’ t have sustainable energy, it means you have unsustainable energy. Eventually you will run out, and **the** laws of economics will drive civilization towards sustainable energy, inevitably. **The** fundamental value of a company like Tesla is **the** degree to which it accelerates **the** advent of sustainable energy, faster than it would otherwise **occur**. So when I think, like, what is **the** fundamental good of a company like Tesla, I would say, hopefully, if it accelerated that by a decade, potentially more than a decade, that would be quite a good thing to **occur**. That ’ s what I consider to be **the** fundamental aspirational good of Tesla. Then there ' s becoming a multiplanet species and space-faring civilization. This is not inevitable. It ' s very important to appreciate this is not inevitable. **The** sustainable energy future I think is largely inevitable, but being a space- faring civilization is definitely not inevitable. If you look at **the** progress in space, in 1969 you were able to send somebody to **the** moon. 1969. Then we had **the** Space Shuttle. **The** Space Shuttle could only take people to low Earth orbit. Then **the** Space Shuttle retired, and **the** United States could take no one to orbit. So that ' s **the** trend. **The** trend is like down to nothing. People are mistaken when they think that technology just automatically improves. It does not automatically improve. It only improves if a lot of people work very hard to make it better, and actually it will, I think, by itself degrade, actually. You look at great civilizations like Ancient Egypt, and they were able to make **the** pyramids, and they forgot how to do that. And then **the** Romans, they built these incredible aqueducts. They forgot how to do it. CA : Elon, it almost seems, listening to you and looking at **the** different things you ' ve done, that you ' ve got this unique double motivation on everything that I find so interesting. One is this desire to work for humanity ' s long-term good. **The** other is **the** desire to do something exciting. And often it feels like you feel like you need **the** one to drive **the** other. With Tesla, you want to have sustainable energy, so you made these super sexy, exciting cars to do it. Solar energy, we need to get there, so we need to make these beautiful roofs. We haven ' t even spoken about your newest thing, which we don ' t have time to do, but you want to save humanity from bad AI, and so you ' re going to create this really cool brain-machine interface to give us all infinite memory and telepathy and so forth. And on Mars, it feels like what you ' re saying is, yeah, we need to save humanity and have a backup plan, but also we need to inspire humanity, and this is a way to inspire. EM : I think **the** value of beauty and inspiration is very much underrated, no question. But I want to be clear. I ' m not trying to be anyone ' s savior. That is not **the** — I ' m just trying to think about **the** future and not be sad. CA : Beautiful statement. I think everyone here would agree that it is not — None of this is going to happen inevitably. **The** fact that in your mind, you dream this stuff, you dream stuff that no one else would dare dream, or no one else would be capable of dreaming at **the** level of complexity that you do. **The** fact that you do that, Elon Musk, is a really remarkable thing. Thank you for helping us all to dream a bit bigger. EM : But you ' ll tell me if it ever starts getting genuinely insane, right? CA : Thank you, Elon Musk. That was really, really **fantastic**. That was really **fantastic**.

We know more about other **planets** than our own, and today, I want to show you a new type of robot designed to help us better understand our own **planet**. It belongs to a category known in **the** oceanographic community as an unmanned **surface** vehicle, or USV. And it uses no fuel. Instead, it relies on wind power for propulsion. And yet, it can sail around **the** globe for months at a time. So I want to share with you why we built it, and what it means for you. A few years ago, I was on a sailboat making its way across **the** Pacific, from San Francisco to Hawaii. I had just spent **the** past 10 years working nonstop, developing video games for hundreds of millions of users, and I wanted to take a step back and look at **the** big picture and get some much-needed thinking time. I was **the** navigator on board, and one evening, after a long session analyzing weather data and plotting our course, I came up on deck and saw this beautiful sunset. And a thought **occurred** to me : How much do we really know about our oceans? **The** Pacific was stretching all around me as far as **the** eye could see, and **the** waves were **rocking** our boat forcefully, a sort of constant reminder of its untold power. How much do we really know about our oceans? I decided to find out. What I quickly learned is that we don ' t know very much. **The** first reason is just how vast oceans are, covering 70 percent of **the planet**, and yet we know they drive complex planetary systems like global weather, which affect all of us on a daily basis, sometimes dramatically. And yet, those activities are mostly invisible to us. Ocean data is scarce by any standard. Back on land, I had grown used to accessing lots of sensors — billions of them, actually. But at **sea**, in situ data is scarce and expensive. Why? Because it relies on a small number of ships and buoys. How small a number was actually a great surprise. Our National Oceanic and Atmospheric Administration, better known as NOAA, only has 16 ships, and there are less than 200 buoys offshore globally. It is easy to understand why : **the** oceans are an unforgiving place, and to collect in situ data, you need a big ship, capable of carrying a vast amount of fuel and large crews, costing hundreds of millions of dollars each, or, big buoys tethered to **the** ocean floor with a four-mile-long cable and weighted down by a set of train wheels, which is both dangerous to deploy and expensive to maintain. What about satellites, you might ask? Well, satellites are **fantastic**, and they have taught us so much about **the** big picture over **the** past few decades. However, **the** problem with satellites is they can only see through one micron of **the surface** of **the** ocean. They have relatively poor spatial and temporal resolution, and their signal needs to be corrected for cloud cover and land effects and other factors. So what is going on in **the** oceans? And what are we trying to measure? And how could a robot be of any use? Let ' s zoom in on a small cube in **the** ocean. One of **the** key things we want to understand is **the surface**, because **the surface**, if you think about it, is **the** nexus of all air-sea interaction. It is **the** interface through which all energy and gases must flow. Our sun radiates energy, which is absorbed by oceans as heat and then partially released into **the** atmosphere. Gases in our atmosphere like CO2 get dissolved into our oceans. Actually, about 30 percent of all global CO2 gets absorbed. Plankton and microorganisms release oxygen into **the** atmosphere, so much so that every other breath you take comes from **the** ocean. Some of that heat generates evaporation, which creates clouds and then eventually leads to precipitation. And pressure gradients create **surface** wind, which moves **the** moisture through **the** atmosphere. Some of **the** heat radiates down into **the** deep ocean and gets stored in different layers, **the** ocean acting as some kind of planetary-scale boiler to store all that energy, which later might be released in short-term events like hurricanes or long-term phenomena like El Nio. These layers can get mixed up by vertical upwelling currents or **horizontal** currents, which are key in transporting heat from **the** tropics to **the** poles. And of course, there is marine life, occupying **the** largest ecosystem in volume on **the planet**, from microorganisms to **fish** to marine mammals, like **seals**, dolphins and **whales**. But all of these are mostly invisible to us. **The** challenge in studying those ocean variables at scale is one of energy, **the** energy that it takes to deploy sensors into **the** deep ocean. And of course, many solutions have been tried — from wave-actuated **devices** to **surface** drifters to sun-powered **electrical** drives — each with their own compromises. Our team breakthrough came from an unlikely source — **the** pursuit of **the** world speed record in a wind-powered land yacht. It took 10 years of research and development to come up with a novel **wing** concept that only uses three watts of power to control and yet can propel a vehicle all around **the** globe with seemingly unlimited autonomy. By adapting this **wing** concept into a marine vehicle, we had **the** genesis of an ocean drone. Now, these are larger than they appear. They are about 15 feet high, 23 feet long, seven feet deep. Think of them as **surface** satellites. They ’ re laden with an **array** of science-grade sensors that measure all key variables, both oceanographic and atmospheric, and a live satellite link transmits this high- resolution data back to shore in real time. Our team has been hard at work over **the** past few years, conducting missions in some of **the** toughest ocean conditions on **the planet**, from **the** Arctic to **the** tropical Pacific. We have sailed all **the** way to **the** polar ice shelf. We have sailed into Atlantic hurricanes. We have rounded Cape Horn, and we have slalomed between **the oil** rigs of **the** Gulf of Mexico. This is one tough robot. Let me share with you recent work that we did around **the** Pribilof Islands. This is a small group of **islands** deep in **the** cold Bering Sea between **the** US and Russia. Now, **the** Bering Sea is **the** home of **the** walleye pollock, which is a whitefish you might not recognize, but you might likely have tasted if you **enjoy fish** sticks or surimi. Yes, surimi looks like crabmeat, but it ’ s actually pollock. And **the** pollock fishery is **the** largest fishery in **the** nation, both in terms of value and volume — about 3. 1 billion **pounds** of **fish** caught every year. So over **the** past few years, a fleet of ocean drones has been hard at work in **the** Bering Sea with **the** goal to help assess **the** size of **the** pollock **fish** stock. This helps improve **the** quota system that ’ s used to manage **the** fishery and help prevent a collapse of **the fish** stock and protects this fragile ecosystem. Now, **the** drones survey **the fishing** ground using acoustics, i. e., a sonar. This sends a sound wave downwards, and then **the** reflection, **the** echo from **the** sound wave from **the** seabed or schools of **fish**, gives us an idea of what ’ s happening below **the surface**. Our ocean drones are actually pretty good at this repetitive task, so they have been gridding **the** Bering Sea day in, day out. Now, **the** Pribilof Islands are also **the** home of a large colony of fur **seals**. In **the** 1950s, there were about two million individuals in that colony. Sadly, these days, **the** population has rapidly declined. There ’ s less than 50 percent of that number left, and **the** population continues to fall rapidly. So to understand why, our science partner at **the** National Marine Mammal Laboratory has fitted a GPS **tag** on some of **the** mother **seals**, glued to their furs. And this **tag** measures location and depth and also has a really cool little camera that ’ s triggered by sudden acceleration. Here is a movie taken by an artistically inclined **seal**, giving us unprecedented insight into an **underwater** hunt deep in **the** Arctic, and **the** shot of this pollock prey just seconds before it gets devoured. Now, doing work in **the** Arctic is very tough, even for a robot. They had to survive a snowstorm in August and interferences from bystanders — that little spotted **seal enjoying** a ride. Now, **the seal tags** have recorded over 200, 000 dives over **the** season, and upon a closer look, we get to see **the** individual **seal** tracks and **the** repetitive dives. We are on our way to decode what is really happening over that foraging ground, and it ’ s quite beautiful. Once you superimpose **the** acoustic data collected by **the** drones, a picture starts to emerge. As **the seals** leave **the islands** and swim from left to right, they are observed to dive at a relatively shallow depth of about 20 meters, which **the** drone identifies is populated by small young pollock with low calorific content. **The seals** then swim much greater distance and start to dive deeper to a place where **the** drone identifies larger, more adult pollock, which are more nutritious as **fish**. Unfortunately, **the** calories expended by **the** mother **seals** to swim this extra distance don ’ t leave them with enough energy to lactate their pups back on **the island**, leading to **the** population decline. Further, **the** drones identify that **the** water temperature around **the island** has significantly warmed. It might be one of **the** driving forces that ’ s pushing **the** pollock north, and to spread in **search** of colder regions. So **the** data analysis is ongoing, but already we can see that some of **the** pieces of **the** puzzle from **the** fur **seal** mystery are coming into focus. But if you look back at **the** big picture, we are mammals, too. And actually, **the** oceans provide up to 20 kilos of **fish** per human per year. As we deplete our **fish** stocks, what can we humans learn from **the** fur **seal** story? And beyond **fish**, **the** oceans affect all of us daily as they drive global weather systems, which affect things like global agricultural output or can lead to devastating destruction of lives and property through hurricanes, extreme heat and floods. Our oceans are pretty much unexplored and undersampled, and today, we still know more about other **planets** than our own. But if you divide this vast ocean in six-by-six-degree squares, each about 400 miles long, you ' d get about 1, 000 such squares. So little by little, working with our partners, we are deploying one ocean drone in each of those boxes, **the** hope being that achieving planetary coverage will give us better insights into those planetary systems that affect humanity. We have been using robots to study distant worlds in our solar system for a while now. Now it is time to quantify our own **planet**, because we cannot fix what we cannot measure, and we cannot prepare for what we don ' t know. Thank you.

My mom has always reminded me that I have **the** same proportions as a LEGO man. And she does actually have a point. LEGO is a company that has succeeded in making everybody believe that LEGO is from their home country. But it ' s not, it ' s from my home country. So you can imagine my excitement when **the** LEGO family called me and asked us to work with them to design **the** Home of **the** Brick. This is **the** architectural model — we built it out of LEGO, obviously. This is **the** final result. And what we tried to do was to design a building that would be as interactive and as engaging and as playful as LEGO is itself, with these kind of interconnected playgrounds on **the** roofscape. You can enter a square on **the** ground where **the** citizens of Billund can roam around freely without a **ticket**. And it ' s probably one of **the** only museums in **the** world where you ' re allowed to touch all **the** artifacts. But **the** Danish word for design is"formgivning,"which literally means to give form to that which has not yet been given form. In other words, to give form to **the** future. And what I love about LEGO is that LEGO is not a toy. It ' s a tool that empowers **the** child to build his or her own world, and then to inhabit that world through play and to invite her friends to join her in cohabiting and cocreating that world. And that is exactly what formgivning is. As human beings, we have **the** power to give form to our future. Inspired by LEGO, we ' ve built a social housing project in Copenhagen, where we **stacked** blocks of wood next to each other. Between them, they leave spaces with extra ceiling heights and balconies. And by gently wiggling **the** blocks, we can actually create curves or any **organic** form, adapting to any urban context. Because adaptability is probably one of **the** strongest drivers of architecture. Another example is here in Vancouver. We were asked to look at **the** site where Granville bridge triforks as it touches downtown. And we started, like, mapping **the** different constraints. There ' s like a 100-foot setback from **the** bridge because **the** city want to make sure that no one looks into **the** traffic on **the** bridge. There ' s a park where we can ' t cast any shadows. So finally, we ' re left with a tiny triangular footprint, almost too small to build. But then we thought, like, what if **the** 100-foot minimum distance is really about minimum distance — once we get 100 feet up in **the** air, we can grow **the** building back out. And so we did. When you drive over **the** bridge, it ' s as if someone is pulling a curtain aback, welcoming you to Vancouver. Or a like a weed growing through **the** cracks in **the** pavement and

blossoming as it gets light and air. Underneath **the** bridge, we ’ ve worked with Rodney Graham and a handful of Vancouver artists, to create what we called **the** Sistine Chapel of street art, an art gallery turned upside down, that tries to turn **the** negative impact of **the** bridge into a positive. So even if it looks like this kind of surreal architecture, it ’ s highly adapted to its surroundings. So if a bridge can become a museum, a museum can also serve as a bridge. In Norway, we are building a museum that spans across a river and allows people to sort of journey through **the** exhibitions as they cross from one side of a sculpture park to **the** other. An architecture sort of adapted to its landscape. In China, we built a headquarters for an energy company and we designed **the** facade like an Issey Miyake fabric. It ’ s rippled, so that facing **the** predominant direction of **the** sun, it ’ s all opaque ; facing away from **the** sun, it ’ s all glass. On average, it sort of transitions from solid to clear. And this very simple idea without any moving parts or any sort of technology, purely because of **the** geometry of **the** facade, reduces **the** energy **consumption** on cooling by 30 percent. So you can say what makes **the** building look elegant is also what makes it perform elegantly. It ’ s an architecture that is adapted to its climate. You can also adapt one culture to another, like in Manhattan, we took **the** Copenhagen courtyard building with a social space where people can hang out in this kind of oasis in **the** middle of a city, and we combined it with **the** density and **the** verticality of an American skyscraper, creating what we ’ ve called a”courtscraper.”From New York to Copenhagen. On **the** waterfront of Copenhagen, we are right now finishing this waste-to-energy power plant. It ’ s going to be **the** cleanest waste-to-energy power plant in **the** world, there are no toxins coming out of **the** chimney. An amazing marvel of engineering that is completely invisible. So we thought, how can we express this? And in Copenhagen we have snow, as you can see, but we have absolutely no mountains. We have to go six hours by bus to get to Sweden, to get alpine skiing. So we thought, let ’ s put an alpine ski **slope** on **the** roof of **the** power plant. So this is **the** first test run we did a few months ago. And what I like about this is that it also show you **the** sort of world-changing power of formgivning. I have a five-month-old son, and he ’ s going to grow up in a world not knowing that there was ever a time when you couldn ’ t ski on **the** roof of **the** power plant. So imagine for him and his generation, that ’ s their baseline. Imagine how far they can leap, what kind of wild ideas they can put forward for their future. So right in front of it, we ’ re building our smallest project. It ’ s basically nine containers that we have **stacked** in a shipyard in Poland, then we ’ ve schlepped it across **the** Baltic **sea** and docked it in **the** port of Copenhagen, where it is now **the** home of 12 students. Each student has a view to **the** water, they can jump out **the** window into **the** clean port of Copenhagen, and they can get back in. All of **the** heat comes from **the** thermal mass of **the sea**, all **the** power comes from **the** sun. This is **the** first 12 units in Copenhagen, another 60 on their way, another 200 are going to Gothenburg, and we ’ re speaking with **the** Paris Olympics to put a small floating village on **the** Seine. So very much this kind of, almost like nomadic, impermanent architecture. And **the** waterfronts of our cities are experiencing a lot of change. Economic change, industrial change and climate change. This is Manhattan before Hurricane Sandy, and this is Manhattan after Sandy. We got invited by **the** city of New York to look if we could make **the** necessary flood protection for Manhattan without building a seawall that would segregate **the** life of **the** city from **the** water around it. And we got inspired by **the** High Line. You probably know **the** High Line — it ’ s this amazing new park in New York. It ’ s basically decommissioned train tracks that now have become one of **the** most popular promenades in **the** city. So we thought, could we design **the** necessary flood protection for Manhattan so we don ’ t have to wait until we shut it down before it gets nice? So we sat down with **the** citizens living along **the** waterfront of New York, and we worked with them to try to design **the** necessary flood protection in such a way that it only makes their waterfront more accessible and more enjoyable. Underneath **the** FDR, we are putting, like, pavilions with **pocket** walls that can **slide** out and protect from **the** water. We are creating little stepped terraces that are going to make **the** underside more enjoyable, but also protect from flooding. Further north in **the** East River Park, we are creating rolling hills that protect **the** park from **the** noise of **the highway**, but in turn also become **the** necessary flood protection that can stop **the** waves during an incoming storm surge. So in a way, this project that we have called **the** Dryline, it ’ s essentially **the** High Line — **The** High Line that ’ s going to keep Manhattan dry. It ’ s scheduled to break ground on **the** first East River portion at **the** end of this year. But it has essentially been codesigned with **the** citizens of Lower Manhattan to take all of **the** necessary infrastructure for resilience and give it positive social and environmental side effects. So, New York is not alone in facing this situation. In fact, by 2050, 90 percent of **the** major cities in **the** world are going to be dealing with rising **seas**. In Hamburg, they ’ ve created a whole neighborhood where **the** bottom floors are designed to withstand **the** inevitable flood. In Sweden, they ’ ve designed a city where all of **the** parks are **wet** gardens, designed to deal with storm water and waste water. So we thought, could we perhaps — Actually, today, three million people are already permanently living on **the sea**. So we thought, could we actually imagine a floating city designed to incorporate all of **the** Sustainable Development Goals of **the** United Nations into a whole new human-made ecosystem. And of course, we have to design it so it can produce its own power, harvesting **the** thermal mass of **the** oceans, **the** force of **the** tides, of **the** currents, of **the** waves, **the** power of **the** wind, **the** heat and **the** energy of **the** sun. Also, we are going to collect all of **the** rain water that drops on this man-made archipelago and deal with it organically and mechanically and store it and clean it. We have to grow all of our food locally, it has to be fish- and plant-based, because you won ’ t have **the** space or **the** resources for a dairy diet. And finally, we are going to deal with all **the** waste locally, with compost, recycling, and turning **the** waste into energy. So imagine where a traditional urban master plan, you typically draw **the** street grid where **the** cars can drive and **the** building plots where you can put some buildings. This master plan, we sat down with a handful of scientists and basically started with all of **the renewable**, available natural resources, and then we started channeling **the** flow of resources through this kind of human- made ecosystem or this kind of urban metabolism. So it ’ s going to be modular, it ’ s going to be buoyant, it ’ s going to be designed to resist a tropical storm. You can prefabricate it at scale, and tow it to dock with others, to form a small community. We ’ re designing these kind of coastal additions, so that even if it ’ s modular and rational, each **island** can be unique with its own coastal landscape. **The** architecture has to remain relatively low to keep **the** center of gravity buoyant. We ’ re going to take all of **the agriculture** and use it to also create social space so you can actually **enjoy the** permaculture gardens. We ’ re designing it for **the** tropics, so all of **the** roofs are maximized to harvest solar power and to shade from **the** sun. All **the** materials are going to be light and **renewable**, like bamboo and wood, which is also going to create this charming, warm environment. And any architecture is supposed to be able to fit on this platform. Underneath we have all **the** storage inside **the** pontoon, almost like a mega version of **the** student housings that we ’ ve already worked with. We have all **the** storage for **the** energy that ’ s produced, all of **the** water storage and remediation. We are sort of dealing with all of **the** waste and **the** composting.

And we also have some backup farming with aeroponics and hydroponics. So imagine almost like a vertical section through this landscape that goes from **the** air above, where we have vertical farms ; below, we have **the** aeroponics and **the** aquaponics. Even further below, we have **the** ocean farms and where we tie **the island** to **the** ground, we ’ re using biorock to create new reefs to regenerate **habitat**. So think of this small **island** for 300 people. It can then group together to form a cluster or a neighborhood that then can sort of group together to form an entire city for 10, 000 people. And you can imagine if this floating city flourishes, it can sort of grow like a culture in a petri dish. So one of **the** first places we are looking at placing this, or anchoring this floating city, is in **the** Pearl River delta. So imagine this kind of canopy of photovoltaics on this archipelago floating in **the sea**. As you sail towards **the island**, you will see **the** maritime residents moving around on alternative forms of aquatic **transportation**. You come into this kind of community port. You can roam around in **the** permaculture gardens that are productive landscapes, but also social landscapes. **The greenhouses** also become orangeries for **the** cultural life of **the** city, and below, under **the sea**, it ’ s teeming with life of farming and science and social spaces. So in a way, you can imagine this community port is where people gather, both by day and by night. And even if **the** first one is designed for **the** tropics, we also imagine that **the** architecture can adapt to any culture, so imagine, like, a Middle Eastern floating city or Southeast Asian floating city or maybe a Scandinavian floating city one day. So maybe just to **conclude**. **The** human body is 70 percent water. And **the surface** of our **planet** is 70 percent water. And it ’ s rising. And even if **the** whole world woke up tomorrow and became carbon-neutral over night, there are still **island** nations that are destined to sink in **the seas**, unless we also develop alternate forms of floating human **habitats**. And **the** only constant in **the universe** is change. Our world is always changing, and right now, our climate is changing. No matter how critical **the** crisis is, and it is, this is also our collective human superpower. That we have **the** power to adapt to change and we have **the** power to give form to our future.

Text Sample 58: POS Dim 1 – 2019 – Score 21.00 – 2019/t001223.txt

It may seem like we ’ re all standing on solid earth right now, but we ’ re not. **The rocks** and **the** dirt underneath us are crisscrossed by tiny little fractures and empty spaces. And these empty spaces are filled with astronomical quantities of microbes, such as these ones. **The** deepest that we found microbes so far into **the** earth is five kilometers down. So like, if you pointed yourself at **the** ground and took off running into **the** ground, you could run an entire 5K race and microbes would line your whole path. So you may not have ever thought about these microbes that are deep inside earth ’ s crust, but you probably thought about **the** microbes living in our guts. If you add up **the** gut microbiomes of all **the** people and all **the** animals on **the planet**, collectively, this weighs about 100, 000 tons. This is a huge biome that we carry in our bellies every single day. We should all be proud. But it pales in comparison to **the** number of microbes that are covering **the** entire **surface** of **the** earth, like in our soils, our rivers and our oceans. Collectively, these weigh about two billion tons. But it turns out that **the** majority of microbes on earth aren ’ t even in oceans or our guts or sewage treatment plants. Most of them are actually inside **the** earth ’ s crust. So collectively, these weigh 40 billion tons. This is one of **the** biggest biomes on **the planet**, and we didn ’ t even know it existed until a few decades ago. So **the** possibilities for what life is like down there, or what it might do for humans, are limitless. This is a map showing a red dot for every place where we ’ ve gotten pretty good deep subsurface samples with modern microbiological methods, and you may be impressed that we ’ re getting a pretty good global coverage, but actually, if you remember that these are **the** only places that we have samples from, it looks a little worse. If we were all in an alien spaceship, trying to reconstruct a map of **the** globe from only these samples, we ’ d never be able to do it. So people sometimes say to me,”Yeah, there ’ s a lot of microbes in **the** subsurface, but... aren ’ t they just kind of dormant?”This is a good point. **Relative** to a ficus plant or **the** measles or my kid ’ s guinea pigs, these microbes probably aren ’ t doing much of anything at all. We know that they have to be slow, because there ’ s so many of them. If they all started dividing at **the** rate of E. coli, then they would double **the** entire weight of **the** earth, **rocks** included, over a single night. In fact, many of them probably haven ’ t even undergone a single cell division since **the** time of ancient Egypt. Which is just crazy. Like, how do you wrap your head around things that are so long- lived? But I thought of an analogy that I really love, but it ’ s weird and it ’ s complicated. So I hope that you can all go there with me. Alright, let ’ s try it. It ’ s like trying to figure out **the** life cycle of a tree... if you only lived for a day. So like if human life span was only a day, and we lived in winter, then you would go your entire life without ever seeing a tree with a leaf on it. And there would be so many human generations that would pass by within a single winter that you may not even have access to a history book that says anything other than **the** fact that trees are always lifeless sticks that don ’ t do anything. Of course, this is ridiculous. We know that trees are just waiting for summer so they can reactivate. But if **the** human life span were significantly shorter than that of trees, we might be completely oblivious to this totally mundane fact. So when we say that these deep subsurface microbes are just dormant, are we like people who die after a day, trying to figure out how trees work? What if these deep subsurface organisms are just waiting for their version of summer, but our lives are too short for us to see it? If you take E. coli and **seal** it up in a test tube, with no food or nutrients, and leave it there for months to years, most of **the** cells die off, of course, because they ’ re starving. But a few of **the** cells survive. If you take these old surviving cells and compete them, also under starvation conditions, against a new, fast-growing culture of E. coli, **the** grizzled old tough guys beat out **the** squeaky clean upstarts every single time. So this is evidence there ’ s actually an **evolutionary** payoff to being extraordinarily slow. So it ’ s possible that maybe we should not equate being slow with being unimportant. Maybe these out-of-sight, out-of-mind microbes could actually be helpful to humanity. OK, so as far as we know, there are two ways to do subsurface living. **The** first is to wait for food to trickle down from **the surface** world, like trying to eat **the** leftovers of a picnic that happened 1, 000 years ago. Which is a crazy way to live, but shockingly seems to work out for a lot of microbes in earth. **The** other possibility is for a microbe to just say,”Nah, I don ’ t need **the surface** world. I ’ m good down here.”For microbes that go this route, they have to get everything that they need in order to survive from inside **the** earth. Some things are actually easier for them to get. They ’ re more abundant inside **the** earth, like water or nutrients, like nitrogen and **iron** and phosphorus, or places to live. These are things that we literally kill each other to get ahold of up at **the surface** world. But in **the** subsurface, **the** problem is finding enough energy. Up at **the surface**, plants can chemically knit together **carbon** dioxide molecules into yummy sugars as fast as **the** sun ’ s **photons** hit their leaves. But in **the** subsurface, of course, there ’ s no sunlight, so this ecosystem has to solve **the** problem of who is going to make **the** food for everybody else. **The** subsurface needs something that ’ s like a plant but it breathes **rocks**. Luckily, such a thing exists, and it ’ s called a chemolithoautotroph. Which is a microbe that uses chemicals —”chemo,”from **rocks** —”litho,”to make food —”autotroph.”And they can do this with a ton of different elements. They can do this with sulphur, **iron**, manganese, nitrogen, **carbon**, some of them can use pure electrons, straight up. Like, if you cut **the** end off of an **electrical** cord, they could breathe it like a snorkel. These chemolithoautotrophs take **the** energy that they get from these processes and use it to make food, like plants do. But we know that plants do more than just make food. They also make a waste product, oxygen, which we are 100 percent dependent upon. But **the** waste product that these chemolithoautotrophs make is often in **the** form of minerals, like rust or pyrite, like fool ’ s gold, or carminites, like limestone. So what we have are microbes that are really, really slow, like **rocks**, that get their energy from **rocks**, that make as their waste product other **rocks**. So am I talking about **biology**, or am I talking about geology? This stuff really blurs **the** lines. So if I ’ m going to do this thing, and I ’ m going to be a biologist who studies microbes that kind of act like **rocks**, then I should probably start studying geology. And what ’ s **the** coolest part of geology? Volcanoes. This is looking inside **the** crater of Pos Volcano in Costa Rica. Many volcanoes on earth arise because an oceanic tectonic **plate** crashes into a continental **plate**. As this oceanic **plate** subducts or gets moved underneath this continental **plate**, things like water and **carbon** dioxide and other materials get squeezed out of it, like ringing a **wet** washcloth. So in this way, subduction zones are like portals into **the** deep earth, where materials are exchanged between **the surface** and **the** subsurface world. So I was recently invited by some of my colleagues in Costa Rica to come and work with them on some of **the** volcanoes. And of course I said yes, because, I mean, Costa Rica is beautiful, but also because it sits on top of one of these subduction zones. We wanted to ask **the** very specific question : Why is it that **the carbon** dioxide that comes out of this deeply buried oceanic tectonic **plate** is only coming out of **the** volcanoes? Why don ’ t we see it distributed throughout **the** entire subduction zone? Do **the** microbes have something to do with that? So this is a picture of me inside Pos Volcano, along with my colleague Donato Giovannelli. That lake that we ’ re standing next to is made of pure battery acid. I know this because we were measuring **the** pH when this picture was taken. And at some point while we were working inside **the** crater, I turned to my Costa Rican colleague Carlos Ramrez and I said,”Alright, if this thing starts erupting right now, what ’ s our exit strategy?”And he said,”Oh, yeah, great question, it ’ s totally easy. Just turn around and **enjoy the** view.””Because it will be your last.”And it may sound like he was being overly dramatic, but 54 days after I was standing next to that lake, this happened. Audience : Oh! Freaking **terrifying**, right? This was **the** biggest eruption this volcano had had in 60-some-odd years, and not long after this video ends, **the** camera that was taking **the** video is obliterated and **the** entire lake that we had been sampling vaporizes completely. But I also want to be clear that we were pretty sure this was not going to happen on **the** day that we were actually in **the** volcano, because Costa Rica monitors its volcanoes very carefully through **the** OVSICORI Institute, and we had scientists from that institute with us on that day. But **the** fact that it erupted illustrates perfectly that if you want to look for where **carbon** dioxide gas is coming out of this oceanic **plate**, then you should look no further than **the** volcanoes themselves. But if you go to Costa Rica, you may notice that in addition to these volcanoes there are tons of cozy little hot **springs** all over **the** place. Some of **the** water in these hot **springs** is actually bubbling up from this deeply buried oceanic **plate**. And our hypothesis was that there should be **carbon** dioxide bubbling up with it, but something deep **underground** was filtering it out. So we spent two weeks driving all around Costa Rica, sampling every hot **spring** we could find — it was awful, let me tell you. And then we spent **the** next two years measuring and analyzing data. And if you ’ re not a scientist, I ’ ll just let you know that **the** big discoveries don ’ t really happen when you ’ re at a beautiful hot **spring** or on a public stage ; they happen when you ’ re hunched over a messy **computer** or you ’ re troubleshooting a difficult instrument, or you ’ re Skyping your colleagues because you are completely confused about your data. Scientific discoveries, kind of like deep subsurface microbes, can be very, very slow. But in our case, this really paid off this one time. We discovered that literally tons of **carbon** dioxide were coming out of this deeply buried oceanic **plate**. And **the** thing that was keeping them **underground** and keeping it from being released out into **the** atmosphere was that deep **underground**, underneath all **the** adorable sloths and toucans of Costa Rica, were chemolithoautotrophs. These microbes and **the** chemical processes that were happening around them were converting this **carbon** dioxide into carbonate mineral and locking it up **underground**. Which makes you wonder : If these subsurface processes are so good at sucking up all **the carbon** dioxide coming from below them, could they also help us with a little **carbon** problem we ’ ve got going on up at **the surface**? Humans are releasing enough **carbon** dioxide into our atmosphere that we are decreasing **the** ability of our **planet** to support life as we know it. And scientists and engineers and entrepreneurs are working on methods to pull **carbon** dioxide out of these point sources, so that they ’ re not released into **the** atmosphere. And they need to put it somewhere. So for this reason, we need to keep studying places where this **carbon** might be stored, possibly in **the** subsurface, to know what ’ s going to happen to it when it goes there. Will these deep subsurface microbes be a problem because they ’ re too slow to actually keep anything down there? Or will they be helpful because they ’ ll help convert this stuff to solid carbonate minerals? If we can make such a big breakthrough just from one study that we did in Costa Rica, then imagine what else is waiting to be discovered down there. This new field of geo-bio-chemistry, or deep subsurface **biology**, or whatever you want to call it, is going to have huge implications, not just for mitigating climate change, but possibly for understanding how life and earth have coevolved, or finding new products that are useful for industrial or medical applications. Maybe even predicting **earthquakes** or finding life outside our **planet**. It could even help us understand **the** origin of life itself. Fortunately, I don ’ t have to do this by myself. I have amazing colleagues all over **the** world who are cracking into **the** mysteries of this deep subsurface world. And it may seem like life buried deep within **the** earth ’ s crust is so far away from our daily experiences that it ’ s kind of irrelevant. But **the** truth is that this weird, slow life may actually have **the** answers to some of **the** greatest mysteries of life on earth. Thank you.

Text Sample 59: POS Dim 1 – 2019 – Score 13.00 – 2019/t000014.txt

I ’ m here to talk to you about something important that may be new to you. **The** governments of **the** world are about to conduct an unintentional experiment on our climate. In 2020, new rules will require ships to lower their sulfur **emissions** by scrubbing their dirty exhaust or switching to cleaner fuels. For human health, this is really good, but sulfur particles in **the emission** of ships also have an effect on clouds. This is a satellite image of marine clouds off **the** Pacific West Coast of **the** United States. **The** streaks in **the** clouds are created by **the** exhaust from ships. Ships ’ **emissions** include both **greenhouse** gases, which trap heat over long periods of time, and particulates like sulfates that mix with clouds and temporarily make them brighter. Brighter clouds reflect more sunlight back to space, cooling **the** climate. So in fact, humans are currently running two unintentional experiments on our climate. In **the** first one, we ’ re increasing **the** concentration of **greenhouse** gases and gradually warming **the** earth system. This works something like a fever in **the** human body. If **the** fever remains low, its effects are mild, but as **the** fever rises, damage grows more severe and eventually devastating. We ’ re seeing a little of this now. In our other experiment, we ’ re planning to remove a layer of particles that brighten clouds and shield us from some of this warming. **The** effect is strongest in ocean clouds like these, and scientists expect **the** reduction of sulfur **emissions** from ships next year to produce a measurable increase in global warming. Bit of a shocker? In fact, most **emissions** contain sulfates that brighten clouds : **coal**, diesel exhaust, forest fires. Scientists estimate that **the** total cooling effect from **emission** particles, which they call aerosols when they ’ re in **the** climate, may be as much as all of **the** warming we ’ ve experienced up until now. There ’ s a lot of uncertainty around this effect, and it ’ s one of **the** major reasons why we have difficulty predicting climate, but this is cooling that we ’ ll lose as **emissions** fall. So to be clear, humans are currently cooling **the planet** by dispersing particles into **the** atmosphere at massive scale. We just don ’ t know how much, and we ’ re doing it accidentally. That ’ s worrying, but it could mean that we have a fast-acting way to reduce warming, emergency medicine for our climate fever if we needed it, and it ’ s a medicine with origins in nature. This is a NASA simulation of earth ’ s atmosphere, showing clouds and particles moving over **the planet**. **The** brightness is **the** Sun ’ s light reflecting from particles in clouds, and this reflective shield is one of **the** primary ways that nature keeps **the planet** cool enough for humans and all of **the** life that we know. In 2015, scientists assessed possibilities for rapidly cooling climate. They discounted things like mirrors in space, ping-pong balls in **the** ocean, plastic sheets on **the** Arctic, and they found that **the** most viable approaches involved slightly increasing this atmospheric reflectivity. In fact, it ’ s possible that reflecting just one or two percent more sunlight from **the** atmosphere could offset two degrees Celsius or more of warming. Now, I ’ m a technology executive, not a scientist. About a decade ago, concerned about climate, I started to talk with scientists about potential countermeasures to warming. These conversations grew into collaborations that became **the** Marine Cloud Brightening Project, which I ’ ll talk about momentarily, and **the** nonprofit policy organization SilverLining, where I am today. I work with politicians, researchers, members of **the** tech industry and others to talk about some of these ideas. Early on, I met British atmospheric scientist John Latham, who proposed cooling **the** climate **the** way that **the** ships do, but with a natural source of particles : sea-salt mist from seawater sprayed from ships into areas of susceptible clouds over **the** ocean. **The** approach became known by **the** name I gave it then,”marine cloud brightening.”Early modeling studies suggested that by deploying marine cloud brightening in just 10 to 20 percent of susceptible ocean clouds, it might be possible to offset as much as two degrees Celsius ’ s warming. It might even be possible to brighten clouds in local regions to reduce **the** impacts caused by warming ocean **surface** temperatures. For example, regions such as **the** Gulf Atlantic might be cooled in **the** months before a hurricane season to reduce **the** force of storms. Or, it might be possible to cool waters flowing onto coral reefs overwhelmed by heat stress, like Australia ’ s Great Barrier Reef. But these ideas are only theoretical, and brightening marine clouds is not **the** only way to increase **the** reflection of **the** sunlight from **the** atmosphere. Another **occurs** when large volcanoes release material with enough force to reach

the upper layer of **the** atmosphere, **the** stratosphere. When Mount Pinatubo erupted in 1991, it released material into **the** stratosphere, including sulfates that mix with **the** atmosphere to reflect sunlight. This material remained and circulated around **the planet**. It was enough to cool **the** climate by over half a degree Celsius for about two years. This cooling led to a striking increase in Arctic ice cover in 1992, which dropped in subsequent years as **the** particles fell back to earth. But **the** volcanic phenomenon led Nobel Prize winner Paul Crutzen to propose **the** idea that dispersing particles into **the** stratosphere in a controlled way might be a way to counter global warming. Now, this has risks that we don ' t understand, including things like heating up **the** stratosphere or damage to **the** ozone layer. Scientists think that there could be safe approaches to this, but is this really where we are? Is this really worth considering? This is a simulation from **the** US National Center for Atmospheric Research global climate model showing, earth **surface** temperatures through 2100. **The** globe on **the left** visualizes our current trajectory, and on **the** right, a world where particles are introduced into **the** stratosphere gradually in 2020, and maintained through 2100. Intervention keeps **surface** temperatures near those of today, while without it, temperatures rise well over three degrees. This could be **the** difference between a safe and an unsafe world. So, if there ' s even a chance that this could be close to reality, is this something we should consider seriously? Today, there are no capabilities, and scientific knowledge is extremely limited. We don ' t know whether these types of interventions are even feasible, or how to characterize their risks. Researchers hope to explore some basic questions that might help us know whether or not these might be real options or whether we should rule them out. It requires multiple ways of studying **the** climate system, including **computer** models to forecast changes, analytic **techniques** like machine **learning**, and many types of observations. And though it ' s controversial, it ' s also critical that researchers develop core technologies and perform small-scale, real-world experiments. There are two research programs proposing experiments like this. At Harvard, **the** SCoPEx experiment would release very small amounts of sulfates, calcium carbonate and water into **the** stratosphere with a balloon, to study **chemistry** and physics effects. How much material? Less than **the** amount released in one minute of flight from a commercial aircraft. So this is definitely not dangerous, and it may not even be scary. At **the** University of Washington, scientists hope to spray a fine mist of salt water into clouds in a series of land and ocean tests. If those are successful, this would culminate in experiments to measurably brighten an area of clouds over **the** ocean. **The** marine cloud brightening effort is **the** first to develop any technology for generating aerosols for atmospheric sunlight reflection in this way. It requires producing very tiny particles — think about **the** mist that comes out of an asthma inhaler — at massive scale — so think of looking up at a cloud. It ' s a tricky engineering problem. So this one nozzle they developed generates three trillion particles per second, 80 nanometers in size, from very corrosive saltwater. It was developed by a team of retired engineers in Silicon Valley — here they are — working full-time for six years, without pay, for their grandchildren. It will take a few million dollars and another year or two to develop **the** full spray system they need to do these experiments. In other parts of **the** world, research efforts are emerging, including small modeling programs at Beijing Normal University in China, **the** Indian Institute of Science, a proposed center for climate repair at Cambridge University in **the** UK and **the** DECIMALS Fund, which sponsors researchers in global South countries to study **the** potential impacts of these sunlight interventions in their part of **the** world. But all of these programs, including **the** experimental ones, lack significant funding. And understanding these interventions is a hard problem. **The** earth is a vast, complex system and we need major investments in climate models, observations and basic science to be able to predict climate much better than we can today and manage both our accidental and any intentional interventions. And it could be urgent. Recent scientific reports predict that in **the** next few decades, earth ’ s fever is on a path to devastation : extreme heat and fires, major loss of ocean life, collapse of Arctic ice, displacement and suffering for hundreds of millions of people. **The** fever could even reach tipping points where warming takes over and human efforts are no longer enough to counter accelerating changes in natural systems. To prevent this circumstance, **the** UN ’ s International Panel on Climate Change predicts that we need to stop and even reverse **emissions** by 2050. How? We have to quickly and radically transform major economic sectors, including energy, construction, **agriculture**, **transportation** and others. And it is imperative that we do this as fast as we can. But our fever is now so high that climate experts say we also have to remove massive quantities of CO2 from **the** atmosphere, possibly 10 times all of **the** world ’ s annual **emissions**, in ways that aren ’ t proven yet. Right now, we have slow-moving solutions to a fast-moving problem. Even with **the** most optimistic assumptions, our exposure to risk in **the** next 10 to 30 years is unacceptably high, in my opinion. Could interventions like these provide fast-acting medicine if we need it to reduce **the** earth ’ s fever while we address its underlying causes? There are real concerns about this idea. Some people are very worried that even researching these interventions could provide an excuse to delay efforts to reduce **emissions**. This is also known as a moral hazard. But, like most medicines, interventions are more dangerous **the** more that you do, so research actually tends to draw out **the** fact that we absolutely, positively cannot continue to fill up **the** atmosphere with **greenhouse** gases, that these kinds of alternatives are risky and if we were to use them, we would need to use as little as possible. But even so, could we ever learn enough about these interventions to manage **the** risk? Who would make decisions about when and how to intervene? What if some people are worse off, or they just think they are? These are really hard problems. But what really worries me is that as climate impacts worsen, leaders will be called on to respond by any means available. I for one don ’ t want them to act without real information and much better options. Scientists think it will take a decade of research just to assess these interventions, before we ever were to develop or use them. Yet today, **the** global level of investment in these interventions is effectively zero. So, we need to move quickly if we want policymakers to have real information on this kind of emergency medicine. There is hope! **The** world has solved these kinds of problems before. In **the** 1970s, we identified an existential threat to our protective ozone layer. In **the** 1980s, scientists, politicians and industry came together in a solution to replace **the** chemicals causing **the** problem. They achieved this with **the** only legally binding environmental agreement signed by all countries in **the** world, **the** Montreal Protocol. Still in force today, it has resulted in a recovery of **the** ozone layer and is **the** most successful environmental protection effort in human history. We have a far greater threat now, but we do have **the** ability to develop and agree on solutions to protect people and restore our climate to health. This could mean that to remain safe, we reflect sunlight for a few decades, while we green our industries and remove CO2. It definitely means we must work now to understand our options for this kind of emergency medicine. Thank you,

Hello there, this is Chris Anderson, and I am hugely, hugely, tremendously excited to welcome you to a new series of **the** TED interview. Now, then, this season, we ' re trying something new. We ' re organising **the** whole season around a single **theme**, albeit a **theme** that some of you may consider inappropriate. But hear me out. **The theme** is **the** case for optimism. And yes, I know **the** world has been hit with extraordinarily ugly things in **the** last few years. Political division, a racial reckoning, technology run amuck, not to mention a global pandemic and impending climate catastrophe. What on earth are we thinking in this context? Optimism just seems so naive and unwanted, almost annoying. So here ' s my position. Don ' t think of optimism as a feeling. It ' s not just this sort of shallow feeling of hope. Optimism is a **search**. It ' s a determination to look for a pathway forward somewhere out there. I believe I truly believe there are amazing people whose minds contain **the** ideas, **the** visions, **the** solutions that can actually create that pathway forward. If given **the** support and resources they need, they may very well light **the** path out of this dark place we ' re in. So these are **the** people who can present not optimism, but a case for optimism. They ' re **the** people I ' m talking to this season. So let ' s see if they can persuade us now. Then **the** place I want to start is with A. I. **artificial** intelligence. This, of course, is **the** next innovative technology that is going to change everything as we know it, for better or for worse. Today was painted not with **the** usual dystopian brush, but by someone who truly believes in its potential. Sam Altman is **the** former president of Y Combinator, **the** legendary startup accelerator. And in 2015, he and a team launched a company called Open Eye, dedicated to one noble purpose to develop A. I. so that it benefits humanity as a whole. You may have heard, by **the** way, recently a lot of buzz around in A. I. technology called T3 that was developed by open eye improve **the** quality of **the** amazing team of researchers and developers they have work in. There will be hearing a lot about three in **the** conversation ahead. But sticking to this lofty mission of developing A. I. for humanity and finding **the** resources to realize it haven ' t been simple. Open A. I. is certainly not without its critics, but their goal couldn ' t be more important. And honestly, I found it really quite exciting to hear Sam ' s vision for where all this could lead. OK, let ' s do this. So, Sam Altman, welcome. Thank you for having me. So, Sam, here we are in 2021. A lot of people are fearful of **the** future at this moment in world history. How would you describe your attitude to **the** future? I think that **the** combination of scientific and technological progress and better societal decision making, better societal governance is going to solve in **the** next couple of decades all of our current most pressing problems, there will be new ones. But I think we are going to get very safe, very inexpensive, **carbon** free nuclear energy to work. And I think we ' re going to talk about that time that **the** climate disaster looks so bad and how lucky we are. We got saved by science and technology, I think. And we ' ve already now seen this with **the** rapidity that we were able to get vaccines deployed. We are going to find that we are able to cure or at least treat a significant percentage of human disease, including I think we ' ll just actually make progress in helping people have much longer decades, longer health spans. And I think in **the** next couple of decades, that will look pretty clear. I think we will build systems with AI and otherwise that make access to an incredibly high quality education more possible than ever before. I think **the** lives we look forward like one hundred years, fifty years, even **the** quality of life available to anyone then will be much better than **the** quality of life available in **the** very best case to anyone today, to any single person today. So, yeah, I ' m super optimistic. I think, like, it ' s always easy to do scroll and think about how bad are **the** bad things are, but **the** good things are really good and getting much better. Is it your sincere belief that **artificial** intelligence can actually make that future better? Certainly. How look, with any technology. I don ' t think it will all be better. I think there are always positive and negative use cases of anything new, and it ' s our job to maximize **the** positive ones, minimize **the** negative ones. But I truly, genuinely believe that **the** positive impacts will be orders of magnitude bigger than **the** negative ones. I think we ' re seeing a glimpse of that now. Now that we have **the** first general purpose built out in **the** world and available via things like RPI, I think we are seeing evidence of just **the** breadth of services that we will be able to offer as **the** sort of technological revolution really takes hold. And we will have people interact with services that are smart, really smart, and it will feel like as strange as **the** world before mobile phones feels now to us. Hmm, yeah, you mentioned your API, I guess that stands for what, application programming interface? It ' s **the** technology that allows complex technology to be accessible to others. So give me a sense of a couple of things that have got you most excited that are already out there and then how that gives you visibility to a pathway forward that is even more exciting. So I think that **the** things that we ' re seeing now are very much glimpse of **the** future. We released three, which is a general-purpose natural language text model in **the** summer of twenty twenty. You know, there ' s hundreds of applications that are now using it in production that ' s ramping up all of **the** time. But there are things where people use three to really understand **the** intent behind **the** **search** query and deliver results and sort of understand not only intent, but all of **the** data and deliver **the** thing of what you want. So you can sort of describe a fuzzy thing and it ' ll understand documents. It can understand, you know, short documents, not full books yet, but bring you back to **the** context of what you want. There ' s been a lot of excitement about using **the** generative capabilities to create sort of games or sort of interactive stories or letting people develop characters or chat with a sort of virtual friend. There are applications that, for example, help a job seeker polish a tailored application for each individual company. There ' s **the** beginning of tutors that can sort of teach people about different concepts and take on different personas. And we can go on for a long time. But I think anything that you can imagine that you do today via **computer** that you would like to really understand and get to know you. And not only that, but understand all of **the** data and knowledge in **the** world and help you have **the** best experience that is is possible that that will happen. So what gets opened up? What new adjacent possible state is that as a result of these powers from this question, from **the** point of view of someone who ' s starting out on a career, for example, they ' re trying to figure out what would be a really interesting thing to do in **the** future that has only recently become possible. What are some new things that this opens up in a world where you can talk to a **computer**? And get. **The** output that would normally require you hiring **the** world experts back immediately for almost no money, I would say think about what ' s possible there. So that could be like, as you said, what can normally only **the** best programmer in **the** world or a really great programmer do for me. And can I now instead just ask in English and have that program written? So all these people that, you know, want to develop an app and they have an idea, but they don ' t know how to program. Now they can have it. You know, what is **the** service look like when anyone on Earth who wants really great medical advice? Can get better medical advice than any single doctor could ever get, because this has **the** total medical knowledge and reasoning ability that **the** some humanity has ever produced. When you want to learn something, you have sort of a tutor that understands your **exact** style, how you best learn everything you know, and custom teaches you whatever concept you want to learn someday. You can imagine that like. You have an eye that reads your email and your task list and your calendar and **the** documents you ' ve been sent and in any meeting maximally perfectly prepares you and has all of **the** information that you need in all **the** context of your entire career right there for you to go on for a long time. But I think this will just be powerful systems. So it ' s really fun playing around with Chapatti three, one compelling example of someone who ' s more tax base is try Googling **The** Guardian essay that was written entirely by different GP2 three queries and stitched together. It ' s an essay on why **artificial** intelligence isn ' t a threat to humanity. And that ' s impressive. It ' s very compelling. I actually tried inputting one of **the** three online uses. I asked **the** question what is interesting about some ollman? Oh no. Here ' s what it came back with. It was it was rather philosophical, actually. Came back with. I don ' t understand what you mean by interesting. It seems to me that this word has no unambiguous meaning in **the** context of human society beyond its literal definition as somewhat pleasing or entertaining. I do not believe there to be any such thing as INTERESTINGNESS except in **the** mind of a human or other sentient being that to my knowledge, this is an entirely subjective state that varies from person to person. However, I will grant that this is an interesting question to ask. This does not mean it has been answered. There is no answer to be found. Well, so you can agree that somewhere between profound and gibberish is that almost well, with **the** state of play is I mean, that ' s where we are today. I think somewhere between profound and jibberish is **the** right way to think about **the** current capabilities of CGP three. I think they would definitely had a bubble of hype about three last summer. But **the** thing about bubbles is **the** reason that smart people fall for them is there ' s a kernel of something really real and really interesting that people get overexcited about. And I think people definitely got and still are overexcited about 3:00 today, but still probably underestimated **the** potential of where these models will go in **the** future. And so maybe there ' s this like short term overhyped and long term under hype for **the** entire field, for tax models, for whatever you ' d like. It ' s going on. And as you said, there ' s clearly some gibberish in there. But on **the** other hand, those were like well-formed sentences. And there were a couple of ideas and there that I was like, oh, like they actually maybe that ' s right. And I think if **artificial** intelligence, even in its current very larval state, can make us confront new things and sort of inspire new ideas, that ' s already pretty impressive. Give us a sense of what ' s actually happening in **the** background there. I think it ' s hard to understand because you read these words seem like someone is trying to mean something. Obviously, I think you believe that there ' s whatever you ' ve built there, that there ' s a sort of thinking, sentient thing that ' s going, oh, I must answer this question. So so what how would you describe what ' s going on? You ' ve got something that has read **the** entire Internet, essentially all of Wikipedia, etc. We ' ve read something that ' s read like a small **fraction** of a random sampling of **the** Internet. We will eventually train something that has read as much of **the** Internet or more of **the** Internet than we ' ve done right now. But we have a very long way to go. I mean, we ' re still, I think, **relative** to what we will have operated at quite small scale with quite small eyes. But what is happening is there is a model that is ingesting lots of text and it is trying to predict **the** next word. So we use Transformer ' s they take in a context, which is a particular architecture of an A. I. model, they take in a context of a lot of words, let ' s say like a thousand or something like that. And they try to predict **the** word that comes next in **the** sequence. And there ' s like a lot of other things that happen, but fundamentally that ' s it, and I think this is interesting because in **the** process of playing that little game of trying to predict **the** next word, these models have to develop a representation and understanding of what is likely to come next and. I think it is maybe not perfectly accurate, but certainly worth considering to say that intelligence is very near **the** ability to make accurate predictions. What ' s confusing about this is that there are so many words on **the** Internet which are foolish as well as **the** words that are wise. And and how do you build a model that can distinguish between those two? And this is prompted actually by another example that I typed in. Like I asked, you know, what is a powerful idea, very interested in ideas. That was my question as a powerful idea. And it came back with several things, some of which seemed moderately pronouncements, which seemed moderately gibberish. But then he was he was one that it came back with **the** idea that **the** human race has, quote, **evolved**, unquote, is false **evolution** or adaptation within a species was abandoned by **biology** and genetics long ago. Wait a sec. That ' s news to me. What have you been reading? And I presume this has been pulled out of some recesses of **the** Internet, but how is it possible, even in theory, to imagine how a model can gravitate towards truth, wisdom, as opposed to just like majority views? Or how how how do you avoid something taking us further into **the** sort of **the** maze of errors and bad thinking and so forth that has already been a worrying feature for **the** last few years? It ' s a **fantastic** question, and I think it is **the** most interesting area of research that we need to pursue. Now, I think at this point, **the** questions of whether we can build really powerful general-purpose AI system, I won ' t say there in **the** rearview mirror. We still have a lot of hard engineering work to do, but I ' m pretty confident we ' re going to be able to. And now **the** questions are like, what should we build? And how and why and what data should we train on and how do we build systems not just that can do these like phenomenally impressive things, but that we can ensure do **the** things that we want and that understand **the** concepts of truth and falsehood and, you know, alignment with human values and misalignment with human values. One of **the** pieces of research that we put out last year that I was most proud of and most excited about is what we call reinforcement learning from human feedback. And we showed that we can take these giant models that are trained on a bunch of stuff, some of it good, some of **the** bad, and then with a really quite small amount of feedback from human judgment about, hey, this is good, this is bad, this is wrong, this is **the** behavior I want I don ' t want this behavior. We can feed that information from **the** human judges back into **the** model and we can teach **the** model, behave more like this and less like that. And it works better than I ever imagined it would. And that gives me a lot of hope that we can build an aligned system. We ' ll do other things, too, like I think curating data sets where there ' s just less sort of bad data to train on. It will go a very long way. And as these models get smarter, I think they inherently develop **the** ability to sort out bad data from good data. And as they get really smart, they ' ll even start to do something we call active **learning**, which is where they ask us for exactly **the** data they need when they ' re missing something, when they ' re unsure, when they don ' t understand. But I think as a result of simply scaling these models up, building better, I hate to use **the** word cognition because it sounds so anthropomorphic, but let ' s say building a better ability to reason into **the** models, to think, to challenge, to try to understand and combining that with this idea of online into human values via this **technique** we developed, that ' s going to go a very long way. Now, there ' s another question, which you sort of just kicked **the** ball down **the** field, too, which is how do we as a society decide to which set of human values do we align these powerful systems? Yeah, indeed. So if I if I understand rightly what you ' re saying, that you ' re saying that it ' s possible to look at **the** output at any one time of three. And if we don ' t like what it ' s coming up with, some ways human can say, no, that was off, don ' t do that. Whatever algorithm or process led you to that, undo it. Yeah. And that **the** system is that incredibly powerful at avoiding that same kind of mistake in future because it sort of replicates **the** instructions, correct? Yeah. And eventually and not much longer, I believe that we ' ll be able to not only say that was good, that was bad, but say that was bad for this reason. And also tell me how you got to that answer so I can make sure I understand. But at **the** end of **the** day, someone needs to decide who is **the** wise human or short humans who are looking at **the** results. So it ' s a big difference. Someone who who grew up with intelligent design world view could look at that and go, that ' s a brilliant outcome. Well, Goldstar done. And someone else would say something is done awfully wrong here. So how do you avoid and this is a version of **the** problem that a lot of **the**, I guess, Silicon Valley companies are facing right now in terms of **the** pushback they ' re getting on **the** output of social media and so forth. How do you assemble that pool of experts who stand for human values that we actually want? I mean, we talk about this all **the** time, I don ' t think this is like solely or even not even close to majorly up to opening night to decide, I think we need to begin a societal conversation now about how we ' re going to make those decisions, how we ' re going to make sure we have representational input in that, and how we sort of make these very difficult global governance systems. My personal belief is that we should have pretty broad rules about what these systems will never do and will always do. But then **the** individual user should get a system that kind of behaves like they want. And there will be people do have very different value systems. Some of them are just fundamentally incompatible. No one gets to use eye to, like, exploit other people, for example, and hopefully we can all agree on. But do you want **the** AI to like. You know, support you and your belief of intelligent design, like, do I think openly, I should say it can ' t, even though I disagree with that is like a scientific conclusion. No, I wouldn ' t take that stance. I think **the** thing to remember about all of this is that history is still quite extraordinarily weak. It ' s still has such big problems and it ' s still so unreliable that for most use cases it ' s still unsuitable. But when we think about a system that is like a thousand times more powerful and let ' s say a million times more reliable, it just doesn ' t it doesn ' t say gibberish very often. It doesn ' t totally lose **the** plot and get distracted or system like that is going to be one that a lot of **the** economic activity in **the** world comes to rely on. And I think it ' s very important that we don ' t have a small group of people sort of saying you can never use it for this thing that, like most of **the** world wants to use it for because it doesn ' t match our personal beliefs. Talk a bit more about some of **the** other uses of it, because one of **the** things that ' s most surprising is it ' s not just about sort of text responses. It ' s it can take generalized human instructions and build things up. For example, you can say to it, write a Python program that is designed to put a flashing cursor in one corner of **the** screen, in **the** Google logo in **the** other corner. And and it can go your way and do something like that. Shockingly, quite well, effectively. Yeah, I it can. That ' s amazing. I mean, this is amazing to me. That opens **the** door to. An entirely way to think about programers for **the** future, that you could you could have people who can program just in human natural language potentially and gain rapid efficiency. I do **the** engineering. We ' re not that far away from that world. We ' re not that far away from **the** world where you will write a spec in English. And for a simple enough program, I will just write **the** code for you. As you said, you can see glimpses of that even in this very week three which was not trained to code like. I think this is important to remember. We trained it on **the** language on **the** Internet very rarely, you know, Internet let language on **the** Internet also includes some code snippets. And that was enough, so if we really try to go train a model on code itself and that ' s where we decide to put **the** horsepower of **the** model into, just imagine what will be possible will be quite impressive. But I think what you ’ re pointing to there is that because models like three to some degree or other, and it ’ s like very hard to know exactly how much understand **the** underlying concepts of what ’ s going on. And they ’ re not just regurgitating things they found in a website, but they can really apply them and say, oh, yeah, I kind of like know about this word and this idea and code. And this is probably what you ’ re trying to do. And I won ’ t get it right always. But sometimes I will just generate this like a brand new program for nothing that anyone has ever asked before. And it will work. That ’ s pretty cool. And data is data. So it can do that from English to code. It can do that from English to French. Again, we never told it to learn about translation. We never told it about **the** concepts of English and French, but it learned them, even though we never said this is what English is and this is what French is and this is what it means to translate, it can still do it. Wow, I mean, for creative people, is there a world coming where **the** sort of **the** palette of possibility that they can be exposed to is just explodes? I mean, if you ’ re a musician, is there a near future where you can say to your eye, OK, I ’ m going to bed now, but in **the** morning I ’ d love you to present me with a thousand tuba jingles with words attached that you have of a sort of mean factor to **the** and you come down in **the** morning and **the computer** shows you **the** stuff. And one of them, you go, wow, that is it. That is a top 10 hit and you build a song from it. Or is that going to be released? Actually be **the** value add. We released something last year called Jukebox, which is very near what you described, where you can say I want music generated for me in this style or this kind of stuff, and it can come up with **the** words as well. And it ’ s like pretty cool. And I really **enjoy** listening to music that it creates. And I can sort of do four songs, two bars of a jingle, whatever you ’ d like. And one of my very favorite artists reached out, called to open it after we release this and said that he wanted to talk. And I was like, well, I like total fanboy here. I ’ d love to join that call. And I was so nervous that he was going to say, this is terrible. This is like a really sad thing for human creativity. Like, you know, why are you doing this? This is like whatever. And he was so excited. And he ’ s like, this has been so inspiring. I want to do a new album with this. You know, it ’ s like, give me all these new ideas. It ’ s making me much better at my job. I ’ m going to make better music because of this tool. And that was awesome. And I hope that ’ s how it all continues to go. And I think it is going to lead to this. We see a similar thing now with Dolly, where graphic designers sometimes tell us that they just they see this new set of possibilities because there ’ s new creative inspiration and they ’ re cycle time, like **the** amount of time it takes to just come up with an idea and be able to look at it and then decide whether to go down that path or head in a different direction goes down so much. And so I think it ’ s going to just be this like incredible creative **explosion** for humans. And how far away are we some before? And I it comes up with a genuinely powerful new idea, an idea that solves **the** problem that humans have been wrestling with. It doesn ’ t have to be as quite on **the** scale as of, OK, we ’ ve got a virus coming. Please describe to us what a what a national rational response should look like, but some kind of genuinely innovative idea or solution like one one internal question we ’ ve asked ourselves is, when will **the** first genuinely interesting, purely AI written TED talk show up? I think that ’ s a great milestone. I will say it ’ s always hard to guess timeline ’ s I ’ m sure I ’ ll be wrong on this, but I would guess **the** first genuinely interesting. Ted talk, thought of written delivered by an AIDS within **the** kind of **the** seven ish year time frame. Maybe a little bit less. And it feels like I mean, just reading that Guardian essay that was kind of it was a composite of several different GPG three responses to questions about, you know, **the** threats of robotics or whatever. If you throw in a human editor into **the** mix, you could probably imagine something much sooner. Indeed. Like tomorrow. Yeah. So **the** hybrid **the** hybrid version where it ’ s basically a tool assisted TED talk, but that it is better than any TED talk a human could generate in one hundred hours or whatever, if you can sort of combine human discretion with A. I. horsepower. I suspect that ’ s like our next year or two years from now kind of thing where it ’ s just really quite good. That ’ s that ’ s really interesting. How do you view **the** impact of A. I. on jobs? There ’ s obviously been **the** familiar story is that every White-Collar job is now up for destruction. What ’ s what ’ s your view there? You know, it ’ s I think it ’ s always hard to make these predictions. That is definitely **the** familiar story now. Five years ago, it was every **blue** collar job is up for destruction, maybe like last year it was. Every creative job is up for destruction because of things like Jukebox I. I think there will be an enormous impact on. **The** job market, and I really hate it, I think it ’ s kind of gross when people like working on I pretend like there ’ s not going to be or sort of say, oh, don ’ t worry about it. It ’ ll just all obviously better. It doesn ’ t always obviously get better. I think what is true is. Every technological revolution produces a change in jobs, we always find new ones, at least so far. It ’ s difficult to predict from where we ’ re sitting now what **the** new ones will be and this technological revolution is likely to be. Again, it ’ s always tempting to say this time it ’ s different. Maybe I ’ ll be totally wrong. But from what I see now, this technological revolution is likely to be more. Dramatic. More of a staccato note than most, and I think we as a society need to figure out how we ’ re going to cushion everybody through that. I ’ ve got my own ideas about how to do that. I, I wouldn ’ t say that I have any reason to believe they ’ re **the** right ones, but doing nothing and not really engaging with **the** magnitude of what ’ s about to happen, I think it ’ s like not an acceptable answer. So there ’ s going to be huge impact. It ’ s difficult to predict where it shows up **the** most. I think previous predictions have mostly been wrong, but I I ’ d like to see us all as a society, certainly as a field, engage in what what **the** shifts we want to make to **the** social contract are to kind of get through that in a way that is maximally beneficial to everybody. I mean, in every past revolution, there ’ s always been a space for humans to move to. That is, if you like, moving up **the** food chain, it ’ s sort of we ’ ve retreated to **the** things that humans could uniquely do, think better, be more creative and so forth. I guess **the** worry about A. I. is that in principle, I believe this, that there is no human cognitive feat that won ’ t ultimately be doable, probably better by **artificial** general touch, simply because of **the** extra firepower that ultimately they can have, **the** vast knowledge they bring to **the** table and so forth. Is that basically right, that there is ultimately no safe sort of space where we can say, oh, but that would never be able to do that on a very long time horizon? I agree with you, but that ’ s such a long time horizon. I think that, you know, like maybe we ’ ve merged by that point, like maybe we ’ re all plugged in and then, like, we ’ re this sort of symbiotic thing. Like, I think there ’ s an interesting example, as we were talking about a few minutes ago, where right now we have these systems that have sort of enormous horsepower but no steering wheel. It ’ s like, you know, incredible capabilities, but no judgment. And there ’ s like these obvious ways in which today even a human plus three is far better than either on their own. Many people speak about a world where it ’ s sort of A. I. as this external threat you speak about. At some point, we actually merge with eyes in some way. What do you mean by that? There ’ s a lot of different versions of what I think is possible there, you know, in some sense, I ’ d argue **the** merge has already like begun **the** human technology merge like we have this thing in our hands that sort of dictates a lot of what we think, but it gives us real superpowers and that can go much, much further. Maybe it goes all **the** way to like **the** Elon Musk vision of neuro link and having our brains plugged into **computers** and sort of like literally we have a **computer** on **the** back of our head or goes **the** other direction and we get uploaded into one. Or maybe it ' s just that we all have a chat bot that kind of constantly steers us and helps us make better decisions than we could. But in any case, I think **the** fundamental thing is it ' s not like **the** humans versus **the** eyes competing to be **the**. Smartest sentient thing on earth or beyond. But it ' s that this idea of being on **the** same team. Hmm. I certainly get very excited by **the** sort of **the** medium term potential for creative people of all sorts if they ' re willing to expand their palette of possibilities. But with **the** use of A. I. to be willing to. I mean, **the** one thing that **the** history of technology has shown again and again is that something this powerful and with this much benefit is unstoppable and you will get rewarded for embracing it **the** most and **the** earliest. So talk about what can go wrong with that, so let ' s move away from just **the** sort of economic displacement factor. You were a co-founder of Open Eye because you saw existential risks to humanity from high today. What would you put as **the** sort of **the** most worrying of those risks? And how is open eye working to minimize? I still think all of **the** really horrifying risks exist. I am more confident, much more confident than I was five years ago when we started that there are technical things we can do about. How we build these systems and **the** research and **the** alignment that make us much more likely to end up in **the** kind of really wonderful camp, but, you know, like maybe open I fall behind and maybe somebody else feels ajai that thinks about it in a very different way or doesn ' t care as much as we ' d like about safety and **the** risks or how to strike a different trade off of how fast we should go with this and where we should sort of just say, like, you know, like let ' s push on for **the** economic benefits. But I think all of this sort of like, you know, traditionally what ' s been in **the** realm of sci fi risks are real and we should not ignore them. And I still lose sleep over them. And just to update people is **artificial** general intelligence. Right now, we have incredible examples of powerful AI operating on specific areas. Ajai is **the** ability of a **computer** mind to connect **the** dots and to make decisions at **the** same level of breadth that that humans have had. What ' s your sort of elevator pitch on Ajai about how to identify and how to think of it? Yeah, I mean, **the** way that I would say it is that for a while we were in this world of like very narrow A. I., you know, that could like classify images of cats or whatever, more advanced stuff in that. But that kind of thing. We are now in **the** era of general purpose, AI, where you have these systems that are still very much imperfect tools, but that can generalize. And one thing like GPP three can write essays and translate between languages and write **computer** code and do very complicated **search**. It ' s like a single model that understands enough of what ' s really going on to do a broad **array** of tasks and learn new things quickly, sort of like people can. And then eventually we ' ll get to this other realm. Some people call it ajai, some people call ostler things. But I think it implies that **the** systems are like to some degree self directed, have some intentionality of their own is a simple summary to say that, like **the** fundamental risk is that there ' s **the** potential with general **artificial** intelligence of a sort of runaway effect of self-improvement that can happen far faster than any kind of humans can even keep up with, so that **the** day after you get to ajai, suddenly **computers** are thousands of times more advanced than us and we have no way of controlling what they do with that power. Yeah, and that is certainly in **the** risk space, which is that we build this thing and at some point somewhat suddenly, it ' s much more powerful than we are, we haven ' t really done **the** full merge yet. There ' s an event horizon there and it ' s sort of hard to see to **the** other side of it. Again, lots of reasons to think it will go OK. Lots of reasons to think we won ' t even get to that scenario. But that is something that. I don ' t think people should brush under **the** rug as much as they do, it ' s in **the** possibility space for sure, and in **the** possibility subspace of that is one where, like, we didn ' t actually do as good of a job on **the** alignment work as we thought. And this sort of child of humanity kind of acts in a very different way than we think. A framework that I find useful is to sort of think about like a two by two matrix, which is short timelines to ajai and long timelines to ajai and a slow take off and a fast take off on **the** other axis. And in **the** short timelines, fast take off quadrant, which is not where I think we ' re going to be. But if we get there, I think there ' s a lot of scenarios in **the** direction that you are describing that are worrisome. And we would want to spend a lot of effort planning for. I mean, **the** fact that a **computer** could start editing its own code and improving itself while we ' re asleep and you wake up in **the** morning and it ' s got smarter, that is **the** start of something super powerful and potentially scary. I have tremendous misgivings about letting my system, not one we have today, but one that we might not have and too many more years start editing its own code while we ' re not paying attention. I think that ' s **the** kind of thing that is worth a great deal of societal discussion about, you know, just because we can do that. Should we? Yes, because one of **the** things that ' s that ' s been most shocking to you about **the** last few years has been just **the** power of unintended consequences. It ' s like you don ' t have to have a belief that there ' s some sort of waking up of of an alien intelligence that suddenly decided it wants to wreak havoc on humans. That may never happen. What you can have is just incredible power that goes amok. So a lot of people would argue that what ' s happened in technology in **the** last few years is actually an example of that. You know, social media companies created these intelligences that were programmed to maximally harvest attention, for example, for sure. And they understand this from that turned out to be in some ways horrifying and extraordinarily damaging. Is that a meaningful sort of canary in **the coal** mine saying, look out, humanity, this could be really dangerous? And how how on earth do you protect against those kinds of unintended consequences? I think you raise a great point in general, which is these systems don ' t have to wish ill to humanity to cause ill just when you have, like, very powerful systems. I mean, unintended consequences for sure. But another version of that is and I think this applies at **the** technical level, at **the** company level, at **the** societal level, incentives are superpower ' s. Charlie Munger had this thing on, which is incentives are so powerful that if you can spend any time whatsoever working on **the** incentive system, that ' s what you should do before you work on anything else. And I really believe that. And I think that applies to **the** individual models we build and what their reward functions look like. I think it applies to society in a big way, and I think it applies to our corporate structure at open. I you know, we sort of observe that if you have very well-meaning people, but they have this incentive to sort of maximize attention harvesting and profit forever through no one ' s ill intentions, that leads to a quite undesirable outcome. And so we set up opening is this thing called a capped profit model specifically so that we don ' t have **the** system incentive to just generate maximum value forever with an AGI that seems like obviously quite broken. But even though we knew that was bad and even though we all like to think of ourselves as good people, it took us a long time to figure out **the** right structure, to figure out a charter that ' s going to govern us and a set of incentives that we believe will let us do our work. And kind of these we have these like three elements that we talk about a lot research sort of engineering, development and deployment policy and safety. Put those all together under a system where you don ' t have to rely on. Anything but **the** natural incentives to push in a direction that we hope will minimize **the** sort of negative unintended consequences. So help me understand this, because this is I think this is confusing to some people. So you started opening. I initially I think Elon Musk, **the** co-founder, and there was a group of you and **the** argument was this technology is too powerful to be left, developed in secret and to be left developed purely by corporations who have whatever incentive they may have. We need a nonprofit that will develop and share knowledge openly. First of all, just even at that early stage, some people were confused about this. It was saying if this thing is so dangerous, why on earth would you want to make it secrets even more available? Well, maybe giving **the** tools to that sort of AI **terrorist** in his bedroom somewhere, I think I think we got misunderstood in **the** way we were talking about that. We certainly don ' t think that **the** right thing to do is to, like, build this a super weapon and hand it to a **terrorist**. That ' s obviously awful. One of **the** reasons that we like our API model is it lets us make **the** most powerful AI technology anyone in **the** world has, as far as we know, available to ever would like to use it, but to put some controls on its usage. And also, if we make a mistake, to be able to pull it back or change it or tweak it or improve it or whatever. But we do want to put and this is continued will continue to be true with appropriate restrictions and guardrails, very powerful technology in **the** hands of people. I think that is fair. I think that will lead to **the** best results for **the** society as a whole. And I think it will sort of maximize benefit. But that ' s very different than sort of shipping **the** whole model and saying, here, do whatever you want with it. We ' re able to enforce rules on it. We also think and this is part of **the** mission that like something **the** field was doing a lot of that we didn ' t feel good about was sort of saying like, oh, we ' re going to keep **the** pace of progress and capabilities secret. That doesn ' t feel right, because I think we do need a societal conversation about what ' s what ' s going on here, what **the** impacts are going to be. And so we although we don ' t always say, like, you know, here ' s **the** super weapon, hopefully we do try to say, like, this is really serious. This is a big deal. This is going to affect all of us. We need to have a big conversation about what to do with it. Help me understand **the** structure a bit better, because you definitely surprised much people when you announced that Microsoft were putting a billion dollars into **the** organization and in return, I guess they get certain exclusive licensing rights. And so, for example, they are **the** exclusive licensee of CP3. So talk about that structure of how you win. Microsoft presumably have invested not purely for altruistic purposes. They think that they will make money on that billion dollars. I sure hope they do. I love capitalism, but I think that I really loved even more about Microsoft as a partner. And I ' ll talk about **the** structure and **the** exclusive license in a minute is that we like went around to people that might find us. And we said one of **the** things here is that we ' re going to try to make you some money. But like Adjei going well is more important. And we need you to sign this document that says if things don ' t go **the** way we think and we can ' t make you money like you just cheerfully walk away from it and we do **the** right thing for humanity. And they were like, yes, we are enthusiastic about that. We get that **the** mission comes first here. So again, I hope a phenomenal investment for them. But they were like they really pleasantly surprised us on **the** upside of how aligned they were with us, about how strange **the** world may get here and **the** need for us to have flexibility and put our mission first, even if that means they lose all their money, which I hope they don ' t and don ' t think they will. So **the** way it ' s set up is that if at some point in **the** coming year or two, two years, Microsoft decide that there ' s some incredible commercial opportunity that they could realize out of **the** eye that you ' ve built and you feel actually, no, that ' s that ' s damaging. You can block it. You can veto it. Correct. So **the** four most powerful version of three and its successors are available via **the** API, and we intend for that to continue. What Microsoft has is **the** ability to sort of put that model directly into their own technology. If they want to do that. We don ' t plan to do that with other people because we can ' t have all these controls that we talked about earlier. But they ' re like a close trusted partner and they really care about safety, too. But our goal is that anybody who wants to use **the** API can have **the** most powerful versions of what we ' ve trained. And **the** structure of **the** API lets us continue to increase **the** safety and fix problems when we find them. But but **the** structure. So we start out as a non-profit, as you said, we realized pretty quickly that although we went into this thinking that **the** way to get to ajai would be about smarter and smarter algorithms, that we just needed bigger and bigger **computers** as well. And that was going to require a scale of capital that no one will, at least certainly not me, could figure out how to raise is a nonprofit. We also needed to sort of be able to compensate very highly compensated, talented individuals that do this, but are full for profit company had runaway incentives problem, among other things. Also just one about sort of fairness in society and wealth concentration that didn ' t feel right to us either. And so we came up with this kind of hybrid where we have a nonprofit that governs what we do, and it has a subsidiary, LLC, that we structure in a way to make a fixed amount of profit so that all of our investors and employees, hopefully if things go how we like, if not no one gets any money, but hopefully they get to make this one time great return on their investment or **the** time that they spent it open their equity here. And then beyond that, all **the** value flows back to **the** nonprofit and we figure out how to share it as fairly as we can with **the** world. And I think that this structure and this nonprofit with this very strong charter in place and everybody who joins signing up for **the** mission come in first and **the** fact **the** world may get strange, I think that. That was at least **the** best idea we could come up with, and I think it feels so far like **the** incentive system is working, just as I sort of watch **the** way that we and our partners make decisions. But if I read it right, **the** cap on **the** gain that investors can make is 100 Axum. It ' s a massive call that was for our very first round investors. It ' s way, way lower. Like as we now take a bit of capital, it ' s way, way lower. So your deal with Microsoft isn ' t you can only make **the** first hundred billion dollars. I don ' t know. It ' s way lower than after that. We ' re giving it to **the** world. It ' s way lower than that. Have you disclosed what I don ' t know if we have, so I won ' t accidentally do it now. All right. OK, so explain a bit more about **the** charter and how it is that you. Hope to avoid or I guess help contribute to an eye that is safe for humanity. What do you see as **the** keys to us avoiding **the** worst mistakes and really holding on to something that ' s that ' s beneficial for humanity? My answer there is actually more about, like technical and societal issues than **the** charter. So if it ' s OK for me to answer it from that perspective, sure. OK, I ' m happy to talk about **the** charter to. I think this question of alignment that we talked about a little earlier is paramount, and then I think to understand that it ' s useful to differentiate between accidental misuse of a system and intentional misuse of a system. So like intentional would be a bad actor saying, I ' ve got this powerful system, I ' m going to use it to like hack into all **the computers** in **the** world and wreak havoc on **the** power grids. And accidental would be kind of **the** Nick Bostrom make a lot of paper **clips** and view humans as collateral damage in both cases. But to varying degrees, if we can really, truly, technically solve **the** alignment problem and **the** societal problem of deciding to which set of human values do we align, then **the** systems understand right and wrong, and they understand probably better than we ever can, unintended consequences from complex actions and very complex systems. And, you know, if we can train a system which is like. Don ' t harm humanity and **the** system can really understand what we mean when we say that, again, who is we and what does that have some asterisks on them? Sorry, go ahead. Well, that ' s if they could understand what it means to not harm humanity, that there ' s a lot wrapped up in that sentence. Because what ' s been so striking to me about efforts so far is that they seem to have been based on a very naive view of human nature. Go back to **the** sort of Facebook and Twitter examples of, well, **the** engineers building some of **the** systems would say we ' ve just designed them around what humans want to do. You said, well, if someone wants to click on something, we will give them more of that thing. And what could possibly be wrong with that? We ' re just supporting human choice, ignoring **the** fact that humans are complicated, farshid animals for sure, who are constantly making choices, that a more effective version of themselves would agree is not in their long term interests. So that ' s one part of it. And then you ' ve got layered on top of that or **the** complications of systemic complexity where, you know, multiple choices by thousands of people end up creating a reality that possibly have designed for how how to cut through that. Like an AI has to make a decision based on a moment, on a specific data set. As those decisions get more powerful, how can we be confident that they don ' t lead to this sort of system crashing basically in some way? I think that I ' ve heard a lot of behavioral psychologists and other people that have studied this say in different ways, are that I hate to keep picking on Facebook, but we can do it one more time since we ' re on **the** topic. Maybe you can ' t in any given moment in night where you ' re tired and you have a stressful day, stop yourself from **the** dopamine hit of scrolling and Instagram, even though you know that ' s bad for you and it ' s not leading to your best life. But if you were asked in a reflective moment where you were sort of fully alert and thoughtful, do you want to spend as much time as you do scrolling through Instagram? Does it make you happier or not? You would actually be able to give like **the** right long term answer? It ' s sort of **the** spirit is willing, but **the** flesh is weak kind of moment. And one thing that I am hopeful is that humans do know what we want and what. On **the** whole, and presented with research or sort of an objective view about what makes us happy and doesn ' t we ' re pretty, what ' s so great about it, they ' re pretty good. But in any particular moment, we are subjected to our animal instincts and it is easy for **the** lower brain to take over **the** eye. Well, I think be an even higher brain. And as we can teach it, you know, here is what we really do value. Here ' s what we really do want. It will help us make better decisions than we are capable of, even in our best moments. So is that being proposed and talked about as an actual rule? Because it strikes me that there is something potentially super profound here to introduce some kind of rule for development of AIDS that they have to tap into not. What humans one, which is an ill defined question, but as to what humans in reflective mode want. Yeah, we talk about this a lot. I mean, do you see a real chance where something like that could be incorporated as a sort of an absolute golden rule and and if you like, spread around **the** community so that it seeps into corporations and elsewhere? Because that I ' ve seen no evidence that, well, a little corporation that was potentially a game changer. Corporations have this weird incentive problem. Right. What I was trying to speak about was something that I think should be technologically possible, and that ' s something that we as a society should demand. And I think it is technically possible for this to be sort of like a layer above **the** neocortex that makes even better decisions for us and our welfare and our long term happiness and fulfillment than we could make on our own. And I think it is possible for us as a society to demand that. And if we can do like a pincer move between what **the** technology is capable of and what we what we as society demand, maybe we can make everybody in **the** middle that way. I mean, there are instances of even though companies have their incentives to make money and so forth, they also in **the** knowledge age. Can ' t make money if they have pissed off too many of their employees and customers and investors by analogy of **the** climate space right now, you can see more and more companies, even those that are emitting huge amounts of **carbon** dioxide, saying, wait a sec, we ' re struggling to recruit talented people because they don ' t want to work for someone who ' s evil. And their customers are saying, we don ' t want to buy something that is evil. And so, you know, ultimately you can picture processes where they do better. And I I believe that most engineers, for example, work in Silicon Valley. Companies are actually good people who want to design great products for humanity. I think that **the** people who run these companies want to be a net contribution to humanity. It ' s we ' ve we ' ve rushed really quickly and design stuff without thinking it through properly. And it ' s led to a mess up. So it ' s like, OK, don ' t move fast, break things, slow down and build beautiful things that are built on a real version of human nature and on a real version of system complexity and **the** risks associated with systemic complexity. Is that **the** agenda that fundamentally you think that you can push somehow? Yes, but I think **the** way we can push it is by getting **the** incentive system right. I think most people are fundamentally extremely good. Very few people wake up in **the** morning thinking about how can I make **the** world a worse place? But **the** incentive systems that we ' re in are so powerful. And even those engineers who join with **the** absolute best of intentions get sucked into this world where they ' re like trying to go up from it all for and five or whatever Facebook calls those things and you like, it ' s pretty exciting. You get caught up playing **the** game, you ' re rewarded for kind of doing things that move **the** company ' s key metrics. It ' s like fun to get promoted. It feels good to make more money and **the** incentive systems of **the** company. And that ' s what it rewards. An individual performance are maybe like not what we all want. And here I don ' t want to pick on Facebook at all because I think there ' s versions of this at play it like every big tech company, including in some ways I ' m sure it open I but to **the** degree that we can better align **the** incentives of companies with **the** welfare of society and then **the** incentives of an individual at those companies within **the** now realign incentives for those companies, **the** more likely we are to be able to have things like ajai that. Follow an incentive system of. What we want in our most reflective best moments and are even better than what we could think of ourselves is is it still **the** vision for open eye that you will get to? **Artificial** general intelligence ahead of. **The** corporations, so that you can somehow put a stake in **the** ground and build it **the** right way. Is that really a realistic thing to to dream for? And if not, how do you live up to **the** mission and help ensure that this thing doesn ' t go off **the** rails? I think it is. Look, I certainly don ' t think we will be **the** only group to build an AGI, but I think we could be **the** first. And I think if you are **the** first, you have a lot of norms that empower. And I think you ' ve already seen that. You know, we have released some of **the** most powerful systems to date. And I think **the** way that we have done that kind of in controlled release where we ' ve released a bigger model than a bigger one than a bigger one, and we sort of try and talk about **the** potential misuse cases and we try to like talk about **the** importance of releasing this behind an API so that you can make changes. Other groups have followed suit in some of those directions, and I think that ' s good. So, yes, I don ' t think we can be **the** only I do think we can be ahead. And if we are ahead, I think we can use that leverage to hopefully push people in a better direction or maybe we ' re wrong and somebody else has a better direction. We ' re doing something about do you have a structural advantage in that your mission is to do this for everyone as opposed to for some corporate objective. And that that that allows you that. Why is it that we came out of open eye and not someone else? It ’ s like it ’ s surprising in some ways when you ’ re up against so much money and so much talent in these other companies that you came up with this platform ahead of. You know, in some sense it ’ s surprising and in some sense, like **the** startup wins most of **the** time, like I ’ m a huge believer in startups as **the** best force for innovation we have in **the** world today. I talked a little bit about how we combine these three. Different clans of research, engineering and sort of safety and policy that don ’ t normally combine well and I think we have an unusual strength, there were clearly like well funded. We have super talented people. But what we really have is like intense focus and self belief that what we ’ re doing is possible and good. And I appreciate **the** implied compliment. But, you know, we, like, work really hard. And if we stop doing that, I ’ m sure someone would run by us fast. Tell us a bit more about some of your prior life sentences. Yeah, for several years, you were running Y Combinator, which had incredible impact on some 70 companies. There are so many startup stories that began at Y Combinator. What were key drivers in your own life that took you on **the** path you ’ re on? And how did that path end up at Y Combinator? No exaggeration. I think I have back to back had **the** two jobs that are at least **the** most interesting to me in all of Silicon Valley. I, I was I went to college to study **computer** science. I was a major **computer** nerd growing up. I knew like a little bit about startups, but not very much. I started working on this project **the** same year I started working on that. This thing called Y Combinator started and funded me and my co-founders. And we dropped out of school and did this company, which I ran for like seven years. And then after that I got acquired. I had stayed close to my comment **the** whole time. I thought it was just this incredible group of people and spirit and set of incentives and just badly misunderstood by most of **the** world, but obvious to everyone within it that it was going to create huge amounts of value and do a lot of new things. My company had acquired PJI, who is **the** founder of ICI, and like truly one of **the** most incredible humans and business people. And Paul Burrell, Paul Graham asked me if I wanted to run it. And kind of like **the** central **learning** of my career, why I individual startups has been that if you really scale them up, remarkable things can happen. And I. I did it and I was like, one of **the** things that would make this exciting for me personally motivating would be if I could sort of push it in **the** direction of doing these hard tech companies, one of which became open. I describe actually what Y Combinator is, you know, how many people come through it to give us a couple of stories of its impact. Yeah. So you basically apply as a handful of people and an idea, maybe a prototype and say, I would like to start a company and will you please fund me? And we review those applications and we I shouldn ’ t say we anymore. I guess they fund four hundred companies a year. You get about one hundred and fifty thousand dollars while she takes about seven percent ownership and then gives you lots of advice and then networking and sort of this like fast track program for starting a startup. I haven ’ t looked at this in a while, but at one point a significant **fraction** of **the** billion dollar plus companies in **the** US that got started. It all came through **the** Wiki program, some recently in **the** news ones have been like Airbnb, Jordache, Coinbase, insta card stripe. And I think it ’ s just it has become an incredible way to help. People who understand technology get a three month course in business, but instead of like herding you with an MBA, we actually teach you **the** things that matter and kind of go on to do incredible, incredible work. What is it about entrepreneurs? Why do they matter? Some people just find them kind of annoying. But I think you would argue I think I would argue that they have done as much as anyone to shape

the future. Why? What is it about them? I think it is **the** ability to take. And idea and by force of will to make it happen in **the** world and in an incentive system that rewards you for making **the** most impact on **the** most people like in our system. That ' s how we get most of **the** things that that we use. That ' s how we got **the computer** that I ' m using, **the** software I ' m using to talk to you on it. Like all of this, you know, everyone in life, everything has a balance sheet. There ' s plenty of very annoying things about them. And there ' s plenty of very annoying things about **the** system that sort of idolizes them. But we do get something really important in return. And I think that as a force for making things that make all of our lives better happen, it ' s very cool. Otherwise, you know, like if you have, like, a great idea, but you don ' t actually do anything useful with it for people, that ' s still cool. It ' s still intellectually interesting. But like, there ' s got to be something about **the** reward function in society that is like, did you actually do something useful? Did you create value? And I think entrepreneurship and startups are a wonderful way to do that. You know, we get all these great software companies. But I also think it ' s like how we ' re going to get ajai, how we ' re going to get nuclear **fusion**, how we ' re going to get life extension. And like on any of those topics are a long list of other things I could point to. There ' s like a number of startups that I think are doing incredible work, some of which will actually deliver. It is a truly amazing thing when you put **the** camera back and to believe that a human being could be lying awake at night and something pops inside their mind as a patterning of **the** neurons in their brain that is effectively them saying, aha, I can see a way where **the** future could be better and and they can actually picture it. And then they wake up and then they talk to other people and they persuade them and they persuade investors and so forth. And **the** fact that this this system can happen and that they can then actually change **the** history changes in some sense. It is mind boggling that that happens that way and it happens again and again. So you ' ve seen so many of these stories happen. What would you say? Is **the** is there a key thing that differentiates good entrepreneurs from others? If you could double down on one trait, what would it be? If I could pick only one, I would pick determination. I think that is **the** biggest predictor of success, **the** biggest differentiator predictor. And if you would allow a second, I would pick like communication skills or evangelism or something in that direction as well. There are all of **the** obvious ones that matter, like intelligence, but there ' s like a lot of smart people in **the** world. And when I look back at kind of **the** thousands of entrepreneurs I ' ve worked with, all of many of whom were like quite capable, I would say that ' s like one and two of **the** surprisingly differentiated characteristics. What it ' s it ' s what I look at, **the** different things that you ' ve built and you ' re working on. I mean, it could not be more foundational for **the** future. I mean, entrepreneurship. I know this is I agree that this is really what has driven **the** future. Do you see some people get really now they look at Silicon Valley and they look at this story and they worry about **the** culture. Right. That it ' s this is a bro culture. Do you see prospects of that changing anytime soon? And would you welcome it? Can we get better companies by really working to expand a group of people who can be entrepreneurs and who can contribute to aid, for example? For sure. And in fact, I think I ' m hopeful, since these are **the** two things I ' ve thought **the** most about. I ' m excited for **the** day when someone combines them and uses A. I. to better select who did more fairly, maybe even select who to fund and how to advise them and really kind of make entrepreneurship super widely available that will lead to like better outcomes and sort of more societal wealth for all of us. So are. So, yeah, I think. Broadening **the** set of people able to start companies and that sort of get **the** resources that you need, that is like an unequivocally good thing and it ’ s something that I think Silicon Valley is making some progress in. But I hope we see a lot more. And I do really, truly think that **the** technology industry entrepreneurship is one of **the** greatest forces for self betterment. If we can just figure out how to be a little bit more inclusive in how we do things. My last question today is about ideas were spreading. If you could inject one idea into **the** mind of everyone listening, what what would **the** idea be? We ’ ve touched on it a bunch, but **the** one idea would be **the** ajai really is going to happen. You have to engage with it seriously, and you shouldn ’ t just listen to this and then brush aside and go about life as if it ’ s not going to happen because it is going to affect everything. And we will all we all, I think, have an obligation, but also an opportunity to figure out what not means and how we want **the** world and this sort of one time shift to go on. I ’ m kind of awed by **the** breadth of things are engaged with. Thank you so much for spending so much time sharing your vision. Thanks so much for having me. OK, that ’ s it for today. You can read more about open eyes, vision and progress at open eye dotcom. If you want to try playing with yourself, it ’ s a little tricky. You have to find a website that has licensed **the** API. **The** one I went to was philosopher ehi dot com, where you just you pay a few dollars to get access to a very strange mind. That ’ s actually quite a lot of fun. **The** interview is part of **the** TED Audio Collective, a **collection** of podcasts dedicated to sparking curiosity and sharing ideas that matter. This show is produced by Kim Net2Phone Pittas and edited by Grace Rubenstein and Sheila Boffano, Sambor Islamic Sir. Fact Check is by Paul Durbin and special thanks to Michele Quent, Colin Helmes and Anna Felin. If you like **the** show, please write and review it. It helps other people find us. We read every review, so thanks so much for listening. See you next time.

Text Sample 61: POS Dim 1 – 2021 – Score 23.00 – 2021/t004046.txt

Bruno Giussani : Hello. Bill Gates calls himself an imperfect messenger on climate because of his high **carbon** footprint and lifestyle. However, he has just made a major contribution to our thinking about confronting climate change via a book, a book about decarbonising our economy and society. It ’ s an optimistic”can-do”kind of book with a strong focus on technological solutions. He discusses **the** things we have, such as wind and solar power, **the** things we need to develop, such as carbon-free cement or carbon-free steel, and long-term energy storage. And he talks about **the** economics of it all, introducing **the** concept of green premium. **The** gist of **the** book, and really I ’ m simplifying here a lot, is that fighting climate change is going to be hard, but it ’ s possible, we can do it. There is a pathway to a clean and prosperous future for all. So we want to unpack some of that with **the** author of **the** book. Bill Gates, welcome back to TED. Bill Gates : Thank you. Giussani : Bill, I would like to start where you start, from **the** title of **the** book.”How to Avoid a Climate Disaster,”which, of course, presumes that we are heading towards a climate disaster if we don ’ t act differently. So what is **the** single most important thing we must do to avoid a climate disaster? Gates : Well, **the greenhouse** gases we put into **the** atmosphere, particularly CO2, stay there for thousands of years. And so it ’ s really **the sum** of all those **emissions** are forcing **the** temperature higher and higher, which will have disastrous effects. And so we have to take these **emissions**, which are presently over 51 billion tons per year and drive those all **the** way down to zero. And that ’ s when **the** temperature will stop increasing and **the** disastrous weather events won ’ t get worse and worse. So it ’ s pretty demanding. It ’ s not a 50 percent reduction. It ’ s all **the** way down to zero. Giussani : Now, 51 billion is a big number. It ’ s difficult to register, to understand. Help us visualize **the** scale of **the** problem. Gates : Well, **the** key is to understand all **the** different sources. And people are mostly aware of **the** production of electricity with natural gas and **coal** as being a big source. That ' s about 27 percent. And they ' re somewhat aware of **transportation**, including passenger cars. Passenger cars are seven percent and **transportation** overall is 16 percent. They have far less awareness of **the** other three segments. Agriculture, which is 19 percent, heating and cooling buildings, including using natural gas, are seven percent. And then, sadly, **the** biggest segment of all, manufacturing, including steel and cement. People are least aware of that one. And in fact, that one is **the** most difficult for us to solve. **The** size of all **the** steel plants, cement plants, paper, plastic, **the** industrial economy is gigantic. And we ' re asking that to be changed over in this 30-year period when we don ' t even know how to make that change right now. Giussani : So your core argument, and really, here I ' m simplifying, is that basically we need to clean up all of that, right? **The** way we make things, we grow things, we get around and power our economy. And so to do that, we need to get to a point where green energy is as cheap as **fossil** fuels, and new materials, clean materials, are as cheap as current materials. And you call that"eliminating **the** green premium."So to start, tell us what you mean by green premium. Gates : Yeah, so **the** green premium varies from **emission** sources. It ' s **the** cost to buy that product where there ' s been no **emissions** versus **the** cost we have today. And so for an electric car, **the** green premium is reasonably modest. You pay a little more upfront, you save a bit on **the** maintenance and gasoline, you give up some range, you have a longer charging time. But over **the** next 15 years, because **the** volume is there and **the** R and D is being done, we can expect that **the** electric car will be preferable. It won ' t cost more. It will have a much higher range. And so that green premium that today is about 15 percent is headed to be zero even without any government subsidies. And so that ' s magic. That ' s exactly what we need to do for every other category. Now, an area like cement, where we haven ' t really gotten started yet, **the** green premium today is almost double **the** price. That is, you pay 125 dollars for a ton of cement today but it would be almost double that if you insisted that it be green cement. And so **the** way I think of this is in 2050 we ' ll be talking to India and saying to them,"Please use **the** green products as you ' re building basic shelter, you know, simple air conditioning,"which they ' ll need because of **the** heat increase or lighting at night for students. And unless we ' re willing to subsidize it or **the** price is very low, they ' ll say,"No, this is a problem that **the** rich countries created, that India is suffering from and you need to take care of it."So only by bringing that green premium down very dramatically, about 95 percent across all categories, will that conversation go well so that India can make that shift. And so **the** key thing here is that **the** US ' s responsibility is not just to zero out its **emissions**. That ' s a very hard thing, but we ' re only 15 percent. Unless we, through our power of innovation, make it so cheap for all countries to switch all categories, then we simply aren ' t going to get there. And so **the** US really has to step up and use all of this innovative capacity every year for **the** next 30 years. Giussani : What what needs to happen in order for these breakthroughs to actually **occur**? Who are **the** players who need to come together? Gates : Well, innovation usually happens at a pace of its own. Here we have this deadline, 2050. And so we have to do everything we can to accelerate it. We need to raise **the** R and D budgets in these areas. In 2015 I organized, along with President Hollande and Obama, a side event to **the** Paris climate talks where what Prime Minister Modi had labeled"mission innovation"was a commitment to double R and D budgets over a five-year period. And all **the** big countries came in and made that pledge. Then we need lots of smart people, who, instead of working on other problems, are encouraged to work on these problems. So coming up with funding for them is very, very important. I ' m doing some of that through what I call Breakthrough Energy Fellows. We need high-risk capital to invest in these companies, even though **the** risks are very, very high. And that ' s – There is now – Breakthrough Energy Ventures is one group doing that and drawing lots of other people in. But then **the** most difficult thing is we actually need markets for these products even when they start out being more expensive. And that ' s what I call Catalyst, organizing **the** buying power of consumers and companies and governments so that we get on **the** learning curve, get **the** scale going up, like we did with solar and wind across all these categories. So it ' s both supply of innovation and demand for **the** green products. That ' s **the** combination that can start us to make this change to **the** infrastructure of **the** entire physical economy. Giussani : In terms of funding all this, **the** financial system as a whole right now is essentially funding expansion of **fossil** fuels consistent with three degrees Celsius increase in global heating. What do you say to **the** Finance Committee, beyond **the** venture capital, about **the** need to think and act differently? Gates : Well, if you look at **the** interest rates for a solar field versus any other type of investments, it ' s not lower. You know, money is very fungible. It ' s going to, you know, different projects. But, there ' s no, sort of, special rate for climate-related projects. Now, you know, governments can decide through tax incentives to improve those things. But you know, this is not just about reporting numbers. It ' s good to report numbers. But **the** steel industry is providing a vital service. Even gasoline, for 98 percent of **the** cars being purchased today, allows people to get to their job. And so, you know, just divestment alone is not going to be **the** thing that creates **the** new alternative and brings **the** cost of that down. So **the** finance side will be important because **the** speed of deployment – Solar and wind needs to be accelerated dramatically beyond anything we ' ve done today. In fact, you know, on average, we ' ll have to deploy three times as much every year as **the** peak year so far. And so those are a key part of **the** solution. They ' re not **the** whole solution. But you know, people sometimes think just by putting numbers, disclosing numbers, that somehow it all changes or by divesting that it all changes. **The** financial sector is important, but without **the** innovation, there ' s nothing they can do. Giussani : A lot of **the** current focus is on cutting **emissions** by half by 2030 and on **the** way to reaching that zero by 2050. And in **the** book, you write that there is danger in that kind of thinking, that we should keep our main focus on 2050. Can you explain that? Gates : Well, **the** only real measure of how well we ' re doing is **the** green premium, because that ' s what determines whether India and other developing countries will choose to use **the** zero **emission** approach in 2050. **The** idea, you know – If you ' re focusing on short-term reductions, then you could say, oh, it ' s **fantastic**, we just put billions of dollars into natural-gas plants. And even ignoring that there ' s a lot of leakage that doesn ' t get properly measured, you know, give them full credit and say that ' s a 50 percent reduction. **The** lifetime of that plant is greater than 30 years. You financed it, assuming you ' re getting value out of it over a longer period of time. So to say,"Hey, hallelujah, we switched from **coal** to natural gas,"that has nothing to do with reaching zero. It sets you back because of **the** capital spending involved there. And so it ' s not a path to zero if you ' re just working on **the** easy parts of **the emission**. That ' s not a path. **The** path is to take every source of **emission** and say,"Oh, my goodness, how am I going to get that green premium down? How am I going to get that green premium down?"Otherwise, getting to 50 percent does not stop **the** problems. This is very tough because **the** nature is zero. It ' s not just, you know, a small decrease. Giussani : So getting **the** green premium down, so you mentioned India. To make sure that **the** transition, **the** clean transition, is also an Indian story and an African story and not only a Western story, should rich countries adopt **the** expensive clean alternatives now, to kind of buy down **the** green premium and make technology, therefore, more accessible to low-income countries? Gates : Absolutely. You have to pick which product paths with scale will become low green-premium products. And so you don ’ t want to just randomly pick things that are low-emission. You have to pick things that will come down. So like, you know, so far, hydrogen fuel cells have not done that. Now they might in **the** future. Solar, wind and lithium-ion, we ’ ve seen these incredible cost reductions. And so we have to duplicate that for other areas, things like offshore wind, heat pump, new ways of doing transmission. You know, we have to keep **the** electricity grid reliable, even in very bad weather conditions. And so that ’ s where storage or nuclear and transmission will have to be scaled up in a very significant way, which we now have this **open-source** model to look at that. And so **the** buying of green products that demand signal, what I call Catalyst, we ’ re going to have to orchestrate a lot of money, many tens of billions of dollars for that, that is one of **the** most expensive pieces so that **the** improvements come in these other areas and some of them we haven ’ t even gotten started on. Giussani : Many people believe actually that **the** climate question is mostly a question of consuming less and particularly consuming less energy. And in **the** book, you actually write several times that we need to consume more energy. Why? Gates : Well, **the** basic living conditions that we take for granted should be made available to all humans. And **the** human population is growing. And so you ’ re going – as you provide shelter, heating and air conditioning, which anywhere near **the** equator will be more in demand since you ’ ll have many days where you can ’ t go outdoors at all. So we ’ re not going to stop making shelter. We ’ re not going to stop making food. And so we need to be able to multiply those processes by zero. That is, you make shelter, but there ’ s no **emissions**. You make food, but there ’ s no **emissions**. That ’ s how you get all **the** way down to zero. Now, it ’ s made somewhat easier if rich countries are consuming less, but how far will that go? Giussani : So if I summarize in my head your book, you are basically suggesting that if we eliminate **the** green premium, **the** transition somehow can **occur**, **the** cost and technology, green premium and breakthroughs are **the** key drivers. But, you know, you think of climate and climate is kind of a wicked problem. It has implications that are social, political, behavioral. It requires significant citizen involvement. Are you focusing too much on tech and not enough on those other variables? Gates : Well, we need all these things. If you don ’ t have a deep engagement, particularly by **the** younger generation making this a top priority every year for **the** next 30 years across all **the** developed countries, we will not succeed. And I ’ m not **the** one who knows how to activate all those people. I ’ m super glad that **the** people who are smart about that are thinking. It ’ s a necessary element. Likewise, **the** piece that I do have experience in, innovation ecosystems, that ’ s a necessary element. You will not get there just by saying,”Please stop using steel.”You know, it won ’ t happen. And so **the** innovation piece has to come along and particularly encouraging consumers to buy electric cars or **artificial** meat or electric heat pumps, they ’ re part of driving that demand, what I call **the** catalytic demand. That alone won ’ t do it, because some of these big projects, like green hydrogen or green aviation fuel require billions in capital expense. But **the** demand signal from enlightened consumers is very important. Their political voice is very important. Their pushing **the** companies they work at is very important. And so I absolutely agree that **the** broad community who cares about this, particularly if they understand how hard it is and don ’ t say,”Oh, we can do it in 10 years,”they are super important. Giussani : You mentioned **artificial** meat and I know you love burgers. Have you tried an **artificial** burger, and how did you find it? Gates : Yes, I ’ m an investor in all these Impossible, Beyond and various people. And I have to say, **the** progress in that sector is greater than I expected. Five years ago, I would have said that is as hard as manufacturing. Now it ’ s very hard, but not as hard as manufacturing. There is no Impossible Foods of green steel and **the** quality is going to keep improving. It ’ s quite good today. You know, there ’ s other companies coming in to that space covering different types of food. And as **the** volume goes up, **the** price will go down. And so I think it ’ s quite promising. I have to admit, 100 percent of my burgers aren ’ t **artificial** yet, it ’ s about 50 percent, but I ’ ll get there. Giussani : It ’ s a start. You ’ re already on 2030 on that on that front. So you mentioned your expertise in innovation. You have a couple of lines of – how to say it? – of exquisite modesty in **the** book where you say you think like an engineer, you don ’ t know much about politics, but actually you talk to top politicians more than any of us. What do you ask them and what do you hear in return? Gates : Well, they ’ re mostly responding to voters interest. Most of **the** countries we ’ re talking about are democracies. And you know, there are resources that will need to be put in like tax credits that encourage buying green products or government purchasing of green products at slightly higher prices. Those are real trade-offs. And, you know, making sure that **the** areas where there ’ s lots of jobs in, say, **coal** mining, or things where **the** demand will go down, having that political sensitivity and thinking through, can we put **the** new jobs in that area and what are **the** departments that handle that. This is a tough political problem. And, you know, my admonition to people is not only to get educated themselves, but help educate other people. And often, like in **the** US, if it ’ s people of both parties, that ’ s even better. **The** level of interest is high, but it needs to get even higher, almost like a moral mission of all young people to go beyond their individual success, that they believe that getting to zero by 2050 is critical. Giussani : Thank you. Now, before we continue **the** interview, I would like to take a short detour for one minute because my colleagues at TED-Ed have produced a series of seven animated videos inspired by your book. They introduce **the** concept of net zero **emissions**, they discuss other questions and challenges that we are facing relating to climate. So I would like to share one short **clip** from one of those animations. You flip a switch, **coal** burns in a furnace which turns water into steam. That steam spins a **turbine** which activates a generator which pushes electrons through **the** wire. This current propagates through hundreds of miles of electric cables and arrives at your home. All around **the** world, countless people are doing this every second : flipping a switch, plugging in, pressing an”on”button. So how much electricity does humanity need? Giussani : **The** answer to that and to many other climate questions, of course, is in **the** seven animations available on **the** TED-Ed site, and **the** TED-Ed YouTube channel. Bill, you mentioned **the** younger generation before. How does **the** younger generation ’ s role in solving this problem inspire you? Gates : Well, they... can make sure this is a priority. And if we have, you know, it ’ s a priority for four years, then it ’ s not for four years, you can ’ t ask **the** trillions of investment in **the** new approach to take place. It ’ s got to be pretty clear that even though political parties may disagree on **the** tactics, **the** same way they agree there should be a strong defense that they agree this zero by 2050 is a shared goal, and then discuss, OK, where does government come in, where does **the** private sector come in, which area deserves priority? That will be a huge milestone where it ’ s a discussion about how to get there versus whether to get there. And **the** US is **the** most fraught in terms of it being politicized, even in terms of, is this a huge problem or not. So, you know, young people, they ' re going to be around to see **the** good news if we ' re able to achieve this. You know, I won ' t be around. But, they speak with moral authority and they have particular people who are stepping up on this. But I hope that ' s just **the** beginning. And that ' s why this year, I think, is so important. All this recovery money being programed, people thinking about, do governments protect us **the** way they should, do governments work together? You know, **the** pandemic has teed this up, it ' s OK, what ' s **the** next big problem we need to collaborate around? And I ' m hoping that climate appears there because of these activists. Giussani : Yeah, we ought to come back to **the** pandemic question. But I want to talk a moment about some specific technology breakthroughs that you mention in **the** book. But you also just mentioned **the** organization you set up, Breakthrough Energy, to invest in clean tech start-up and advocate for policies. And I assume somehow your book is kind of a blueprint for what Breakthrough Energy is going to do. There is a branch in that organization, called Catalyst, that ' s prioritizing several technologies, including green hydrogen direct carbon-capture, aviation biofuels. I don ' t want to ask you about specific investments, but I would like to ask you to describe why those priorities, maybe starting with green hydrogen. Gates : If we can get green hydrogen that ' s very cheap, and we don ' t know that we can, that becomes a magic ingredient to a lot of processes that lets you make fertilizer without using natural gas, it lets you reduce **iron** ore for steel production without using any form of **coal**. And so there ' s two ways to make it. You can take water and split it into hydrogen and oxygen. You can take natural gas and pull out **the** hydrogen. And so it ' s kind of a holy grail, you know, and so we need to get going. We need to get all **the** components to be very, very cheap. And only by actually doing projects, significant scale projects, do you get on to that learning curve. And so Catalyst will fund **the** early pilot projects along with governments to go make green hydrogen, get **the** electrolyzers to get up in volume and get a lot cheaper, because that would be a huge advance. Lot of manufacturing, not all of it, but a lot of it would be solved with that. Giussani : So just for those who don ' t know, green hydrogen is produced with clean energy sources, wind, solar and so, nitrogen produced from natural gas or **fossil** gas is called gray hydrogen. **The** second priority that you have set is direct **carbon** capture, pulling **carbon** from **the** atmosphere. And at least in theory, we can find a way to do that at large scale. Together with other technologies **the** problem could be solved, but it ' s a very early-stage, unproven technology. You describe it yourself in **the** book as a thought experiment at this stage. But you are one of **the** main investors in this sector in **the** world. So what ' s **the** real potential for direct **carbon** capture? Gates : So there ' s a company today, Climeworks, that for a bit over 600 dollars a ton will do capture. Now it ' s at fairly small scale. I ' m a customer of theirs as part of my program where I eliminate all of my **carbon emissions** in a gold standard way. There are other people who are trying to do larger-scale plants like Carbon Engineering. Breakthrough Energy is investing in a number of these carbon-capture entities. In a way, **the carbon** capture is for **the** part that you can ' t solve any other way. It ' s kind of **the** brute-force piece, and no one knows what that price will be. If it ' s 100 dollars a ton, then **the** cost against current **emissions** would be five trillion a year. Can we get below 100 dollars a ton? It ' s not clear that we can, but it would be **fantastic** to take **the** final 10, 15 percent of **emissions**, and instead of making **the** change at **the** place where **the emission** takes place, just do this, direct air capture. To be clear, direct air capture means you ' re just filtering **the** air, and you ' re pulling out **the** 410 million current parts per million and putting that into a pressurized form of CO2 that then you sequester in someplace that you know it ' ll stay for millions of years. And so this industry is just at **the** very, very beginning. But it ’ s a necessary piece for **the** tail of **emissions**. Giussani : And a third priority is aviation biofuels. Now flying over **the** last several years has become a symbol of a **polluting** lifestyle, let ’ s say. Why aviation biofuels as a priority? Gates : Well, **the** great thing about passenger cars is that even though batteries don ’ t store energy as well as gasoline does, there ’ s dramatic difference, you can afford to have **the** extra size and weight of those batteries. On a plane that is a large plane going a long distance, there ’ s no chance that batteries will ever have that energy density. I mean, there ’ s some crazy people who are working on it, and I ’ ll be glad to fund them, but you wouldn ’ t want to count on that. And so you either have to use hydrogen as a plane fuel, that has certain challenges, or you just want to make today ’ s aviation fuel with green processes, like using plants as **the** source of how you make those. And so I ’ m **the** biggest individual customer of a group that makes green aviation fuel. So that ’ s what I ’ m using now, costs over twice as much as **the** normal aviation fuel. But as **the** demand scales up, that ’ s one of those green premiums that we hope to bring down so that at some point lots of consumers will say,”Yes, I ’ ll pay a little extra on my plane **ticket**,”probably through Catalyst or through **the** airline to make sure that we ’ re building up that industry and trying to get **the** costs, that green premium down quite a bit. So this is a super important area that, you know, I was amazed when I went to buy that I was by far **the** biggest individual customer. Giussani : It ’ s also, of course, a very symbolic area, right? People think of cars and think of **airplanes** when they think of pollution and **emissions**. There is a fourth technology that I want to bring up because you are an advocate of and an investor in nuclear power, which is also not universally accepted as clean energy because of **the** risks, because of radioactive waste. Can you make **the** case, briefly, but can you make your case for nuclear? Gates : Well, one thing that needs to be appreciated is that energy has to come from somewhere. And so as you stop using natural gas to heat homes and gasoline to power cars, **the** electric grid will have to grow dramatically. And even in **the** case of **the** US, where electricity demand has been flat **the** last few decades, will need to be almost three times as large. As you do that with weather-dependent sources, **the** reliability of **the** electricity generation goes away, that as you get big cold fronts that for 10 days can stop most of **the** wind and solar, say, in **the** Midwest. So **the** question is, how do you use massive amounts of transmission and storage and non weather-dependent sources which at scale nuclear as **the** only choice there, to maintain that reliability and not have people, say, freeze to death. And nuclear – People will be pretty impressed with how valuable it is to create that reliability. Now, 80 percent, at least in **the** US, will be wind and solar. So we have to build that faster than ever. But what is that piece that ’ s always available is where nuclear would fit in. Giussani : Now, you talk a lot about scaling up technologies in **the** book. I want to ask you a question about scaling down, because one thing that ’ s absent from your book is a discussion about scaling down **fossil** fuel production, maybe starting with at least not expanding it anymore, with adopting a sort of **fossil** fuel nonproliferation approach, because right now we are talking about a green transition, but at **the** same time we are building out further **fossil** fuel infrastructure. What ’ s your view on that? Gates : Well, it ’ s all about **the** demand for **fossil** fuels and **the** fact that **the** green premium is very high. If you want to restrict supply, then you ’ ll just drive **the** price up. People still want to drive to their job. If you know, say you made **fossil** fuels illegal. You know, try that for a few weeks. My view is you have to create a substitute because **the** services provided by **the** **fossil** fuel are actually quite valuable. Electricity is valuable. Transportation is valuable. And are you willing to drop demand for those things to zero? So

the capitalistic economy will respond. If it ’ s clear, you know, how you ’ re going to do your tax policies and your credit, you ’ re going to drive innovation, then **the** infrastructure investments in those things will go down. We see that with **coal** already today. But... Just speaking against something when you haven ’ t created an alternative isn ’ t going to get you to zero. Giussani : OK, I want to shift topics. You mentioned before **the** pandemic, and your main focus since you set up **the** Gates Foundation has been on global health. I actually read **the** letter, **the** annual letter you wrote with your wife, Melinda, in January 2021, which was very much about **the** COVID-19 pandemic. And I found myself marveling at how what you write resonates with **the** climate challenge. What lessons from **the** pandemic can be actually applied to climate? Gates : Well I think **the** biggest lesson is that governments got to, on our behalf, avoid disastrous future outcomes. And individual citizens aren ’ t equipped to either do those evaluations or think through that R and D and deployment plan that ’ s necessary here. And so we have to make it an imperative that governments, hopefully of any party, join in to this. **The** pandemic, we did eventually get global cooperation. **The** US didn ’ t play its normal role there, but **the** private sector innovation created **the** vaccine. Now, sadly, with climate, **the** pain it ’ s causing gets worse over time. So with **the** pandemic, we had all these deaths, and people were like,”Wow, OK, we should do something.”With climate you can ’ t wait. You know, **the** coral reefs will have died off, **the** species will be gone. And so if you say,”OK, well, let ’ s, when it gets bad, we ’ ll invent something like a vaccine.”That doesn ’ t work, because to stop **the emissions**, you have to change every steel plant, cement plant, car, things that have massive lead times and literally trillions of dollars of investment. And so with **the** pandemic, we messed up. We didn ’ t pay attention. You know, people like myself said it was a problem. But, now we ’ re getting our way out of it through innovation. But climate ’ s harder, much harder problem. And so **the** political will to get it right needs to be unprecedented compared to **the** pandemic or almost any other political cause. Giussani : I want to correct you about private-sector innovation, because, of course, a lot of public money went into funding research and guaranteed purchases. And so for **the** vaccines. But that ’ s a separate interview. Gates : Well, **the** Pfizer vaccine used no government money. Giussani : That ’ s absolutely true. Bill, still related to our reaction to these big challenges, over half of **the** total **greenhouse** gas **emissions** since 2017, 50 or 51 have gone up in **the** atmosphere in **the** last 30 years. And we have known for more than 30 years that they have pernicious effects, to say **the** least. So if we could mobilize such enormous resources and policies and collaborations and global collaborations against COVID-19, what ’ s **the** lever we can use to mobilize **the** same against climate? Gates : Well, until 2015, nobody pushed for **the** R and D budgets to go up. So, you know, there are times when I think”Wow, are we serious, are we not?”You know, that R and D question just wasn ’ t discussed. And you could read every paper on green steel and there were hardly any. And so we are just starting to get serious about climate. And you know, we ’ ve wasted a lot of time that we should have used to work on **the** hard parts of climates, just having short-term goals and not focusing on **the** R and D piece, you know, **the** last 20 years, we don ’ t have much to show for **the** hard categories. Now, there ’ s still time to get there. We will have to fund adaptation a great deal because **the** 2050 goal is not because that ’ s a goal that gives you zero damage. It ’ s simply **the** goal that is **the** most ambitious that has a chance of being achieved. And we are causing problems for subsistence farmers and sea-level rise and wildfires and natural ecosystems. And so **the** adaptation side is even more underfunded than **the** mitigation side. For example, helping poor farmers with seeds that can deal with **the droughts** and high temperatures is funded at less than a billion a year, which is deeply tragic. Giussani : Bill, we ’ re getting towards **the** end. I mentioned at **the** beginning, in **the** book you describe yourself as an imperfect messenger on climate. What changes have you made in your personal and family life to reduce your footprint? Gates : Well, I ’ m certainly driving an electric car, you know, putting solar panels on **the** houses where that makes sense. Using this green aviation fuel, I still can ’ t say that I ’ ve stopped eating meat or that I never fly. And so it ’ s mostly by funding at over seven million a year **the** products that although their green premiums are very high today, like **the carbon** capture or like **the** aviation fuel, by funding those, you actually get those on to **the** learning curve to get those prices down very dramatically. One area that I do is I fund putting in electric heat-pumps into low-cost housing. And so instead of using natural gas, they get a lower bill because it ’ s done with electricity. And I paid that extra capital cost as an offset. So, you know, accelerating those demand things. I ’ ve tried to get out in front of that. Giussani : You also talk in **the** book about paying more than market value or **the** current market price for offsets, and you hinted to them before, talking about **the** golden standard. Tell us about what kind of – offsets can be kind of confusing and controversial. What are **the** right offsets? Gates : Well, first of all, it ’ s great that we ’ re finally talking about offsets, and any company that actually looks at their **emissions** and pays for offsets is way better than a company that either doesn ’ t look at their **emissions** or looks at them and doesn ’ t pay for offsets. And so **the** leading companies are now buying offsets, some of them spending hundreds of millions to buy offsets. That is a very, very good thing. **The** ability to see which offsets actually have long-term benefit that really keep **the carbon** out for **the** over thousands of years that count. There are now organizations that I and others are funding to label offsets as either gold standard or different levels of impact. And **the** price of offsets range from 15 dollars a ton to 600 dollars a ton. Some of **the** low-cost ones may be really legitimate, like reducing natural gas leakage. That is pretty dramatic in some cases in terms of **the** dollars per tons avoided there. A lot of **the** forestry things will probably not end up looking that good, as you really look at **the** lifetime of **the** tree or what would have happened otherwise. But, you know, at least we ’ re talking about offsets now. And now we ’ re going to do it in a thoughtful way. Giussani : So some of **the** people listening to this interview may already be very involved with climate, others may be looking for ways to step up. And at **the** end of your book, you have a chapter about individual action. Give us maybe, say, two examples, two practical examples of things that individual citizens in **the** US, but also elsewhere, can do to play a meaningful role in tackling climate change. Gates : I think everybody should start by learning more, you know. How much steel do we make and where are those steel plants? **The** industrial economy is kind of a miracle, although sadly, it ’ s a source of so many **emissions**. Once you really educate yourself, then you ’ re in a position to educate others, hopefully, of diverse political beliefs about why this is so important. And yet it ’ s also very, very hard to do. You have all your buying behavior, electric cars, **artificial** meat, you know, and you ’ ll see for all **the** different products various things that indicate how green that product is. And your demand doesn ’ t just save those **emissions**, it also encourages **the** improvement of **the** green product. Political voice, I ’ d still put it number one. Making sure your company is measuring its **emissions** and is starting to fund offsets and is willing to be a customer for breakthrough storage solutions or green aviation fuel. That is catalytic. And a lot of those funds hopefully will go through this vehicle that ’ s really identifying which projects globally are technologies that won ’ t stay expensive but can do like what solar and wind did and come down in price. So individuals are what drive this thing. **The** democracies are where most of **the** innovation power is and they have to get activated and set **the** example. Giussani : I would like to end on **the** outcome. Maybe we should have started with **the** outcome, but let ' s imagine a world where we will actually have done all of what you describe in **the** book and everything else that ' s necessary. What would that future everyday life look like? Gates : Well, I think everybody will be really proud that humanity came together on a global basis to make this radical change and there ' s no precedent for it. Even world wars, where we orchestrated lots of resources, it was, like, four or five year duration. And here we ' re talking about three decades of hard work dealing with an enemy that **the** super bad stuff is out in **the** future. And so you ' re benefiting young people and future generations. In some ways, you know, life will look a lot like it does today. You ' ll still have buildings, you ' ll have air conditioning, you ' ll have lights at night. But all of those you ' ll multiply by zero in terms of what **the emissions** that come out of those activities are. During **the** same time frame we ' ll have advances in medicine of curing cancer and finishing polio and **malaria** and all sorts of things. And so by taking away this one super negative thing, then all **the** progress we make in other areas won ' t get reduced by this awful thing that, if it goes unchecked, **the** migration out of **the** equatorial regions, **the** number of deaths, it ' ll make **the** pandemic look like nothing. I think so from a moral point of view and letting **the** other improvements not be offset by this. It ' ll be a source of great pride that, hey, we came together. Giussani : OK, let ' s hope that we actually do. Bill Gates, thank you for sharing your knowledge, thank you for this very, very important book. And thank you for coming back to TED. I want to close by showing another short **clip** from **the** TED-Ed animation series inspired by Bill ' s book. This one is about material that ' s all around us, has a big **carbon** footprint and how to reinvent it. Now, **the** series includes seven videos. You can watch them all for free at ed. ted. com / planforzero. That ' s planforzero, one single word. And on **the** TED-Ed YouTube channel. Thank you. Goodbye. Look around your home. Refrigeration, along with other heating and cooling, makes up about six percent of total **emissions**. Agriculture, which produces our food, accounts for 18 percent. Electricity is responsible for 27 percent. Walk outside and **the** cars zipping past, planes overhead, trains ferrying commuters to work. Transportation, including **shipping**, contributes 16 percent of **greenhouse** gas **emissions**. Even before we use any of these things, making them produces **emissions**, a lot of **emissions**. Making materials, concrete, steel, plastic, glass, aluminum and everything else accounts for 31 percent of **greenhouse** gas **emissions**. [Watch **the** full animated series at ed. ted. com / planforzero and youtube. com / ted-ed]

Text Sample 62: POS Dim 1 – 2021 – Score 22.00 – 2021/t003892.txt

So **the** climate crisis, in my way of thinking about it, is **the** most serious manifestation of an underlying collision between human civilization as we ' ve presently organized it and **the** Earth ' s ecological systems. And **the** system most in jeopardy is **the** very thin shell of atmosphere surrounding our **planet**, because we ' re spewing 162 million tons of human-caused global warming pollution into it every single day, as if this is an open sewer. It ' s not an open sewer. It ' s so thin that if you could drive an automobile at autobahn speeds to **the** top of that **blue** shell, you ' d reach it in about five minutes. And that ' s where all **the greenhouse** gases are. **The** accumulated amount, coming from **the** burning of **fossil** fuels primarily, CO2 – fastest-growing source of methane is from **fossil** fuels as well, also, **agriculture** as you have heard – **the** accumulated amount traps as much heat now as would be released by 600, 000 Hiroshima-class atomic bombs exploding every day. So **the** temperatures are going up at almost record levels every year. Last year was **the** hottest year in recorded history, according to NASA, and **the** scientists say it ' s absolutely unequivocal that we are **the** cause of that. And we ' re hearing Mother Nature and seeing **the** extreme events. **The** most anomalous extreme event since records began 200 years ago was in **the** Pacific Northwest of North America. Forty nine and a half degrees, 121 degrees Fahrenheit in British Columbia. In **the** tropics and subtropics, **the** combination of temperature and humidity is now making larger areas literally uninhabitable, **the** area so described is relatively small now, but if we continue over **the** next few decades, these areas are predicted to expand, and billions of people will be in areas where it is not safe to stay outside for more than a couple of hours. Already, **the** climate refugees and migrants are four times more from **the** climate crisis than from all **the** wars and conflicts going on right now. And **the** respected"Lancet"commission has predicted as many as a billion climate refugees in this century. That ' s one of **the** reasons why we are seeing this wave of populist authoritarianism. Sea level rise is also contributing, and of course, 93 percent of **the** extra heat is absorbed in **the** oceans, and **the** ocean temperatures are reaching record levels as well. And that means more water vapor comes off **the** oceans, and **the** warmer ocean temperature makes **the** cyclonic storms, like hurricanes and typhoons much stronger. Hurricane Ida struck **the** Gulf Coast as a category four, and as is so often **the** case, communities of color and poor people were disproportionately victimized. This storm continued on north and northeast across North America to New York, New Jersey and Pennsylvania, killed a lot of people and dropped rain bombs. And in New York City some basement apartments were flooded. And I appreciate this family giving me **the** right to show this video. He ' s safe, **the** guy is screaming for his mother. He and his mother were both rescued by his brother, who punched a hole through **the** roof from **the** floor above. These rain bombs are becoming much more frequent and much more extreme. And actually **the** water coming off **the** oceans is held in much greater volumes by **the** warmer air. Atmospheric rivers are becoming larger. Here ' s one, from Hawaii in **the** lower left to Silicon Valley in **the** upper right, 2, 300 kilometers. What was happening in Silicon Valley when this satellite picture was made? Well, that ' s what happens when these rain bombs drop, and **the** average atmospheric river now contains as much moisture as 25 Mississippi Rivers. They ' re creating what you could call"atmospheric **tsunamis**"in some areas. **The** downpours get much bigger and much more frequent, four times more frequent now than in 1980. One of them dropped on Germany and neighboring countries in July, killed more than 200 people. Look at **the** before and after. This is an example of what we ' re doing to our **planet**. Ten days ago, in part of Italy, there were 74 centimeters that fell in 12 hours, 29 **inches** of rain in 12 hours. One year ago, October 3rd, as much rain fell here in **the** UK as there is water in Loch Ness. And as a result, **the** insurance industry is now seeing record recoveries, and those recoveries I showed you from last year may get a tiny bit larger, depending on **the** outcome of this lawsuit. **The** owners and operators of this giant replica of Noah ' s Ark have sued their insurance company for a million dollars in flood damages. Hard to make some of this stuff up. **The** same extra heat is pulling **the** moisture out of **the** first meter of **the** soil, creating **the** worst **droughts** in memory. 93 percent of **the** American West is in **drought** now, 100 percent of California, half of California is in **the** most extreme form of **drought**, and **the** same heat is also draining **the** reservoirs, evaporating **the** reservoirs. Lake Mead is down to levels not seen since they started filling it in **the** 1930s. In Brazil, **the** same thing is happening. In Eastern Europe,

the Czech Republic has been going through **the** worst **drought** in at least 500 years. And in **the** southern cone of Africa, 100 million people are experiencing food insecurity primarily because of **the** extended **droughts**. And when **the** temperatures go up, **the** fires get a lot worse and **the** worst fires in California and western US history have been in **the** last two years. Also in Siberia, in Australia, in southern Europe. It doesn ' t have to ruin your **golf** game. And this is a serious point, because we can ' t let these conditions become **the** new normal. It ' s not fine. And this is an example of why it ' s not fine. A lightning strike hitting a natural gas leak in **the** middle of **the** Gulf of Mexico. Lightning gets more common with **the** climate crisis. We ' re relying on dead plants and animals, leaving their residue in **the** atmosphere to threaten **the** species that are still alive, and 50 percent of them are in danger of extinction in this century. And as we push into previously wild areas of **the** world, we encounter millions of new viruses that we have not dealt with in **the** past. Five new infectious diseases every year, emerging, three quarters of them from animals, like **the** COVID-19 pandemic. Which raises some of **the** same questions that are raised by **the** climate crisis. When **the** world ' s leading scientists are setting their hair on fire to get our attention, should we listen to them? Check. Can our interconnected global civilization suddenly be turned upside down? Check. Are **the** poor and marginalized populations of **the** world **the** most affected? Check. Can science and technology give us nearly miraculous solutions in record time? Check. Will we deploy those solutions in time? That is **the** question. We have inequitable vaccine distribution in **the** world, and it threatens everyone in **the** world. We also have solutions to **the** climate crisis, but they ' re not equitably distributed. Worldwide, 90 percent of all of **the** new electricity generation installed last year was renewables. Almost all of it from solar and wind. Just one year before **the** Paris Agreement, solar and wind electricity was cheaper than **fossil** electricity in only one percent of **the** world. Five years later, two thirds of **the** world. Three years from now, it will be **the** cheapest source in 100 percent of **the** world. **Coal** is not getting cheaper. Gas is not getting cheaper. Nuclear has been getting more expensive. Wind is cheaper than all three, and solar is continuing to plummet in cost and is **the** cheapest of all now because **the** cost of making **the** solar panels and **the** windmills continues to come down. By **the** way, **the famous coal** museum in Kentucky just installed solar panels on its roof in order to save in its operating budget. Now we ' re getting battery storage. I ' ll rescale this graph to show you **the** predicted emergence of a new one-trillion-dollar industry in **the** next few decades and green hydrogen on top of that. **The** car batteries are getting cheaper as demand continues to increase. And within less than two years in some model categories, **the** EVs will be cheaper than their internal combustion engine counterparts and within four years in all model categories. So, **the oil** and gas industry has been **the** worst investment in global markets for more than a decade, while **the** clean energy companies are really becoming more profitable. Now **the oil** and gas companies say that they ' re going to invest a lot more in renewables and CCS. Yes, it ' s **the** fastest-growing – they ' ve tripled their investments all **the** way up to four percent. Ninety-six percent of **the** money they ' re spending is still going into **oil** and gas and **coal**. **The** impression they ' ve given us is not an honest impression, not for **the** first time. And they ' re telling a different story to Wall Street. They still have planes, trains, a few automobiles and ships, but they ' re telling Wall Street and financial markets they ' re going to make it up in plastics, which is 75 percent of their third-largest market, petrochemicals. How ' s that working out for us? Not so well. Banning single-use plastics is one of **the** many things that we have to do. We have to shift to **sustainability**. And here ' s **the** good news, **the sustainability** revolution is **the** single biggest business opportunity in **the** history of **the** world. It has **the** scale of **the** industrial revolution coupled with **the** speed of **the** digital revolution. And what we ’ re seeing is that we have to seize this opportunity, but we need reforms in **the** current version of capitalism. Capitalism does a lot of things great. It balances supply and demand and allocates resources efficiently and often **unlocks** a higher **fraction** of **the** human potential. And by **the** way, **the** alternatives on **the** left and right explored in **the** 20th century didn ’ t work out very well. But in order to see how we need to change capitalism, we have to pull out our focus. And let me present an analogy. **The** electromagnetic spectrum from **the** long radio waves to **the** short gamma rays and all **the** things in between, **the** portion of visible light that we can see with our eyes makes up only 0. 1 percent of **the** total. For **the** eight years I worked in **the** White House, I got a daily report from **the** intelligence community that collected from all parts of **the** spectrum, and it was a much more accurate picture. Here ’ s **the** analogy. **The** value spectrum is something we too frequently look at through **the** very narrow aperture of short-term profits for one stakeholder, **the** shareholders. But this leaves out negative externalities, as **the** economists call them, like **the** pollution. That ’ s why we need a price on **carbon** and a price on plastic pollution. It also leaves out positive externalities. So we ’ re chronically underinvesting in education and health care and environmental protection, pandemic preparedness. We ’ re ignoring **the** depletion of resources like topsoil and **underground** water aquifers. And we ’ re ignoring **the** distribution of incomes and net worths to **the** point where one percent of **the** people have almost half of **the** world ’ s wealth. That ’ s one of **the** other factors that ’ s driving populist authoritarianism. We have to take account of **the** environmental effects and **the** effects on people and their families and **the** communities where they live and **the** communities in their supply chain and **the** ethics in **the** C-suites. And we have to realize that hyper inequality is a threat to both capitalism and to democracy. There is an emergent form called multistakeholder capitalism, and it is driving a lot of new decisions. For example, in asset management, almost half of all **the** assets in **the** world under management are now in portfolios committed to net-zero. One reason is that **the** Paris Agreement set **the** direction of travel, where every country in **the** world committed to net-zero. So just last May, **the** G7 nations banned financing of **coal** plants overseas. And just three weeks ago, China did, which is good, because they were financing most of them. I hope that they will cut down on **the coal** chain in China domestically as well. And now more than half of all **the greenhouse** gas **emissions** and two thirds of global GDP is coming from countries that have set net-zero targets. So here ’ s **the** hope. Once we reach net-zero, then with a lag time of as little as three to five years, **the** temperatures in **the** world will stop going up. And once we reach net-zero within as little as 25 to 30 years, half of **the** human-caused CO2 will fall out of **the** atmosphere. It is as if we have a switch that we can flip in order to stop **the** climate crisis. Regrettably, some damage has been done, but we can stop **the** temperatures from going up and start **the** healing process. But we all have to flip this switch known as reaching net-zero. **The** young people are telling us that we have to, and they ’ re marching in every country in **the** world. And what ’ s **the** response? As recently as this morning we heard,”Well, it may be impossible.”Well, it ’ s not impossible. Nelson Mandela said,”It always seems impossible until it ’ s done.”That ’ s what they told **the** abolitionists.”It ’ s impossible to eliminate slavery.”That ’ s what they told **the** women ’ s suffragettes.”It ’ s impossible to have equal rights for women.”In **the** civil rights movement in my country and **the** anti-apartheid movement in South Africa and more recently, **the** lesbian and gay liberation and equal rights movement. We can do this. This is **the** biggest emergent social movement in all of history. We can do this. And if anybody thinks that we don ’ t have **the** political will, remember, political will is itself a **renewable** resource. Thank you very much. Thank you.

Text Sample 63: POS Dim 1 – 2023 – Score 26.00 – 2023/t003333.txt

Christiana Figueres : There ’ s no doubt that we are facing exponential impacts of climate change. There is also, however, no doubt that that is being met with exponential progress of **the** technologies that can help to address climate change. So what we have here is, frankly, a race between two exponential curves. By 2030, we collectively will have chosen between door number one. And door number two. Julio Friedmann : **The** question I am most commonly asked about climate change is :”Should I be optimistic or pessimistic?”Cynthia Williams : Here ’ s what we need to do to make sure that we ’ re ready for an all-electric future. Anika Goss : Being financially secure and climate resilient should be **the** most important priority. Faustine Delasalle : It ’ s really easy when you look at where we are today and where we ought to be by 2030, to feel like there ’ s a huge gap that will never be filled. But we have good reasons to say that that gap is actually fixable. Nigel Topping : If you ’ re not worried or anxious, you ’ re probably not paying attention. But we should also not be defeatist. We shouldn ’ t say,”We ’ ve done nothing, we ’ re failing.”We ’ ve really started 20 years too late, but it takes a long time to get **the** flywheel of momentum going. Kingsmill Bond : **The** tide of change is coming. **The** costs keep falling. **The** political pressure keeps increasing. JF : We ’ re going to build a thriving, exciting world. AG : We can do this. JF : Full of potential. AG : We have to do this. [TED Explores A New Climate Vision] Manoush Zamorodi : When it comes to climate change, are you an optimist or a pessimist? News about **the** climate can be overwhelming and emotional, to **the** point that many of us just feel numb. I ’ m Manoush Zomorodi, a longtime public media journalist and host of **the** TED Radio Hour. And today, we want to bring you something special : an hour of nuance, of real people and clarity about what is happening to our **planet** and what we ’ re doing about it. Because we all know there ’ s plenty of bad news when it comes to **the** climate crisis. But guess what? There ’ s also some really good news. That ’ s why we ’ re here in Detroit at **the** TED Countdown Summit, where a cross-section of people who know **the** most and who are doing **the** most have gathered to share their ideas and plans with each other and with you. You ’ re going to hear from some incredible speakers about their personal stories and tested solutions. But first, let ’ s get a quick reminder on **the** basics : climate change in a minute or so. [Prologue : What is Climate Change?] David Biello : **The** air we breathe has changed. **The** mix of gases is shifting, with more and more **greenhouse** gases like **carbon** dioxide. And **the** shift is happening faster each year. In just a few hundred years, **fossil** fuels formed over eons have been burned as **coal**, **oil** and gas. **The** exhaust has transformed **the** entire atmosphere and ocean. It ’ s like a pollution blanket. And **the** result we know as climate change. **The planet** has already warmed more than one degree Celsius and is on a path to heat up even more. That may not seem like a lot, but it ’ s already caused major destruction across **the** globe. To give us some room to breathe, **the** world must reduce **greenhouse** gas pollution by more than seven percent each year, every year of this decade. There are a number of ways to do that. Let ’ s start by looking at **the greenhouse** gases themselves. CO2 makes up nearly 75 percent of **the** pollution emitted each year. And then there ’ s methane or natural gas, which makes up 17 percent. Finally, there ’ s nitrous oxide, making up six percent of **the** problem. There are other **greenhouse** gases, but these three make up **the** bulk of

the climate challenge. Where do they come from? There are several ways to break down **the** sources of **greenhouse** gas **emissions**. Here we ' re using **the** public Climate Watch data. Start with energy. **The** majority of modern energy comes from burning **fossil** fuels, which makes **the** energy sector 76 percent of **the** climate challenge, including **the** fuels used for **transportation**, industrial processes and agricultural production. Farming and animal raising also have to change, as **agriculture** accounts for 12 percent of **greenhouse** gas pollution. **The** remaining 12 percent comes from a grab bag of human activities like industrial heating, clearing forests and more. This is **the** climate challenge we face : going from adding billions of metric tons of **greenhouse** gases to **the** air each year to adding zero. Will it be easy? No. Can we do it? Yes, if we choose to. MZ : OK, so that ' s **the** situation. Where do we go from here? Well, we ' ve all heard of a tipping point, that moment when an idea or concept finally takes hold and then changes **the** world. Well, **the** UN ' s climate chief, Simon Stiell, believes we are almost at a tipping point for massive action on climate change. And to get you ready, he wants to take you back to **the** early ' 90s, when he was an executive at Nokia, and **the** world wasn ' t sending text messages yet. [Chapter 1 : Exponential Change] Simon Stiell : I want you to imagine it ' s 1992, and you ' re talking to a telecoms expert. She tells you that mobile phone text messaging is going to fundamentally change **the** way we communicate. You think, why on Earth am I going to go from this to tapping on a screen with my fingers and my thumbs? But then, after a slow start, text-based services exploded. Today, over 23 billion messages are sent every single day. This paved **the** way for **the smartphone** revolution. I know how much we struggle to comprehend and predict what exponential change means, because I was at Nokia in 1993 when that technological revolution started. And now, as head of UN climate change, I ' m here to tell you that what was true for mobile phones is also true for climate action today. We ' re here in Detroit, **the** heart of car manufacturing. Take a look at this graph. Electric vehicle sales are expected to increase to become 70 percent by 2030. Another example, solar energy. Between 2010 and 2020, we moved from 20 gigawatts of solar energy installed to 150 gigawatts. And by 2030, that number is expected to increase again, to 1, 000 gigawatts per year. Change can come fast. FD : So exponential change means that change happens very slowly at first and then comes a tipping point. And suddenly things accelerate and accelerate and accelerate. NT : It ' s a mathematical term, but it means basically stuff happens very slowly and then it goes really fast. Tessa Kahn : Governments and experts have consistently underestimated **the** pace and scale at which we can deploy **renewable** energy and how quickly **renewable** energy and associated technologies become affordable. Ramez Naam : I predicted in 2011 that we ' d have solar as cheap as **coal** in some parts of **the** world by 2015 and half **the** cost of **coal** by 2020, and everyone thought I was crazy, I ' ve got to say, almost. And in fact, I was wrong. **The** actual decline in **the** cost of solar happened twice as fast as I thought it would. Solar prices today are a century ahead of where **the** world ' s leading energy experts thought they ' d be in 2010. KB : It ' s now spreading from solar, so it ' s happening also in **the** wind sector, it ' s happening in **the** battery sector, it ' s happening in **the** electric vehicle sector. CF : I don ' t think that we do a good job at communicating **the** fact that we are progressing more than is commonly known. Nili Gilbert : **The** human brain is trained best at thinking about linear change. But when you think about an exponential curve, next to a line, at first **the** exponential curve is below **the** line, and so it ' s moving more slowly than you would think. And then it crosses **the** line and it ' s moving faster than you would think. Habiba Daggash : We call it cautious optimism. We ' re very hopeful about **the** trajectories that we ' ve seen. But we shouldn ' t let up yet.

KB : So we can make this change happen slow or we can make it happen fast. **The** key point to say is we have agency. MZ : This idea of exponential growth sounds awesome. It sounds amazing, but is it actually happening? Well, I ' m headed into a workshop with industry and climate leaders to find out. **The** moderators of **the** workshop challenged us to hold two competing ideas in our minds at **the** same time. NT : What we ' re really going to explore today is two apparently opposing realities, and they ' re often two opposing narratives. **The** one which is true, right, is that in terms of **the** Paris goals, we ' re way off track. We ' re deep into **the** emergency. But what we ' re going to explore today is **the** other reality that we know what to do. Exponential change is happening, but it doesn ' t happen by magic. MZ : So what are we seeing in different industries? Well, let ' s start with one that ' s known to be really difficult to decarbonize : cement. Vicente Saiso Alva : I think everything converges into making climate a huge urgent matter for society. We started to feel **the** pressure from all different types of stakeholders, and in one year of running this program, we realized how fast we could move and how fast we were going in reducing CO2 **emissions**, which means now to go from 40 to close to 50 percent reduction by 2030. MZ : Encouraging, but to tackle that remaining 50 percent may require technologies that don ' t exist at scale yet. OK, what about **shipping**? Narin Phol : In Maersk, a few years back, we came out with a net-zero ambition by 2050, and in a few years later, based on **the** data that we have got, we ' ve really seen a path that we can really accelerate that one. That ' s why **the** revised target of 2040 came in. MZ : **The** news in offshore wind was quite dramatic. Jennie Dodson : So my moment of mindset shift was in 2019. **The** government put out a request to bid for offshore wind permits. And that year **the** price that came in was two thirds less than just four years before. And really critically, it was **the** same price as **the** mainstream market. And that was transformative. Nobody expected that when they started. MZ : **The** conversation got pretty technical and a bit wonky. NP : So to drive exponential growth, you focus on a reinforcing loop to make sure it works and you slow down on **the** balancing loop. MZ : But **the** takeaway is that certain sectors, like EVs and renewables, are being upended, while others, like cement and heavy industry are further behind. But generally across every industry – JD : It ' s amazing stuff. MZ : There ' s an understanding that they all need to work together. And **the** message? Big change can happen. It ' s going to be hard, but some of us are already doing it, so learn from us. [Chapter 2 : **The** Electric Vehicle Revolution] OK, we are in an exponential mindset. And as you heard, one example of exponential growth might be sitting in your driveway right now. Electric vehicles are finally really happening, which means that people here in Detroit are rethinking **the** auto industry. They ' re rethinking their jobs, their identity. Take Cynthia Williams, head of **sustainability** at Ford. I sat down with her at Lucky Detroit, a local coffee and barber shop, where she told me that there are three things that need to happen for electric vehicles to go to **the** next level, from this tipping point to exponential growth. CW : **The** three things for me are change, collaboration and capacity. So **the** change piece of it is changing **the** way folks think about **the** vehicle, making sure that they understand we ' re bringing a better vehicle to **the** customers. MZ : So you don ' t have to make a sacrifice. CW : I think one of **the** things we need to do is actually get people in **the** cars and show them how fun it is. And it ' s no different, it ' s just powered by a battery. We are at a tipping point. We ' re at a point of acceleration of electric vehicles. Many are calling it **the** electric vehicle revolution. Now with that comes unprecedented change that will require us to build new capacity and collaborate in ways that we ' ve never seen before. To make things happen faster, you have to think differently. You can ' t just collaborate with **the** same people because you get

the same answer, right? You need to broaden your collaboration space. Go outside of your industry, understand what worked in Norway, for example, to get them to where they are. MZ : Where ’ s **the** weak link, Cynthia? What ’ s **the** thing that you ’ re like, that if we don ’ t push through that, we may not get to this full adoption? CW : **The** critical things that we hear from **the** consumers is they need infrastructure. That ’ s what it ’ s taking for us to work with governments to make sure that we bring more charging to everyone, whether it ’ s rural, urban, wealthy, low-income, we all need chargers. And I ’ m not saying we need one on every corner, but we do need many, many more. When we start building out **the** charging infrastructure, we need lighting. We need, you know, security, shelter, we need restrooms. We need other amenities so that people know where to go, where to charge. Next comes capacity. We have to invest in new facilities and talent. Now, that ’ s true for any industry transitioning to greener goals and strategies. And we ’ re investing in talent, we ’ re investing in education and training, and we ’ re also listening to **the** communities where we live and operate. MZ : So a young Cynthia Williams, now, your counterpart who ’ s studying engineering, will she be learning something very different if she wants to go and work in **the** automotive industry in Detroit? CW : There will be different options, right. And so, I ’ m a mechanical engineer by trade, but I think there will be opportunities for **electrical** engineering, software engineering. And there ’ s even certificates that students can get instead of going through a four-year college. It ’ s **the** proper training to get them right, to be dedicated, to build **the** vehicles that we need for **the** future. At **the** end of this year, globally, we ’ ll have **the** ability to produce 600, 000 electric vehicles. And in 2026, we ’ ll have a global goal to produce two million electric vehicles. And it just goes up from there. MZ : What is this going to look like, this growth for me in **the** next couple of years, in five years, in 20 years? CW : Clean air. That ’ s what I look at. If you think about when we were, during **the** pandemic, when everybody stopped driving and they were at home, clear skies and moving to zero tailpipe **emission** vehicles. And if you chose an electric vehicle, that ’ s you participating and you contributing to a better world, to a better future. We have come a long way. It ’ s so gratifying to see electric vehicles on **the** road, to move from aspiration to reality. To see plants dedicated to building electric vehicles. We have **the** technology, we have **the** leadership, we have **the** ingenuity to respond to **the** environmental crisis with courage. And I ’ ll tell you, as a person who ’ s dedicated my entire career to **sustainability**, **the** road ahead is paved with promise. TED-Ed : If you were buying a car in 1899, you would have had three major options to choose from. You could buy a steam-powered car, typically relying on gas-powered boilers. These could drive as far as you wanted, provided you also wanted to lug around extra water to refuel and didn ’ t mind waiting 30 minutes for your engine to heat up. Alternatively, you could buy a car powered by gasoline. However, **the** internal combustion engines in these models required dangerous hand cranking to start and emitted loud noises and foul smelling exhaust while driving. So your best bet was probably option number three : a battery-powered electric vehicle. These cars were quick to start, clean and quiet to run, and if you lived somewhere with access to electricity, easy to refuel overnight. If this seems like an easy choice, you ’ re not alone. By **the** end of **the** 19th century, nearly 40 percent of American cars were electric. In cities with early electric systems, battery-powered cars were a popular and reliable alternative to their occasionally explosive competitors. But electric vehicles had one major problem. Batteries. MZ : Flash forward to **the** present and batteries are still on everyone ’ s mind. So I visited Mujeeb Ijaz, **the** founder of **the** energy storage company One, who also happens to be an electric vehicle history buff. Mujeeb Ijaz : So this is a 1922 Detroit Electric. MZ

: OK, so 100-year-old vehicle. MI : That ’ s right, electric vehicle. And then this was Walter Baker. He developed **the** Baker Electric. And he made **the** range run 201 miles on a single charge. He also felt strongly that you should be able to wear your top hat, you know, so he has a taller carriage. These had lead acid batteries to begin with. And then Thomas Edison introduced **the** nickel-iron battery. So this is **the** battery compartment, one of **the** battery compartments. And this is where you would charge. MZ : Right there? MI : And we ’ re building on what these original pioneers did. And I think it ’ s important to not think about us starting from scratch now. But go **backwards**, think about how they solved **the** problem, what disrupted their ability to advance this to **the** market, and then pick those problems up and make sure we don ’ t get stuck again. MZ : So we ’ ve been here before, a moment when electric vehicles could have taken off but didn ’ t. So what do we need to do differently this time? MI : Electric vehicles were able to deal with mobility in urban areas, but there were charging deserts where rural driving resulted in no way to get back because you couldn ’ t find electric charging everywhere. And that was a problem. MZ : And that ’ s what people are worried about right now. We ’ re at **the** same thing. We ’ re worried about range, we ’ re worried about accessibility. All of **the** things are **the** same. But **the** key difference being that we now know that our **planet** can ’ t keep going like this. MI : That ’ s right. Had **the** vision of **the** Model T assembly line and mass manufacturing been applied to electric car, **the** electric car would have also dropped in price, but range and charging deserts would have still been **the** obstruction. MZ : OK. We didn ’ t have **the** technology, but we do now. MI : We do now. MZ : In **the** US, there hasn ’ t been a mass move to electric vehicles... yet. Mujeeb ’ s company is one of many who want to change that by building batteries that give drivers longer range. And these batteries aren ’ t just for cars. MI : So we produce battery packs for **transportation**, but we ’ ve also started developing **the** same battery products into grid batteries. So micro-grids are those technologies that combine solar and storage and replace a **coal** plant or a natural gas plant for generating electricity. So buildings and industry and **transportation** all working together. And that ’ s an exciting future, is all these industries working together, that makes me more confident that we ’ re at **the** time in history where this transition will take place. MZ : How many years till we get to that? MI : I think it ’ s within 10 years. MZ : No way, 10 years? MI : We ’ re in a place where that transition is going to be much more visible, and then we just need technologies to drive it up to **the** mass markets. MZ : I am so excited. Like, genuinely so excited. Everyone everywhere driving electric sounds great, but that also means that **the** power to charge all those vehicles needs to be green. And that brings us to **the** energy sector, which is also changing at an incredible pace, even though **renewable** energy has been years in **the** making. [Chapter 3 : Renewables] TED-Ed : In **the** **spring** of 1954, **the** press excitedly gathered around Bell Laboratories ’ latest invention : a silicon-based solar cell that could efficiently convert **the** sun ’ s energy into **electrical** current. **The** creation was celebrated as **the** dawn of a new era, as reporters touted that civilization would soon run on **the** sun ’ s limitless energy. But **the** dream had a catch. As this first commercially sold solar cell cost around 300 dollars per watt, meaning at its current rate it would cost well over a million dollars to buy a unit large enough to power a single home. But today, in many countries, solar is **the** cheapest form of energy to produce, surpassing **fossil** fuel alternatives like **coal** and natural gas. Millions of homes are equipped with rooftop solar, with most units paying for themselves in their first seven to 12 years and then generating further savings. So how did solar become so affordable? A turning point in solar ’ s price history **occurred** on **the** floor of Germany ’ s parliament, where in 2000, Hermann Scheer introduced **the Renewable** Energy Sources Act. This legislation laid out a vision for **the** country ' s energy future in solar and wind. It incentivized citizens to personally invest in rooftop solar panels by guaranteeing payment to homeowners for **the renewable** energy they generated and sold to **the** grid. **The** pay rate for this electricity was highly subsidized, at times reaching four times **the** market price. Several other countries soon followed Germany ' s example, implementing similar policies and incentives to drive their country ' s solar use. This created unprecedented demand for solar panels worldwide. Manufacturers were able to scale up production and innovate in ways that cut costs. As a result, solar panel prices dropped while efficiency grew. HD : We see **the** cost reduction in solar and other **renewable** energy technologies has been so steep, but a lot of it is because of **the** enabling regulatory and policy environments created in places like **the** European Union and **the** US. Akil Callender : We cannot divert catastrophic climate change without addressing **emissions** coming from our energy systems. Currently, **emissions** from **the** energy system account for around two thirds of global **greenhouse** gas **emissions**. So **the** good news is, yes, we are seeing tremendous progress across **the** globe in **renewable** energy. It ' s rolling out faster than ever before. Luisa Neubauer : **The** brilliant thing about energy supply in **the** world is that we have alternatives. So we don ' t need **fossil** fuels to provide safe and equitable access to energy systems. Ramón Méndez Galain : Almost 90 percent of **the** total new installed capacity all over **the** world is just **renewable**. This is a tremendous change. AC : There ' s more finance than ever before going into clean energy. In many countries, it is **the** largest contributor to their electricity system for **the** first time ever. KB : And also because China is **the** leading manufacturing nation in **the** world, change is happening there much faster. And those innovations are then spreading around **the** world. Hongquiao Liu : China ' s **coal** demand might not have peaked, and China will continue to consume quite a lot of **coal** in **the** next few years. But **the** decarbonization is happening. It ' s happening faster than anyone has expected, and China is adding an astonishing amount of wind and solar to its grid every year. Eduarda Zoghbi : I think one of **the** biggest obstacles today are natural resources, in **the** sense that we ' re talking more and more about critical minerals and **the** role that they have. And batteries are demanding a lot of critical minerals that are present in most of **the** developing countries. So I think that even though costs are decreasing, we have to be more and more creative when it comes to recycling **the** batteries. We also have to think of how they ' re impacting local communities. KB : So to give you **the** numbers, we extract, at **the** moment, 15, 000 million tons of **fossil** fuels every year. **The** International Energy Agency says that we will need about 43 million tons of critical materials in order to build out **the** clean energy economy. So that ' s 300 times less stuff that is required. It ' s worth saying that **the** impact of extracting 300 times less stuff upon nature is dramatically lower. And I know that it ' s often argued that **the renewable** economy may be damaging for nature. Again, this is a completely false statement. It ' s in fact, our only chance of reducing **the** pressure upon our natural resources, because there ' s far less of it. MZ : Of course, transitioning to using clean energy, upending industries, it has to happen across **the** world, not just here in **the** US. And it can be hard to even imagine what life will be like. But **carbon** scientist and futurist Julio Friedmann can help us. Julio Friedmann : I think we need a compelling vision of **the** future that gets people excited about **the** energy transition and solving climate change. Right now, it ' s like we ' re at a restaurant and there ' s two options : burnt toast, unflavored oatmeal. And people are not excited about either, right? **The** burnt toast option for me is what I call **the** big switch. Everything ' s **the** same, it ' s just clean, but it costs a lot of money and it ’ s super hard to do. **The** other vision is kind of like,”Thou shalt not.”That vision is a narrower sort of,”eat your peas,”hair shirt kind of vision of **the** future. And a lot of people don ’ t want that either. And there ’ s nothing in **the** physics, **chemistry** or **biology** that says we can ’ t have a super interesting, exciting, vibrant world. And that is compelling in a way that we have not heard yet. MZ : Help me out here, what does that even look like? JF : So, for lack of a better word, like, I like **the** Marvel cinematic **universe**. MZ : OK, I ’ ll go with you. JF : So a place like Wakanda, right? It ’ s got flying cars, it ’ s got maglev trains, and it ’ s a totally fabulous place to live. Like, they ’ ve got lots of food. That is built on abundant, sustainable, cheap energy. MZ : OK, so like, we ’ re not Wakanda, we ’ re not in **the** Marvel **universe**. This is real life, sort of. How do we make this possible? JF : So what can you actually do here on Earth, constrained by economics and engineering and all **the** rest of it, right? And **the** answer is we can do an incredible amount. Abundant, available where you want it, when you want it. Everybody should have energy, including **the** three billion people who use less electricity than my refrigerator uses. Well, **the** good news is, every day, **the** Earth receives 163, 000 terawatts of energy from **the** sun. About half of that bounces back to space, but about 80, 000 terawatts arrive at **the** Earth in a form we can use. For reference, today, **the** world uses about 26 terawatts of energy, and we got more than solar and wind. We have geothermal, we have hydro, we have nuclear. There ’ s other kinds of clean energies. And some of **the** best resources are, in fact, in **the** Global South. These places are not simply future climate victims. These places are latent energy superpowers. My favorite example of this is Chile. Almost eight years ago now their government said, wait a second, we can make **the** cheapest green electricity on Earth. We have hydropower, we have solar power, we have wind power and **the** best resources anywhere in **the** world. So let ’ s start by making a lot of green electricity. And then they said, because of that, we can also make green hydrogen cheaper than anywhere else. And then Japan was like, hello, we want your green hydrogen. Can you ship it to us? MZ : Is that possible? JF : Totally. And Japan is like, we will also give you money to pay for these projects. We ’ ll loan you money to pay for these projects. Could you please use Japanese technology? So they ’ re using Japanese **turbines**, electrolyzers, they ’ re using Japanese ships to haul **the** ammonia around. So Japan gets rich on this, Chile gets rich on this. MZ : Win-win. JF : Totally win-win. MZ : Win-win-win, **planet**, too. JF : And that model, other countries are looking at that, going, I want some of that. And that ’ s why I like this vision of abundance. 15 years ago, solar was **the** most expensive power. Now it is **the** cheapest form of electricity, right? Which is astonishing, it ’ s totally amazing. And a whole bunch of people are like, now we ’ re done. And I ’ m like, no, we can do that with everything. We can do that with wind. We can do that with nuclear, we can do that with geothermal. But these projects take time, money and people. We need to develop **the** human capital as part of these investment projects for decades. And innovation, we need much more energy in many places, much cheaper. That ’ s an innovation agenda. For solar, that was **the** United States, Germany, China and others acting together. Well, if that ’ s **the** recipe, we can do that again. We ’ re already doing it with electric vehicles and clean hydrogen production. We can certainly do it by turning electricity into fuels. MZ : It sounds like **the** climate discussion needs to be kind of like improv, that it ’ s a”yes and”sort of thing. JF : I ’ m so glad you said that. So many people don ’ t understand my love of improv comedy. Yes, it is a”yes and”circumstance. Because mostly it is about room for agreement. Where do you find **the** point where everybody is like, I can agree on that? One of **the** things I love about **the** infrastructure bill, one of **the** things I love about **the** Inflation Reduction Act, neither of them had **the** word climate in it. They were both massive climate bills, right? That was a way to get everybody on **the** same page. Nationwide, they basically tripled **the** clean energy research budget. That ' s a good start. But that made it all of one percent of GDP. And for comparison, we spend twice that on pharmaceuticals. So I think it ' s fair to say we should get going. We should spend a lot more money. We ' ve done stuff like this before. We ' ve done World War II, we ' ve done **the** Marshall Plan, like, we ' ve done **the** space shot, like we actually know how to move really quickly as a nation. We did this for COVID. Collective action, building together is what makes **the** difficult possible and nourishes **the** soul through mission and purpose. We know what to do and we can act, not out of anger or fear, but out of generosity and common purpose, bringing aspiration and humility together. We ' re going to build a thriving, vibrant, exciting world full of potential that ' s going to be built on **the** back of infrastructure, innovation and investment that will harness **the** abundant, sustainable, cheap energy that is our **planet** ' s endowment. Thank you. [Chapter 4 : A Just Transition] FD : There is a high risk that when those exponential kick in, we see businesses running after those opportunities. But then **the** distribution of **the** benefits being very unequal. EZ : Many people like discussing **the** importance of **the** just energy transition. And a lot of people don ' t understand what justice really means. If we are to reach a revolution, a **renewable** energy future has to be inclusive. AC : We have this push for what we ' re calling a just and equitable energy transition. We need to make sure that we are not exacerbating inequality, but rather we are ensuring that that gap is closed and that **the** groups that have been historically marginalized are not once again being marginalized in a new way. NT : Most of **emissions** come from wealthy, energy-guzzling citizens, but a lot of **the** economic benefit and human development benefit will come not from decarbonizing high-carbon lives and lifestyles, but from providing clean, distributed energy and tools and solutions to those who don ' t have access to any of them. LN : When we speak of countries in need of economic development, we mostly speak of countries that are hit by **the** climate crisis **the** hardest right now. It should be **the** biggest wish and job and task for all those countries who have burned so much **fossil** fuel already to support any other country in **the** so-called Global South, to get an economy running without **fossil** fuels, to not repeat all **the** mistakes that we have made. HD : To ensure that **the** solar revolution that has been seen around **the** world comes to places like Africa, we need to be really conscious that **the** history and **the** lived experience when it comes to energy is very different for poor countries. Rebekah Shirley : We love to remind Global South communities, especially Africa, about **the** vast **renewable** energy potential that they have, which is true. But **the** finance flows to deliver on that potential remain very scarce. Africa, despite being 90 percent of those across **the** entire globe that still do not have access to electricity and being 17 percent of **the** global population, we ' re actually two percent of international finance. Money doesn ' t actually flow to these spaces naturally, and we need to do a lot of work to get global finance to these spaces. MZ : A world of abundant clean energy for everyone. That is **the** goal. But what about in **the** short term? Take Detroit. This once-wealthy city has been through some seriously hard times. How is it rebuilding itself so that everyone here can thrive while dealing with extreme heat, flooding, and other climate problems? Anika Goss is looking to Detroit ' s past to plan its future. AG : I am a third-generation Detroiter. My grandmother moved to Detroit in 1936 during **the** Great Migration and brought all of her southern ways with her. She owned a home and knew that home ownership would create wealth and opportunity for her growing family. Up until **the** late 1950s, Detroit was a haven for middle-class families living in neighborhoods where there was green space and community connectivity and opportunity. My grandmother, she had this amazing garden, and it was just abundant. There were all kinds of flowers and food. You know, she grew vegetables back there, and it was just a magical place for a little girl. MZ : I mean, what you ' re describing is a Detroit that, yes, has huge problems, segregation. But at **the** same time, a woman, she can have a job, she can own a house, she can raise her family, she can have fresh fruits and vegetables. AG : It was certainly a place where you could gain economic opportunity faster than you can now. My grandmother ' s Detroit is not **the** Detroit that I live in today. All of those sites where there was manufacturing and industrial sites that led to our economic boom, many stand vacant and abandoned. These industrial sites have led to dangerous contamination to our land and our water and our air. MZ : So, just lay it out for us. For people who maybe don ' t see, like, how is there a link between economic inequality and climate change? AG : You know, I ' m so surprised that it feels like separate problems. But I ' m also really glad that people are asking. Because if you ' re living around and working in a community that is low-income, where there are fewer jobs, **the** housing is deteriorated, this is a neighborhood that ' s also more likely to be closer to a factory that ' s emitting pollutants, likely to have water that ' s contaminated, probably has fewer parks and fewer intentional green spaces. **The** people who are living in those communities are at risk for climate impacts first. So we have to do something in those neighborhoods right away. MZ : So what can this healthier future look like? Anika showed me some of **the** work she ' s done in partnership with different neighborhoods in Detroit, to make them both more enjoyable and more resilient. First, she took me to **the** Circle Forest. It ' s an oasis right in **the** middle of **the** city. AG : This is six lots that were vacant, and we all worked together with this community to build a forest. MZ : Beautiful and a great example of how nonprofits can work with communities to transform them into sustainable, welcoming places. AG : We might have a good idea about gardens and tree planting, but this is where people live. And so you ask first. This is a new effort, of this idea of a resilient neighborhood or calling it that. So these are large tracts of vacancy that can be used to provide environmental **sustainability**, community resilience and beauty. Watch for **the** poison ivy. It ' s not pretend. MZ : Next we met up with Katrina Watkins, **the** founder and CEO of **the** Bailey Park Neighborhood Development Corporation, a group revitalizing this historic area by turning vacant lots into parks that can stand up to extreme weather. Katrina Watkins : My family has been in this neighborhood since 1946. I grew up hearing **the** stories from my dad, him telling me about how people thought it was a ghetto, but it wasn ' t. Those were families, and people worked and had businesses, and people looked out for each other. And it was those type of stories that made me say, wow, we just really need to bring that back. MZ : So then briefly fill us in about how things changed. KW : Things deteriorated in this neighborhood. **The** homes got torn down, left just a lot of vacant lots, a lot of overgrowth. It wasn ' t safe. I would see my little nieces and nephews. They would just be on their little skateboards, you know, not paying attention, **the** stop sign is covered. And me and my dad was like, we just have to do something. So we started out as Bailey Park Project, focusing on **the** park and green infrastructure and trees and flowers. And then over **the** course of **the** years, we started doing more community development. MZ : I wonder, like, how do you describe it to people when you explain what ' s happening, what you ' re trying to do for your neighborhood, **the** changes that you ' re making and how it relates to climate change? KW : One really great example, when people come to **the** park, like right now, this is like, literally a heat **island** because our trees haven ' t grown. So it is very hot. So sometimes it ' s so hot that **the** kids don ' t come out and play until **the** evening. That education of knowing **the** benefit of trees and cooling down an environment, how it makes **the** air cleaner. There ’ s a lot of people that suffer from asthma. So trees can make a difference. And if you go to places like Grosse Pointe, you will see this beautiful tree canopy down. Like their homes are probably 20 degrees cooler you know, than our homes, AG : Having a lot of green space actually contributes to **the** climate resiliency for this neighborhood. So all of this grass actually can manage stormwater better. **The** idea of leading new development in this neighborhood with green, what it says to me is that **the** residents are really envisioning **the** neighborhood that they want to live in. And that I just – I ’ m really excited about that. MZ : Turning great loss and upheaval into even greater opportunities. These Detroiters are creating a blueprint for an urban future that every city can learn from. [Chapter 5 : Agriculture] TED-Ed : About 10, 000 years ago, humans began to farm. This agricultural revolution was a turning point in our history that enabled people to settle, build and create. In short, **agriculture** enabled **the** existence of civilization. Today, approximately 40 percent of our **planet** is farmland. Spread all over **the** world, these agricultural lands are **the** pieces to a global puzzle we are all facing. In **the** future, how can we feed every member of a growing population a healthy diet? Meeting this goal will require nothing short of a second agricultural revolution. **The** first agricultural revolution was characterized by expansion and exploitation, feeding people at **the** expense of forests, wildlife and water, and destabilizing **the** climate in **the** process. That ’ s not an option **the** next time around. Agriculture depends on a stable climate with predictable seasons and weather patterns. This means we can ’ t keep expanding our agricultural lands, because doing so will undermine **the** environmental conditions that make **agriculture** possible in **the** first place. Instead, **the** next agricultural revolution will have to increase **the** output of our existing farmland for **the** long term while protecting biodiversity, conserving water, and reducing pollution and **greenhouse** gas **emissions**. So what will **the** future farms look like? In Bangladesh, Cambodia and Nepal, new approaches to rice production may dramatically decrease **greenhouse** gas **emissions** in **the** future. Rice is a staple food for three billion people and **the** main source of livelihood for millions of households. More than 90 percent of rice is grown in flooded paddies, which use a lot of water and release 11 percent of annual methane **emissions**, which accounts for one to two percent of total annual **greenhouse** gas **emissions** globally. By experimenting with new strains of rice, irrigating less and adopting less labor-intensive ways of planting seeds, farmers in these countries have already increased their incomes and crop yields while cutting down on **greenhouse** gas **emissions**. MZ : Related technologies are also taking root in **the** US. Father and daughter farmers, Jim and Jessica Whitaker, have come up with their own strategies to reduce methane that are working on their farm in Arkansas. But convincing everyone else to change is their next big challenge. So let ’ s go back to how you got to be such a big supplier of rice in this country. You tell a story about how you were 22 and you were like, I ’ m going to start my own farm, but – not that easy. Jim Whitaker : No, it ’ s not. Let me tell you something about renting a farm when you ’ re 22 years old. No one rents you a farm unless no one else wants to rent it. It was a big piece of land, it was cash rent, I mean, **the** stakes were set. We were doomed to fail. And we weren ’ t focused on environmental **sustainability** back then. We were focused on economic **sustainability**. How do we make higher yield? How do we use less fertilizer? How do we get to **the** next year and feed our family? It happens that economic and environmental **sustainability** go hand in hand along with social **sustainability**. As we used less fertilizer, used less water, our yield started going up. MZ : Can you spell out for me what **the** problem is with rice when it comes to **the** environment? JW : Soil is full of microbes. And what they ’ re doing in **the** soil on a basic level is they ’ re down there chewing away, eating up **the** biomass that ’ s left over from **the** crop before. And out of that comes methane, **the** same way it happens in cattle operations or whatever. MZ : But you decided to do it a different way. JW : We do it a little bit differently. Arkansas is a very water-rich state, but we have a dry season, right in **the** middle of summer is a dry season. So when we dry **the** soil, that anaerobic microbial that ’ s living in that **soup**, that mushy soil, either dies or goes dormant. So we break his life cycle. MZ : Oh! JW : And then it stops emitting methane. But it doesn ’ t hurt **the** rice. That actually helps rice, when you use less water. We have less runoff, less erosion, less nutrients leaving our field. Nothing leaves our field unless we want it to. Jessica Whitaker Allen : We started tracking this. We saw that our water use was down and we thought, OK, well, we need to add to that, let ’ s add more data points to that. Let ’ s add our fertilizer, let ’ s add our fuel usage. And so we really started recording all this stuff by hand in just an Excel spreadsheet. We didn ’ t know what we were doing. MZ : But you knew you were on to something. JWA : Yes, so we started recording everything. MZ : Do you remember if there was a moment when **the** two of you thought, like, what we ’ re doing, it shouldn ’ t be special to us. Why aren ’ t more people – JW : To collect **the** data, have **the** equipment and **the** cloud-based technology and **the** stuff in **the** field to record it, it ’ s just massively time-consuming, and consumers don ’ t pay for it. JWA : Well and people like us, why would you want to do it? I mean, take a walk through your **supermarket**. Everything ’ s sustainable, everything ’ s greenwashed. You can put whatever you want to on a package, there ’ s no rules, there ’ s no standards. So we ’ re trying to make that standard. We live and work in southeast Arkansas. Our town has 4, 000 residents and one stoplight. **The** nearest airport, Starbucks shopping mall, Whole Foods, is two hours away in any direction. Without places like this and farmers like us, you ’ d be hungry, naked and sober. I ’ m a farmer, but not in **the** way you might think. I don ’ t drive **the** tractors, and I don ’ t plant **the** rice. But I know how to take what my dad has learned and what he is doing and share that with others. We are going to work with farmers in southeast Arkansas to educate them about **the** benefits of growing sustainable rice. JW : Let me tell you why that ’ s important. There are 400 million acres of rice grown globally. And our methods, if used, can reduce **greenhouse** gas by 50 percent, reduce water use by 50 percent, increase yields to feed a hungry world. MZ : We hear a lot about how weather has gotten more extreme, flooding, heat. What ’ s it been like in Arkansas? JW : So in 2016, we had a 500-year flood. We were... We get a picture of our place flooded. 14 **inches** of rain. That was a 500-year flood. Hurt a lot of people. And then we had a 1, 000-year flood. And we lost so many acres. And you know, when houses get flooded in rural communities, they don ’ t come back. I mean, when you have whole neighborhoods get flooded, they don ’ t rebuild them, they don ’ t come back. JWA : I feel like almost every day I ’ m getting a notification from **the** weather Channel of an excessive heat warning or thunderstorm warning or hail threat. You know, you don ’ t really know what you ’ re going to expect. MZ : When you think about what it will be like, I don ’ t know, five years, 10 years, for someone to go into **the supermarket** and think, oh, right, I need to get rice off my grocery list. What ideally would you like to see on **the** shelf there? JW : So I think it ’ s going to change, because I like to study what companies want. I mean, if you figure out what they want, then you know what to give them. And when you read their **sustainability** goals, they ’ re all saying they ’ re going to be net zero. **The** only way they can be net zero is they bring **the** farmer into **the** loop. So if we ’ re able to do this, in five years, everybody ' s doing these practices, **the** US rice industry will be **the** most sustainable industry in **the** world. MZ : Can you do it? JW : Oh, yeah. It ' s about to happen. MZ : You ' ve just heard a lot of ideas, a lot of stories and a lot of big plans. So we want to wrap things up by asking our experts : What if we actually achieved our climate goals? What would that future even look like? They, of course, had a lot of thoughts. We ' ll let you pick your favorites. Thanks for watching. NT : If we are successful in addressing **the** climate crisis, we massively reduce **the** vulnerability and improve **the** economic and **the** creative prospects of billions of people around **the** world who currently are basically excluded from all of **the** opportunities which we have, which come from having abundant material and energy all around us. That ' s **the** real prize. FD : A world where we have had that exponential would be a world in which we have clean, cheap energy for all. KB : At **the** end of this decade, **the** International Energy Agency believes that we will have enough capacity to be producing 10 billion, 10 billion batteries a year. It ' s enough for every person on **the planet** to have their own battery. AC : I ' m constantly surrounded by young people just like me who are really, really, really passionate about **the** world that we live in. For obvious reasons. It ' s **the** world that we will inherit. EZ : Women are very important for **the** energy transition. So if we ' re talking about a world where we have, you know, where we tackle climate change, all I want to see is, you know, women in power. I want to see more solutions being driven by young people. And I want our politicians to be truly and meaningfully engaged in making change. NG : We always tend to underestimate **the** pace of ultimate adoption and change. Today, there are more than 150 pathways, scientific pathways that we could take to limit global warming. Al Gore : If we get to true net zero, astonishingly, global temperatures will stop going up with a lag time of as little as three to five years. Colin Averill : We ' ve been able to accelerate tree growth and **carbon** capture and tree stems by 30 to 70 percent. Dan Jørgensen : Offshore wind has **the** potential to cover **the** current electricity demand of **the** entire world not once, not twice, 18 times. NG : We need to decarbonize **the** old economy that we have and invest to create **the** new economy that we need Paul Hawken : Regenerative farming is fairly simple in concept. It means creating **the** conditions for more life. Josephine Phillips : We need to buy less stuff, and we need to look after what we buy. Valuing **the** things that we own is a climate solution. Vishaan Chakrabarti : We can all live in this transit-rich, carbon-negative, affordable way and leave **the** vast majority of **the planet** for nature, for **agriculture**, for clean oceans. We can do this. Susan Ruffo : **The** ocean is a powerful source of solutions that we ' ve overlooked for far too long. Al Roker : You have to be engaged. Let your elected officials know that this is important to you. You have to vote, you have to go out there and support politicians who are going to support our **planet**. Peggy Shepard : We can create a legacy of environmental quality and climate resilience for all. Fehinti Balogun : You are not powerless that **the**"oh, there ' s nothing we can do, just keep going"is symptom, not cure. But you are needed. Avinash Persaud : **The** power of what we can do when it matters to us is unlimited. CF : It ' s not that we ' re simply going to avoid **the** worst impacts of climate change. It ' s that we ' re going to improve **the** quality of life for humans, both in **the** urban and in **the** rural sector, and for non-humans.

Text Sample 64: POS Dim 1 – 2023 – Score 19.00 – 2023/t003440.txt

The most important question these days is how can we speed up **the** solutions to **the** climate crisis? I ' m convinced we are going to solve **the** climate crisis.

We ’ ve got this. But **the** question remains, will we solve it in time? Others have said we ’ re kind of in a race. I ’ ll give you **the the** shortest definition of **the** problem. If I was going to give a one-slide **slide** show, it would be this **slide**. That ’ s **the** troposphere, **the** lowest part of **the** atmosphere. And you already know why it ’ s **blue**. That ’ s **the** oxygen that refracts **the blue** light. And if you could drive a car at **highway** speed straight up in **the** air, you ’ d get to **the** top of that **blue** line in about five to seven minutes. You could walk it in an hour. And all of **the greenhouse** gas pollution is below you. That ’ s what we ’ re using as an open sewer. That ’ s **the** problem. And it ’ s causing a lot of second and third order consequences. And we saw some of them in **the** northern-tier cities, including Detroit. This one ’ s from New York City, all **the** fires in Canada. And we have gotten used to **the** fact that **the** world suffers deep **droughts** and huge rain bombs and downpours and floods simultaneously. **The** really ingenious new gravity-measuring satellite has given us, for **the** first time, **the** opportunity to see how this plays out worldwide. We get these huge surpluses of water, **the** rain bombs and **the drought** simultaneously. And as you can see, **the** amplitude is increasing. And at both ends of our **planet** right now, we ’ re seeing signs of distress. Of course, you know, I ’ ve often said, every night on **the** TV news is like a nature hike through **the** Book of Revelation. And just today, big flooding in Montpelier, Vermont, in southern Japan, in India. And I haven ’ t done a complete scan, but every single day, it ’ s like that. But in Antarctica, some scientists who are normally pretty levelheaded are getting a little bit freaked out, I would say, is a fair definition, about **the** lowest level ever, at this point in **the** year, of **sea** ice. And at **the** other pole, in **the** North Atlantic, we ’ re seeing literally off-the-charts temperatures. So obviously, **the** crisis has to be addressed. And **the** good news is, as others have often said, we are seeing tremendous progress. And it starts with **the** Inflation Reduction Act here in **the** United States. President Biden, **the** Congress, they have passed **the** best, biggest climate legislation in all of history, and it ’ s said to be 369 billion. But **the** heavy lifting is done by tax credits, and most of them are open-ended. And **the** early applications already show it ’ s going to be well over a trillion dollars, maybe 1. 2 trillion. So this is really good news. And one month after that passed, Australia changed its government and started changing its laws. And it ’ s now a pro-climate nation. A month after that, Brazil did **the** same thing, new president, new policies protecting **the** Amazon. And throughout, **the** European Union has resisted **the** efforts of Russia to blackmail it into supporting its sadistic and cruel invasion of Ukraine. And there are other signs of success as well. China ’ s reached its renewables target five years ahead of time. It ’ s still building a lot of **coal**, but only 50 percent capacity utilization. So there is lots of good news. But still, in spite of this progress, **the emissions** are still going up. And **the** crisis is still getting worse faster than we are deploying **the** solutions. So maybe it ’ s time to look at **the** obstacles that are standing in our way. I ’ m going to focus on two of them this afternoon. First of all, **the** unrelenting opposition from **the fossil** fuel industry. A lot of people think they ’ re on side and trying to help. But let me tell you, and **the** activists will all tell you this, every piece of legislation, whether it ’ s at **the** municipal level, **the** regional or provincial level, **the** national level or **the** international level, they ’ re in there with their lobbyists and with their fixers and with their revolving-door colleagues doing everything they can to slow down progress. So speeding up progress means doing something about this. They have used fraud on a massive scale. They ’ ve used falsehoods on an industrial scale. And they ’ ve used their legacy political and economic networks, lavishly funded, to capture **the** policy-making process in too many countries around **the** world. And **the** [UN] Secretary General said **the fossil** fuel industry is **the** polluted heart of **the** climate crisis. Now, that ’ s not to say that **the** men and women who ’ ve worked in **fossil** fuel for **the** last century and a half are not due our gratitude. They are, and they didn ’ t cause this. But for decades now, **the** companies have had **the** evidence. They know **the** truth, and they consciously decided to lie to publics all around **the** world in order to calm down **the** political momentum for doing something about it so they can make more money. It ’ s simple as that. And now they have brazenly seized control of **the** COP process, especially this year ’ s COP in Dubai in **the** United Arab Emirates. And concern has been building about this for quite some time. I remember when there were so many **fossil** fuel delegates in Madrid, but by **the** time we got to Glasgow a year and a half ago, **the** delegates from **the fossil** fuel companies made up a larger group than **the** largest national delegation. And why? Why? Because they ’ re helping? They ’ re not helping, they ’ re trying to stop progress. And last year in Egypt, they had more delegates than **the** combined delegations of **the** ten most affected countries by climate. And now this year ’ s host, which is a petro state, has appointed **the** president of COP28, in spite of **the** fact that he has a blatant conflict of interest, he ’ s **the** CEO of **the** Abu Dhabi National Oil Company owned by Abu Dhabi. Their **emissions** are larger than those of ExxonMobil, and they have no credible plan whatsoever to reduce them. So this is **the** person in charge of **the** COP. He ’ s a nice guy. He ’ s a smart guy. But a conflict of interest is a conflict of interest. And a matter of fact, they have a plan now to have a new increase in their **emissions**. Their plan is to increase **the** production of both **oil** and gas by as much as 50 percent by 2030. Which is **the** same time frame when **the** world is trying to reduce **emissions**, by 50 percent by 2030. And **the** same person has been put in charge of both of those efforts. Direct conflict of interest. I think it ’ s time to say, wait a minute, do you take us for fools? Do you think you can just completely remove **the** disguise and we won ’ t notice? **The fossil** fuel industry has captured this process and is slowing it down. And we need to do something about it. Now, they plan to increase their **emissions** – Getting all hot and bothered here. **The** head of **the** International Energy Agency was talking about several **oil** companies who have publicly pledged to increase their **oil** and gas and simultaneously pledged to comply with **the** Paris Agreement. Do you take us for fools? You cannot do both of those things simultaneously. And if you think we believe you when you say that, we beg to differ. Last year at **the** COP, **the fossil** fuel petro states vetoed any mention of phasing down **fossil** fuels. They say, oh, that ’ s not **the** problem. One of **the** secretary of state equivalent in Saudi Arabia said, we don ’ t see this as a discussion about **fossil** fuels. Let me tell you, **the** climate crisis is a **fossil** fuel crisis. **The** solutions are going to come from a discussion and collaboration about phasing out **fossil** fuels. And there ’ s only so much longer they can hold this up and tie us down and keep us from doing **the** right thing. Now **the** director general of this year ’ s COP, working under Sultan Al Jaber, he worked for ADNOC also, he was seconded for several years to ExxonMobil. He said, no, that ’ s all changed. This year, they ’ ve changed. **The fossil** fuel companies are really engaging us. They have changed. Yes, they have changed. They ’ ve changed for **the** worse this year. You don ’ t believe me? Look at this, BP. They said,”We ’ re going to net zero, there ’ s no turning back.”A few months ago this year, they turned back and they decided to roll back their investments. ExxonMobil. Oh, my God. This is minor compared to their industrial-scale lying, you know. But they ’ ve had all **the** TV ads on, particularly in **the** US, about revolutionizing biofuels.”You wouldn ’ t believe what algae can do.”Well, for 14 years they ran this program. And they spent 50 percent as much on **the** ads about **the** program as they did on actually trying to come up with new biofuels. And then a couple of months ago, they said,”Oh, we ’ ve changed our mind. We ’ re just going to cancel that program.”**The** industry as a whole has not been acting in good faith. Shell reversed its commitment to increase their investments in **fossil** fuels. They announced just a couple of months ago they ’ re going to plow that money into expanding **oil** and gas production instead. So did they miss **the** memo? Well, no, they say they ’ ve discovered a way out. They ’ re telling us now that **the** problem is not **fossil** fuels. It ’ s **the emissions** from **fossil** fuels. And so all we have to do is to capture **the emissions** from **the fossil** fuels. Now, I ’ m all for research and development into trying to capture **emissions** or sucking it out of **the** air if they want to do that. But let ’ s don ’ t pretend it ’ s for real. Maybe someday it will be. Maybe someday it will be. This is **the** head of ExxonMobil saying,”Not **oil** and gas, it ’ s **the emissions**.”And Abu Dhabi, they have said they ’ ve already decreased their **emissions** from producing **oil** and gas, 99. 2 percent. **The** point two makes it sound even more authoritative. Is that feasible? Have they really done that? Is their **carbon** capture technology that ’ s that good? Well, Climate TRACE can measure. Now, let ’ s just look. There ’ s their CCS capability. Oh, but they ’ ve got a great improvement in **the** work. Seven years from now, they ’ re going to have a 500 percent increase in their capacity. But here are **the emissions** from **oil** and gas production alone. And here are **the emissions** of **greenhouse** gases from Abu Dhabi, from **the** UAE. Now, **the** pathetic little sliver there compared to **the** reality, again, do they think we don ’ t see what they ’ re doing, don ’ t understand what they ’ re doing? A lot of people maybe just want to look away from it. Pretty ironic here in this country. You know, **the** coal-burning utilities have been given a new mandate this year by **the** EPA. You ’ ve got to clean up your act. Now, you can keep on burning **coal** and you can keep on producing electricity with it if you use **carbon** capture and sequestration. Well, they scream bloody murder. Another story about it this morning, but they say, that technology? That ’ s not feasible. It ’ s not technically feasible, not economically feasible. So they need to get their story straight, in my opinion. So **the** technology of CCS has been around for a long time, 50 years, and we get used to technologies automatically getting cheaper and better, you know, with **the computer** chips and **the** cell phones and all that. Well, University of Oxford did a whole study, and some come down in cost fast, some slow. A few are in a category called non-improving technologies. And that ’ s where **carbon** capture and storage is. 50 years, not any price decline. Well, could we get a breakthrough in spite of that? Maybe. We ’ re throwing a lot of money at it. We had to do that to get **the** compromise that passed **the** IRA, and we ought to continue **the** research. But again, let ’ s don ’ t pretend that it ’ s here. It ’ s not here now. And to use it as an excuse, and now they ’ ve got another one. Now it ’ s called direct air capture. These are giant vacuum cleaners that use an awful lot of energy. It ’ s technically feasible, but it ’ s extremely expensive. And it also uses so much energy. But it is tremendously useful. You know what it ’ s used for? **The** CEO of one of **the** largest **oil** companies in **the** US had told us what it ’ s useful for. It ’ s useful to give them an excuse for not ever stopping **oil**. A few months later, she said,”This gives us, this new technology, a license to continue operating.”Some people call that a moral hazard. For them, **the** moral hazard is not a bug, it ’ s a feature, as **the** old saying goes. And so let ’ s just look, this is state-of-the-art. It looks pretty impressive, doesn ’ t it? This is **the** backside of one of these machines. I had **the** same thought. Now this, they ’ re improving this. They ’ re improving this. And **the** new model, seven years from now, each of these machines is going to be able to capture 27 seconds ’ worth of annual **emissions**. Woohoo. That gives them a license to continue producing more and more **oil** and gas. Or so they claim. Well, they also say, **the** experts, that in order to be economically feasible, it has to come in at 100 dollars a ton or less. **The** leading company says that 27 years from now, it may come down below three times that amount. So again, if this sounds kind of incredible, it is not credible. But they ' re using it in order to gaslight us, literally. But I didn ' t mean it as a pun, but that ' s what they ' re using it to do. And we can ' t fall for it. **The** biggest obstacle to direct air capture is probably physics. And what I mean by that, they ' ve explained this to me. CO2 makes up 0. 035 percent of **the** air so we ' re going to vacuum **the** other 99. 96 percent to get that little bit out. Come on, really? Come on. And it doesn ' t even pretend to catch **the** methane or **the** soot or **the** mercury or **the** particulate pollution that kills 9 million people a year around **the** world. And that ' s why **the** climate justice advocates are so down on this kind of nonsense. They say, here ' s one of them says, look, we need to fight climate change, but don ' t do it by pretending to do it and continue dumping all this pollution on **the** front line communities that are downwind from **the** smokestacks. And that ' s why they have not ever really liked **the carbon** capture. And what about all **the** energy that ' s needed? Is it going to come from more **fossil** fuels? Well, in case of Occidental, yes. But could it come from more solar and wind? Well, if so, why not use **the** solar and wind to replace **the fossil** fuel-burning plants that are putting all that stuff up there in **the** first place? Doesn ' t that make sense? Am I missing something? Anyway, this is **the** environmental justice advocate who is making **the** point that you can ' t do it without protecting those who are victimized downwind from **the** smokestacks, downstream from **the** pollution. Now, some of **the** companies, of course, you say we ' re going to offset our **emissions**. And again, offsets can play a role, a small role, five to 10 percent according to **the** Science Based Targets initiative, **the** most authoritative source on all of this. But, you know, Chevron just had its offsets analyzed. It turned out 93 percent of them were worthless and junk. And that ' s too often **the** case. It ' s not a get-out-of-jail-free card. And their offsets were only aimed at 10 percent of their **emissions** in **the** first place. Eighty percent of **the fossil** fuel companies just completely ignore **the** Scope Three **emissions**, which is **the** main part of their pollution problem. So they say that they have increased by 400 percent **the** share of their spending on energy that goes to green technologies and **carbon** capture. And yes, they have, they ' ve increased it all **the** way up to four percent. And it ' s not even as good as that, because if you look at **the** windfall profits they ' ve been getting, what have they done with that? Well, they gave it back to **the** shareholders through dividends and stock buybacks. So **the** amount of money **the fossil** fuel industry is investing in renewables and **carbon** capture is one percent. Does that mean they are sincere actors, working in good faith? I don ' t think so. A lot of people still think so. They think they ' re on our side. I don ' t think it ' s in their nature to be on our side. I think they ' re driven by incentives that push them in **the** opposite direction. But in any case, they produce no solutions whatsoever that are scalable or remotely feasible. And again, they have actively fought against **the** solutions that others have been trying to bring. I ' ve seen it personally. Many of you have seen it personally. And it ' s happening all over **the** world. No progress. They ' ve even gone **backwards**. Now, if a company says, look, we shouldn ' t be excluded from **the** COP process, we know a lot about energy. Here ' s a simple test. Do they actually have, does **the** company have real net-zero commitments, a genuine phase-down plan, yes or no? Are they committed to full disclosure? Yes or no? Are they going to spend windfall profits on **the** transition? Yes or no? Are they committed to transparency? Will they end their anti-climate lobbying? Will they end their greenwashing? Will they be in favor of reforming **the** COP process so that **the** petro states don ' t have an absolute veto on anything **the** world wants to discuss or act on? We ' ve got to change that. In order to move faster, we have got to empower **the** global community in a way that frees them from **the** hammerlock that **the fossil** fuel companies have on them today. And any company that doesn ’ t pass this test, I ’ m telling you, ought to be prohibited from taking part in **the** COP process. What about **the** company that ’ s led by **the** president of this year ’ s COP, **the** Abu Dhabi National Oil Company? Well, it ’ s rated one of **the** least responsible of all **the oil** and gas companies. It no longer even releases information on any of its **emissions**, has no transition plan, no short or mid-term target scores, a pathetic three on 100-scale on their transition plans. And **the** nation ’ s plan is rated highly insufficient. They just put out a new one, it ’ s still insufficient. So that ’ s **the** first obstacle. Second one ’ s a lot clearer. This one has to be removed in order to get to **the** faster solutions. But in order to remove it, we ’ ve got to do something about **the** second obstacle, and that is **the** financial system, **the** global allocation of capital and **the** subsidies for **fossil** fuels. Governments last year around **the** world subsidized with taxpayer money more than a trillion dollars, subsidizing **fossil** fuels. That ’ s five times larger than **the** amount in 2020. Are we going in **the** right direction or **the** wrong direction? Well, there are a lot of good things I ’ ll show you, but this has to stop. And **the** 60 largest global banks have put 5. 5 trillion extra dollars into **the fossil** fuel companies since **the** Paris agreement. And preposterously, 49 of them have also signed net-zero pledges. So we... Global allocation of capital. **The** borrowing of private capital is ruled out for many developing countries. Nigeria has to pay an interest rate seven times higher than Europe or **the** US. Political risk, corruption risk, currency risk, off-take risk, it ’ s rule of law risk. That ’ s why **the** World Bank and **the** other multilateral development banks are supposed to take those top layers of risk off. And that ’ s why we need reform in **the** World Bank. Thank goodness so many fought to get a new head of **the** World Bank, and I ’ m very excited about his progress. Now, when these obstacles are removed, we can really accelerate progress. They ’ ll still be problems, of course, but we have everything we need and proven deployment models to reduce **emissions** 50 percent in **the** next seven years. But we will still need better grids, more resilient grids, more solar and wind, much more regenerative **agriculture**. That ’ s a way to really pull **carbon** out of **the** air. More electric vehicles and charging stations and more energy storage. I ’ ll show you that just before we quit here. And more green hydrogen, so more electrolyzers to produce it. And these are all surmountable obstacles. Already, renewables account for 90 percent of all **the** new electricity generation being installed each year worldwide. Ninety-three percent solar and wind in India last year. And of course, **the** solar ’ s taking off and so is wind and so are **the** electric vehicles and battery storage. It has grown so dramatically. You ’ ve got to rescale **the** graph to look at **the** trillion-dollar industry emerging. Now, just seven years ago, there was one gigafactory. I learned from one of you at a session a couple of hours ago and had my staff research it, there are now 195 gigafactories and another 300 in **the** pipeline. So will we succeed? Some people fight with a vulnerability to despair. You know, **the** old cliche,”denial ain ’ t just a river in Egypt.”Despair ain ’ t just a tire in **the** trunk. There are people that are vulnerable. But let me close with what I regard as amazingly good news. What if we could stop **the** increase in temperatures? Well, if you look at **the** temperature increases, if we get to true net-zero, astonishingly, global temperatures will stop going up with a lag time of as little as three to five years. They used to think that positive feedback loops would keep that process going. No, it will not. **The** temperatures will stop going up. **The** ice will continue melting and some other things will continue, but we can stop **the** increase of temperatures. Even better, if we stay at true net zero, in as little as 30 years, half of all **the** human-caused

CO_2 will come out of **the** atmosphere into **the** upper ocean and **the** trees and vegetation. So young people are demanding that we do **the** right thing. Do not be vulnerable to despair. We are going to do this. And if you doubt that we, as human beings have **the** will to act, please always remember that **the** will to act is itself a **renewable** resource. Thank you very much. Thank you.

Text Sample 65: POS Dim 1 – 2023 – Score 18.00 – 2023/t003429.txt

Twenty-five hundred years ago, Heraclitus said,”**The** world bubbles forth.”Here ’ s bubbling. What is actual now enables what is next possible, **the** adjacent possible. **The** biosphere has been bubbling forth for four billion years, creating new possibilities in **the universe** in that bubbling. It ’ s critical that physics cannot talk at all about bubbling new bubbles. Life on Earth started four billion years ago. For **the** first 2. 5 billion years were single-celled organisms co-evolving. Even by existing, organisms create new possibilities. If I ’ m a bacterium and you ’ re a bacterium and I have a flat **surface**, I ’ m a possible **highway** you can walk over to get food. That ’ s bubbling forth. So 2. 5 billion years after life started, six times multicell organisms emerged. A billion years after that, 3. 5 billion years after life started, is **the** extraordinary Cambrian **explosion**. 540 million years ago, for 50 million years, there was just this burst of creativity, making all of **the** phyla that exist now. And now we have this guy. I ’ m scared of having him in bed, I really am. So I don ’ t know what to call him. It ’ s a vote afterwards. So here ’ s a gentler guy and I ’ m in love with him. Look at his eyes looking at you, you know.”You ’ re doing what?”In order to talk about how **the** biosphere has been creative, I have to talk about **the** functions of parts of an organ. You all know your heart keeps you alive, but in particular, your heart pumps **blood**. It ’ s not by making heart sounds. So this means something fundamental. **The** function of a part is that subset of its causal properties that sustain **the** whole. Your heart pumping **blood** and you. But doing that is jury-rigging, finding subsets of causal features of use. Some years ago, my daughter dropped her purse in a shallow well. I took a wire coat hanger, **slid** it over a mop handle, and I **fished** out her purse. Anything can be used for more than one thing. For example, a screwdriver can be used to screw in a screw, but it ’ s great for scraping putty off **the** wall. An engine block can have eight holes drilled and you make an engine out of it. It ’ s actually a superb paperweight, and much research done only by scientists demonstrates that **the** corners are sharp and can crack open a coconut. I was very proud of that. So. But if you ’ re using an engine block as a paperweight, can you deduce, oh, I can use this thing to crack open coconuts. You can ’ t. It might be a banana peel. But that means also something fundamental. Finding new uses for things, jury-rigging is not a computation. It ’ s not a deduction. Jury-rigging is not a computation at all. **Computers** are. **The** biosphere is forever innovating in this kind of way that ’ s not a deduction. For example, there are things called Darwinian preadaptations. Dinosaurs had scales that were **evolved** for thermoregulation that were jury-rigged into flight feathers. Your eyes have clear crystallins that were perfectly normal-colored enzymes. And this, too, means something fundamental. We cannot deduce what is in **the** adjacent possible that **the evolving** biosphere will create, then become. We do not even know what can happen. In fact, we can use no mathematics based on set theory, which is all of mathematics, to deduce what **the** biosphere is going to become, or **the** economy. This means we are at a **fantastic** third-phase transition in science, we ’ re beyond Newton, we ’ re beyond quantum mechanics. We ’ re beyond **the** exquisite view that Copernicus had 480 years ago, that **the** world is a clockwork. **The** biosphere is not a clockwork. **The** paper that just published, it came out three days ago, and I ’ m pretty proud of it, it ’ s actually worth reading. We can ’ t deduce what is in **the** biosphere and will become, but we can make a mathematical theory of **the** statistics of **the** process. I call it **the** Theory of **the** Adjacent Possible or TAP. It ’ s really based on one idea. Things can be combined to make new things. So there is **the** equation. Mt is **the** number of things in **the** economy at some time now, say 10 things. So how many things will be in **the** economy in **the** next period? Well, if **the** 10 things work, we ’ ll keep them, but we could actually try to jury-rig something new out of any single thing among **the** 10 or out of pair of things among **the** 10. **The** printing press is a recombination between movable type and a wine press or any three things or four things. Watch what happens to **the** number of things, pairs of things, when **the** number of things goes up. If there ’ s 10 things, there ’ s 45 pairs of things that we might fiddle with. If there ’ s 100 things, there ’ s 4, 500 things we might jury-rig with. And if there ’ s 1, 000 things, there ’ s a half a million things we might fiddle with. Therefore, this process, **the** TAP process, has **the** property that for a long time **the** number of things increases very, very, very slowly, then something **stunning** happens. There ’ s a hockey-stick **explosion** and **the** number of things reaches infinity in a finite time. There ’ s a singularity and a brief burst **explosion** for 40 million years of **the** Cambrian **explosion**. **The** same pattern is showing up in our own **evolution**. Australopithecus flourished – I ’ d never know what flourishing means, I guess they had a good lunch – in Africa, 3. 3 million years ago. A million and a half years later, Homo erectus had about 20 **crude** stone tools. Watch how slowly things change. A mere 30, 000 years ago, Cro-Magnon in **the** south of France had about 100 or 150 of these exquisite pressure flake tools. A mere 28, 000 years after that is Mesopotamia with needles and chariots. There ’ s something interesting about **the** fact – of course, we invented writing, which is a wonderful story – once you have a clay tablet, it calls forth **the** tool that ’ s its complement. You need a stylus. So tools make niches for new tools and for new jobs. Scribes earned a living for quite a while. This is us in **the** late Middle Ages to now, and this is us now. We have billions of tools ranging from knitting needles to **the** space station. There ’ s always an adjacent possible. Once you ’ ve made a bow, a crossbow is in **the** adjacent possible. **The** pattern that we saw in **the** Cambrian, of a long period nothing happening and then a burst, is here right now. This is **the** size of human **habitats** in **the** last 300, 000 years. **The horizontal** line is time before present, and **the** vertical line as **the** logarithm of sizes of settlements. Nothing happened for 290, 000 years then it burst upward. Watch this, **the** same thing is true of GDP. GDP was flat since **the** time of Christ. In fact, for **the** last 100, 000 years. GDP burst up in **the** last two centuries. It ’ s going up vertically now. It ’ s wonderful. We ’ re lifting millions from poverty. And **the** theory explains it. It ’ s **the** same delay and burst, and there it is. We start making more complex things, selling them, and we make a profit. There ’ s another feature of all of this that I ’ ve lived in my lifetime, I ’ m 83. I was born in 1939. Just like **the** Cambrian **explosion**, watch **the** number of things that have come into existence in my lifetime. We didn ’ t have any helicopters, we didn ’ t have television. I listened to”**The** Lone Ranger,”which maybe you know, on radio, six o ’ clock at night. We didn ’ t have... **computers**, we didn ’ t have plastics, which are now all over **the planet**. We didn ’ t have microwaves, we didn ’ t have lasers. Look at **the** number of things that came into existence in one lifetime of 83 years. Not much happened 50, 000 years ago in 83 years. So what ’ s going on? **The** TAP process has **the** following property. Every time you make something new, **the** waiting time for **the** next new thing is cut in half. A thousand years, 500 years, 250, a year, six months, three months, we ’ re going to get a great acceleration. We are. So this is TAP. And watch that thing explode upward. That ’ s it. That **explosion** is **the** Cambrian, and it ’ s where we are now. And **the** signatures of **the** Anthropocene are exploding upward, now all over **the** place. This ends 25 years ago. We need to find a better adjacent possible. We ’ re rampaging over **the planet**, and **the** hope is in soils. So I ’ m going to talk briefly about compost. There are very fine compost, this is now terribly important. A very good compost is **the** Johnson-Su compost. Less land use, fewer degradations of... of our forests, fewer extinction events, fewer pandemics. Well, let ’ s get rid of fertilizer. And **the** most important point I ’ m going to take is – This is really bad news and good news. Last year we emitted 40. 5 billion tons of **carbon** dioxide. We have to find a way of solving it, and we can. We can take this Johnson-Su compost and get it out across **the** landscape. But more fundamentally, we can find good fungal bacterial communities and we can coat seeds with it and sell **the** seeds around **the planet**, or we can fill biochar and we can use biochar to get her across **the planet**. Most usefully, we can take a really good fungal bacterial community, put it into biochar or some other matrix, mix it into fertilizer, and get that fertilizer out across **the planet**. I ’ m going to just end with **the** following. Fungal bacterial communities are precisely something that can create novel adjacent possibles, that can bubble forth with solutions to soil problems. **The** good news is we can do it now. **The planet** ’ s on fire. We are of nature, ladies and gentlemen, we ’ re not above nature. Thank you.

I ’ d like to introduce you to a tiny microorganism that you ’ ve probably never heard of : its name is Prochlorococcus, and it ’ s really an amazing little being. For one thing, its ancestors changed **the** earth in ways that made it possible for us to **evolve**, and hidden in its genetic code is a blueprint that may inspire ways to reduce our dependency on **fossil** fuel. But **the** most amazing thing is that there are three billion billion billion of these tiny cells on **the planet**, and we didn ’ t know they existed until 35 years ago. So to tell you their story, I need to first take you way back, four billion years ago, when **the** earth might have looked something like this. There was no life on **the planet**, there was no oxygen in **the** atmosphere. So what happened to change that **planet** into **the** one we **enjoy** today, teeming with life, teeming with plants and animals? Well, in a word, photosynthesis. About two and a half billion years ago, some of these ancient ancestors of Prochlorococcus **evolved** so that they could use solar energy and absorb it and split water into its component parts of oxygen and hydrogen. And they used **the** chemical energy produced to draw CO2, **carbon** dioxide, out of **the** atmosphere and use it to build sugars and proteins and amino acids, all **the** things that life is made of. And as they **evolved** and grew more and more over millions and millions of years, that oxygen accumulated in **the** atmosphere. Until about 500 million years ago, there was enough in **the** atmosphere that larger organisms could **evolve**. There was an **explosion** of life- forms, and, ultimately, we appeared on **the** scene. While that was going on, some of those ancient photosynthesizers died and were compressed and buried, and became **fossil** fuel with sunlight buried in their **carbon** bonds. They ’ re basically buried sunlight in **the** form of **coal** and **oil**. Today ’ s photosynthesizers, their engines are descended from those ancient microbes, and they feed basically all of life on earth. Your heart is beating using **the** solar energy that some plant processed for you, and **the** stuff your body is made out of is made out of CO2 that some plant processed for you. Basically, we ’ re all made out of sunlight and **carbon** dioxide. Fundamentally, we ' re just hot air. So as terrestrial beings, we ' re very familiar with **the** plants on land : **the** trees, **the** grasses, **the** pastures, **the** crops. But **the** oceans are filled with billions of tons of animals. Do you ever wonder what ' s feeding them? Well there ' s an invisible pasture of microscopic photosynthesizers called phytoplankton that fill **the** upper 200 meters of **the** ocean, and they feed **the** entire open ocean ecosystem. Some of **the** animals live among them and eat them, and others swim up to feed on them at night, while others sit in **the** deep and wait for them to die and settle down and then they chow down on them. So these tiny phytoplankton, collectively, weigh less than one percent of all **the** plants on land, but annually they photosynthesize as much as all of **the** plants on land, including **the** Amazon rainforest that we consider **the** lungs of **the** **planet**. Every year, they fix 50 billion tons of **carbon** in **the** form of **carbon** dioxide into their bodies that feeds **the** ocean ecosystem. How does this tiny amount of biomass produce as much as all **the** plants on land? Well, they don ' t have trunks and stems and flowers and fruits and all that to maintain. All they have to do is grow and divide and grow and divide. They ' re really lean little photosynthesis machines. They really crank. So there are thousands of different species of phytoplankton, come in all different shapes and sizes, all roughly less than **the width** of a human hair. Here, I ' m showing you some of **the** more beautiful ones, **the textbook** versions. I call them **the** charismatic species of phytoplankton. And here is Prochlorococcus. I know, it just looks like a bunch of schmutz on a microscope **slide**. But they ' re in there, and I ' m going to reveal them to you in a minute. But first I want to tell you how they were discovered. About 38 years ago, we were playing around with a technology in my lab called flow cytometry that was developed for biomedical research for studying cells like cancer cells, but it turns out we were using it for this off-label purpose which was to study phytoplankton, and it was beautifully suited to do that. And here ' s how it works : so you inject a sample in this tiny little capillary tube, and **the** cells go single file by a laser, and as they do, they scatter light according to their size and they emit light according to whatever pigments they might have, whether they ' re natural or whether you stain them. And **the** chlorophyl of phytoplankton, which is green, emits red light when you shine **blue** light on it. And so we used this instrument for several years to study our phytoplankton cultures, species like those charismatic ones that I showed you, just studying their basic cell **biology**. But all that time, we thought, well wouldn ' t it be really cool if we could take an instrument like this out on a ship and just squirt seawater through it and see what all those diversity of phytoplankton would look like. So I managed to get my hands on what we call a big rig in flow cytometry, a large, powerful laser with a money-back guarantee from **the** company that if it didn ' t work on a ship, they would take it back. And so a young scientist that I was working with at **the** time, Rob Olson, was able to take this thing apart, put it on a ship, put it back together and take it off to **sea**. And it worked like a charm. We didn ' t think it would, because we thought **the** ship ' s vibrations would get in **the** way of **the** focusing of **the** laser, but it really worked like a charm. And so we mapped **the** phytoplankton distributions across **the** ocean. For **the** first time, you could look at them one cell at a time in real time and see what was going on — that was very exciting. But one day, Rob noticed some faint signals coming out of **the** instrument that we dismissed as electronic noise for probably a year before we realized that it wasn ' t really behaving like noise. It had some regular patterns to it. To make a long story short, it was tiny, tiny little cells, less than one-one hundredth **the** **width** of a human hair that contain chlorophyl. That was Prochlorococcus. So remember this **slide** that I showed you? If you shine **blue** light on that same sample, this is what you see : two tiny little red light-emitting cells. Those are Prochlorococcus. They are **the** smallest and most abundant photosynthetic cell on **the planet**. At first, we didn ’ t know what they were, so we called **the**”little greens.”It was a very affectionate name for them. Ultimately, we knew enough about them to give them **the** name Prochlorococcus, which means”primitive green berry.”And it was about that time that I became so smitten by these little cells that I redirected my entire lab to study them and nothing else, and my loyalty to them has really paid off. They ’ ve given me a tremendous amount, including bringing me here. So over **the** years, we and others, many others, have studied Prochlorococcus across **the** oceans and found that they ’ re very abundant over wide, wide ranges in **the** open ocean ecosystem. They ’ re particularly abundant in what are called **the** open ocean gyres. These are sometimes referred to as **the** deserts of **the** oceans, but they ’ re not deserts at all. Their deep **blue** water is teeming with a hundred million Prochlorococcus cells per liter. If you crowd them together like we do in our cultures, you can see their beautiful green chlorophyl. One of those test tubes has a billion Prochlorococcus in it, and as I told you earlier, there are three billion billion billion of them on **the planet**. That ’ s three octillion, if you care to convert. And collectively, they weigh more than **the** human population and they photosynthesize as much as all of **the** crops on land. They ’ re incredibly important in **the** global ocean. So over **the** years, as we were studying them and found how abundant they were, we thought, hmm, this is really strange. How can a single species be so abundant across so many different **habitats**? And as we isolated more into culture, we learned that they are different ecotypes. There are some that are adapted to **the** high-light intensities in **the surface** water, and there are some that are adapted to **the** low light in **the** deep ocean. In fact, those cells that live in **the** bottom of **the** sunlit zone are **the** most efficient photosynthesizers of any known cell. And then we learned that there are some strains that grow optimally along **the** equator, where there are higher temperatures, and some that do better at **the** cooler temperatures as you go north and south. So as we studied these more and more and kept finding more and more diversity, we thought, oh my God, how diverse are these things? And about that time, it became possible to sequence their **genomes** and really look under **the** hood and look at their genetic makeup. And we ’ ve been able to sequence **the genomes** of cultures that we have, but also recently, using flow cytometry, we can isolate individual cells from **the** wild and sequence their individual **genomes**, and now we ’ ve sequenced hundreds of Prochlorococcus. And although each cell has roughly 2, 000 genes — that ’ s one tenth **the** size of **the** human **genome** — as you sequence more and more, you find that they only have a thousand of those in common and **the** other thousand for each individual strain is drawn from an enormous gene pool, and it reflects **the** particular environment that **the** cell might have thrived in, not just high or low light or high or low temperature, but whether there are nutrients that limit them like nitrogen, phosphorus or **iron**. It reflects **the habitat** that they come from. Think of it this way. If each cell is a **smartphone** and **the** apps are **the** genes, when you get your **smartphone**, it comes with these built-in apps. Those are **the** ones that you can ’ t delete if you ’ re an iPhone person. You press on them and they don ’ t jiggle and they don ’ t have x ’ s. Even if you don ’ t want them, you can ’ t get rid of them. Those are like **the** core genes of Prochlorococcus. They ’ re **the** essence of **the** phone. But you have a huge pool of apps to draw upon to make your phone custom- designed for your particular lifestyle and **habitat**. If you travel a lot, you ’ ll have a lot of travel apps, if you ’ re into financial things, you might have a lot of financial apps, or if you ’ re like me, you probably have a lot of weather apps, hoping one of them will tell you what you want to hear. And I ’ ve learned **the** last couple days in Vancouver that you don ’ t need a weather app — you just need an umbrella. So — So just as your **smartphone** tells us something about how you live your life, your lifestyle, reading **the genome** of a Prochlorococcus cell tells us what **the** pressures are in its environment. It ’ s like reading its diary, not only telling us how it got through its day or its week, but even its **evolutionary** history. As we studied — I said we ’ ve sequenced hundreds of these cells, and we can now project what is **the** total genetic size — gene pool — of **the** Prochlorococcus federation, as we call it. It ’ s like a superorganism. And it turns out that projections are that **the** collective has 80, 000 genes. That ’ s four times **the** size of **the** human **genome**. And it ’ s that diversity of gene pools that makes it possible for them to dominate these large regions of **the** oceans and maintain their stability year in and year out. So when I daydream about Prochlorococcus, which I probably do more than is healthy — I imagine them floating out there, doing their job, maintaining **the planet**, feeding **the** animals. But also I inevitably end up thinking about what a masterpiece they are, finely tuned by millions of years of **evolution**. With 2, 000 genes, they can do what all of our human ingenuity has not figured out how to do yet. They can take solar energy, CO2 and turn it into chemical energy in **the** form of **organic carbon**, locking that sunlight in those **carbon** bonds. If we could figure out exactly how they do this, it could inspire designs that could reduce our dependency on **fossil** fuels, which brings my story full circle. **The fossil** fuels that are buried that we ’ re burning took millions of years for **the** earth to bury those, including those ancestors of Prochlorococcus, and we ’ re burning that now in **the** blink of an eye on geological timescales. **Carbon** dioxide is increasing in **the** atmosphere. It ’ s a **greenhouse** gas. **The** oceans are starting to warm. So **the** question is, what is that going to do for my Prochlorococcus? And I ’ m sure you ’ re expecting me to say that my beloved microbes are doomed, but in fact they ’ re not. Projections are that their populations will expand as **the** ocean warms to 30 percent larger by **the** year 2100. Does that make me happy? Well, it makes me happy for Prochlorococcus of course — but not for **the planet**. There are winners and losers in this global experiment that we ’ ve **undertaken**, and it ’ s projected that among **the** losers will be some of those larger phytoplankton, those charismatic ones which are expected to be reduced in numbers, and they ’ re **the** ones that feed **the** zooplankton that feed **the fish** that we like to harvest. So Prochlorococcus has been my muse for **the** past 35 years, but there are legions of other microbes out there maintaining our **planet** for us. They ’ re out there ready and waiting for us to find them so they can tell their stories, too. Thank you.

Text Sample 67: POS Dim 1 – 2018 – Score 17.00 – 2018/t000713.txt

After 13. 8 billion years of cosmic history, our **universe** has woken up and become aware of itself. From a small **blue planet**, tiny, conscious parts of our **universe** have begun gazing out into **the** cosmos with telescopes, discovering something humbling. We ’ ve discovered that our **universe** is vastly grander than our ancestors imagined and that life seems to be an almost imperceptibly small perturbation on an otherwise dead **universe**. But we ’ ve also discovered something inspiring, which is that **the** technology we ’ re developing has **the** potential to help life flourish like never before, not just for centuries but for billions of years, and not just on earth but throughout much of this amazing cosmos. I think of **the** earliest life as”Life 1. 0”because it was really dumb, like bacteria, unable to learn anything during its lifetime. I think of us humans as”Life 2. 0”because we can learn, which we in nerdy, **geek** speak, might think of as installing new software into our brains, like languages and job skills.”Life 3. 0,”which can design not only its software but also its hardware of course doesn ’ t exist yet. But perhaps our technology has already made us”Life 2. 1,”with our **artificial** knees, pacemakers and cochlear implants. So let ’ s take a closer look at our relationship with technology, OK? As an example, **the** Apollo 11 moon mission was both successful and inspiring, showing that when we humans use technology wisely, we can accomplish things that our ancestors could only dream of. But there ’ s an even more inspiring journey propelled by something more powerful than rocket engines, where **the** passengers aren ’ t just three astronauts but all of humanity. Let ’ s talk about our collective journey into **the** future with **artificial** intelligence. My friend Jaan Tallinn likes to point out that just as with rocketry, it ’ s not enough to make our technology powerful. We also have to figure out, if we ’ re going to be really ambitious, how to steer it and where we want to go with it. So let ’ s talk about all three for **artificial** intelligence : **the** power, **the** steering and **the** destination. Let ’ s start with **the** power. I define intelligence very inclusively — simply as our ability to accomplish complex goals, because I want to include both biological and **artificial** intelligence. And I want to avoid **the** silly carbon- chauvinism idea that you can only be smart if you ’ re made of meat. It ’ s really amazing how **the** power of AI has grown recently. Just think about it. Not long ago, robots couldn ’ t walk. Now, they can do backflips. Not long ago, we didn ’ t have self-driving cars. Now, we have self-flying rockets. Not long ago, AI couldn ’ t do face recognition. Now, AI can generate fake faces and simulate your face saying stuff that you never said. Not long ago, AI couldn ’ t beat us at **the** game of Go. Then, Google DeepMind ’ s AlphaZero AI took 3, 000 years of human Go games and Go wisdom, ignored it all and became **the** world ’ s best player by just playing against itself. And **the** most impressive feat here wasn ’ t that it crushed human gamers, but that it crushed human AI researchers who had spent decades handcrafting game-playing software. And AlphaZero crushed human AI researchers not just in Go but even at chess, which we have been working on since 1950. So all this amazing recent progress in AI really begs **the** question : How far will it go? I like to think about this question in terms of this **abstract** landscape of tasks, where **the** elevation represents how hard it is for AI to do each task at human level, and **the sea** level represents what AI can do today. **The sea** level is rising as AI improves, so there ’ s a kind of global warming going on here in **the** task landscape. And **the** obvious takeaway is to avoid careers at **the** waterfront — which will soon be automated and disrupted. But there ’ s a much bigger question as well. How high will **the** water end up rising? Will it eventually rise to flood everything, matching human intelligence at all tasks. This is **the** definition of **artificial** general intelligence — AGI, which has been **the** holy grail of AI research since its inception. By this definition, people who say,”Ah, there will always be jobs that humans can do better than machines,”are simply saying that we ’ ll never get AGI. Sure, we might still choose to have some human jobs or to give humans income and purpose with our jobs, but AGI will in any case transform life as we know it with humans no longer being **the** most intelligent. Now, if **the** water level does reach AGI, then further AI progress will be driven mainly not by humans but by AI, which means that there ’ s a possibility that further AI progress could be way faster than **the** typical human research and development timescale of years, raising **the** controversial possibility of an intelligence **explosion** where recursively self- improving AI rapidly leaves human intelligence far behind, creating what ’ s known as superintelligence. Alright, reality check : Are we going to get AGI any time soon? Some **famous** AI researchers, like Rodney Brooks, think it won ’ t happen for hundreds of years. But others, like Google Deep-

Mind founder Demis Hassabis, are more optimistic and are working to try to make it happen much sooner. And recent surveys have shown that most AI researchers actually share Demis ' s optimism, expecting that we will get AGI within decades, so within **the** lifetime of many of us, which begs **the** question — and then what? What do we want **the** role of humans to be if machines can do everything better and cheaper than us? **The** way I see it, we face a choice. One option is to be complacent. We can say,"Oh, let ' s just build machines that can do everything we can do and not worry about **the** consequences. Come on, if we build technology that makes all humans obsolete, what could possibly go wrong?"But I think that would be embarrassingly lame. I think we should be more ambitious — in **the** spirit of TED. Let ' s envision a truly inspiring high-tech future and try to steer towards it. This brings us to **the** second part of our rocket metaphor : **the** steering. We ' re making AI more powerful, but how can we steer towards a future where AI helps humanity flourish rather than flounder? To help with this, I cofounded **the** Future of Life Institute. It ' s a small nonprofit promoting beneficial technology use, and our goal is simply for **the** future of life to exist and to be as inspiring as possible. You know, I love technology. Technology is why today is better than **the** Stone Age. And I ' m optimistic that we can create a really inspiring high-tech future... if — and this is a big if — if we win **the** wisdom race — **the** race between **the** growing power of our technology and **the** growing wisdom with which we manage it. But this is going to require a change of strategy because our old strategy has been learning from mistakes. We invented fire, screwed up a bunch of times — invented **the** fire extinguisher. We invented **the** car, screwed up a bunch of times — invented **the** traffic light, **the** seat belt and **the** airbag, but with more powerful technology like nuclear weapons and AGI, learning from mistakes is a lousy strategy, don ' t you think? It ' s much better to be proactive rather than reactive ; plan ahead and get things right **the** first time because that might be **the** only time we ' ll get. But it is funny because sometimes people tell me,"Max, shhh, don ' t talk like that. That ' s Luddite scaremongering."But it ' s not scaremongering. It ' s what we at MIT call safety engineering. Think about it : before NASA launched **the** Apollo 11 mission, they systematically thought through everything that could go wrong when you put people on top of explosive fuel tanks and launch them somewhere where no one could help them. And there was a lot that could go wrong. Was that scaremongering? No. That ' s was precisely **the** safety engineering that ensured **the** success of **the** mission, and that is precisely **the** strategy I think we should take with AGI. Think through what can go wrong to make sure it goes right. So in this spirit, we ' ve organized conferences, bringing together leading AI researchers and other thinkers to discuss how to grow this wisdom we need to keep AI beneficial. Our last conference was in Asilomar, California last year and produced this list of 23 principles which have since been signed by over 1, 000 AI researchers and key industry leaders, and I want to tell you about three of these principles. One is that we should avoid an arms race and lethal autonomous weapons. **The** idea here is that any science can be used for new ways of helping people or new ways of harming people. For example, **biology** and **chemistry** are much more likely to be used for new medicines or new cures than for new ways of killing people, because biologists and chemists pushed hard — and successfully — for bans on biological and chemical weapons. And in **the** same spirit, most AI researchers want to stigmatize and ban lethal autonomous weapons. Another Asilomar AI principle is that we should mitigate AI-fueled income inequality. I think that if we can grow **the** economic pie dramatically with AI and we still can ' t figure out how to divide this pie so that everyone is better off, then shame on us. Alright, now raise your hand if your **computer** has ever crashed.

Wow, that ' s a lot of hands. Well, then you ' ll appreciate this principle that we should invest much more in AI safety research, because as we put AI in charge of even more decisions and infrastructure, we need to figure out how to transform today ' s buggy and hackable **computers** into robust AI systems that we can really trust, because otherwise, all this awesome new technology can malfunction and harm us, or get hacked and be turned against us. And this AI safety work has to include work on AI value alignment, because **the** real threat from AGI isn ' t malice, like in silly Hollywood movies, but competence — AGI accomplishing goals that just aren ' t aligned with ours. For example, when we humans drove **the** West African black rhino extinct, we didn ' t do it because we were a bunch of evil rhinoceros haters, did we? We did it because we were smarter than them and our goals weren ' t aligned with theirs. But AGI is by definition smarter than us, so to make sure that we don ' t put ourselves in **the** position of those rhinos if we create AGI, we need to figure out how to make machines understand our goals, adopt our goals and retain our goals. And whose goals should these be, anyway? Which goals should they be? This brings us to **the** third part of our rocket metaphor : **the** destination. We ' re making AI more powerful, trying to figure out how to steer it, but where do we want to go with it? This is **the elephant** in **the** room that almost nobody talks about — not even here at TED — because we ' re so fixated on short-term AI challenges. Look, our species is trying to build AGI, motivated by curiosity and economics, but what sort of future society are we hoping for if we succeed? We did an opinion poll on this recently, and I was struck to see that most people actually want us to build superintelligence : AI that ' s vastly smarter than us in all ways. What there was **the** greatest agreement on was that we should be ambitious and help life spread into **the** cosmos, but there was much less agreement about who or what should be in charge. And I was actually quite amused to see that there ' s some some people who want it to be just machines. And there was total disagreement about what **the** role of humans should be, even at **the** most basic level, so let ' s take a closer look at possible futures that we might choose to steer toward, alright? So don ' t get me wrong here. I ' m not talking about space travel, merely about humanity ' s metaphorical journey into **the** future. So one option that some of my AI colleagues like is to build superintelligence and keep it under human control, like an enslaved god, disconnected from **the** internet and used to create unimaginable technology and wealth for whoever controls it. But Lord Acton warned us that power corrupts, and absolute power corrupts absolutely, so you might worry that maybe we humans just aren ' t smart enough, or wise enough rather, to handle this much power. Also, aside from any moral qualms you might have about enslaving superior minds, you might worry that maybe **the** superintelligence could outsmart us, break out and take over. But I also have colleagues who are fine with AI taking over and even causing human extinction, as long as we feel **the** **the** AIs are our worthy descendants, like our children. But how would we know that **the** AIs have adopted our best values and aren ' t just unconscious zombies tricking us into anthropomorphizing them? Also, shouldn ' t those people who don ' t want human extinction have a say in **the** matter, too? Now, if you didn ' t like either of those two high-tech options, it ' s important to remember that low-tech is suicide from a cosmic perspective, because if we don ' t go far beyond today ' s technology, **the** question isn ' t whether humanity is going to go extinct, merely whether we ' re going to get taken out by **the** next killer **asteroid**, supervolcano or some other problem that better technology could have solved. So, how about having our cake and eating it... with AGI that ' s not enslaved but treats us well because its values are aligned with ours? This is **the** gist of what Eliezer Yudkowsky has called"**friendly** AI,"and if we can do this, it could be awesome. It could not only eliminate negative experiences like disease, poverty, crime and other suffering, but it could also give us **the** freedom to choose from a **fantastic** new diversity of positive experiences — basically making us **the** masters of our own destiny. So in summary, our situation with technology is complicated, but **the** big picture is rather simple. Most AI researchers expect AGI within decades, and if we just bumble into this unprepared, it will probably be **the** biggest mistake in human history — let ' s face it. It could enable brutal, global dictatorship with unprecedented inequality, surveillance and suffering, and maybe even human extinction. But if we steer carefully, we could end up in a **fantastic** future where everybody ' s better off : **the** poor are richer, **the** rich are richer, everybody is healthy and free to live out their dreams. Now, hang on. Do you folks want **the** future that ' s politically right or left? Do you want **the** pious society with strict moral rules, or do you an hedonistic free-for-all, more like Burning Man 24 / 7? Do you want beautiful beaches, forests and lakes, or would you prefer to rearrange some of those atoms with **the computers**, enabling virtual experiences? With **friendly** AI, we could simply build all of these societies and give people **the** freedom to choose which one they want to live in because we would no longer be limited by our intelligence, merely by **the** laws of physics. So **the** resources and space for this would be astronomical — literally. So here ' s our choice. We can either be complacent about our future, taking as an article of blind faith that any new technology is guaranteed to be beneficial, and just repeat that to ourselves as a mantra over and over and over again as we drift like a rudderless ship towards our own obsolescence. Or we can be ambitious — thinking hard about how to steer our technology and where we want to go with it to create **the** age of amazement. We ' re all here to celebrate **the** age of amazement, and I feel that its essence should lie in becoming not overpowered but empowered by our technology. Thank you.

All life, every living thing ever, has been built according to **the** information in DNA. What does that mean? Well, it means that just as **the** English language is made up of alphabetic letters that, when combined into words, allow me to tell you **the** story I ' m going to tell you today, DNA is made up of genetic letters that, when combined into genes, allow cells to produce proteins, strings of amino acids that fold up into complex structures that perform **the** functions that allow a cell to do what it does, to tell its stories. **The** English alphabet has 26 letters, and **the** genetic alphabet has four. They ' re pretty **famous**. Maybe you ' ve heard of them. They are often just referred to as G, C, A and T. But it ' s remarkable that all **the** diversity of life is **the** result of four genetic letters. Imagine what it would be like if **the** English alphabet had four letters. What sort of stories would you be able to tell? What if **the** genetic alphabet had more letters? Would life with more letters be able to tell different stories, maybe even more interesting ones? In 1999, my lab at **the** Scripps Research Institute in La Jolla, California started working on this question with **the** goal of creating living organisms with DNA made up of a six-letter genetic alphabet, **the** four natural letters plus two additional new man-made letters. Such an organism would be **the** first radically altered form of life ever created. It would be a semisynthetic form of life that stores more information than life ever has before. It would be able to make new proteins, proteins built from more than **the** 20 normal amino acids that are usually used to build proteins. What sort of stories could that life tell? With **the** power of synthetic **chemistry** and molecular **biology** and just under 20 years of work, we created bacteria with six-letter DNA. Let me tell you how we did it. All you have to remember from your high school **biology** is that **the** four natural letters pair together to form two base pairs. G pairs with C and A pairs with T, so to create our new letters, we synthesized hundreds of new candidates, new candidate letters, and examined their abilities to selectively pair with each other. And after about 15 years of work, we found two that paired together really well, at least in a test tube. They have complicated names, but let ' s just call them X and Y. **The** next thing we needed to do was find a way to get X and Y into cells, and eventually we found that a protein that does something similar in algae worked in our bacteria. So **the** final thing that we needed to do was to show that with X and Y provided, cells could grow and divide and hold on to X and Y in their DNA. Everything we had done up to then took longer than I had hoped — I am actually a really impatient person — but this, **the** most important step, worked faster than I dreamed, basically immediately. On a weekend in 2014, a graduate student in my lab grew bacteria with six- letter DNA. Let me take **the** opportunity to introduce you to them right now. This is an actual picture of them. These are **the** first semisynthetic organisms. So bacteria with six-letter DNA, that ' s really cool, right? Well, maybe some of you are still wondering why. So let me tell you a little bit more about some of our motivations, both conceptual and practical. Conceptually, people have thought about life, what it is, what makes it different from things that are not alive, since people have had thoughts. Many have interpreted life as being perfect, and this was taken as evidence of a creator. Living things are different because a god breathed life into them. Others have sought a more scientific explanation, but I think it ' s fair to say that they still consider **the** molecules of life to be special. I mean, **evolution** has been optimizing them for billions of years, right? Whatever perspective you take, it would seem pretty impossible for chemists to come in and build new parts that function within and alongside **the** natural molecules of life without somehow really screwing everything up. But just how perfectly created or **evolved** are we? Just how special are **the** molecules of life? These questions have been impossible to even ask, because we ' ve had nothing to compare life to. Now for **the** first time, our work suggests that maybe **the** molecules of life aren ' t that special. Maybe life as we know it isn ' t **the** only way it could be. Maybe we ' re not **the** only solution, maybe not even **the** best solution, just a solution. These questions address fundamental issues about life, but maybe they seem a little esoteric. So what about practical motivations? Well, we want to explore what sort of new stories life with an expanded vocabulary could tell, and remember, stories here are **the** proteins that a cell produces and **the** functions they have. So what sort of new proteins with new types of functions could our semisynthetic organisms make and maybe even use? Well, we have a couple of things in mind. **The** first is to get **the** cells to make proteins for us, for our use. Proteins are being used today for an increasingly broad range of different applications, from materials that protect soldiers from injury to **devices** that **detect** dangerous compounds, but at least to me, **the** most exciting application is protein drugs. Despite being relatively new, protein drugs have already revolutionized medicine, and, for example, insulin is a protein. You ' ve probably heard of it, and it ' s manufactured as a drug that has completely changed how we treat diabetes. But **the** problem is that proteins are really hard to make and **the** only practical way to get them is to get cells to make them for you. So of course, with natural cells, you can only get them to make proteins with **the** natural amino acids, and so **the** properties those proteins can have, **the** applications they could be developed for, must be limited by **the** nature of those amino acids that **the** protein ' s built from. So here they are, **the** 20 normal amino acids that are strung together to make a protein, and I think you can see, they ' re not that different-looking. They don ' t bring that many different functions. They don ' t make that many different functions available. Compare that with **the** small molecules that synthetic chemists make as drugs. Now, they ' re much simpler than proteins, but they ' re routinely built from a much broader range of diverse things. Don ' t worry about **the** molecular details, but I think you can see how different they are. And in fact, it ' s their differences that make them great drugs to treat different diseases. So it ' s really provocative to wonder what sort of new protein drugs you could develop if you could build proteins from more diverse things. So can we get our semisynthetic organism to make proteins that include new and different amino acids, maybe amino acids selected to confer **the** protein with some desired property or function? For example, many proteins just aren ' t stable when you inject them into people. They are rapidly degraded or eliminated, and this stops them from being drugs. What if we could make proteins with new amino acids with things attached to them that protect them from their environment, that protect them from being degraded or eliminated, so that they could be better drugs? Could we make proteins with little fingers attached that specifically grab on to other molecules? Many small molecules failed during development as drugs because they just weren ' t specific enough to find their target in **the** complex environment of **the** human body. So could we take those molecules and make them parts of new amino acids that, when incorporated into a protein, are guided by that protein to their target? I started a biotech company called Synthorx. Synthorx stands for synthetic organism with an X added at **the** end because that ' s what you do with biotech companies. Synthorx is working closely with my lab, and they ' re interested in a protein that recognizes a certain receptor on **the surface** of human cells. But **the** problem is that it also recognizes another receptor on **the surface** of those same cells, and that makes it toxic. So could we produce a variant of that protein where **the** part that interacts with that second bad receptor is shielded, blocked by something like a big umbrella so that **the** protein only interacts with that first good receptor? Doing that would be really difficult or impossible to do with **the** normal amino acids, but not with amino acids that are specifically designed for that purpose. So getting our semisynthetic cells to act as little factories to produce better protein drugs isn ' t **the** only potentially really interesting application, because remember, it ' s **the** proteins that allow cells to do what they do. So if we have cells that make new proteins with new functions, could we get them to do things that natural cells can ' t do? For example, could we develop semisynthetic organisms that when injected into a person, seek out cancer cells and only when they find them, secrete a toxic protein that kills them? Could we create bacteria that eat different kinds of **oil**, maybe to clean up an **oil spill**? These are just a couple of **the** types of stories that we ' re going to see if life with an expanded vocabulary can tell. So, sounds great, right? Injecting semisynthetic organisms into people, dumping millions and millions of gallons of our bacteria into **the** ocean or out on your favorite beach? Oh, wait a minute, actually it sounds really scary. This dinosaur is really scary. But here ' s **the** catch : our semisynthetic organisms in order to survive, need to be fed **the** chemical precursors of X and Y. X and Y are completely different than anything that exists in nature. Cells just don ' t have them or **the** ability to make them. So when we prepare them, when we grow them up in **the** controlled environment of **the** lab, we can feed them lots of **the** unnatural food. Then, when we deploy them in a person or out on a beach where they no longer have access that special food, they can grow for a little bit, they can survive for a little, maybe just long enough to perform some intended function, but then they start to run out of **the** food. They start to starve. They starve to death and they just **disappear**. So not only could we get life to tell new stories, we get to tell life when and where to tell those stories. At **the** beginning of this talk I told you that we reported in 2014 **the** creation of semisynthetic organisms that store more information, X and Y, in their DNA. But all **the** motivations that we just talked about require cells to use X and Y to make proteins, so we started working on that. Within a couple years, we showed that **the** cells could take DNA with X and Y and **copy** it into RNA, **the** working **copy** of DNA. And late last year, we showed that they could then use X and Y to make proteins. Here they are, **the** stars of **the** show, **the** first fully- functional semisynthetic organisms. These cells are green because they ' re making a protein that glows green. It ' s a pretty **famous** protein, actually, from jellyfish that a lot of people use in its natural form because it ' s easy to see that you made it. But within every one of these proteins, there ' s a new amino acid that natural life can ' t build proteins with. Every living cell, every living cell ever, has made every one of its proteins using a four-letter genetic alphabet. These cells are living and growing and making protein with a six-letter alphabet. These are a new form of life. This is a semisynthetic form of life. So what about **the** future? My lab is already working on expanding **the** genetic alphabet of other cells, including human cells, and we ' re getting ready to start working on more complex organisms. Think semisynthetic worms. **The** last thing I want to say to you, **the** most important thing that I want to say to you, is that **the** time of semisynthetic life is here. Thank you. Chris Anderson : I mean, Floyd, this is so remarkable. I just wanted to ask you, what are **the** implications of your work for how we should think about **the** possibilities for life, like, in **the universe**, elsewhere? It just seems like so much of life, or so much of our assumptions are based on **the** fact that of course, it ' s got to be DNA, but is **the** possibility space of self-replicating molecules much bigger than DNA, even just DNA with six letters? Floyd Romesberg : Absolutely, I think that ' s right, and I think what our work has shown, as I mentioned, is that there ' s been always this prejudice that sort of we ' re perfect, we ' re optimal, God created us this way, **evolution** perfected us this way. We ' ve made molecules that work right alongside **the** natural ones, and I think that suggests that any molecules that obey **the** fundamental laws of **chemistry** and physics and you can optimize them could do **the** things that **the** natural molecules of life do. There ' s nothing magic there. And I think that it suggests that life could **evolve** many different ways, maybe similar to us with other types of DNA, maybe things without DNA at all. CA : I mean, in your mind, how big might that possibility space be? Do we even know? Are most things going to look something like a DNA molecule, or something radically different that can still self-reproduce and potentially create living organisms? FR : My personal opinion is that if we found new life, we might not even recognize it. CA : So this obsession with **the search** for Goldilocks **planets** in exactly **the** right place with water and whatever, that ' s a very parochial assumption, perhaps. FR : Well, if you want to find someone you can talk to, then maybe not, but I think that if you ' re just looking for any form of life, I think that ' s right, I think that you ' re looking for life under **the** light post. CA : Thank you for boggling all our minds. Thank so much, Floyd.

Chris Anderson : Elon Musk, great to see you. How are you? Elon Musk : Good. How are you? CA : We ' re here at **the** Texas Gigafactory **the** day before this thing opens. It ' s been pretty crazy out there. Thank you so much for making time on a busy day. I would love you to help us, kind of, cast our minds, I don

’ t know, 10, 20, 30 years into **the** future. And help us try to picture what it would take to build a future that ’ s worth getting excited about. **The** last time you spoke at TED, you said that that was really just a big driver. You know, you can talk about lots of other reasons to do **the** work you ’ re doing, but fundamentally, you want to think about **the** future and not think that it sucks. EM : Yeah, absolutely. I think in general, you know, there ’ s a lot of discussion of like, this problem or that problem. And a lot of people are sad about **the** future and they ’ re... Pessimistic. And I think... this is... This is not great. I mean, we really want to wake up in **the** morning and look forward to **the** future. We want to be excited about what ’ s going to happen. And life cannot simply be about sort of, solving one miserable problem after another. CA : So if you look forward 30 years, you know, **the** year 2050 has been labeled by scientists as this, kind of, almost like this doomsday deadline on climate. There ’ s a consensus of scientists, a large consensus of scientists, who believe that if we haven ’ t completely eliminated **greenhouse** gases or offset them completely by 2050, effectively we ’ re inviting climate catastrophe. Do you believe there is a pathway to avoid that catastrophe? And what would it look like? EM : Yeah, so I am not one of **the** doomsday people, which may surprise you. I actually think we ’ re on a good path. But at **the** same time, I want to caution against complacency. So, so long as we are not complacent, as long as we have a high sense of urgency about moving towards a sustainable energy economy, then I think things will be fine. So I can ’ t emphasize that enough, as long as we push hard and are not complacent, **the** future is going to be great. Don ’ t worry about it. I mean, worry about it, but if you worry about it, ironically, it will be a self-unfulfilling prophecy. So, like, there are three elements to a sustainable energy future. One is of sustainable energy generation, which is primarily wind and solar. There ’ s also hydro, geothermal, I ’ m actually pro-nuclear. I think nuclear is fine. But it ’ s going to be primarily solar and wind, as **the** primary generators of energy. **The** second part is you need batteries to store **the** solar and wind energy because **the** sun doesn ’ t shine all **the** time, **the** wind doesn ’ t blow all **the** time. So it ’ s a lot of stationary battery packs. And then you need electric transport. So electric cars, electric planes, boats. And then ultimately, it ’ s not really possible to make electric rockets, but you can make **the** propellant used in rockets using sustainable energy. So ultimately, we can have a fully sustainable energy economy. And it ’ s those three things : solar / wind, stationary battery pack, electric vehicles. So then what are **the** limiting factors on progress? **The** limiting factor really will be battery cell production. So that ’ s going to really be **the** fundamental rate driver. And then whatever **the** slowest element of **the** whole lithium-ion battery cells supply chain, from mining and **the** many steps of refining to ultimately creating a battery cell and putting it into a pack, that will be **the** limiting factor on progress towards **sustainability**. CA : All right, so we need to talk more about batteries, because **the** key thing that I want to understand, like, there seems to be a scaling issue here that is kind of amazing and alarming. You have said that you have **calculated** that **the** amount of battery production that **the** world needs for **sustainability** is 300 terawatt hours of batteries. That ’ s **the** end goal? EM : Very rough numbers, and I certainly would invite others to check our calculations because they may arrive at different conclusions. But in order to transition, not just current electricity production, but also heating and transport, which roughly triples **the** amount of electricity that you need, it amounts to approximately 300 terawatt hours of installed capacity. CA : So we need to give people a sense of how big a task that is. I mean, here we are at **the** Gigafactory. You know, this is one of **the** biggest buildings in **the** world. What I ’ ve read, and tell me if this is still right, is that **the** goal here is to eventually produce 100 gigawatt hours of batteries here a year eventually. EM : We will probably do more than that, but yes, hopefully we get there within a couple of years. CA : Right. But I mean, that is one – EM : 0. 1 terrawat hours. CA : But that ’ s still 1 / 100 of what ’ s needed. How much of **the** rest of that 100 is Tesla planning to take on let ’ s say, between now and 2030, 2040, when we really need to see **the** scale up happen? EM : I mean, these are just guesses. So please, people shouldn ’ t hold me to these things. It ’ s not like this is like some – What tends to happen is I ’ ll make some like, you know, best guess and then people, in five years, there ’ ll be some jerk that writes an article :”Elon said this would happen, and it didn ’ t happen. He ’ s a liar and a fool.”It ’ s very annoying when that happens. So these are just guesses, this is a conversation. CA : Right. EM : I think Tesla probably ends up doing 10 percent of that. Roughly. CA : Let ’ s say 2050 we have this amazing, you know, 100 percent sustainable electric grid made up of, you know, some mixture of **the** sustainable energy sources you talked about. That same grid probably is offering **the** world really low-cost energy, isn ’ t it, compared with now. And I ’ m curious about like, are people entitled to get a little bit excited about **the** possibilities of that world? EM : People should be optimistic about **the** future. Humanity will solve sustainable energy. It will happen if we, you know, continue to push hard, **the** future is bright and good from an energy standpoint. And then it will be possible to also use that energy to do **carbon** sequestration. It takes a lot of energy to pull **carbon** out of **the** atmosphere because in putting it in **the** atmosphere it releases energy. So now, you know, obviously in order to pull it out, you need to use a lot of energy. But if you ’ ve got a lot of sustainable energy from wind and solar, you can actually sequester **carbon**. So you can reverse **the** CO2 parts per million of **the** atmosphere and oceans. And also you can really have as much fresh water as you want. Earth is mostly water. We should call Earth”Water.”It ’ s 70 percent water by **surface** area. Now most of that ’ s seawater, but it ’ s like we just happen to be on **the** bit that ’ s land. CA : And with energy, you can turn seawater into – EM : Yes. CA : Irrigating water or whatever water you need. EM : At very low cost. Things will be good. CA : Things will be good. And also, there ’ s other benefits to this non-fossil fuel world where **the** air is cleaner – EM : Yes, exactly. Because, like, when you burn **fossil** fuels, there ’ s all these side reactions and toxic gases of various kinds. And sort of little particulates that are bad for your lungs. Like, there ’ s all sorts of bad things that are happening that will go away. And **the** sky will be cleaner and quieter. **The** future ’ s going to be good. CA : I want us to switch now to think a bit about **artificial** intelligence. But **the** segue there, you mentioned how annoying it is when people call you up for bad predictions in **the** past. So I ’ m possibly going to be annoying now, but I ’ m curious about your timelines and how you predict and how come some things are so amazingly on **the** money and some aren ’ t. So when it comes to predicting sales of Tesla vehicles, for example, you ’ ve kind of been amazing, I think in 2014 when Tesla had sold that year 60, 000 cars, you said,”2020, I think we will do half a million a year.”EM : Yeah, we did almost exactly a half million. CA : You did almost exactly half a million. You were scoffed in 2014 because no one since Henry Ford, with **the** Model T, had come close to that kind of growth rate for cars. You were scoffed, and you actually hit 500, 000 cars and then 510, 000 or whatever produced. But five years ago, last time you came to TED, I asked you about full self-driving, and you said,”Yeah, this very year, I ’ m confident that we will have a car going from LA to New York without any intervention.”EM : Yeah, I don ’ t want to blow your mind, but I ’ m not always right. CA : What ’ s **the** difference between those two? Why has full self-driving in particular been so hard to predict? EM : I mean, **the** thing that really got me, and I think it ’ s going to get a lot of other people, is that there are just so many false dawns with self-driving, where you think you ’ ve got **the** problem, have a handle on **the** problem, and then it, no, turns out you just hit a ceiling. Because if you were to plot **the** progress, **the** progress looks like a log curve. So it ’ s like a series of log curves. So most people don ’ t know what a log curve is, I suppose. CA : Show **the** shape with your hands. EM : It goes up you know, sort of a fairly straight way, and then it starts tailing off and you start getting diminishing returns. And you ’ re like, uh oh, it was trending up and now it ’ s sort of, curving over and you start getting to these, what I call local maxima, where you don ’ t realize basically how dumb you were. And then it happens again. And ultimately... These things, you know, in retrospect, they seem obvious, but in order to solve full self-driving properly, you actually have to solve real-world AI. Because what are **the** road networks designed to work with? They ’ re designed to work with a biological neural net, our brains, and with vision, our eyes. And so in order to make it work with **computers**, you basically need to solve real-world AI and vision. Because we need cameras and silicon neural nets in order to have self-driving work for a system that was designed for eyes and biological neural nets. You know, I guess when you put it that way, it ’ s sort of, like, quite obvious that **the** only way to solve full self-driving is to solve real world AI and sophisticated vision. CA : What do you feel about **the** current architecture? Do you think you have an architecture now where there is a chance for **the** logarithmic curve not to tail off any anytime soon? EM : Well I mean, admittedly these may be infamous last words, but I actually am confident that we will solve it this year. That we will exceed – **The probability** of an accident, at what point do you exceed that of **the** average person? I think we will exceed that this year. CA : What are you seeing behind **the** scenes that gives you that confidence? EM : We ’ re almost at **the** point where we have a high-quality unified vector space. In **the** beginning, we were trying to do this with image recognition on individual images. But if you get one image out of a video, it ’ s actually quite hard to see what ’ s going on without ambiguity. But if you look at a video segment of a few seconds of video, that ambiguity resolves. So **the** first thing we had to do is tie all eight cameras together so they ’ re synchronized, so that all **the** frames are looked at simultaneously and labeled simultaneously by one person, because we still need human labeling. So at least they ’ re not labeled at different times by different people in different ways. So it ’ s sort of a surround picture. Then a very important part is to add **the** time **dimension**. So that you ’ re looking at surround video, and you ’ re labeling surround video. And this is actually quite difficult to do from a software standpoint. We had to write our own labeling tools and then create auto labeling, create auto labeling software to amplify **the** efficiency of human labelers because it ’ s quite hard to label. In **the** beginning, it was taking several hours to label a 10-second video **clip**. This is not scalable. So basically what you have to have is you have to have surround video, and that surround video has to be primarily automatically labeled with humans just being editors and making slight corrections to **the** labeling of **the** video and then feeding back those corrections into **the** future auto labeler, so you get this flywheel eventually where **the** auto labeler is able to take in vast amounts of video and with high accuracy, automatically label **the** video for cars, lane lines, drive space. CA : What you ’ re saying is... **the** result of this is that you ’ re effectively giving **the** car a 3D model of **the** actual **objects** that are all around it. It knows what they are, and it knows how fast they are moving. And **the** remaining task is to predict what **the** quirky behaviors are that, you know, that when a pedestrian is walking down **the** road with a smaller pedestrian, that maybe that smaller pedestrian might do something unpredictable or things like that. You have to build into it before you can really call it safe. EM : You basically need to have memory across time and space. So what I mean by that is... Memory can ’ t be infinite, because it ’ s using up a lot of **the computer** ’ s RAM basically. So you have to say how much are you going to try to remember? It ’ s very common for things to be occluded. So if you talk about say, a pedestrian walking past a truck where you saw **the** pedestrian start on one side of **the** truck, then they ’ re occluded by **the** truck. You would know intuitively, OK, that pedestrian is going to pop out **the** other side, most likely. CA : A **computer** doesn ’ t know it. EM : You need to slow down. CA : A skeptic is going to say that every year for **the** last five years, you ’ ve kind of said, well, no this is **the** year, we ’ re confident that it will be there in a year or two or, you know, like it ’ s always been about that far away. But we ’ ve got a new architecture now, you ’ re seeing enough improvement behind **the** scenes to make you not certain, but pretty confident, that, by **the** end of this year, what in most, not in every city, and every circumstance but in many cities and circumstances, basically **the** car will be able to drive without interventions safer than a human. EM : Yes. I mean, **the** car currently drives me around Austin most of **the** time with no interventions. So it ’ s not like... And we have over 100, 000 people in our full self-driving beta program. So you can look at **the** videos that they post online. CA : I do. And some of them are great, and some of them are a little **terrifying**. I mean, occasionally **the** car seems to veer off and scare **the** hell out of people. EM : It ’ s still a beta. CA : But you ’ re behind **the** scenes, looking at **the** data, you ’ re seeing enough improvement to believe that a this-year timeline is real. EM : Yes, that ’ s what it seems like. I mean, we could be here talking again in a year, like, well, another year went by, and it didn ’ t happen. But I think this is **the** year. CA : And so in general, when people talk about Elon time, I mean it sounds like you can ’ t just have a general rule that if you predict that something will be done in six months, actually what we should imagine is it ’ s going to be a year or it ’ s like two-x or three-x, it depends on **the** type of prediction. Some things, I guess, things involving software, AI, whatever, are fundamentally harder to predict than others. Is there an element that you actually deliberately make aggressive prediction timelines to drive people to be ambitious? Without that, nothing gets done? EM : Well, I generally believe, in terms of internal timelines, that we want to set **the** most aggressive timeline that we can. Because there ’ s sort of like a law of gaseous expansion where, for schedules, where whatever time you set, it ’ s not going to be less than that. It ’ s very rare that it ’ ll be less than that. But as far as our predictions are concerned, what tends to happen in **the** media is that they will report all **the** wrong ones and ignore all **the** right ones. Or, you know, when writing an article about me – I ’ ve had a long career in multiple industries. If you list my sins, I sound like **the** worst person on Earth. But if you put those against **the** things I ’ ve done right, it makes much more sense, you know? So essentially like, **the** longer you do anything, **the** more mistakes that you will make cumulatively. Which, if you **sum** up those mistakes, will sound like I ’ m **the** worst predictor ever. But for example, for Tesla vehicle growth, I said I think we ’ d do 50 percent, and we ’ ve done 80 percent. CA : Yes. EM : But they don ’ t mention that one. So, I mean, I ’ m not sure what my **exact** track record is on predictions. They ’ re more optimistic than pessimistic, but they ’ re not all optimistic. Some of them are exceeded probably more or later, but they do come true. It ’ s very rare that they do not come true. It ’ s sort of like, you know, if there ’ s some radical technology prediction, **the** point is not that it was a few years late, but that it happened at all. That ’ s **the** more important part. CA : So it feels like at some point in **the** last year, seeing **the** progress on understanding, **the** Tesla AI understanding **the** world around it, led to a kind of, an aha moment at Tesla. Because you really surprised people recently when you said probably **the** most important product development going on at Tesla this year is this robot, Optimus. EM : Yes. CA : Many companies out there have tried to put out these robots, they ' ve been working on them for years. And so far no one has really cracked it. There ' s no mass adoption robot in people ' s homes. There are some in manufacturing, but I would say, no one ' s kind of, really cracked it. Is it something that happened in **the** development of full self-driving that gave you **the** confidence to say,"You know what, we could do something special here."EM : Yeah, exactly. So, you know, it took me a while to sort of realize that in order to solve self-driving, you really needed to solve real-world AI. And at **the** point of which you solve real-world AI for a car, which is really a robot on four wheels, you can then generalize that to a robot on legs as well. **The** two hard parts I think – like obviously companies like Boston Dynamics have shown that it ' s possible to make quite compelling, sometimes alarming robots. CA : Right. EM : You know, so from a sensors and actuators standpoint, it ' s certainly been demonstrated by many that it ' s possible to make a humanoid robot. **The** things that are currently missing are enough intelligence for **the** robot to navigate **the** real world and do useful things without being explicitly instructed. So **the** missing things are basically real-world intelligence and scaling up manufacturing. Those are two things that Tesla is very good at. And so then we basically just need to design **the** specialized actuators and sensors that are needed for humanoid robot. People have no idea, this is going to be bigger than **the** car. CA : So let ' s dig into exactly that. I mean, in one way, it ' s actually an easier problem than full self-driving because instead of an **object** going along at 60 miles an hour, which if it gets it wrong, someone will die. This is an **object** that ' s engineered to only go at what, three or four or five miles an hour. And so a mistake, there aren ' t lives at stake. There might be embarrassment at stake. EM : So long as **the** AI doesn ' t take it over and murder us in our sleep or something. CA : Right. So talk about – I think **the** first applications you ' ve mentioned are probably going to be manufacturing, but eventually **the** vision is to have these available for people at home. If you had a robot that really understood **the** 3D architecture of your house and knew where every **object** in that house was or was supposed to be, and could recognize all those **objects**, I mean, that ' s kind of amazing, isn ' t it? Like **the** kind of thing that you could ask a robot to do would be what? Like, tidy up? EM : Yeah, absolutely. Make dinner, I guess, mow **the** lawn. CA : Take a cup of tea to grandma and show her family pictures. EM : Exactly. Take care of my grandmother and make sure – CA : It could obviously recognize everyone in **the** home. It could play catch with your kids. EM : Yes. I mean, obviously, we need to be careful this doesn ' t become a dystopian situation. I think one of **the** things that ' s going to be important is to have a localized ROM chip on **the** robot that cannot be updated over **the** air. Where if you, for example, were to say,"Stop, stop, stop,"if anyone said that, then **the** robot would stop, you know, type of thing. And that ' s not updatable remotely. I think it ' s going to be important to have safety features like that. CA : Yeah, that sounds wise. EM : And I do think there should be a regulatory agency for AI. I ' ve said that for many years. I don ' t love being regulated, but I think this is an important thing for public safety. CA : Let ' s come back to that. But I don ' t think many people have really sort of taken seriously **the** notion of, you know, a robot at home. I mean, at **the** start of **the** computing revolution, Bill Gates said there ' s going to be a **computer** in every home. And people at **the** time said, yeah, whatever, who would even want that. Do you think there will be basically like in, say, 2050 or whatever, like a robot in most homes, is what there will be, and people will love them and count on them? You ' ll have your own butler basically. EM : Yeah, you ’ ll have your sort of buddy robot probably, yeah. CA : I mean, how much of a buddy? How many applications have you thought, you know, can you have a romantic partner, a sex partner? EM : It ’ s probably inevitable. I mean, I did promise **the** internet that I ’ d make catgirls. We could make a robot catgirl. CA : Be careful what you promise **the** internet. EM : So, yeah, I guess it ’ ll be whatever people want really, you know. CA : What sort of timeline should we be thinking about of **the** first models that are actually made and sold? EM : Well, you know, **the** first units that we intend to make are for jobs that are dangerous, boring, repetitive, and things that people don ’ t want to do. And, you know, I think we ’ ll have like an interesting prototype sometime this year. We might have something useful next year, but I think quite likely within at least two years. And then we ’ ll see rapid growth year over year of **the** usefulness of **the** humanoid robots and decrease in cost and scaling up production. CA : Initially just selling to businesses, or when do you picture you ’ ll start selling them where you can buy your parents one for Christmas or something? EM : I ’ d say in less than ten years. CA : Help me on **the** economics of this. So what do you picture **the** cost of one of these being? EM : Well, I think **the** cost is actually not going to be crazy high. Like less than a car. Initially, things will be expensive because it ’ ll be a new technology at low production volume. **The** complexity and cost of a car is greater than that of a humanoid robot. So I would expect that it ’ s going to be less than a car, or at least equivalent to a cheap car. CA : So even if it starts at 50k, within a few years, it ’ s down to 20k or lower or whatever. And maybe for home they ’ ll get much cheaper still. But think about **the** economics of this. If you can replace a $30, 000, $40, 000-a-year worker, which you have to pay every year, with a one-time payment of $25, 000 for a robot that can work longer hours, a pretty rapid replacement of certain types of jobs. How worried should **the** world be about that? EM : I wouldn ’ t worry about **the** sort of, putting people out of a job thing. I think we ’ re actually going to have, and already do have, a massive shortage of labor. So I think we will have... Not people out of work, but actually still a shortage labor even in **the** future. But this really will be a world of abundance. Any goods and services will be available to anyone who wants them. It ’ ll be so cheap to have goods and services, it will be ridiculous. CA : I ’ m presuming it should be possible to imagine a bunch of goods and services that can ’ t profitably be made now but could be made in that world, courtesy of legions of robots. EM : Yeah. It will be a world of abundance. **The** only scarcity that will exist in **the** future is that which we decide to create ourselves as humans. CA : OK. So AI is allowing us to imagine a differently powered economy that will create this abundance. What are you most worried about going wrong? EM : Well, like I said, AI and robotics will bring out what might be termed **the** age of abundance. Other people have used this word, and that this is my prediction : it will be an age of abundance for everyone. But I guess there ’ s... **The** dangers would be **the artificial** general intelligence or digital superintelligence decouples from a collective human will and goes in **the** direction that for some reason we don ’ t like. Whatever direction it might go. You know, that ’ s sort of **the** idea behind Neuralink, is to try to more tightly couple collective human world to digital superintelligence. And also along **the** way solve a lot of brain injuries and spinal injuries and that kind of thing. So even if it doesn ’ t succeed in **the** greater goal, I think it will succeed in **the** goal of alleviating brain and spine damage. CA : So **the** spirit there is that if we ’ re going to make these AIs that are so vastly intelligent, we ought to be wired directly to them so that we ourselves can have those superpowers more directly. But that doesn ’ t seem to avoid **the** risk that those superpowers might... turn ugly in unintended ways. EM : I think it ’ s a risk, I agree. I ’ m not saying that I have some certain answer to that risk. I ’ m just saying like maybe one of **the** things that would be good for ensuring that **the** future is one that we want is to more tightly couple **the** collective human world to digital intelligence. **The** issue that we face here is that we are already a cyborg, if you think about it. **The computers** are an extension of ourselves. And when we die, we have, like, a digital ghost. You know, all of our text messages and social media, emails. And it ’ s quite eerie actually, when someone dies but everything online is still there. But you say like, what ’ s **the** limitation? What is it that inhibits a human-machine symbiosis? It ’ s **the** data rate. When you communicate, especially with a phone, you ’ re moving your thumbs very slowly. So you ’ re like moving your two little meat sticks at a rate that ’ s maybe 10 bits per second, optimistically, 100 bits per second. And **computers** are communicating at **the** gigabyte level and beyond. CA : Have you seen evidence that **the** technology is actually working, that you ’ ve got a richer, sort of, higher bandwidth connection, if you like, between like external electronics and a brain than has been possible before? EM : Yeah. I mean, **the** fundamental principles of reading neurons, sort of doing read-write on neurons with tiny electrodes, have been demonstrated for decades. So it ’ s not like **the** concept is new. **The** problem is that there is no product that works well that you can go and buy. So it ’ s all sort of, in research labs. And it ’ s like some cords sticking out of your head. And it ’ s quite gruesome, and it ’ s really... There ’ s no good product that actually does a good job and is high-bandwidth and safe and something actually that you could buy and would want to buy. But **the** way to think of **the** Neuralink **device** is kind of like a Fitbit or an Apple Watch. That ’ s where we take out sort of a small section of skull about **the** size of a quarter, replace that with what, in many ways really is very much like a Fitbit, Apple Watch or some kind of smart watch thing. But with tiny, tiny wires, very, very tiny wires. Wires so tiny, it ’ s hard to even see them. And it ’ s very important to have very tiny wires so that when they ’ re implanted, they don ’ t damage **the** brain. CA : How far are you from putting these into humans? EM : Well, we have put in our FDA application to aspirationally do **the** first human implant this year. CA : **The** first uses will be for neurological injuries of different kinds. But rolling **the** clock forward and imagining when people are actually using these for their own enhancement, let ’ s say, and for **the** enhancement of **the** world, how clear are you in your mind as to what it will feel like to have one of these inside your head? EM : Well, I do want to emphasize we ’ re at an early stage. And so it really will be many years before we have anything approximating a high-bandwidth neural interface that allows for AI-human symbiosis. For many years, we will just be solving brain injuries and spinal injuries. For probably a decade. This is not something that will suddenly one day it will have this incredible sort of whole brain interface. It ’ s going to be, like I said, at least a decade of really just solving brain injuries and spinal injuries. And really, I think you can solve a very wide range of brain injuries, including severe depression, morbid obesity, sleep, potentially schizophrenia, like, a lot of things that cause great stress to people. Restoring memory in older people. CA : If you can pull that off, that ’ s **the** app I will sign up for. EM : Absolutely. CA : Please hurry. EM : I mean, **the** emails that we get at Neuralink are heartbreaking. I mean, they ’ ll send us just tragic, you know, where someone was sort of, in **the** prime of life and they had an accident on a motorcycle and someone who ’ s 25, you know, can ’ t even feed themselves. And this is something we could fix. CA : But you have said that AI is one of **the** things you ’ re most worried about and that Neuralink may be one of **the** ways where we can keep abreast of it. EM : Yeah, there ’ s **the** short-term thing, which I think is helpful on an individual human level with injuries. And then **the** long-term thing is an attempt to address **the** civilizational risk of

AI by bringing digital intelligence and biological intelligence closer together. I mean, if you think of how **the** brain works today, there are really two layers to **the** brain. There ' s **the** limbic system and **the** cortex. You ' ve got **the** kind of, animal brain where – it ' s kind of like **the** fun part, really. CA : It ' s where most of Twitter operates, by **the** way. EM : I think Tim Urban said, we ' re like somebody, you know, stuck a **computer** on a monkey. You know, so we ' re like, if you gave a monkey a **computer**, that ' s our cortex. But we still have a lot of monkey instincts. Which we then try to rationalize as, no, it ' s not a monkey instinct. It ' s something more important than that. But it ' s often just really a monkey instinct. We ' re just monkeys with a **computer** stuck in our brain. But even though **the** cortex is sort of **the** smart, or **the** intelligent part of **the** brain, **the** thinking part of **the** brain, I ' ve not yet met anyone who wants to delete their limbic system or their cortex. They ' re quite happy having both. Everyone wants both parts of their brain. And people really want their phones and their **computers**, which are really **the** tertiary, **the** third part of your intelligence. It ' s just that it ' s... Like **the** bandwidth, **the** rate of communication with that tertiary layer is slow. And it ' s just a very tiny straw to this tertiary layer. And we want to make that tiny straw a big **highway**. And I ' m definitely not saying that this is going to solve everything. Or this is you know, it ' s **the** only thing – it ' s something that might be helpful. And worst-case scenario, I think we solve some important brain injury, spinal injury issues, and that ' s still a great outcome. CA : Best-case scenario, we may discover new human possibility, telepathy, you ' ve spoken of, in a way, a connection with a loved one, you know, full memory and much faster thought processing maybe. All these things. It ' s very cool. If AI were to take down Earth, we need a plan B. Let ' s shift our attention to space. We spoke last time at TED about reusability, and you had just demonstrated that spectacularly for **the** first time. Since then, you ' ve gone on to build this monster rocket, Starship, which kind of changes **the** rules of **the** game in spectacular ways. Tell us about Starship. EM : Starship is extremely fundamental. So **the** holy grail of rocketry or space transport is full and rapid reusability. This has never been achieved. **The** closest that anything has come is our Falcon 9 rocket, where we are able to recover **the** first stage, **the** boost stage, which is probably about 60 percent of **the** cost of **the** vehicle of **the** whole launch, maybe 70 percent. And we ' ve now done that over a hundred times. So with Starship, we will be recovering **the** entire thing. Or at least that ' s **the** goal. CA : Right. EM : And moreover, recovering it in such a way that it can be immediately re-flown. Whereas with Falcon 9, we still need to do some amount of refurbishment to **the** booster and to **the** fairing nose cone. But with Starship, **the** design goal is immediate re-flight. So you just refill propellants and go again. And this is gigantic. Just as it would be in any other mode of transport. CA : And **the** main design is to basically take 100 plus people at a time, plus a bunch of things that they need, to Mars. So, first of all, talk about that piece. What is your latest timeline? One, for **the** first time, a Starship goes to Mars, presumably without people, but just equipment. Two, with people. Three, there ' s sort of, OK, 100 people at a time, let ' s go. EM : Sure. And just to put **the** cost thing into perspective, **the** expected cost of Starship, putting 100 tons into orbit, is significantly less than what it would have cost or what it did cost to put our tiny Falcon 1 rocket into orbit. Just as **the** cost of flying a 747 around **the** world is less than **the** cost of a small **airplane**. You know, a small **airplane** that was thrown away. So it ' s really pretty mind-boggling that **the** giant thing costs less, way less than **the** small thing. So it doesn ' t use exotic propellants or things that are difficult to obtain on Mars. It uses methane as fuel, and it ' s primarily oxygen, roughly 77-78 percent oxygen by weight. And Mars has a CO_2 atmosphere and has water ice, which is CO2 plus H2O, so you can make CH4, methane, and O2, oxygen, on Mars. CA : Presumably, one of **the** first tasks on Mars will be to create a fuel plant that can create **the** fuel for **the** return trips of many Starships. EM : Yes. And actually, it ’ s mostly going to be oxygen plants, because it ’ s 78 percent oxygen, 22 percent fuel. But **the** fuel is a simple fuel that is easy to create on Mars. And in many other parts of **the** solar system. So basically... And it ’ s all propulsive landing, no parachutes, nothing thrown away. It has a heat shield that ’ s capable of entering on Earth or Mars. We can even potentially go to Venus. but you don ’ t want to go there. Venus is hell, almost literally. But you could... It ’ s a generalized method of transport to anywhere in **the** solar system, because **the** point at which you have propellant depo on Mars, you can then travel to **the asteroid** belt and to **the** moons of Jupiter and Saturn and ultimately anywhere in **the** solar system. CA : But your main focus and SpaceX ’ s main focus is still Mars. That is **the** mission. That is where most of **the** effort will go? Or are you actually imagining a much broader **array** of uses even in **the** coming, you know, **the** first decade or so of uses of this. Where we could go, for example, to other places in **the** solar system to explore, perhaps NASA wants to use **the** rocket for that reason. EM : Yeah, NASA is planning to use a Starship to return to **the** moon, to return people to **the** moon. And so we ’ re very honored that NASA has chosen us to do this. But I ’ m saying it is a generalized – it ’ s a general solution to getting anywhere in **the** greater solar system. It ’ s not suitable for going to another star system, but it is a general solution for transport anywhere in **the** solar system. CA : Before it can do any of that, it ’ s got to demonstrate it can get into orbit, you know, around Earth. What ’ s your latest advice on **the** timeline for that? EM : It ’ s looking promising for us to have an orbital launch attempt in a few months. So we ’ re actually integrating – will be integrating **the** engines into **the** booster for **the** first orbital flight starting in about a week or two. And **the** launch complex itself is ready to go. So assuming we get regulatory approval, I think we could have an orbital launch attempt within a few months. CA : And a radical new technology like this presumably there is real risk on those early attempts. EM : Oh, 100 percent, yeah. **The** joke I make all **the** time is that excitement is guaranteed. Success is not guaranteed, but excitement certainly is. CA : But **the** last I saw on your timeline, you ’ ve slightly put back **the** expected date to put **the** first human on Mars till 2029, I want to say? EM : Yeah, I mean, so let ’ s see. I mean, we have built a production system for Starship, so we ’ re making a lot of ships and boosters. CA : How many are you planning to make actually? EM : Well, we ’ re currently expecting to make a booster and a ship roughly every, well, initially, roughly every couple of months, and then hopefully by **the** end of this year, one every month. So it ’ s giant rockets, and a lot of them. Just talking in terms of rough orders of magnitude, in order to create a self-sustaining city on Mars, I think you will need something on **the** order of a thousand ships. And we just need a Helen of Sparta, I guess, on Mars. CA : This is not in most people ’ s heads, Elon. EM : **The planet** that launched 1, 000 ships. CA : That ’ s nice. But this is not in most people ’ s heads, this picture that you have in your mind. There ’ s basically a two-year window, you can only really fly to Mars conveniently every two years. You were picturing that during **the** 2030s, every couple of years, something like 1, 000 Starships take off, each containing 100 or more people. That picture is just completely mind-blowing to me. That sense of this armada of humans going to – EM : It ’ ll be like”Battlestar Galactica,”**the** fleet departs. CA : And you think that it can basically be funded by people spending maybe a couple hundred grand on a **ticket** to Mars? Is that price about where it has been? EM : Well, I think if you say like, what ’ s required in order to get enough people and enough cargo to Mars to build a self-sustaining city. And it ' s where you have an intersection of sets of people who want to go, because I think only a small percentage of humanity will want to go, and can afford to go or get sponsorship in some manner. That intersection of sets, I think, needs to be a million people or something like that. And so it ' s what can a million people afford, or get sponsorship for, because I think governments will also pay for it, and people can take out loans. But I think at **the** point at which you say, OK, like, if moving to Mars costs are, for argument ' s sake, $100, 000, then I think you know, almost anyone can work and save up and eventually have $100, 000 and be able to go to Mars if they want. We want to make it available to anyone who wants to go. It ' s very important to emphasize that Mars, especially in **the** beginning, will not be luxurious. It will be dangerous, cramped, difficult, hard work. It ' s kind of like that Shackleton ad for going to **the** Antarctic, which I think is actually not real, but it sounds real and it ' s cool. It ' s sort of like, **the** sales pitch for going to Mars is,"It ' s dangerous, it ' s cramped. You might not make it back. It ' s difficult, it ' s hard work."That ' s **the** sales pitch. CA : Right. But you will make history. EM : But it ' ll be glorious. CA : So on that kind of launch rate you ' re talking about over two decades, you could get your million people to Mars, essentially. Whose city is it? Is it NASA ' s city, is it SpaceX ' s city? EM : It ' s **the** people of Mars ' city. **The** reason for this, I mean, I feel like why do this thing? I think this is important for maximizing **the** probable lifespan of humanity or consciousness. Human civilization could come to an end for external reasons, like a giant meteor or super volcanoes or extreme climate change. Or World War III, or you know, any one of a number of reasons. But **the** probable life span of civilizational consciousness as we know it, which we should really view as this very delicate thing, like a small candle in a vast darkness. That is what appears to be **the** case. We ' re in this vast darkness of space, and there ' s this little candle of consciousness that ' s only really come about after 4. 5 billion years, and it could just go out. CA : I think that ' s powerful, and I think a lot of people will be inspired by that vision. And **the** reason you need **the** million people is because there has to be enough people there to do everything that you need to survive. EM : Really, like **the** critical threshold is if **the** ships from Earth stop coming for any reason, does **the** Mars City die out or not? And so we have to – You know, people talk about like, **the** sort of, **the** great filters, **the** things that perhaps, you know, we talk about **the** Fermi paradox, and where are **the** aliens? Well maybe there are these various great filters that **the** aliens didn ' t pass, and so they eventually just ceased to exist. And one of **the** great filters is becoming a multi-planet species. So we want to pass that filter. And I ' ll be long-dead before this is, you know, a real thing, before it happens. But I ' d like to at least see us make great progress in this direction. CA : Given how tortured **the** Earth is right now, how much we ' re beating each other up, shouldn ' t there be discussions going on with everyone who is dreaming about Mars to try to say, we ' ve got a once in a civilization ' s chance to make some new rules here? Should someone be trying to lead those discussions to figure out what it means for this to be **the** people of Mars ' City? EM : Well, I think ultimately this will be up to **the** people of Mars to decide how they want to rethink society. Yeah there ' s certainly risk there. And hopefully **the** people of Mars will be more enlightened and will not fight amongst each other too much. I mean, I have some recommendations, which people of Mars may choose to listen to or not. I would advocate for more of a direct democracy, not a representative democracy, and laws that are short enough for people to understand. Where it is harder to create laws than to get rid of them. CA : Coming back a bit nearer term, I ' d love you to just talk a bit about some of **the** other possibility space that Starship seems to have created.

So given – Suddenly we ’ ve got this ability to move 100 tons-plus into orbit. So we ’ ve just launched **the** James Webb telescope, which is an incredible thing. It ’ s unbelievable. EM : Exquisite piece of technology. CA : Exquisite piece of technology. But people spent two years trying to figure out how to fold up this thing. It ’ s a three-ton telescope. EM : We can make it a lot easier if you ’ ve got more volume and mass. CA : But let ’ s ask a different question. Which is, how much more powerful a telescope could someone design based on using Starship, for example? EM : I mean, roughly, I ’ d say it ’ s probably an order of magnitude more resolution. If you ’ ve got 100 tons and a thousand cubic meters volume, which is roughly what we have. CA : And what about other exploration through **the** solar system? I mean, I ’ m you know – EM : Europa is a big question mark. CA : Right, so there ’ s an ocean there. And what you really want to do is to drop a submarine into that ocean. EM : Maybe there ’ s like, some squid civilization, cephalopod civilization under **the** ice of Europa. That would be pretty interesting. CA : I mean, Elon, if you could take a submarine to Europa and we see pictures of this thing being devoured by a squid, that would honestly be **the** happiest moment of my life. EM : Pretty wild, yeah. CA : What other possibilities are out there? Like, it feels like if you ’ re going to create a thousand of these things, they can only fly to Mars every two years. What are they doing **the** rest of **the** time? It feels like there ’ s this **explosion** of possibility that I don ’ t think people are really thinking about. EM : I don ’ t know, we ’ ve certainly got a long way to go. As you alluded to earlier, we still have to get to orbit. And then after we get to orbit, we have to really prove out and refine full and rapid reusability. That ’ ll take a moment. But I do think we will solve this. I ’ m highly confident we will solve this at this point. CA : Do you ever wake up with **the** fear that there ’ s going to be this Hindenburg moment for SpaceX where... EM : We ’ ve had many Hindenburg. Well, we ’ ve never had Hindenburg moments with people, which is very important. Big difference. We ’ ve blown up quite a few rockets. So there ’ s a whole compilation online that we put together and others put together, it ’ s showing rockets are hard. I mean, **the sheer** amount of energy going through a rocket boggles **the** mind. So, you know, getting out of Earth ’ s gravity well is difficult. We have a strong gravity and a thick atmosphere. And Mars, which is less than 40 percent, it ’ s like, 37 percent of Earth ’ s gravity and has a thin atmosphere. **The** ship alone can go all **the** way from **the surface** of Mars to **the surface** of Earth. Whereas getting to Mars requires a giant booster and orbital refilling. CA : So, Elon, as I think more about this incredible **array** of things that you ’ re involved with, I keep seeing these synergies, to use a horrible word, between them. You know, for example, **the** robots you ’ re building from Tesla could possibly be pretty handy on Mars, doing some of **the** dangerous work and so forth. I mean, maybe there ’ s a scenario where your city on Mars doesn ’ t need a million people, it needs half a million people and half a million robots. And that ’ s a possibility. Maybe **The** Boring Company could play a role helping create some of **the** subterranean dwelling spaces that you might need. EM : Yeah. CA : Back on **planet** Earth, it seems like a partnership between Boring Company and Tesla could offer an unbelievable deal to a city to say, we will create for you a 3D network of tunnels populated by robo-taxis that will offer fast, low-cost transport to anyone. You know, full self-driving may or may not be done this year. And in some cities, like, somewhere like Mumbai, I suspect won ’ t be done for a decade. EM : Some places are more challenging than others. CA : But today, today, with what you ’ ve got, you could put a 3D network of tunnels under there. EM : Oh, if it ’ s just in a tunnel, that ’ s a solved problem. CA : Exactly, full self-driving is a solved problem. To me, there ’ s amazing synergy there. With Starship, you know, Gwynne Shotwell talked about by 2028 having from city to city, you know, transport on **planet** Earth. EM : This is a real possibility. **The** fastest way to get from one place to another, if it ’ s a long distance, is a rocket. It ’ s basically an ICBM. CA : But it has to land – Because it ’ s an ICBM, it has to land probably offshore, because it ’ s loud. So why not have a tunnel that then connects to **the** city with Tesla? And Neuralink. I mean, if you going to go to Mars having a telepathic connection with loved ones back home, even if there ’ s a time delay... EM : These are not intended to be connected, by **the** way. But there certainly could be some synergies, yeah. CA : Surely there is a growing argument that you should actually put all these things together into one company and just have a company devoted to creating a future that ’ s exciting, and let a thousand flowers bloom. Have you been thinking about that? EM : I mean, it is tricky because Tesla is a publicly-traded company, and **the** investor base of Tesla and SpaceX and certainly Boring Company and Neuralink are quite different. Boring Company and Neuralink are tiny companies. CA : By comparison. EM : Yeah, Tesla ’ s got 110, 000 people. SpaceX I think is around 12, 000 people. Boring Company and Neuralink are both under 200 people. So they ’ re little, tiny companies, but they will probably get bigger in **the** future. They will get bigger in **the** future. It ’ s not that easy to sort of combine these things. CA : Traditionally, you have said that for SpaceX especially, you wouldn ’ t want it public, because public investors wouldn ’ t support **the** craziness of **the** idea of going to Mars or whatever. EM : Yeah, making life multi-planetary is outside of **the** normal time horizon of Wall Street analysts. To say **the** least. CA : I think something ’ s changed, though. What ’ s changed is that Tesla is now so powerful and so big and throws off so much cash that you actually could connect **the** dots here. Just tell **the** public that x-billion dollars a year, whatever your number is, will be diverted to **the** Mars mission. I suspect you ’ d have massive interest in that company. And it might **unlock** a lot more possibility for you, no? EM : I would like to give **the** public access to ownership of SpaceX, but I mean **the** thing that like, **the** overhead associated with a public company is high. I mean, as a public company, you ’ re just constantly sued. It does occupy like, a fair bit of... You know, time and effort to deal with these things. CA : But you would still only have one public company, it would be bigger, and have more things going on. But instead of being on four boards, you ’ d be on one. EM : I ’ m actually not even on **the** Neuralink or Boring Company boards. And I don ’ t really attend **the** SpaceX board meetings. We only have two a year, and I just stop by and chat for an hour. **The** board overhead for a public company is much higher. CA : I think some investors probably worry about how your time is being split, and they might be excited by you know, that. Anyway, I just woke up **the** other day thinking, just, there are so many ways in which these things connect. And you know, just **the** simplicity of that mission, of building a future that is worth getting excited about, might appeal to an awful lot of people. Elon, you are reported by Forbes and everyone else as now, you know, **the** world ’ s richest person. EM : That ’ s not a sovereign. CA : EM : You know, I think it ’ s fair to say that if somebody is like, **the** king or de facto king of a country, they ’ re wealthier than I am. CA : But it ’ s just harder to measure – So $300 billion. I mean, your net worth on any given day is rising or falling by several billion dollars. How insane is that? EM : It ’ s bonkers, yeah. CA : I mean, how do you handle that psychologically? There aren ’ t many people in **the** world who have to even think about that. EM : I actually don ’ t think about that too much. But **the** thing that is actually more difficult and that does make sleeping difficult is that, you know, every good hour or even minute of thinking about Tesla and SpaceX has such a big effect on **the** company that I really try to work as much as possible, you know, to **the** edge of sanity, basically. Because you know, Tesla ’ s getting to **the** point where probably will get to **the** point later this year, where every high-quality minute of thinking is a million dollars impact on Tesla. Which is insane. I mean, **the** basic, you know, if Tesla is doing, you know, sort of $2 billion a week, let ' s say, in revenue, it ' s sort of $300 million a day, seven days a week. You know, it ' s... CA : If you can change that by five percent in an hour ' s brainstorm, that ' s a pretty valuable hour. EM : I mean, there are many instances where a half-hour meeting, I was able to improve **the** financial outcome of **the** company by $100 million in a half-hour meeting. CA : There are many other people out there who can ' t stand this world of billionaires. Like, they are hugely offended by **the** notion that an individual can have **the** same wealth as, say, a billion or more of **the** world ' s poorest people. EM : If they examine sort of – I think there ' s some axiomatic flaws that are leading them to that conclusion. For sure, it would be very problematic if I was consuming, you know, billions of dollars a year in personal **consumption**. But that is not **the** case. In fact, I don ' t even own a home right now. I ' m literally staying at friends ' places. If I travel to **the** Bay Area, which is where most of Tesla engineering is, I basically rotate through friends ' spare bedrooms. I don ' t have a yacht, I really don ' t take vacations. It ' s not as though my personal **consumption** is high. I mean, **the** one exception is a plane. But if I don ' t use **the** plane, then I have less hours to work. CA : I mean, I personally think you have shown that you are mostly driven by really quite a deep sense of moral purpose. Like, your attempts to solve **the** climate problem have been as powerful as anyone else on **the planet** that I ' m aware of. And I actually can ' t understand, personally, I can ' t understand **the** fact that you get all this criticism from **the** Left about,"Oh, my God, he ' s so rich, that ' s disgusting."When climate is their issue. Philanthropy is a topic that some people go to. Philanthropy is a hard topic. How do you think about that? EM : I think if you care about **the** reality of goodness instead of **the** perception of it, philanthropy is extremely difficult. SpaceX, Tesla, Neuralink and **The** Boring Company are philanthropy. If you say philanthropy is love of humanity, they are philanthropy. Tesla is accelerating sustainable energy. This is a love – philanthropy. SpaceX is trying to ensure **the** long-term survival of humanity with a multiple-planet species. That is love of humanity. You know, Neuralink is trying to help solve brain injuries and existential risk with AI. Love of humanity. Boring Company is trying to solve traffic, which is hell for most people, and that also is love of humanity. CA : How upsetting is it to you to hear this constant drumbeat of,"Billionaires, my God, Elon Musk, oh, my God?"Like, do you just shrug that off or does it does it actually hurt? EM : I mean, at this point, it ' s water off a duck ' s back. CA : Elon, I ' d like to, as we wrap up now, just pull **the** camera back and just think... You ' re a father now of seven surviving kids. EM : Well, I mean, I ' m trying to set a good example because **the** birthrate on Earth is so low that we ' re facing civilizational collapse unless **the** birth rate returns to a sustainable level. CA : Yeah, you ' ve talked about this a lot, that depopulation is a big problem, and people don ' t understand how big a problem it is. EM : Population collapse is one of **the** biggest threats to **the** future of human civilization. And that is what is going on right now. CA : What drives you on a day-to-day basis to do what you do? EM : I guess, like, I really want to make sure that there is a good future for humanity and that we ' re on a path to understanding **the** nature of **the universe**, **the** meaning of life. Why are we here, how did we get here? And in order to understand **the** nature of **the** **universe** and all these fundamental questions, we must expand **the** scope and scale of consciousness. Certainly it must not diminish or go out. Or we certainly won ' t understand this. I would say I ' ve been motivated by curiosity more than anything, and just desire to think about **the** future and not be sad, you know? CA : And are you? Are you not sad? EM : I ' m sometimes sad, but mostly I ' m feeling I guess relatively optimistic about **the** future these days. There are certainly some big risks that humanity faces. I think **the** population collapse is a really big deal, that I wish more people would think about because **the** birth rate is far below what ’ s needed to sustain civilization at its current level. And there ’ s obviously... We need to take action on climate **sustainability**, which is being done. And we need to secure **the** future of consciousness by being a multi-planet species. We need to address – Essentially, it ’ s important to take whatever actions we can think of to address **the** existential risks that affect **the** future of consciousness. CA : There ’ s a whole generation coming through who seem really sad about **the** future. What would you say to them? EM : Well, I think if you want **the** future to be good, you must make it so. Take action to make it good. And it will be. CA : Elon, thank you for all this time. That is a beautiful place to end. Thanks for all you ’ re doing. EM : You ’ re welcome.

Here ’ s what gives me hope for humanity. I believe that we can change our human nature for **the** better. This chance is unique. It ’ s where we stand in history right now. No other generation has stood here before us. Homo sapiens has been around for about 300, 000 years. Other humanoid life forms have come and gone. We find their traces. We **search** for their stories. But we are **the** success story. We ’ ve survived natural disasters, famines, floods, **earthquakes**, plagues, woolly mammoths, mess-ups of our own making. We ’ re smart, no question. **The** question is : Are we smart enough to survive how smart we are? It ’ s not looking so good just now, is it? We stand facing **the** possibility of global conflict. If that happens, it will be our Third World War in not much more than 100 years. If Putin ’ s violence stops today, **the** problem doesn ’ t go away. As across **the** globe dictatorism threatens democracy. I wonder whether as a species we can survive any of this, even if those threats **disappear**. Those living inside **the** snow globe of their magical thinking will not be insulated against **the** facts of climate breakdown. And yet, still, we go on heating up **the planet**. Still we go on **polluting the** earth. Still we despoil our precious natural resources. 250 years ago, we kick-started **the** Industrial Revolution. **The** machine age. It ’ s when we first hear **the** buzzwords of **the** modern moment. Disruption, acceleration. That ’ s Karl Marx, actually. Acceleration of production, **the** factory system, acceleration of transport, **the** coming of **the** railways. No need for ships to wait for **the** wind. Coal-fired, steam-powered. Acceleration of information. **The** global village. And it ’ s when we start digging **fossil** fuels out of **the** ground in planet-changing quantities, when we start pushing **carbon** dioxide into **the** atmosphere. In a salami slice of space-time, human beings have changed **the** way that we live on **the planet** forever. We ’ ve moved out of **the** agricultural economies of our **evolutionary** inheritance into **the** industrial economies and beyond of where we are now. There ’ s no one else for us to turn to. There ’ s no one else for us to blame. There is no us and them. There ’ s only us. So will we continue to be **the** success story of **the** known **universe**, or are we writing our own obituary? **The** suicide species? Now I was raised in an evangelical household. We lived in end time. We were waiting for things to get so bad that Jesus would come back and save us. **The** apocalypse. It ’ s what **the** prepper communities are, well, prepping for. And it ’ s why super rich white guys are buying up tracts of land, hoping that they can live inside a kind of wi-fi-enabled Noah ’ s Ark. Well, we can have **the** end time if we want it. We know those stories from our religions, our sci-fi, our movies. We are uniquely placed to bring on **the** apocalypse. And we ’ re uniquely placed to save ourselves, too. If we could accept that as a species, Homo sapiens needs to **evolve** further. And that ’ s what gives me hope, because we have **the** means to **evolve** further. And that ’ s AI. Now look, I don ’ t mean **the geeks** will inherit **the** earth. I ’ m sorry, **geeks**. You won ’ t. I don ’ t really want to talk about narrow- goal **artificial** intelligence at all. That term of John McCarthy ’ s,”**artificial** intelligence,”is it any use to us now? I ’ d rather call it alternative intelligence. And I think humankind is in need of some alternative intelligence. In 1965, Jack Good talked about AI as our last invention. He meant superintelligence, **the** kind of thing that worries Bill Gates and Elon Musk. You know, **the**”Terminator”scenario. **The** final us and them. But I think that ’ s all to do with our doomster mindset. We don ’ t have to vote for **the** apocalypse. Jack Good worked at Bletchley Park with Alan Turing during World War II, building **the** early computing machinery that would crack **the** Nazi Enigma code. Now after **the** war, Turing, wrestling with **the** problems of a stored, programmed **computer** had a bigger dream on his mind. And in 1950, Alan Turing published a paper called”Computing Machinery and Intelligence.”And in there, there ’ s a chapter that ’ s titled”Lady Lovelace ’ s Objection”where Turing time-travels back 100 years to have a conversation with that long-dead genius, Ada Lovelace, **the** first person to write mathematical programs for **the computer** not yet built by her friend Charles Babbage. Now Ada wrote that as well as doing awesome stuff with numbers, **the computer** would, if correctly programmed, be able to write novels and compose music. That is a pretty big insight in 1843.”But,”said Ada,”**The computer** should never have any pretensions to originate anything.”She meant, think creatively. Well, Ada ’ s father was Lord Byron, England ’ s most **famous** poet, and England is **the** land of Shakespeare. More poets. And Ada had seen Charles Babbage ’ s kit all over **the** floor, and she wasn ’ t having some steampunk, coal-fired **nuts**, bolts, bezels, levers, gears, cogs and chains, crank-handled machine writing poetry.”Well,”said Alan Turing,”Was Lady Lovelace, correct? Could a **computer** ever be said to originate anything? And what would be **the** difference between computing intelligence and human intelligence?”Well, I ’ ll tell you one difference, and it ’ s optimistic. Computing power uses binary, but computing intelligence is nonbinary. It ’ s humans who are obsessed with false binaries. Male, female. Masculine, feminine. Black, white. Human, nonhuman. Us, them. AI has no skin color. AI has no race, no gender, no faith in a sky God. AI is not interested in men being superior to women, in white folks being smarter than people of color. Straight, gay, gay, trans are not separating categories for AI. AI does not distinguish between success and failure by gold bars, yachts and Ferraris. AI is not motivated by fame and fortune. If we develop alternative intelligence, it will be Buddhist in its non-needs. Now I am aware that **the** algorithms ubiquitous in everyday life are racist, sexist, gendered, trivializing, stoke division, amplify bias. But what is this teaching us about ourselves? AI is a tool. We are **the** ones who are using **the** tool. Hatred and contempt, money and power are human agendas, not AI agendas. We ’ ve been forced to recognize **the** paucity, **the** inadequacy of our data sets. And humans are trained on data sets too. We ’ ve had to recognized **the** unacknowledged ideologies that we live by every day. Rationality, neutrality, logic, objective decision-making. What can we say about any of that when we see what we are reflected back to us in **the** small screen? And it ’ s not a pretty sight. AI is not yet self-aware. But we are becoming more self-aware as we work with AI and we realize that Homo sapiens is no longer fit for purpose. We need a reboot. So what are we going to choose? Apocalypse or an alternative? I believe that humans have a strong future as a hybrid species as we start to merge with **the** biotechnology we ’ re creating, whether that ’ s nanobots in **the** bloodstream, monitoring our vital systems, whether it ’ s genetic editing, whether it ’ s 3D printing of bespoke body parts, whether it ’ s neural implants that will connect us directly to **the web** and to one another, insourcing information, enhancing our cognitive capacities. And if we manage to upload consciousness, I think that **the** shift from **the** transhuman to **the** posthuman world will seem natural, an **evolutionary** necessity. Why do I say that? I say that because for millennia, all human beings have been obsessed with **the** big question, **the** absurdity of death. We asked,”Do we have souls?”We watched **the** spirit wait to leave **the** body. We created **the** world ’ s first disruptive startup, **the** afterlife. Now a multinational company, with a vast VR real estate portfolio. A mansion in **the** sky, sir? Our earliest extant written narrative, **The** Epic of Gilgamesh, is a journey to discover if there is life after death. And what is life after death? It is **the** extension of **the** self beyond biological limits. Now I ’ m a writer, and I wonder, have we been telling **the** story **backwards**? Did we know we would always get here, capable of creating **the** kind of superintelligence that we said created us? We ’ re told were made in God ’ s image. God is immortal. God is not a biological entity. Since **the** 17th century, **the** Enlightenment, science and religion have parted company. And science said, all that God thinking, **the** afterlife stuff, it ’ s folly, It ’ s ignorance, it ’ s superstition. Suppose it was intuition. Suppose it was **the** only way we could talk about what we knew, a fundamental, deep truth that this is not **the** last word. This is not **the** end of **the** story. That we are not time-bound creatures caught in our bodies. That there is further to go. I ’ m fascinated that computing, science and religion, like parallel lines that do meet in space, are now asking **the** same question : Is consciousness obliged to materiality? Now... I accept that machine intelligence will challenge human intelligence. But **the** mythos of **the** world is built around a group of stories that showcase an encounter between a human and a nonhuman entity. Think of Jacob wrestling **the** angel. Think of Prometheus bringing fire down from **the** gods. In these encounters, both parties are changed, not always for **the** better. But it generally works out. We ’ ve been thinking about this stuff forever. It ’ s time that we created it. And we could have some fun stuff too. Who wants their own AI angel? Me. There ’ s a message in a bottle about this 200 years ago. When Ada Lovelace was busy getting born, her father, Lord Byron, was on holiday on Lake Geneva with his friend, **the** poet Percy Shelley, and Shelley ’ s wife, Mary Shelley. On a **wet** weekend with no internet Byron said –”Let ’ s write horror stories.”You know what happened. Out of that came **the** world ’ s most **famous** monster, Frankenstein. This is 1816, **the** start of **the** Industrial Revolution. Mary Shelley is just 19 years old. In that novel, there is an alternative intelligence made out of **the** body parts from **the** graveyard and electricity. An astonishing vision because electricity was not in any practical use at all and was hardly understood as a force. You know what happens. **The** monster is not named. Not educated. Is outcast by his panicky creator, Victor Frankenstein. And **the** whole thing ends in a chase across **the** Arctic ice towards a Götterdämmerung of death and destruction. **The** death wish that human beings are so drawn to, perhaps because it ’ s easier to give up than to carry on. Well, we ’ re **the** first generation who can read Mary Shelley ’ s novel in **the** right way, as a flare flung across time, because we too could create an alternative intelligence, not out of **the** body parts from **the** graveyard using electricity, but out of zeros and ones of code. And how is this going to end? Utopia or dystopia? It ’ s up to us. Endings are not set in stone. We change **the** story because we are **the** story. Now, Marvin Minsky called alternative intelligence our”mind children.”Could we as proud parents accept that **the** new generation that we will create will be smarter than we are? And could we accept that **the** new generation we create need not be on a substrate made of meat? Thank you. Thank you. Thank you very much. Thank you. Thank you. Helen Walters : Jeanette, stay right there. I have some questions. Jeanette Winterson : I know you want your lunch. Me too. HW : No. Everybody, stop. OK. That was amazing. Thank you. What would you say our odds were of survival? JW : Look – I ’ m an optimist. I ’ m a glass-half-full girl. So I know that we ’ re running out of time, time is **the** most precious resource we have, and there isn ’ t much of it. If we get this right soon, it can really work. If we get it wrong, will be fighting each other with sticks and stones for scraps of food and water on an overheated **planet** in **the** ruins of dictator-world. But – OK. But we could get it right. That ’ s why I feel we ’ ve arrived at this moment before, and it might **disappear** back into space-time. Then we ’ ll have to wait billions of years to get here again, which is so dull. So let ’ s not fuck it up. HW : I ’ ve got another question. I just wanted to have a moment of eye to eye. Don ’ t fuck it up. Don ’ t fuck it up. OK. JW : That ’ s **the** message. **The** whole TED Talk is :”Don ’ t fuck it up.”HW : But wait, I have another question. JW : I could have saved 12 minutes, 55 seconds. HW : Yeah, well, I ’ ll just be **the** title that we put online. Jeanette Winterson :”Don ’ t fuck it up.”OK. I want to talk about love. So in your memoir, which everybody should read, it is called”Why Be Happy When You Can Be Normal?”**The** very end of that book is about – it ’ s a good title – t ’ s about love. And you write,”Love, **the** difficult word. Where everything starts, where we always return. Love. Love ’ s lack. **The** possibility of love.”Now I don ’ t want to bastardize Ada Lovelace. She was all about originating. But what about love? What about alternative intelligence and love? JW : We ’ ll teach it. HW : We ’ ll teach it? JW : Yeah. And listen, any of you who ever fell in love with your teddy bear, which is all of you, know what it ’ s like to have an intense relationship with a nonbiological lifeform. HW : Jeanette Winterson, I love you. JW : Thank you. HW : Thank you so much. Thank you.

Text Sample 71: POS Dim 1 – 2022 – Score 16.00 – 2022/t003763.txt

Chris Anderson : I want you to come with me to Tesla ’ s huge gigafactory in Austin, Texas. So **the** day before it opened last week, **the** evening before, I was allowed to walk around it, no one else there. And what I saw there was, honestly, pretty mind-blowing. This is Elon Musk ’ s **famous** machine that builds **the** machine, and in his view, **the** secret to a sustainable future, is not just making electric car. It ’ s making a system that churns out huge numbers of electric cars with a margin, so that they can fund further growth. When I was there, none of us knew whether Elon would actually be able to make it here today, so I took **the** chance to sit down with him and record an epic interview. And I just want to show you an eight-minute excerpt of that interview. So here from Austin, Texas, Elon Musk. I want us to switch now to think a bit about **artificial** intelligence. I ’ m curious about your timelines and how you predict and how come some things are so amazingly on **the** money and some aren ’ t. So when it comes to predicting sales of Tesla vehicles, for example, you ’ ve kind of been amazing. I think in 2014 when Tesla had sold that year 60, 000 cars, you said,”2020, I think we will do half a million a year.”Elon Musk : Yeah, we did almost exactly a half million. CA : Five years ago, last time you came to TED, I asked you about full self-driving, and you said,”Yeah, this very year I ’ m confident that we will have a car going from LA to New York without any intervention.”EM : Yeah, I don ’ t want to blow your mind, but I ’ m not always right. CA : What ’ s **the** difference between those two? Why has full self-driving in particular been so hard to predict? EM : I mean, **the** thing that really got me, and I think it ’ s going to get a lot of other people, is that there are just so many false dawns with self-driving where you think you ' ve got **the** problem, have a handle on **the** problem, and then it, no, turns out you just hit a ceiling. Because if you were to plot **the** progress, **the** progress looks like a log curve. So it ' s like a series of log curves. So most people don ' t know what a log curve is, I suppose. CA : Show **the** shape with your hands. EM : It goes up, you know, sort of a fairly straight way, and then it starts tailing off and you start getting diminishing returns. You know, in retrospect, they seem obvious, but in order to solve full self-driving properly, you actually have to solve real-world AI. Because what are **the** road networks designed to work with? They ' re designed to work with a biological neural net, our brains, and with vision, our eyes. And so in order to make it work with **computers**, you basically need to solve real-world AI and vision. Because we need cameras and silicon neural nets in order to have self-driving work for a system that was designed for eyes and biological neural nets. You know, I guess when you put it that way, it ' s sort of, like, quite obvious that **the** only way to solve full self-driving is to solve real-world AI and sophisticated vision. CA : What do you feel about **the** current architecture? Do you think you have an architecture now where there is a chance for **the** logarithmic curve not to tail off anytime soon? EM : Well I mean, admittedly these maybe infamous last words, but I actually am confident that we will solve it this year. That we will exceed – **The probability** of an accident, at what point do you exceed that of **the** average person? I think we will exceed that this year. We could be here talking again in a year, like, well, another year went by and it didn ' t happen. But I think this is **the** year. CA : Is there an element that you actually deliberately make aggressive prediction timelines to drive people to be ambitious? Without that, nothing gets done? So it feels like at some point in **the** last year, seeing **the** progress on understanding that **the** Tesla AI understanding **the** world around it, led to a kind of, an aha moment at Tesla. Because you really surprised people recently when you said probably **the** most important product development going on at Tesla this year is this robot, Optimus. Is it something that happened in **the** development of full self-driving that gave you **the** confidence to say,"You know what, we could do something special here."EM : Yeah, exactly. So, you know, it took me a while to sort of realize that in order to solve self-driving, you really needed to solve real-world AI. And at **the** point of which you solve real-world AI for a car, which is really a robot on four wheels, you can then generalize that to a robot on legs as well. **The** things that are currently missing are enough intelligence for **the** robot to navigate **the** real world and do useful things without being explicitly instructed. So **the** missing things are basically real-world intelligence and scaling up manufacturing. Those are two things that Tesla is very good at. And so then we basically just need to design **the** specialized actuators and sensors that are needed for a humanoid robot. People have no idea, this is going to be bigger than **the** car. CA : So talk about – I think **the** first applications you ' ve mentioned are probably going to be in manufacturing, but eventually, **the** vision is to have these available for people at home. If you had a robot that really understood **the** 3D architecture of your house and knew where every **object** in that house was or was supposed to be and could recognize all those **objects**, I mean, that ' s kind of amazing, isn ' t it, like, **the** kind of thing that you could ask a robot to do would be what? Like, tidy up? EM : Yeah, absolutely. Make dinner, I guess, mow **the** lawn. CA : Take a cup of tea to grandma and show her family pictures. EM : Exactly. Take care of my grandmother and make sure – CA : It could obviously recognize everyone in **the** home. It could play catch with your kids. EM : Yes. I mean, obviously, we need to be careful this doesn ' t become a dystopian situation. I think one of **the** things that ' s going to be important is to have a localized ROM chip on **the** robot that cannot be updated over **the** air. Where if you, for example, were to say,"Stop, stop, stop,"if anyone said that, then **the** robot would stop, you know, type of thing. And that ' s not updatable remotely. I think it ' s going to be important to have safety features like that. CA : Yeah, that sounds wise. EM : And I do think there should be a regulatory agency for AI. I ' ve said this for many years. I don ' t love being regulated, but I think this is an important thing for public safety. CA : Do you think there will be basically like in, say, 2050 or whatever, like, a robot in most homes, is what there will be, and people will love them and count on them? You ' ll have your own butler basically. EM : Yeah, you ' ll have your sort of buddy robot probably, yeah. CA : I mean, how much of a buddy? How many applications have you thought, you know, can you have a romantic partner, a sex partner? EM : It ' s probably inevitable. I mean, I did promise **the** internet that I ' d make catgirls. We could make a robot catgirl. CA : Be careful what you promise **the** internet. EM : So, yeah, I guess it ' ll be whatever people want really, you know. CA : What sort of timeline should we be thinking about of **the** first models that are actually made and sold? EM : Well, you know, **the** first units that we intend to make are for jobs that are dangerous, boring, repetitive and things that people don ' t want to do. And, you know, I think we ' ll have like, an interesting prototype some time this year. We might have something useful next year, but I think quite likely within at least two years. And then we ' ll see rapid growth year over year of **the** usefulness of **the** humanoid robots and decrease in cost and scaling up production. CA : Help me on **the** economics of this. So what do you picture **the** cost of one of these being? EM : Well, I think **the** cost is actually not going to be crazy high. Like, less than a car. CA : But think about **the** economics of this. If you can replace a 30, 000-dollar, 40, 000-dollar-a-year worker, which you have to pay every year, with a one-time payment of 25, 000 dollars for a robot that can work longer hours, doesn ' t go an vacation, it could be a pretty rapid replacement of certain types of jobs. How worried should **the** world be about that? EM : I wouldn ' t worry about **the** sort of, putting people out of a job thing. I think we ' re actually going to have, and already do have, a massive shortage of labor. So I think we will have... Not people out of work, but actually still a shortage of labor even in **the** future. But this really will be a world of abundance. Any goods and services will be available to anyone who wants them. It ' ll be so cheap to have goods and services, it will be ridiculous. CA : And now, arguably, **the** biggest visionary of them all, Elon Musk. Hey, Elon, welcome. So, Elon, a few hours ago, you made an offer to buy Twitter. Why? EM : How ' d you know? CA : A little bird tweeted in my ear or something, I don ' t know. EM : By **the** way, have you seen **the** movie"Ted,"about **the** bear? CA : I have. EM : It ' s a good movie. CA : Don ' t mention that here. EM : So, yeah, yeah, so... Was there a question? CA : Why make that offer? EM : Oh, so, well, I think it ' s very important for there to be an inclusive arena for free speech where all... Twitter has become, kind of, **the** de facto town square. It ' s just really important that people have both **the** reality and **the** perception that they are able to speak freely within **the** bounds of **the** law. And, you know, one of **the** things that I believe Twitter should do is **open-source the** algorithm and make any changes to people ' s tweets, or if they ' re emphasized or de-emphasized, that action should be made apparent so anyone can see that action has been taken. So there ' s no, sort of, behind **the** scenes manipulation, either algorithmically or manually. CA : Last week when we spoke, Elon, I asked you whether you were thinking of taking over. You said, no way. You said,"I do not want to own Twitter. It is a recipe for misery. Everyone will blame me for everything."What on Earth changed? EM : No I think everyone will still blame me for everything. If I acquire Twitter and something goes wrong, it ' s my fault, 100 percent. I think there will be quite a few arrows, yes. CA : It will be miserable. But you still want to do it. Why? EM : I mean, I hope it ’ s not too miserable. I just think it ’ s important to **the**... It ’ s important to **the** function of democracy. It ’ s important to **the** function of **the** United States as a free country and many other countries. And to actually help freedom in **the** world, more broadly than **the** US. And so I think it ’ s, you know, I think **the** civilizational risk is decreased **the** more we can increase **the** trust of Twitter as a public platform. And so I do think this will be somewhat painful. And I ’ m not sure that I will actually be able to acquire it. And I should also say **the** intent is to retain as many shareholders as is allowed by **the** law in a private company, which I think is around 2, 000 or so. So it ’ s definitely not, from **the** standpoint of,”Let me figure out how to monopolize or maximize my ownership of Twitter.”But I will try to bring along as many shareholders as we ’ re allowed to. CA : You don ’ t necessarily want to pay out 40 or whatever it is, billion dollars in cash. You ’ d like them to come with you in **the** new company. EM : I mean, you know, I could technically afford it. CA : I heard that. EM : But what I ’ m saying is, this is not a way to, sort of, make money, you know. It ’ s just that I think this is... My strong intuitive sense is that having a public platform that is maximally trusted and broadly inclusive is extremely important to **the** future of civilization. CA : But you ’ ve described yourself – EM : I don ’ t care about **the** economics at all. CA : OK, that ’ s cool to hear. This is not about **the** economics. It ’ s for **the** moral good that you think it will achieve. You ’ ve described yourself, Elon, as a”free speech absolutist.”But does that mean that there ’ s literally nothing that people can ’ t say, and it ’ s OK? EM : Well, I think, obviously, Twitter or any forum is bound by **the** laws of **the** country that it operates in. So obviously, there are some limitations on free speech in **the** US. And of course, Twitter would have to abide by those rules. CA : So you can ’ t incite people to violence, like, a direct incitement to violence you know, you can ’ t do **the** equivalent of crying”fire”in a movie theater, for example. EM : No, that would be a crime. It should be a crime. CA : But here ’ s **the** challenge, it ’ s such a nuanced difference between different things. So there ’ s incitement to violence. That ’ s a no if it ’ s illegal. There ’ s hate speech, which, some forms of hate speech are fine. You know,”I hate spinach.”EM : I mean, if it ’ s sauteed in, you know, cream sauce, it can be quite nice. CA : But **the** problem is, so let ’ s say someone says – OK, here ’ s one tweet,”I hate politician X.”Next tweet is,”I wish politician X wasn ’ t alive,”as some of us have said about Putin right now, for example. So that ’ s legitimate speech. Another tweet is,”I wish politician X wasn ’ t alive”with a picture of their head with a gunsight over it. Or that plus their address. I mean, at some point someone has to make a decision as to which of those is not OK. Can an algorithm do that, or surely you need human judgment at some point? EM : No, I think, like I said, in my view, Twitter should match **the** laws of **the** country. And really, you know, there ’ s an obligation to do that. But going beyond that, and having it be **unclear** who ’ s making what changes to where, having tweets sort of, mysteriously be promoted and demoted with no insight into what ’ s going on, having a black-box algorithm promote some things and not other things, I think this can be quite dangerous. CA : So, **the** idea of opening **the** algorithm is a huge deal, and I think many people would welcome that of understanding exactly how it ’ s making **the** decision. EM : And critique it, like, what I mean is like, I think **the** code should be on GitHub, you know. So people can look through it and say, like,”I see a problem here.””I don ’ t agree with this.”They can highlight issues, suggest changes in **the** same way that you update Linux or Signal or something like that, you know. CA : As I understand it, at some point right now, what **the** algorithm would do is it would look at, for example, how many people have flagged a tweet as obnoxious. And then at some point a human has to look at it and make a decision as to, does this cross **the** line or not, that **the** algorithm itself can ' t, I don ' t think yet, tell **the** difference between legal and OK and definitely obnoxious. And so **the** question is, which humans, you know, make that call? I mean, do you have a picture of that? Right now, Twitter and Facebook and others, you know, they ' ve hired thousands of people to try to help make wise decisions. And **the** trouble is that no one can agree on what is wise. How do you solve that? EM : Well I think we would want to err on **the** side – if in doubt, let **the** speech exist. If it ' s, you know, a gray area, I would say let **the** tweet exist. But obviously, you know, in a case where there ' s perhaps a lot of controversy that you would not want to necessarily promote that tweet. So I ' m not saying that I have all **the** answers here. But I do think that we want to be just very reluctant to delete things and just be very cautious with permanent bans. You know, time-outs, I think, are better than, sort of, permanent bans. And... But just in general, like I said... It won ' t be perfect, but I think we want it to really have **the** perception and reality that speech is as free as reasonably possible. And a good sign as to whether there ' s free speech is : is someone you don ' t like allowed to say something you don ' t like? And if that is **the** case, then we have free speech. And it ' s damn annoying when someone you don ' t like says something you don ' t like. That is a sign of a healthy, functioning, free speech situation. CA : I think many people would agree with that. And looking at **the** reaction online, many people are excited by you coming in and **the** changes you ' re proposing. Some others are absolutely horrified. Here ' s how they would see it. They would say,"Wait a sec. We agree that Twitter is an incredibly important town square. It is where **the** world exchanges opinion about life and death matters. How on Earth could it be owned by **the** world ' s richest person? That can ' t be right."So what ' s **the** response there? Is there any way that you can distance yourself from **the** actual decision making that matters on content in some very clear way that is convincing to people? EM : Well, like I said, I think it ' s very important that **the** algorithm be open-sourced and that any manual adjustments be identified. So if somebody did something to a tweet, there ' s information attached to it that action was taken. And I won ' t personally be, you know, in there editing tweets. But you ' ll know if something was done to promote, demote or otherwise affect a tweet. You know, as for media sort of ownership, I mean, you ' ve got, you know, Mark Zuckerberg owning Facebook and Instagram and WhatsApp and with a share ownership structure that will have Mark Zuckerberg XIV still controlling those entities. Like, literally. We won ' t have that at Twitter. CA : If you commit to opening up **the** algorithm that definitely gives some level of confidence. Talk about some of **the** other changes that you ' ve proposed. **The** edit button, that ' s definitely coming if you have your way. EM : Yeah. I think, I mean, frankly... **The** top priority I would have is eliminating **the** spam and scam bots and **the** bot armies that are on Twitter. You know, I think these influence – they make **the** product much worse. You know, if I had a Dogecoin for every crypto scam I saw. I would have 100 billion Dogecoin. CA : Do you regret sparking a sort of, storm of excitement over DOGE and, you know, where it ' s gone? EM : I mean, I think DOGE is fun. And, you know, I ' ve always said don ' t bet **the** farm on Dogecoin, FYI. But I think it ' s, I like dogs and I like memes, and it ' s got both of those. CA : But just on **the** edit button, how do you get around **the** problem of, so someone tweets,"Elon **rocks**"and it ' s tweeted by two million people. And then after that, they edit it"Elon sucks,"and then all those retweets they ' re all embarrassed. How do you avoid that type of changing of meaning so that retweeters are exploited? EM : Well, I think you ' d only have **the** edit capability for a short period of time. And probably **the** thing to do upon **the** edit would be to zero out all retweets and favorites. CA :

OK. EM : I ’ m open to ideas though, you know. CA : So in one way, **the** algorithm works kind of well for you right now, I wanted to show you this. This is a typical tweet of mine, kind of lame and wordy and whatever. And **the** amazing response it gets is this, oh, my God, 97 likes. And then I tried another one. [I get to interview @elonmusk on Thursday here at TED. What questions would YOU ask him?] 29, 000 likes. So **the** algorithm, at least seems to be, at **the** moment, you know :”If, expand to **the** world immediately.”Not bad, right? EM : Yeah, I guess so, I mean, that is cool. CA : So help us understand how it is you ’ ve built this incredible following on Twitter yourself when some of **the** people who love you **the** most look at some of what you tweet and they think it ’ s somewhere between embarrassing and crazy, some of it ’ s amazing. EM : It is a little... CA : But is that actually why it ’ s worked, why has it worked? EM : I mean, I don ’ t know. I ’ m tweeting more or less stream of consciousness, you know. It ’ s not like, let me think about some grand plan about my Twitter or whatever. You know, I ’ m, like, literally, on **the** toilet or something, like,”Ha ha, this is funny.”And then tweet that out. That ’ s like most of them. That ’ s, you know, oversharing. CA : But you are obsessed with getting **the** most out of every minute of your day. And so why not? EM : So, I don ’ t know. I try to tweet out things that are interesting or funny. And then people seem to like it. CA : So if you are unsuccessful – actually, before I ask that, let me ask this. So how can I say, is funding secured? EM : I have sufficient assets to complete... This is not a forward-looking statement, blah blah blah. I mean, I can do it if possible. I should say, actually even originally with Tesla back in **the** day, funding was actually secured. I want to be clear about that. In fact, this may be a good opportunity to clarify that. Funding was indeed secured, and I should say, like, why do I not have respect for **the** SEC in that situation? And I don ’ t mean to blame everyone at **the** SEC, but certainly **the** San Francisco office, it ’ s because **the** SEC knew that funding was secured, but they pursued an active public investigation nonetheless. At **the** time, Tesla was in a precarious financial situation, and I was told by **the** banks that if I did not agree to settle with **the** SEC that **the** banks would cease providing working capital and Tesla would go bankrupt immediately. So that ’ s like having a gun to your child ’ s head. So I was forced to concede to **the** SEC unlawfully. Those bastards. And now it makes it look like I lied when I did not, in fact, lie. I was forced to admit that I lied to save Tesla ’ s life. And that ’ s **the** only reason. CA : Given what ’ s actually happened – Given what ’ s actually happened to Tesla since then, though, aren ’ t you glad that you didn ’ t take it private? EM : Yeah. I mean... It ’ s difficult to put yourself in **the** position at **the** time, Tesla was under **the** most relentless short seller attack in **the** history of **the** stock market. There ’ s something called”short and distort,”where **the** barrage of negativity that Tesla was experiencing from short sellers on Wall Street was beyond all belief. Tesla was **the** most shorted stock in **the** history of stock markets. This is saying something. So, you know, this was affecting our ability to hire people, it was affecting our ability to sell cars, it was... Yeah, it was terrible. They wanted Tesla to die so bad, they could taste it. CA : Well, most of them have paid **the** price. EM : Yes. Where are they now? CA : So that was a very strong statement. Obviously, a lot of people who support you, I would ’ ve thought, would say, you have so much to offer **the** world on **the** upside, on **the** vision side, don ’ t waste your time getting distracted by these battles that bring out negativity and make people feel that you ’ re being defensive. People don ’ t like fights, especially with powerful government authorities. They ’ d rather buy into your dream. Aren ’ t you encouraged by people just to edit that temptation out and go with **the** bigger story? EM : Well, I mean, I would say, like, you know, I ’ m somewhat of a mixed bag, you know. CA : Well, you ’ re a fighter and you don ’ t... You don ’ t like to lose and you are determined that you don ’ t. Basically, I mean. EM : Sure I don ’ t like to lose, I ’ m not sure many people do. But **the** truth matters to me a lot. Sort of, pathologically, it matters to me. CA : OK. So you don ’ t like to lose, if in this case you are not successful in, you know, **the** board does not accept your offer, you ’ ve said you won ’ t go higher. Is there a plan B? EM : There is. CA : I think we would like to hear a little bit about plan B. EM : For another time, I think. CA : Another time, alright. I... That ’ s a nice tease. Alright. I would love to try to understand this brain of yours more, Elon. With your permission, I ’ d like to just play this. Oh, actually, before we do that, here was one of **the** thousands of questions that people asked. I thought this was actually quite a good one.”If you could go back in time and change one decision you made along **the** way”– do your own edit button –”which one would it be and why?”EM : Do you mean like a career decision or something? CA : Just any decision over **the** last few years, like your decision to invest in Twitter in **the** first place or your... Anything. EM : I mean, **the** worst business decision I ever made was not starting Tesla with just JB Straubel. By far **the** worst decision I ’ ve ever made is not just starting Tesla with JB. That ’ s number one by far. CA : Alright, so JB Straubel was **the** visionary cofounder who was obsessed with and knew so much about batteries. And your decision to go with Tesla, **the** company as it was, meant that you got locked into what you **concluded** was a weird architecture now. EM : There ’ s a lot of confusion. Tesla did not exist in any... Tesla was a shell company with no employees, no intellectual property, when I invested. But a false narrative has been created by one of **the** other cofounders, Martin Eberhard. And I don ’ t want to get into **the** nastiness here, but I didn ’ t invest in an existing company. We created a company. And ultimately, **the** creation of that company was done by JB and me. And unfortunately, there ’ s someone else, another cofounder who has made it his life ’ s mission to make it sound like he created **the** company, which is false. CA : Wasn ’ t there another issue right at **the** heart of **the** development of **the** Tesla Model 3, where Tesla almost went bankrupt? And I think you have said that part of **the** reason for that was that you overestimated **the** extent to which it was possible, at that time, to automate a factory. Huge amount was spent kind of over-automating, and it didn ’ t work, and it nearly took **the** company down. Is that fair? EM : I mean, first of all, it ’ s important to understand, like, what has Tesla actually accomplished that is most noteworthy. It is not **the** creation of an electric vehicle or creating an electric vehicle prototype or low-volume production of a car. There have been hundreds of car start-ups over **the** years, hundreds. And in fact, at one point, Bloomberg counted up **the** number of electric vehicle start-ups, and I think they got to almost 500. So **the** hard part is not creating a prototype or going into limited production. **The** absolutely difficult thing, which has not been accomplished by an American car company in 100 years, is reaching volume production without going bankrupt. That is **the** actual hard thing. **The** last company, American company, to reach volume production without going bankrupt, was Chrysler in **the** ’ 20s. CA : And it nearly happened to Tesla. EM : Yes, but it ’ s not like, oh, geez, I guess if we ’ d just done more manual stuff, things would have been fine. Of course not. That is definitely not **the** case. So we basically messed up almost every aspect of **the** Model 3 production line, from cells to packs to drive inverters, motors, body line, **the** paint shop, final assembly, everything. Everything was messed up. I lived in **the** Fremont and Nevada factories for three years, fixing that production line, running around like a maniac through every part of that factory. Living with **the** team. I slept on **the** floor, so **the** team, who was going through a hard time, could see me on **the** floor. That they knew that I was not in some ivory tower. When whatever pain they experienced, I had it more.

CA : And some people who knew you well actually thought you were making a terrible mistake, that you were driving yourself to **the** edge of sanity, almost. And that you were in danger of making bad choices. And in fact, I heard you say last week, Elon, that you, because of Tesla ' s huge value now and, you know, **the** significance of every minute that you spend, that you are in danger of sort of, obsessing over it, spending all this time to **the** edge of sanity. That doesn ' t sound super wise. Isn ' t there... Your time, your completely sane, centered, rested time and decision making is more powerful and compelling than that sort of,"I can barely hold my eyes open."So surely it should be an absolute strategic priority to look after yourself. EM : I mean, there wasn ' t any other way to make it work. They were three years of hell. 2017, 2018 and 2019 were **the** longest period of excruciating pain in my life. There wasn ' t any other way, and we barely made it. And we were on **the** ragged edge of bankruptcy **the** entire time. It ' s not like I want **the** pain, I don ' t like it. Those were three – So, so, so much pain. But it had to be done or Tesla would be dead. CA : When you looked around **the** Gigafactory that we saw images of earlier last week and just see where **the** company ' s come, do you feel that this challenge of figuring out **the** new way of manufacturing, that you actually have an edge now, that it ' s different, that you ' ve figured out how to do this. And that those three years, won ' t be repeated? You ' ve actually figured out a new way of manufacturing. EM : At this point, I think I know more about manufacturing than anyone currently alive on Earth. I can tell you how every damn part of that car is made. It ' s basically if you just live on **the** factory, you live in **the** factory for three years and – CA : That was nice. EM : Poignant note to something. CA : Someone wants to compose a symphony to that expression of confidence, something like that. I have no idea what that is. EM : Anyway, yeah. Every aspect of a car, six ways to Sunday, I know it. CA : I mean, you talk about scale, right. You ' re in **the** middle of writing your new master plan, and you ' ve said that scale is at **the** heart of it. Why does scale matter? Why are you obsessed with it, what are you thinking? EM : Yeah, well, see, in order to accelerate **the** advent of sustainable energy, there must be scale. Because we ' ve got to transition a vast economy that is currently overly dependent on **fossil** fuels to a sustainable energy economy. One where **the** energy is – Yeah, I mean, we ' ve got to do it. So **the** energy ' s got to be sustainably generated with wind, solar, hydro, geothermal, I ' m a believer in nuclear as Isabelle [Boemeke] gave a talk about. And then since solar and wind is intermittent, you have to have stationary storage batteries, and then we ' ve got to transition all transport to electric. If we do those things, we have a sustainable energy future. **The** faster we do those things, **the** less risk we put to **the** environment. So sooner is better. And so scale is very important. You know, it ' s not about fresh releases. It ' s about tonnage. What was **the** tonnage of batteries produced and obviously done in a sustainable way? And our estimate is that approximately 300 terawatt hours of battery storage is needed to transition transport, electricity and heating and cooling to a fully electric situation. There may be some different estimates out there, but our estimate is 300 terawatt hours. CA : So we dug into this a lot in **the** interview that we recorded last week, so people can go in and hear that more. But I mean, **the** context is, that is, I think about 1, 000 times **the** current installed battery capacity. I mean, **the** scale up needed is breathtaking, basically. And... So your vision is to commit Tesla to try to deliver on a meaningful percentage of what is needed. And call on others to do **the** rest. This is a task for humanity to massively scale up our response to change **the** energy grid. EM : Yes. It ' s like basically how fast can we scale and encourage others to scale to get to that 300-terawatt-hour installed base of batteries? CA : Right. EM : And then, of course, there ' ll be a tremendous need to recycle those batteries, and it makes sense to recycle them because **the** raw materials are like high grade ore. People shouldn ' t think there will be this big pile of batteries, they can get recycled, because even a dead battery pack is worth about 1, 000 dollars. But this is what ' s needed for a sustainable energy future. So we ' re going to try to take a set of actions that accelerate **the** day and bring **the** day of a sustainable energy future sooner. CA : OK. There ' s going to be a huge interest in your master plan when you publish that. Meanwhile, I just would love to understand more what goes on in this brain of yours, because it is a pretty unique one. I want to play, with your permission, this very funny opening from SNL, Saturday Night Live. Thank you. Thank you very much. It ' s an honor to be hosting Saturday Night Live. I mean that. Sometimes after I say something, I have to say,"I mean that."So people really know that I mean it. That ' s because I don ' t always have a lot of intonational variation in how I speak. Which, I ' m told, makes for great comedy. I ' m actually making history tonight as **the** first person with Asperger ' s to host SNL. CA : And I think you followed that up with – EM : At least **the** first person to admit it. CA : **The** first person to admit it. So this was a brave thing to say. But I would love to understand you know, how you think of Asperger ' s, like, whether you can give us any sense of, even you as a boy, what **the** experience was or as you now understand, with **the** benefit of hindsight. Can you talk about that a bit? EM : Well, I think everyone ' s experience is going to be somewhat different. But I guess for me, **the** social cues were not intuitive. So I was just very bookish, and I didn ' t understand... I guess others could sort of, intuitively understand... What was meant by something. I would just tend to take things very literally, like, **the** words, as spoken, were exactly what they meant. But then that turned out to be wrong. They ' re not simply saying exactly what they mean. There ' s all sorts of other things that are meant. It took me a while to figure that out. I was, you know, bullied quite a lot. So... I did not have a sort of, happy childhood, to be frank. It was quite, quite rough. But I read a lot of books. I read lots and lots of books. And, you know, sort of, gradually understood more from **the** books that I was reading and watched a lot of movies and... You know, just... But it took me a while to understand things that most people intuitively understand. CA : So I ' ve wondered whether it ' s possible that that was, in a strange way, an incredible gift to you and indirectly to many other people. Inasmuch as... Brain ' s, you know, are plastic. And they go where **the** action is. And if for some reason **the** external world and social cues, which so many people spend so much time and mental energy obsessing over, if that is partly cut off, isn ' t it possible that that is partly what gave you **the** ability to understand inwardly **the** world at a much deeper level than most people do? EM : I suppose that ' s certainly possible. I think there ' s maybe some value also from a technology standpoint, because I found it rewarding to spend all night programming **computers** just by myself. And I think most people, most people don ' t **enjoy** typing strange symbols into a **computer** by themselves all night. They think that ' s not fun. But I thought it was, I really liked it. So I would just program all night by myself. And I found that to be quite enjoyable. But I think that is not normal. CA : I ' ve thought a lot about... It ' s a riddle to a lot of people of how you ' ve done this, how you ' ve repeatedly innovated in these different industries. And you know, every entrepreneur sees possibility in **the** future and then acts to make that real. It feels to me like you see possibility just more broadly than almost anyone and can connect **the** dots. So you see scientific possibility based on a deep understanding of physics and knowing what **the** fundamental equations are, what **the** technologies are that are based on that science and where they could go, you see technological possibility. And then really unusually, you combine that with economic possibility, of like what it actually would cost, is there a system you can imagine where you could affordably make that thing, and that... sometimes you then get conviction that there is an opportunity here. Put those pieces together and you could do something amazing. EM : Yeah, I think one aspect of whatever condition I had was I was just absolutely obsessed with truth. Just obsessed with truth. And so **the** obsession with truth is why I studied physics, because physics attempts to understand **the** truth, **the** truth of **the universe**. Physics is just, what are **the** provable truths of **the universe**. And truths that have predictive power. So for me, physics was sort of, a very natural thing to study. Nobody made me study it. I was intrinsically interested to understand **the** nature of **the universe**. And then **computer** science or information theory also to just understand logic. And, you know, there ' s an argument that... That information theory is actually operating at a more fundamental level, more fundamental level than even physics. So just yeah... Physics and information theory were really interesting to me. CA : So when you say truth, I mean, like, some people... What you ' re talking about is **the** truth of **the universe**. **The** fundamental truths that drive **the universe**, it ' s like, a deep curiosity about what this **universe** is, why we ' re here, simulation, we don ' t have time to go into that. But I mean, you ' re just deeply, deeply curious about, what this is for, what this is, this whole thing. EM : Yes, I think **the** why of things is very important. When I was in young teens, I got quite depressed about **the** meaning of life. And I was trying to sort of, understand **the** meaning of life. I ' m looking at, reading religious texts and reading books on philosophy. And I got into **the** German philosophers, which is definitely not wise if you ' re a young teenager, I have to say. It can be a bit dark. Much better read as an adult. And then actually, I ended up reading"**The** Hitchhiker ' s Guide to **the** Galaxy,"which is actually a book on philosophy just sort of disguised as a silly humor book. But it ' s actually a philosophy book. And Adams makes **the** point that it ' s actually **the** question that is harder than **the** answer. You know, he sort of makes a joke that **the** answer is 42. That number does pop up a lot. And 420 is just 10 times 42. CA : Ten times more significant than 42. EM : But, you know, you can make a **triangle** with 42 degrees and two 69s. So there ' s no such thing as a perfect **triangle**, or is there? CA : But even more important than **the** answer is **the** question. That was **the** whole **theme** of that book. I mean, is that basically how you see meaning then, that it ' s **the** pursuit of questions? EM : So I have a sort of, a proposal for a worldview or a motivating philosophy, which is to understand what questions to ask about **the** answer that is **the universe**. And to **the** degree that we expand **the** scope and scale of consciousness, biological and digital, we will be better able to ask these questions, to frame these questions and to understand why we ' re here, how we got here, what **the** heck is going on. And so that is my driving philosophy, is to expand **the** scope and scale of consciousness that we may better understand **the** nature of **the universe**. CA : Elon, one of **the** things that was most touching last week – was seeing you hang out with your kids. Here ' s, if I may... EM : He looks vaguely like a ventriloquist dummy there. I mean, how do you know that ' s real? CA : So that ' s X, and it was just a delight seeing you hang out with him. What ' s his future going to be? I mean, I don ' t mean him personally, but **the** world he ' s going to grow up in. What future do you believe he will grow up in? EM : Well, I mean, a very digital future. A very different world than I grew up in, that ' s for sure. But I think we want to obviously do our absolute best to ensure that **the** future is good for everyone ' s children. And that, you know, that **the** future is something that you can look forward to and not feel sad about. You know, you want to get up in **the** morning and be excited about **the** future. And we should fight for **the** things that make us excited about **the** future. You know, **the** future cannot just be about one miserable thing after another, solving one sad problem after another. There have got to be things that get you excited. Like, you want to live. These things are very important. You should have more of it. CA : And it ’ s not as if it ’ s a done deal, like it ’ s all to play for. Like, **the** future may be horrible. Still, there are scenarios where it is horrible, but you see a pathway to an exciting future both on Earth and on Mars and in our minds through **artificial** intelligence and so forth. I mean, in your heart of hearts, do you really believe that you are helping deliver that exciting future for X and for others? EM : I mean, I ’ m trying my hardest to do so. I, you know, I love humanity, and I think that we should fight for a good future for humanity. And I think we should be optimistic about **the** future and fight to make that optimistic future happen. CA : Elon, I think that ’ s **the** perfect place to close this. Thank you so much for spending time coming here and for **the** work that you ’ re doing. And good luck with finding a wise course through on Twitter and everything else. EM : Alright, thank you.

Text Sample 72: POS Dim 1 – 2020 – Score 32.00 – 2020/t004244.txt
Chris Anderson : Al, welcome. So look, just six months ago – it seems a lifetime ago, but it really was just six months ago – climate seemed to be on **the** lips of every thinking person on **the planet**. Recent events seem to have swept it all away from our attention. How worried are you about that? Al Gore : Well, first of all Chris, thank you so much for inviting me to have this conversation. People are reacting differently to **the** climate crisis in **the** midst of these other great challenges that have taken over our awareness, appropriately. One reason is something that you mentioned. People get **the** fact that when scientists are warning us in ever more dire terms and setting their hair on fire, so to speak, it ’ s best to listen to what they ’ re saying, and I think that lesson has begun to sink in in a new way. Another similarity, by **the** way, is that **the** climate crisis, like **the** COVID-19 pandemic, has revealed in a new way **the** shocking injustices and inequalities and disparities that affect communities of color and low-income communities. There are differences. **The** climate crisis has effects that are not measured in years, as **the** pandemic is, but consequences that are measured in centuries and even longer. And **the** other difference is that instead of depressing economic activity to deal with **the** climate crisis, as nations around **the** world have had to do with COVID-19, we have **the** opportunity to create tens of millions of new jobs. That sounds like a political phrasing, but it ’ s literally true. For **the** last five years, **the** fastest-growing job in **the** US has been solar installer. **The** second-fastest has been wind **turbine** technician. And **the**”Oxford Review of Economics,”just a few weeks ago, pointed **the** way to a very jobs-rich recovery if we emphasize **renewable** energy and **sustainability** technology. So I think we are crossing a tipping point, and you need only look at **the** recovery plans that are being presented in nations around **the** world to see that they ’ re very much focused on a green recovery. CA : I mean, one obvious impact of **the** pandemic is that it ’ s brought **the** world ’ s economy to a shuddering halt, thereby reducing **greenhouse** gas **emissions**. I mean, how big an effect has that been, and is it unambiguously good news? AG : Well, it ’ s a little bit of an illusion, Chris, and you need only look back to **the** Great Recession in 2008 and ’ 09, when there was a one percent decline in **emissions**, but then in 2010, they came roaring back during **the** recovery with a four percent increase. **The** latest estimates are that **emissions** will go down by at least five percent during this induced coma, as **the** economist Paul Krugman perceptively described it, but whether it goes back **the** way it did after **the** Great Recession is in part up to us, and if these green recovery

plans are actually implemented, and I know many countries are determined to implement them, then we need not repeat that pattern. After all, this whole process is **occurring** during a period when **the** cost of **renewable** energy and electric vehicles, batteries and a range of other **sustainability** approaches are continuing to fall in price, and they ' re becoming much more competitive. Just a quick reference to how fast this is : five years ago, electricity from solar and wind was cheaper than electricity from **fossil** fuels in only one percent of **the** world. This year, it ' s cheaper in **two-thirds** of **the** world, and five years from now, it will be cheaper in virtually 100 percent of **the** world. EVs will be cost-competitive within two years, and then will continue falling in price. And so there are changes underway that could interrupt **the** pattern we saw after **the** Great Recession. CA : **The** reason those pricing differentials happen in different parts of **the** world is obviously because there ' s different amounts of sunshine and wind there and different building costs and so forth. AG : Well, yes, and government policies also account for a lot. **The** world is continuing to subsidize **fossil** fuels at a ridiculous amount, more so in many developing countries than in **the** US and developed countries, but it ' s subsidized here as well. But everywhere in **the** world, wind and solar will be cheaper as a source of electricity than **fossil** fuels, within a few years. CA : I think I ' ve heard it said that **the** fall in **emissions** caused by **the** pandemic isn ' t that much more than, actually, **the** fall that we will need every single year if we ' re to meet **emissions** targets. Is that true, and, if so, doesn ' t that seem impossibly daunting? AG : It does seem daunting, but first look at **the** number. That number came from a study a little over a year ago released by **the** IPCC as to what it would take to keep **the** Earth ' s temperatures from increasing more than 1. 5 degrees Celsius. And yes, **the** annual reductions would be significant, on **the** order of what we ' ve seen with **the** pandemic. And yes, that does seem daunting. However, we do have **the** opportunity to make some fairly dramatic changes, and **the** plan is not a mystery. You start with **the** two sectors that are closest to an effective transition – electricity generation, as I mentioned – and last year, 2019, if you look at all of **the** new electricity generation built all around **the** world, 72 percent of it was from solar and wind. And already, without **the** continuing subsidies for **fossil** fuels, we would see many more of these plants being shut down. There are some new **fossil** plants being built, but many more are being shut down. And where **transportation** is concerned, **the** second sector ready to go, in addition to **the** cheaper prices for EVs that I made reference to before, there are some 45 jurisdictions around **the** world – national, regional and municipal – where laws have been passed beginning a phaseout of internal combustion engines. Even India said that by 2030, less than 10 years from now, it will be illegal to sell any new internal combustion engines in India. There are many other examples. So **the** past small reductions may not be an accurate guide to **the** kind we can achieve with serious national plans and a focused global effort. CA : So help us understand just **the** big picture here, Al. I think before **the** pandemic, **the** world was emitting about 55 gigatons of what they call"CO2 equivalent,"so that includes other **greenhouse** gases like methane dialed up to be **the** equivalent of CO2. And am I right in saying that **the** IPCC, which is **the** global organization of scientists, is recommending that **the** only way to fix this crisis is to get that number from 55 to zero by 2050 at **the** very latest, and that even then, there ' s a chance that we will end up with temperature rises more like two degrees Celsius rather than 1. 5? I mean, is that approximately **the** big picture of what **the** IPCC is recommending? AG : That ' s correct. **The** global goal established in **the** Paris Conference is to get to net zero on a global basis by 2050, and many people quickly add that that really means a 45 to 50 percent reduction by 2030 to make that pathway to net zero feasible. CA : And that kind of timeline is **the** kind of timeline where people couldn ’ t even imagine it. It ’ s just hard to think of policy over 30 years. So that ’ s actually a very good shorthand, that humanity ’ s task is to cut **emissions** in half by 2030, approximately speaking, which I think boils down to about a seven or eight percent reduction a year, something like that, if I ’ m not wrong. AG : Not quite. Not quite that large but close, yes. CA : So it is something like **the** effect that we ’ ve experienced this year may be necessary. This year, we ’ ve done it by basically shutting down **the** economy. You ’ re talking about a way of doing it over **the** coming years that actually gives some economic growth and new jobs. So talk more about that. You ’ ve referred to changing our energy sources, changing how we transport. If we did those things, how much of **the** problem does that solve? AG : Well, we can get to – well, in addition to doing **the** two sectors that I mentioned, we also have to deal with manufacturing and all **the** use cases that require temperatures of a thousand degrees Celsius, and there are solutions there as well. I ’ ll come back and mention an exciting one that Germany has just embarked upon. We also have to tackle regenerative **agriculture**. There is **the** opportunity to sequester a great deal of **carbon** in topsoils around **the** world by changing **the** agricultural **techniques**. There is a farmer-led movement to do that. We need to also retrofit buildings. We need to change our management of forests and **the** ocean. But let me just mention two things briefly. First of all, **the** high temperature use cases. Angela Merkel, just 10 days ago, with **the** leadership of her minister Peter Altmaier, who is a good friend and a great public servant, have just embarked on a green hydrogen strategy to make hydrogen with zero marginal cost **renewable** energy. And just a word on that, Chris : you ’ ve heard about **the** intermittency of wind and solar – solar doesn ’ t produce electricity when **the** sun ’ s not shining, and wind doesn ’ t when **the** wind ’ s not blowing – but batteries are getting better, and these technologies are becoming much more efficient and powerful, so that for an increasing number of hours of each day, they ’ re producing often way more electricity than can be used. So what to do with it? **The** marginal cost for **the** next kilowatt-hour is zero. So all of a sudden, **the** very energy-intensive process of cracking hydrogen from water becomes economically feasible, and it can be substituted for **coal** and gas, and that ’ s already being done. There ’ s a Swedish company already making steel with green hydrogen, and, as I say, Germany has just embarked on a major new initiative to do that. I think they ’ re pointing **the** way for **the** rest of **the** world. Now, where building retrofits are concerned, just a moment on this, because about 20 to 25 percent of **the** global warming pollution in **the** world and in **the** US comes from inefficient buildings that were constructed by companies and individuals who were trying to be competitive in **the** marketplace and keep their margins acceptably high and thereby skimping on insulation and **the** right windows and LEDs and **the** rest. And yet **the** person or company that buys that building or leases that building, they want their monthly utility bills much lower. So there are now ways to close that so-called agent-principal divide, **the** differing incentives for **the** builder and occupier, and we can retrofit buildings with a program that literally pays for itself over three to five years, and we could put tens of millions of people to work in jobs that by definition cannot be outsourced because they exist in every single community. And we really ought to get serious about doing this, because we ’ re going to need all those jobs to get sustainable prosperity in **the** aftermath of this pandemic. CA : Just going back to **the** hydrogen economy that you referred to there, when some people hear that, they think,”Oh, are you talking about hydrogen-fueled cars?”And they ’ ve heard that that probably won ’ t be a winning strategy. But you ’ re thinking much more broadly than that, I think, that it ’ s not just hydrogen as a kind of storage mechanism to act as a buffer for **renewable** energy, but also hydrogen could be essential for some of **the** other processes in **the** economy like making steel, making cement, that are fundamentally carbon-intensive processes right now but could be transformed if we had much cheaper sources of hydrogen. Is that right? AG : Yes, I was always skeptical about hydrogen, Chris, principally because it ' s been so expensive to make it, to"crack it out of water,"as they say. But **the** game-changer has been **the** incredible abundance of solar and wind electricity in volumes and amounts that people didn ' t expect, and all of a sudden, it ' s cheap enough to use for these very energy-intensive processes like creating green hydrogen. I ' m still a bit skeptical about using it in vehicles. Toyota ' s been betting on that for 25 years and it hasn ' t really worked for them. Never say never, maybe it will, but I think it ' s most useful for these high-temperature industrial processes, and we already have a pathway for decarbonizing **transportation** with electricity that ' s working extremely well. Tesla ' s going to be soon **the** most valuable automobile company in **the** world, already in **the** US, and they ' re about to overtake Toyota. There is now a semitruck company that ' s been stood up by Tesla and another that is going to be a hybrid with electricity and green hydrogen, so we ' ll see whether or not they can make it work in that application. But I think electricity is preferable for cars and trucks. CA : We ' re coming to some community questions in a minute. Let me ask you, though, about nuclear. Some environmentalists believe that nuclear, or maybe new generation nuclear power is an essential part of **the** equation if we ' re to get to a truly clean future, a clean energy future. Are you still pretty skeptical on nuclear, Al? AG : Well, **the** market ' s skeptical about it, Chris. It ' s been a crushing disappointment for me and for so many. I used to represent Oak Ridge, where nuclear energy began, and when I was a young congressman, I was a booster. I was very enthusiastic about it. But **the** cost overruns and **the** problems in building these plants have become so severe that utilities just don ' t have an appetite for them. It ' s become **the** most expensive source of electricity. Now, let me hasten to add that there are some older nuclear reactors that have more useful time that could be added onto their lifetimes. And like a lot of environmentalists, I ' ve come to **the** view that if they can be determined to be safe, they should be allowed to continue operating for a time. But where new nuclear power plants are concerned, here ' s a way to look at it. If you are – you ' ve been a CEO, Chris. If you were **the** CEO of – I guess you still are. If you were **the** CEO of an electric utility, and you told your executive team,"I want to build a nuclear power plant,"two of **the** first questions you would ask are, number one : How much will it cost? And there ' s not a single engineering consulting firm that I ' ve been able to find anywhere in **the** world that will put their name on an opinion giving you a cost estimate. They just don ' t know. A second question you would ask is : How long will it take to build it, so we can start selling **the** electricity? And again, **the** answer you will get is,"We have no idea."So if you don ' t know how much it ' s going to cost, and you don ' t know when it ' s going to be finished, and you already know that **the** electricity is more expensive than **the** alternate ways to produce it, that ' s going to be a little discouraging, and, in fact, that ' s been **the** case for utilities around **the** world. CA : OK. So there ' s definitely an interesting debate there, but we ' re going to come on to some community questions. Let ' s have **the** first of those questions up, please. From Prosanta Chakrabarty :"People who are skeptical of COVID and of climate change seem to be skeptical of science in general. It may be that **the** singular message from scientists gets diluted and convoluted. How do we fix that?"AG : Yeah, that ' s a great question, Prosanta. Boy, I ' m trying to put this succinctly and shortly. I think that there has been a feeling that experts in general have kind of let **the**

US down, and that feeling is much more pronounced in **the** US than in most other countries. And I think that **the** considered opinion of what we call experts has been diluted over **the** last few decades by **the** unhealthy dominance of big money in our political system, which has found ways to really twist economic policy to benefit elites. And this sounds a little radical, but it ' s actually what has happened. And we have gone for more than 40 years without any meaningful increase in middle-income pay, and where **the** injustice experienced by African Americans and other communities of color are concerned, **the** differential in pay between African Americans and majority Americans is **the** same as it was in 1968, and **the** family wealth, **the** net worth – it takes 11 and a half so-called"typical"African American families to make up **the** net worth of one so-called"typical"White American family. And you look at **the** soaring incomes in **the** top one or **the** top one-tenth of one percent, and people say,"Wait a minute. Whoever **the** experts were that designed these policies, they haven ' t been doing a good job for me."A final point, Chris : there has been an assault on reason. There has been a war against truth. There has been a strategy, maybe it was best known as a strategy decades ago by **the** tobacco companies who hired actors and dressed them up as doctors to falsely reassure people that there were no health consequences from smoking cigarettes, and a hundred million people died as a result. That same strategy of diminishing **the** significance of truth, diminishing, as someone said, **the** authority of knowledge, I think that has made it kind of open season on any inconvenient truth – forgive another buzz phrase, but it is apt. We cannot abandon our devotion to **the** best available evidence tested in reasoned discourse and used as **the** basis for **the** best policies we can form. CA : Is it possible, Al, that one consequence of **the** pandemic is actually a growing number of people have revisited their opinions on scientists? I mean, you ' ve had a chance in **the** last few months to say,"Do I trust my political leader or do I trust this scientist in terms of what they ' re saying about this virus?"Maybe lessons from that could be carried forward? AG : Well, you know, I think if **the** polling is accurate, people do trust their doctors a lot more than some of **the** politicians who seem to have a vested interest in pretending **the** pandemic isn ' t real. And if you look at **the** incredible bust at President Trump ' s rally in Tulsa, a stadium of 19, 000 people with less than **one-third** filled, according to **the** fire marshal, you saw all **the** empty seats if you saw **the** news **clips**, so even **the** most loyal Trump supporters must have decided to trust their doctors and **the** medical advice rather than Dr. Donald Trump. CA : With a little help from **the** TikTok generation, perchance. AG : Well, but that didn ' t affect **the** turnout. What they did, very cleverly, and I ' m cheering them on, what they did was affect **the** Trump White House ' s expectations. They ' re **the** reason why he went out a couple days beforehand and said,"We ' ve had a million people sign up."But they didn ' t prevent – they didn ' t take seats that others could have otherwise taken. They didn ' t affect **the** turnout, just **the** expectations. CA : OK, let ' s have our next question here."Are you concerned **the** world will rush back to **the** use of **the** private car out of fear of using shared public **transportation**?"AG : Well, that could actually be one of **the** consequences, absolutely. Now, **the** trends on mass transit were already **inching** in **the** wrong direction because of Uber and Lyft and **the** ridesharing services, and if autonomy ever reaches **the** goals that its advocates have hoped for then that may also have a similar effect. But there ' s no doubt that some people are going to be probably a little more reluctant to take mass **transportation** until **the** fear of this pandemic is well and truly gone. CA : Yeah. Might need a vaccine on that one. AG : Yeah. CA : Next question. Sonaar Luthra, thank you for this question from LA."Given **the** temperature rise in **the** Arctic this past week, seems like **the** rate we are losing our **carbon** sinks like permafrost or forests is accelerating faster than we predicted. Are our models too focused on human **emissions**?”Interesting question. AG : Well, **the** models are focused on **the** factors that have led to these incredible temperature spikes in **the** north of **the** Arctic Circle. They were predicted, they have been predicted, and one of **the** reasons for it is that as **the** snow and ice cover melts, **the** sun ’ s incoming rays are no longer reflected back into space at a 90 percent rate, and instead, when they fall on **the** dark tundra or **the** dark ocean, they ’ re absorbed at a 90 percent rate. So that ’ s a magnifier of **the** warming in **the** Arctic, and this has been predicted. There are a number of other consequences that are also in **the** models, but some of them may have to be recalibrated. **The** scientists are freshly concerned that **the emissions** of both CO2 and methane from **the** thawing tundra could be larger than they had hoped they would be. There ’ s also just been a brand-new study. I won ’ t spend time on this, because it deals with a kind of geeky term called”climate sensitivity,”which has been a factor in **the** models with large error bars because it ’ s so hard to pin down. But **the** latest evidence indicates, worryingly, that **the** sensitivity may be greater than they had thought, and we will have an even more daunting task. That shouldn ’ t discourage us. I truly believe that once we cross this tipping point, and I do believe we ’ re doing it now, as I ’ ve said, then I think we ’ re going to find a lot of ways to speed up **the emissions** reductions. CA : We ’ ll take one more question from **the** community. Haha.”Geoengineering is making extraordinary progress. Exxon is investing in technology from Global Thermostat that seems promising. What do you think of these air and water **carbon** capture technologies?”Stephen Petranek. AG : Yeah. Well, you and I have talked about this before, Chris. I ’ ve been strongly opposed to conducting an unplanned global experiment that could go wildly wrong, and most are really scared of that approach. However, **the** term”geoengineering”is a nuanced term that covers a lot. If you want to paint roofs white to reflect more energy from **the** cityscapes, that ’ s not going to bring a danger of a runaway effect, and there are some other things that are loosely called”geoengineering”like that, which are fine. But **the** idea of blocking out **the** sun ’ s rays – that ’ s insane in my opinion. Turns out plants need sunlight for photosynthesis and solar panels need sunlight for producing electricity from **the** sun ’ s rays. And **the** consequences of changing everything we know and pretending that **the** consequences are going to precisely cancel out **the** unplanned experiment of global warming that we already have underway, you know, there are glitches in our thinking. One of them is called **the**”single solution bias,”and there are people who just have a hunger to say,”Well, that one solution, we just need to latch on to that and do that, and damn **the** consequences.”Well, it ’ s **nuts**. CA : But let me push back on this just a little bit. So let ’ s say that we agree that a single solution, all-or-nothing attempt at geoengineering is crazy. But there are scenarios where **the** world looks at **emissions** and just sees, in 10 years ’ time, let ’ s say, that they are just not coming down fast enough and that we are at risk of several other liftoff events where this train will just get away from us, and we will see temperature rises of three, four, five, six, seven degrees, and all of civilization is at risk. Surely, there is an approach to geoengineering that could be modeled, in a way, on **the** way that we approach medicine. Like, for hundreds of years, we don ’ t really understand **the** human body, people would try interventions, and some of them would work, and some of them wouldn ’ t. No one says in medicine,”You know, go in and take an all-or-nothing decision on someone ’ s life,”but they do say,”Let ’ s try some stuff.”If an experiment can be reversible, if it ’ s plausible in **the** first place, if there ’ s reason to think that it might work, we actually owe it to **the** future health of humanity to try at least some types of tests to see what could work.

So, small tests to see whether, for example, seeding of something in **the** ocean might create, in a nonthreatening way, **carbon** sinks. Or maybe, rather than filling **the** atmosphere with sulfur dioxide, a smaller experiment that was not that big a deal to see whether, cost-effectively, you could reduce **the** temperature a little bit. Surely, that isn ' t completely crazy and is at least something we should be thinking about in case these other measures don ' t work? AG : Well, there ' ve already been such experiments to seed **the** ocean to see if that can increase **the** uptake of CO2. And **the** experiments were an unmitigated failure, as many predicted they would be. But that, again, is **the** kind of approach that ' s very different from putting tinfoil strips in **the** atmosphere orbiting **the** Earth. That was **the** way that solar geoengineering proposal started. Now they ' re focusing on chalk, so we have chalk dust all over everything. But more serious than that is **the** fact that it might not be reversible. CA : But, Al, that ' s **the** rhetoric response. **The** amount of dust that you need to drop by a degree or two wouldn ' t result in chalk dust over everything. It would be unbelievably – like, it would be less than **the** dust that people experience every day, anyway. I mean, I just – AG : First of all, I don ' t know how you do a small experiment in **the** atmosphere. And secondly, if we were to take that approach, we would have to steadily increase **the** amount of whatever substance they decided. We ' d have to increase it every single year, and if we ever stopped, then there would be a sudden snapback, like"**The** Picture of Dorian Gray,"that old book and movie, where suddenly all of **the** things caught up with you at once. **The** fact that anyone is even considering these approaches, Chris, is a measure of a feeling of desperation that some have begun to feel, which I understand, but I don ' t think it should drive us toward these reckless experiments. And by **the** way, using your analogy to experimental cancer treatments, for example, you usually get informed consent from **the** patient. Getting informed consent from 7. 8 billion people who have no voice and no say, who are subject to **the** potentially catastrophic consequences of this wackadoodle proposal that somebody comes up with to try to rearrange **the** entire Earth ' s atmosphere and hope and pretend that it ' s going to cancel out, **the** fact that we ' re putting 152 million tons of heat-trapping, manmade global warming pollution into **the** sky every day. That ' s what ' s really insane. A scientist decades ago compared it this way. He said, if you had two people on a sinking boat and one of them says,"You know, we could probably use some mirrors to signal to shore to get them to build a sophisticated wave-generating machine that will cancel out **the** **rocking** of **the** boat by these guys in **the** back of **the** boat."Or you could get them to stop **rocking the** boat. And that ' s what we need to do. We need to stop what ' s causing **the** crisis. CA : Yeah, that ' s a great story, but if **the** effort to stop **the** people **rocking** in **the** back of **the** boat is as complex as **the** scientific proposal you just outlined, whereas **the** experiment to stop **the** waves is actually as simple as telling **the** people to stop **rocking the** boat, that story changes. And I think you ' re right that **the** issue of informed consent is a really challenging one, but, I mean, no one gave informed consent to do all of **the** other things we ' re doing to **the** atmosphere. And I agree that **the** moral hazard issue is worrying, that if we became dependent on geoengineering and took away our efforts to do **the** rest, that would be tragic. It just seems like, I wish it was possible to have a nuanced debate of people saying, you know what, there ' s multiple dials to a very complex problem. We ' re going to have to adjust several of them very, very carefully and keep talking to each other. Wouldn ' t that be a goal to just try and have a more nuanced debate about this, rather than all of that geoengineering can ' t work? AG : Well, I ' ve said some of it, you know, **the** benign forms that I ' ve mentioned, I ' m not ruling those out. But blocking **the** Sun ' s rays from **the** Earth, not only do you affect 7. 8 billion people, you affect **the** plants and **the** animals and **the** ocean currents and **the** wind currents and natural processes that we ' re in danger of disrupting even more. Techno-optimism is something I ' ve engaged in in **the** past, but to latch on to some brand-new technological solution to rework **the** entire Earth ' s natural system because somebody thinks he ' s clever enough to do it in a way that precisely cancels out **the** consequences of using **the** atmosphere as an open sewer for heat-trapping manmade gases. It ' s much more important to stop using **the** atmosphere as an open sewer. That ' s what **the** problem is. CA : All right, well, we ' ll agree that that is **the** most important thing, for sure, and speaking of which, do you believe **the** world needs **carbon** pricing, and is there any prospect for getting there? AG : Yes. Yes to both questions. For decades, almost every economist who is asked about **the** climate crisis says,"Well, we just need to put a price on **carbon**."And I have certainly been in favor of that approach. But it is daunting. Nevertheless, there are 43 jurisdictions around **the** world that already have a price on **carbon**. We ' re seeing it in Europe. They finally straightened out their **carbon** pricing mechanism. It ' s an **emissions** trading version of it. We have places that have put a tax on **carbon**. That ' s **the** approach **the** economists prefer. China is beginning to implement its national **emissions** trading program. California and quite a few other states in **the** US are already doing it. It can be given back to people in a revenue-neutral way. But **the** opposition to it, Chris, which you ' ve noted, is impressive enough that we do have to take other approaches, and I would say most climate activists are now saying, look, let ' s don ' t make **the** best **the** enemy of **the** better. There are other ways to do this as well. We need every solution we can rationally employ, including by regulation. And often, when **the** political difficulty of a proposal becomes too difficult in a market-oriented approach, **the** fallback is with regulation, and it ' s been given a bad name, regulation, but many places are doing it. I mentioned phasing out internal combustion engines. That ' s an example. There are 160 cities in **the** US that have already by regulation ordered that within a date certain, 100 percent of all their electricity will have to come from **renewable** sources. And again, **the** market forces that are driving **the** cost of **renewable** energy and **sustainability** solutions ever downward, that gives us **the** wind at our back. This is working in our favor. CA : I mean, **the** pushback on **carbon** pricing often goes further from parts of **the** environmental movement, which is to a pushback on **the** role of business in general. Business is actually – well, capitalism – is blamed for **the** climate crisis because of unrelenting growth, to **the** point where many people don ' t trust business to be part of **the** solution. **The** only way to go forward is to regulate, to force businesses to do **the** right thing. Do you think that business has to be part of **the** solution? AG : Well, definitely, because **the** allocation of capital needed to solve this crisis is greater than what governments can handle. And businesses are beginning, many businesses are beginning to play a very constructive role. They ' re getting a demand that they do so from their customers, from their investors, from their boards, from their executive teams, from their families. And by **the** way, **the** rising generation is demanding a brighter future, and when CEOs interview potential new hires, they find that **the** new hires are interviewing them. They want to make a nice income, but they want to be able to tell their family and friends and peers that they ' re doing something more than just making money. One illustration of how this new generation is changing, Chris : there are 65 colleges in **the** US right now where **the** College Young Republican Clubs have joined together to jointly demand that **the** Republican National Committee change its policy on climate, lest they lose that entire generation. This is a global phenomenon. **The** Greta Generation is now leading this in so many ways, and if you look at **the** polling, again, **the** vast majority of young Republicans are demanding a change on climate policy. This is really a movement that is building still. CA : I was going to ask you about that, because one of **the** most painful things over **the** last 20 years has just been how climate has been politicized, certainly in **the** US. You ' ve probably felt yourself at **the** heart of that a lot of **the** time, with people attacking you personally in **the** most merciless, and unfair ways, often. Do you really see signs that that might be changing, led by **the** next generation? AG : Yeah, there ' s no question about it. I don ' t want to rely on polls too much. I ' ve mentioned them already. But there was a new one that came out that looked at **the** wavering Trump supporters, those who supported him strongly in **the** past and want to do so again. **The** number one issue, surprisingly to some, that is giving them pause, is **the** craziness of President Trump and his administration on climate. We ' re seeing big majorities of **the** Republican Party overall saying that they ' re ready to start exploring some real solutions to **the** climate crisis. I think that we ' re really getting there, no question about it. CA : I mean, you ' ve been **the** figurehead for raising this issue, and you happen to be a Democrat. Is there anything that you can personally do to – I don ' t know – to open **the** tent, to welcome people, to try and say,"This is beyond politics, dear friends"? AG : Yeah. Well, I ' ve tried all of those things, and maybe it ' s made a little positive difference. I ' ve worked with **the** Republicans extensively. And, you know, well after I left **the** White House, I had Newt Gingrich and Pat Robertson and other prominent Republicans appear on national TV ads with me saying we ' ve got to solve **the** climate crisis. But **the** petroleum industry has really doubled down enforcing discipline within **the** Republican Party. I mean, look at **the** attacks they ' ve launched against **the** Pope when he came out with his encyclical and was demonized, not by all for sure, but there were hawks in **the** anti-climate movement who immediately started training their guns on Pope Francis, and there are many other examples. They enforce discipline and try to make it a partisan issue, even as Democrats reach out to try to make it bipartisan. I totally agree with you that it should not be a partisan issue. It didn ' t use to be, but it ' s been artificially weaponized as an issue. CA : I mean, **the** CEOs of **oil** companies also have kids who are talking to them. It feels like some of them are moving and are trying to invest and trying to find ways of being part of **the** future. Do you see signs of that? AG : Yeah. I think that business leaders, including in **the oil** and gas companies, are hearing from their families. They ' re hearing from their friends. They ' re hearing from their employees. And, by **the** way, we ' ve seen in **the** tech industry some mass walkouts by employees who are demanding that some of **the** tech companies do more and get serious. I ' m so proud of Apple. Forgive me for parenthetically praising Apple. You know, I ' m on **the** board, but I ' m such a big fan of Tim Cook and my colleagues at Apple. It ' s an example of a tech company that ' s really doing **fantastic** things. And there ' s some others as well. There are others in many industries. But **the** pressures on **the oil** and gas companies are quite extraordinary. You know, BP just wrote down 12 and a half billion dollars ' worth of **oil** and gas assets and said that they ' re never going to see **the** light of day. **Two-thirds** of **the fossil** fuels that have already been discovered cannot be burned and will not be burned. And so that ' s a big economic risk to **the** global economy, like **the** subprime mortgage crisis. We ' ve got 22 trillion dollars of subprime **carbon** assets, and just yesterday, there was a major report that **the** fracking industry in **the** US is seeing now a wave of bankruptcies because **the** price of **the** fracked gas and **oil** has fallen below levels that make them economic. CA : Is **the** shorthand of what ' s happened there that electric cars and electric technologies and solar and so forth have helped drive down **the** price of **oil** to **the** point where huge amounts of **the** reserves just can ' t be developed profitably? AG : Yes, that ’ s it. That ’ s mainly it. **The** projections for energy sources in **the** next several years uniformly predict that electricity from wind and solar is going to continue to plummet in price, and therefore using gas or **coal** to make steam to turn **the turbines** is just not going to be economical. Similarly, **the** electrification of **the transportation** sector is having **the** same effect. Some are also looking at **the** trend in national, regional and local governance. I mentioned this before, but they ’ re predicting a very different energy future. But let me come back, Chris, because we talked about business leaders. I think you were getting in a question a moment ago about capitalism itself, and I do want to say a word on that, because there are a lot of people who say maybe capitalism is **the** basic problem. I think **the** current form of capitalism we have is desperately in need of reform. **The** short-term outlook is often mentioned, but **the** way we measure what is of value to us is also at **the** heart of **the** crisis of modern capitalism. Now, capitalism is at **the** base of every successful economy, and it balances supply and demand, **unlocks** a higher **fraction** of **the** human potential, and it ’ s not going anywhere, but it needs to be reformed, because **the** way we measure what ’ s valuable now ignores so-called negative externalities like pollution. It also ignores positive externalities like investments in education and health care, mental health care, family services. It ignores **the** depletion of resources like groundwater and topsoil and **the web** of living species. And it ignores **the** distribution of incomes and net worths, so when GDP goes up, people cheer, two percent, three percent – wow! – four percent, and they think,”Great!”But it ’ s accompanied by vast increases in pollution, chronic underinvestment in public goods, **the** depletion of irreplaceable natural resources, and **the** worst inequality crisis we ’ ve seen in more than a hundred years that is threatening **the** future of both capitalism and democracy. So we have to change it. We have to reform it. CA : So reform capitalism, but don ’ t throw it out. We ’ re going to need it as a tool as we go forward if we ’ re to solve this. AG : Yeah, I think that ’ s right, and just one other point : **the** worst environmental abuses in **the** last hundred years have been in jurisdictions that experimented during **the** 20th century with **the** alternatives to capitalism on **the left** and right. CA : Interesting. All right. Two last community questions quickly. Chadburn Blomquist :”As you are reading **the** tea leaves of **the** impact of **the** current pandemic, what do you think in regard to our response to combatting climate change will be **the** most impactful lesson learned?”AG : Boy, that ’ s a very thoughtful question, and I wish my answer could rise to **the** same level on short notice. I would say first, don ’ t ignore **the** scientists. When there is virtual unanimity among **the** scientific and medical experts, pay attention. Don ’ t let some politician dissuade you. I think President Trump is slowly learning that ’ s it ’ s kind of difficult to gaslight a virus. He tried to gaslight **the** virus in Tulsa. It didn ’ t come off very well, and tragically, he decided to recklessly roll **the** dice a month ago and ignore **the** recommendations for people to wear masks and to socially distance and to do **the** other things, and I think that lesson is beginning to take hold in a much stronger way. But beyond that, Chris, I think that this period of time has been characterized by one of **the** most profound opportunities for people to rethink **the** patterns of their lives and to consider whether or not we can ’ t do a lot of things better and differently. And I think that this rising generation I mentioned before has been even more profoundly affected by this interlude, which I hope ends soon, but I hope **the** lessons endure. I expect they will. CA : Yeah, it ’ s amazing how many things you can do without emitting **carbon**, that we ’ ve been forced to do. Let ’ s have one more question here. Frank Hennessy :”Are you encouraged by **the** ability of people to quickly adapt to **the** new normal due to COVID-19 as evidence that people can and will change their habits to respond to climate change?”AG : Yes, but I think we have to keep in mind that there is a crisis within this crisis. **The** impact on **the** African American community, which I mentioned before, on **the** Latinx community, Indigenous peoples. **The** highest infection rate is in **the** Navajo Nation right now. So some of these questions appear differently to those who are really getting **the** brunt of this crisis, and it is unacceptable that we allow this to continue. It feels one way to you and me and perhaps to many in our audience today, but for low-income communities of color, it ’ s an entirely different crisis, and we owe it to them and to all of us to get busy and to start using **the** best science and solve this pandemic. You know **the** phrase”pandemic economics.”Somebody said, **the** first principle of pandemic economics is take care of **the** pandemic, and we ’ re not doing that yet. We ’ re seeing **the** president try to goose **the** economy for his reelection, never mind **the** prediction of tens of thousands of additional American deaths, and that is just unforgivable in my opinion. CA : Thank you, Frank. So Al, you, along with others in **the** community played a key role in encouraging TED to launch this initiative called”Countdown.”Thank you for that, and I guess this conversation is continuing among many of us. If you ’ re interested in climate, watching this, check out **the** Countdown website, countdown. ted. com, and be part of 10 / 10 / 2020, when we are trying to put out an alert to **the** world that climate can ’ t wait, that it really matters, and there ’ s going to be some amazing content free to **the** world on that day. Thank you, Al, for your inspiration and support in doing that. I wonder whether you could end today ’ s session just by painting us a picture, like how might things roll out over **the** next decade or so? Just tell us whether there is still a story of hope here. AG : I ’ d be glad to. I ’ ve got to get one plug in. I ’ ll make it brief. July 18 through July 26, **The** Climate Reality Project is having a global training. We ’ ve already had 8, 000 people register. You can go to climatereality. com. Now, a bright future. It begins with all of **the** kinds of efforts that you ’ ve thrown yourself into in organizing Countdown. Chris, you and your team have been amazing to work with, and I ’ m so excited about **the** Countdown project. TED has an unparalleled ability to spread ideas that are worth spreading, to raise consciousness, to enlighten people around **the** world, and it ’ s needed for climate and **the** solutions to **the** climate crisis like it ’ s never been needed before, and I just want to thank you for what you personally are doing to organize this **fantastic** Countdown program. CA : Thank you. And **the** world? Are we going to do this? Do you think that humanity is going to pull this off and that our grandchildren are going to have beautiful lives where they can celebrate nature and not spend every day in fear of **the** next tornado or **tsunami**? AG : I am optimistic that we will do it, but **the** answer is in our hands. We have seen dark times in periods of **the** past, and we have risen to meet **the** challenge. We have limitations of our long **evolutionary** heritage and elements of our culture, but we also have **the** ability to transcend our limitations, and when **the** chips are down, and when survival is at stake and when our children and future generations are at stake, we ’ re capable of more than we sometimes allow ourselves to think we can do. This is such a time. I believe we will rise to **the** occasion, and we will create a bright, clean, prosperous, just and fair future. I believe it with all my heart. CA : Al Gore, thank you for your life of work, for all you ’ ve done to elevate this issue and for spending this time with us now. Thank you. AG : Back at you. Thank you.

Text Sample 73: POS Dim 1 – 2020 – Score 21.00 – 2020/t004235.txt
Chris Anderson : Dr. Jane Goodall, welcome. Jane Goodall : Thank you, and I

think, you know, we couldn ' t have a complete interview unless people know Mr. H is with me, because everybody knows Mr. H. CA : Hello, Mr. H. In your TED Talk 17 years ago, you warned us about **the** dangers of humans crowding out **the** natural world. Is there any sense in which you feel that **the** current pandemic is kind of, nature striking back? JG : It ' s very, very clear that these zoonotic diseases, like **the** corona and HIV / AIDS and all sorts of other diseases that we catch from animals, that ' s partly to do with destruction of **the** environment, which, as animals lose **habitat**, they get crowded together and sometimes that means that a virus from a reservoir species, where it ' s lived harmoniously for maybe hundreds of years, jumps into a new species, then you also get animals being pushed into closer contact with humans. And sometimes one of these animals that has caught a virus can – you know, provides **the** opportunity for that virus to jump into people and create a new disease, like COVID-19. And in addition to that, we are so disrespecting animals. We hunt them, we kill them, we eat them, we traffic them, we send them off to **the** wild-animal markets in Asia, where they ' re in terrible, cramped conditions, in tiny cages, with people being contaminated with **blood** and urine and feces, ideal conditions for a virus to **spill** from an animal to an animal, or an animal to a person. CA : I ' d love to just dip **backwards** in time for a bit, because your story is so extraordinary. I mean, despite **the** arguably even more sexist attitudes of **the** 1960s, somehow you were able to break through and become one of **the** world ' s leading scientists, discovering this astonishing series of facts about chimpanzees, such as their tool use and so much more. What was it about you, do you think, that allowed you to make such a breakthrough? JG : Well, **the** thing is, I was born loving animals, and **the** most important thing was, I had a very supportive mother. She didn ' t get mad when she found earthworms in my bed, she just said they better be in **the** garden. And she didn ' t get mad when I **disappeared** for four hours and she called **the** police, and I was sitting in a hen house, because nobody would tell me where **the** hole was where **the** egg came out. I had no dream of being a scientist, because women didn ' t do that sort of thing. In fact, there weren ' t any man doing it back then, either. And everybody laughed at me except Mom, who said,"If you really want this, you ' re going to have to work awfully hard, take advantage of every opportunity, if you don ' t give up, maybe you ' ll find a way."CA : And somehow, you were able to kind of, earn **the** trust of chimpanzees in **the** way that no one else had. Looking back, what were **the** most exciting moments that you discovered or what is it that people still don ' t get about chimpanzees? JG : Well, **the** thing is, you say,"See things nobody else had, get their trust."Nobody else had tried. Quite honestly. So, basically, I used **the** same **techniques** that I had to study **the** animals around my home when I was a child. Just sitting, patiently, not trying to get too close too quickly, but it was awful, because **the** money was only for six months. I mean, you can imagine how difficult to get money for a young girl with no degree, to go and do something as bizarre as sitting in a forest. And you know, finally, we got money for six months from an American philanthropist, and I knew with time I ' d get **the** chimps ' trust, but did I have time? And weeks became months and then finally, after about four months, one chimpanzee began to lose his fear, and it was he that on one occasion I saw – I still wasn ' t really close, but I had my binoculars – and I saw him using and making tools to **fish** for termites. And although I wasn ' t terribly surprised, because I ' ve read about things captive chimps could do – but I knew that science believed that humans, and only humans, used and made tools. And I knew how excited [Dr. Louis] Leakey would be. And it was that observation that enabled him to go to **the** National Geographic, and they said,"OK, we ' ll continue to support **the** research,"and they sent Hugo van Lawick, **the** photographer-filmmaker, to record what I was seeing. So a lot of scientists didn ' t want to believe **the** tool-using. In fact, one of them said I must have taught **the** chimps. Since I couldn ' t get near them, it would have been a miracle. But anyway, once they saw Hugo ' s film and that with all my descriptions of their behavior, **the** scientists had to start changing their minds. CA : And since then, numerous other discoveries that placed chimpanzees much closer to humans than people cared to believe. I think I saw you say at one point that they have a sense of humor. How have you seen that expressed? JG : Well, you see it when they ' re playing games, and there ' s a bigger one playing with a little one, and he ' s trailing a vine around a tree. And every time **the** little one is about to catch it, **the** bigger one pulls it away, and **the** little one starts crying and **the** big one starts laughing. So, you know. CA : And then, Jane, you observed something much more troubling, which was these instances of chimpanzee gangs, tribes, groups, being brutally violent to each other. I ' m curious how you process that. And whether it made you, kind of, I don ' t know, depressed about us, we ' re close to them, did it make you feel that violence is irredeemably part of all **the** great apes, somehow? JG : Well, it obviously is. And my first encounter with human, what I call evil, was **the** end of **the** war and **the** pictures from **the** Holocaust. And you know, that really shocked me. That changed who I was. I was 10, I think, at **the** time. And when **the** chimpanzees, when I realized they have this dark, brutal side, I thought they were like us but nicer. And then I realized they ' re even more like us than I had thought. And at that time, in **the** early ' 70s, it was very strange, aggression, there was a big thing about, is aggression innate or learned. And it became political. And it was, I don ' t know, it was a very strange time, and I was coming out, saying,"No, I think aggression is definitely part of our inherited repertoire of behaviors."And I asked a very respected scientist what he really thought, because he was coming out on **the** clean slate, aggression is learned, and he said,"Jane, I ' d rather not talk about what I really think."That was a big shock as far as science was concerned for me. CA : I was brought up to believe a world of all things bright and beautiful. You know, numerous beautiful films of butterflies and bees and flowers, and you know, nature as this gorgeous landscape. And many environmentalists often seem to take **the** stance,"Yes, nature is pure, nature is beautiful, humans are bad,"but then you have **the** kind of observations that you see, when you actually look at any part of nature in more detail, you see things to be terrified by, honestly. What do you make of nature, how do you think of it, how should we think of it? JG : Nature is, you know, I mean, you think of **the** whole spectrum of **evolution**, and there ' s something about going to a pristine place, and Africa was very pristine when I was young. And there were animals everywhere. And I never liked **the** fact that **lions** killed, they have to, I mean, that ' s what they do, if they didn ' t kill animals, they would die. And **the** big difference between them and us, I think, is that they do what they do because that ' s what they have to do. And we can plan to do things. Our plans are very different. We can plan to cut down a whole forest, because we want to sell **the** timber, or because we want to build another shopping mall, something like that. So our destruction of nature and our warfare, we ' re capable of evil because we can sit comfortably and plan **the** torture of somebody far away. That ' s evil. Chimpanzees have a sort of primitive war, and they can be very aggressive, but it ' s of **the** moment. It ' s how they feel. It ' s response to an emotion. CA : So your observation of **the** sophistication of chimpanzees doesn ' t go as far as what some people would want to say is **the** sort of **the** human superpower, of being able to really simulate **the** future in our minds in great detail and make long-term plans. And act to encourage each other to achieve those long-term plans. That that feels, even to someone who spent so much time with chimpanzees, that feels like a fundamentally different skill set that we just have to take responsibility for and use much more wisely than we do. JG : Yes, and I personally think, I mean, there ’ s a lot of discussion about this, but I think it ’ s a fact that we developed **the** way of communication that you and I are using. And because we have words, I mean, animal communication is way more sophisticated than we used to think. And chimpanzees, gorillas, orangutans can learn human sign language of **the** Deaf. But we sort of grow up speaking whatever language it is. So I can tell you about things that you ’ ve never heard of. And a chimpanzee couldn ’ t do that. And we can teach our children about **abstract** things. And chimpanzees couldn ’ t do that. So yes, chimpanzees can do all sorts of clever things, and so can **elephants** and so can crows and so can octopuses, but we design rockets that go off to another **planet** and little robots taking photographs, and we ’ ve designed this extraordinary way of you and me talking in our different parts of **the** world. When I was young, when I grew up, there was no TV, there were no cell phones, there was no **computers**. It was such a different world, I had a pencil, pen and notebook, that was it. CA : So just going back to this question about nature, because I think about this a lot, and I struggle with this, honestly. So much of your work, so much of so many people who I respect, is about this passion for trying not to screw up **the** natural world. So is it possible, is it healthy, is it essential, perhaps, to simultaneously accept that many aspects of nature are **terrifying**, but also, I don ’ t know, that it ’ s awesome, and that some of **the** awesomeness comes from its potential to be **terrifying** and that it is also just breathtakingly beautiful, and that we cannot be ourselves, because we are part of nature, we cannot be whole unless we somehow embrace it and are part of it? Help me with **the** language, Jane, on how that relationship should be. JG : Well, I think one of **the** problems is, you know, as we developed our intellect, and we became better and better at modifying **the** environment for our own use, and creating fields and growing crops where it used to be forest or woodland, and you know, we won ’ t go into that now, but we have this ability to change nature. And as we ’ ve moved more into towns and cities, and relied more on technology, many people feel so divorced from **the** natural world. And there ’ s hundreds, thousands of children growing up in inner cities, where there basically isn ’ t any nature, which is why this movement now to green our cities is so important. And you know, they ’ ve done experiments, I think it was in Chicago, I ’ m not quite sure, and there were various empty lots in a very violent part of town. So in some of those areas they made it green, they put trees and flowers and things, shrubs in these vacant lots. And **the** crime rate went right down. So then of course, they put trees in **the** other half. So it just shows, and also, there have been studies done showing that children really need green nature for good psychological development. But we are, as you say, part of nature and we disrespect it, as we are, and that is so terrible for our children and our children ’ s children, because we rely on nature for clean air, clean water, for regulating climate and rainfall. Look what we ’ ve done, look at **the** climate crisis. That ’ s us. We did that. CA : So a little over 30 years ago, you made this shift from scientist mainly to activist mainly, I guess. Why? JG : Conference in 1986, scientific one, I ’ d got my PhD by then and it was to find out how chimp behavior differed, if it did, from one environment to another. There were six study sites across Africa. So we thought, let ’ s bring these scientists together and explore this, which was fascinating. But we also had a session on conservation and a session on conditions in some captive situations like medical research. And those two sessions were so shocking to me. I went to **the** conference a a scientist, and I left as an activist. I didn ’ t make **the** decision, something happened inside me. CA : So you spent **the** last 34 years sort of tirelessly campaigning for a better relationship between people and nature. What should that relationship look like? JG : Well, you know, again you come up with all these problems. People have to have space to live. But I think **the** problem is that we ’ ve become, in **the** affluent societies, too greedy. I mean, honestly, who needs four houses with huge grounds? And why do we need yet another shopping mall? And so on and so on. So we are looking at short-term economic benefit, money has become a sort of god to worship, as we lose all spiritual connection with **the** natural world. And so we ’ re looking for short-term monetary gain, or power, rather than **the** health of **the planet** and **the** future of our children. We don ’ t seem to care about that anymore. That ’ s why I ’ ll never stop fighting. CA : I mean, in your work specifically on chimpanzee conservation, you ’ ve made it practice to put people at **the** center of that, local people, to engage them. How has that worked and do you think that ’ s an essential idea if we ’ re to succeed in protecting **the planet**? JG : You know, after that **famous** conference, I thought, well, I must learn more about why chimps are vanishing in Africa and what ’ s happening to **the** forest. So I got a bit of money together and went out to visit six range countries. And learned a lot about **the** problems faced by chimps, you know, hunting for bushmeat and **the** live animal trade and caught in snares and human populations growing and needing more land for their crops and their cattle and their villages. But I was also learning about **the** plight faced by so many people. **The** absolute poverty, **the** lack of health and education, **the** degradation of **the** land. And it came to a head when I flew over **the** tiny Gombe National Park. It had been part of this equatorial forest belt right across Africa to **the** west coast, and in 1990, it was just this little **island** of forest, just tiny national park. All around, **the** hills were bare. And that ’ s when it hit me. If we don ’ t do something to help **the** people find ways of living without destroying their environment, we can ’ t even try to save **the** chimps. So **the** Jane Goodall Institute began this program”Take Care,”we call it”TACARE.”And it ’ s our method of community-based conservation, totally holistic. And we ’ ve now put **the** tools of conservation into **the** hand of **the** villagers, because most Tanzanian wild chimps are not in protected areas, they ’ re just in **the** village forest reserves. And so, they now go and measure **the** health of their forest. They ’ ve understood now that protecting **the** forest isn ’ t just for wildlife, it ’ s their own future. That they need **the** forest. And they ’ re very proud. **The** volunteers go to workshops, they learn how to use **smartphones**, they learn how to upload into platform and **the** cloud. And so it ’ s all transparent. And **the** trees have come back, there ’ s no bare hills anymore. They agreed to make a buffer zone around Gombe, so **the** chimps have more forest than they did in 1990. They ’ re opening up corridors of forest to link **the** scattered chimp groups so that you don ’ t get too much inbreeding. So yes, it ’ s worked, and it ’ s in six other countries now. Same thing. CA : I mean, you ’ ve been this extraordinary tireless voice, all around **the** world, just traveling so much, speaking everywhere, inspiring people everywhere. How on earth do you find **the** energy, you know, **the** fire to do that, because that is exhausting to do, every meeting with lots of people, it is just physically exhausting, and yet, here you are, still doing it. How are you doing this, Jane? JG : Well, I suppose, you know, I ’ m obstinate, I don ’ t like giving up, but I ’ m not going to let these CEOs of big companies who are destroying **the** forests, or **the** politicians who are unraveling all **the** protections that were put in place by previous presidents, and you know who I ’ m talking about. And you know, I ’ ll go on fighting, I care about, I ’ m passionate about **the** wildlife. I ’ m passionate about **the** natural world. I love forests, it hurts me to see them damaged. And I care passionately about children. And we ’ re stealing their future. And I ’ m not going to give up. So I guess I ’ m blessed with good genes, that ’ s a gift, and **the** other gift, which I discovered I had, was communication, whether it ’ s writing or speaking. And so, you know, if going around like this wasn ’ t working, but every time I do a **lecture**, people come up and say,”Well, I had given up, but you ’ ve inspired me, I promise to do my bit.”And we have our youth program”Roots and Shoots”now in 65 countries and growing fast, all ages, all choosing projects to help people, animals, **the** environment, rolling up their sleeves and taking action. And you know, they look at you with shining eyes, wanting to tell Dr. Jane what they ’ ve been doing to make **the** world a better place. How can I let them down? CA : I mean, as you look at **the planet** ’ s future, what worries you most, actually, what scares you most about where we ’ re at? JG : Well, **the** fact that we have a small window of time, I believe, when we can at least start healing some of **the** harm and slowing down climate change. But it is closing, and we ’ ve seen what happens with **the** lockdown around **the** world because of COVID-19 : clear skies over cities, some people breathing clean air that they ’ ve never breathed before and looking up at **the** shining skies at night, which they ’ ve never seen properly before. And you know, so what worries me most is how to get enough people, people understand, but they ’ re not taking action, how to get enough people to take action? CA : National Geographic just launched this extraordinary film about you, highlighting your work over six decades. It ’ s titled”Jane Goodall : **The** Hope.”So what is **the** hope, Jane? JG : Well, **the** hope, my greatest hope is all these young people. I mean, in China, people will come up and say,”Well, of course I care about **the** environment, I was in ’ Roots and Shoots ’ in primary school.”And you know, we have”Roots and Shoots”just hanging on to **the** values and they ’ re so enthusiastic once they know **the** problems and they ’ re empowered to take action, they are clearing **the** streams, removing invasive species humanely. And they have so many ideas. And then there ’ s, you know, this extraordinary intellect of ours. We ’ re beginning to use it to come up with technology that really will help us to live in greater harmony, and in our individual lives, let ’ s think about **the** consequences of what we do each day. What do we buy, where did it come from, how was it made? Did it harm **the** environment, was it cruel to animals? Is it cheap because of child slave labor? Make ethical choices. Which you can ’ t do if you ’ re living in poverty, by **the** way. And then finally, this indomitable spirit of people who tackle what seems impossible and won ’ t give up. You can ’ t give up when you have those... But you know, there are things that I can ’ t fight. I can ’ t fight corruption. I can ’ t fight military regimes and dictators. So I can only do what I can do, and if we all do **the** bits that we can do, surely that makes a whole that eventually will win out. CA : So, last question, Jane. If there was one idea, one thought, one seed you could plant in **the** minds of everyone watching this, what would that be? JG : You know, just remember that every day you live, you make an impact on **the planet**. You can ’ t help making an impact. And at least, unless you ’ re living in extreme poverty, you have a choice as to what sort of impact you make. Even in poverty you have a choice, but when we are more affluent, we have a greater choice. And if we all make ethical choices, then we start moving towards a world that will be not quite so desperate to leave to our great-grandchildren. That ’ s, I think, something for everybody. Because a lot of people understand what ’ s happening, but they feel helpless and hopeless, and what can they do, so they do nothing and they become apathetic. And that is a huge danger, apathy. CA : Dr. Jane Goodall, wow. I really want to thank you for your extraordinary life, for all that you ’ ve done and for spending this time with us now. Thank you. JG : Thank you.

Text Sample 74: POS Dim 1 – 2020 – Score 18.00 – 2020/t004300.txt

Hello, I ’ m Chris Anderson. Welcome to **The** TED Interview. We ’ re gearing up for season four with some extraordinary guests, but I don ’ t want to wait for that for today ’ s episode, because we ’ re in **the** middle of a pandemic, and there ’ s a guest I really wanted to talk to now. He is Adam Kucharski, an infectious diseases scientist who focuses on **the** mathematical modeling of pandemics. He ’ s an associate professor at **the** London School of Hygiene and Tropical Medicine and a TED Fellow. Adam Kucharski : So what kind of behavior is actually important for epidemics? Conversations, close physical contacts? What sort of data should we be collecting before an outbreak if we want to predict how infection might spread? To find out, our team built a mathematical model... Chris Anderson : When it comes to figuring out what to make of this pandemic, known technically as COVID-19, and informally as just **the** coronavirus, I find his thinking unbelievably helpful. And I ’ m excited to dive into it with you. A special callout to my friends on Twitter who offered up many suggestions for questions. I know this topic is on everyone ’ s mind right now. And what I hope this episode does is give us all a more nuanced way of thinking about how this pandemic has unfolded so far, what might be to come and what we all collectively can do about it. Let ’ s dive in. Adam, welcome to **the** TED Interview. Adam Kucharski : Thank you. CA : So let ’ s just start with a couple of basics. A lot of skeptical people ’ s response – certainly over **the** last few weeks, maybe less so now – has been,”Oh, come on, this isn ’ t such a big deal, there ’ s a relatively tiny number of cases. Compare it to **the** flu, compare it to anything else. There are much bigger problems in **the** world. Why are we making such a fuss about this?”And I guess **the** answer to that fuss is that it comes down to **the** mathematics. We ’ re talking about **the** mathematics of exponential growth, fundamentally, right? AK : Exactly. And there ’ s a number that we use to get a sense of how easy things spread and **the** level of transmission we ’ re dealing with. We call that **the reproduction** number, and conceptually, it ’ s just, for each case you have, on average, how many others are they infecting? And that gives you a sense of how much is this scaling, how much this growth is going to look like. For coronavirus, we ’ re now seeing, across multiple countries, we ’ re seeing each person on average giving it to two or three more. CA : So that **reproduction** number, **the** first thing to understand is that any number above one means that this thing is going to grow. Any number below one means it ’ s going to diminish. AK : Exactly – if you have it above one, then each group of people infected are going to be generating more infection than there was before. And you will see **the** exponential effect, so if it ’ s two, you will be doubling every round of infection, and if it ’ s below one, you ’ re going to get something that ’ s going to decline, on average. CA : So that number two or higher, I think everyone here is maybe familiar with **the famous** story of **the** chessboard and **the** grains of rice, and if you double **the** number of grains for every square of **the** chessboard, for **the** first 10 or 15 squares nothing much happens, but by **the** time you ’ ve got to **the** 64th square, you suddenly have tons of rice for every individual on **the planet**. Exponential growth is an incredible thing. And **the** small numbers now are really not what you should be paying attention to – you should be paying attention to **the** models of what could be to come. AK : Exactly. Obviously, if you continue **the** exponential growth, you do sometimes get these incredibly large, maybe implausibly large numbers. But even looking at a timescale of say, a month, if **the reproduction** number is three, each person is infecting three on average. **The** gap between these rounds of infection is about five days. So if you imagine that you ’ ve got one case now, that ’ s, kind of, six of these five-day steps in a month. So by **the** end of that month, that one person could have generated, I think it works out at about 729 cases. So even in a month, just **the** scale of this thing can really shoot up if it ' s not controlled. CA : And so certainly, that seems to be happening on most numbers that you look at now, certainly where **the** virus is in **the** early stages of entering a country. You ' ve given a model whereby we can much more clearly understand this **reproduction** number, because it seems to me this is almost like **the** core to how we think of **the** virus and how we respond to it and how much we should fear it, almost. And in your thinking, you sort of break it down into four components, which you call DOTS : Duration, Opportunities, Transmission **probability** and Susceptibility. And I think it would be really helpful, Adam, for you to just explain each of these, because it ' s quite a simple equation that links those four things to **the** actual **reproduction** number. So talk about them in turn. Duration, what does that mean? AK : Duration measures how long someone is infectious for. If, for example, intuitively, if someone is infectious for a longer period of time, say, twice as long as someone else, then that ' s twice **the** length that they ' ve got to be spreading infection. CA : And what is **the** duration number for this virus, compared with, say, flu or with other pathogens? AK : It depends a little bit on what happens when people are infectious, if they ' re being isolated very quickly, that shortens that period of time, but potentially, we ' re looking at around a week people are effectively infectious before they might be isolated in hospital. CA : And during that week, they may not even be showing symptoms for that full week either, right? So someone gets infected, there ' s an incubation period. There ' s a period some way into that incubation period where they start being infectious, and there may be a period after that, where they start to show symptoms, and it ' s not clear, quite, how those dates align. Is that right? AK : No, we ' re getting more information. One of **the** signals we see in data that suggest that you may have that early transmission going on is when you have this delay from one infection to **the** next. So that seems to be around five days. That incubation period, **the** time for symptoms to appear, is also about five days. So if you imagine that most people are only infecting others when they ' re symptomatic, you ' d have that incubation period and then you ' d have some more time when they ' re infecting others. So **the** fact that those values seem to be similar, suggesting that some people are transmitting either very early on or potentially before they ' re showing clear symptoms. CA : So almost implies that on average, people are infecting others as much before they show symptoms as after. AK : Potentially. Obviously these are early data sets, but I think there ' s good evidence that a fair number of people, either before they ' re showing clear symptoms or maybe they ' re not showing **the** kind of very distinctive fever and cough but they ' re feeling unwell and they ' re shedding virus during that period. CA : And does that make it quite different from **the** flu, for example? AK : It makes it actually similar to flu in that regard. One of **the** reasons pandemic flu is so hard to control and so feared as a threat is because so much transmission happens before people are severely ill. And that means that by **the** time you identify these cases, they ' ve probably actually spread it to a number of other people. CA : Yeah, so this is **the** trickery of **the** thing, and why it ' s so hard to do anything about it. It is ahead of us all **the** time, and you can ' t just pay attention to how someone feels or what they ' re doing. I mean, how does that happen, by **the** way? How does someone infect someone else before they ' re even showing symptoms themselves, because classically, we think of, you know, **the** person sneezing and droplets go through **the** air and someone else breathes them in and that ' s how infection happens. What is actually going on for infection pre-symptoms? AK : So **the** level of transmission we see with this virus isn ' t what we see, for example, with measles, where someone sneezes and a lot of virus gets out and potentially lots of susceptible people can get exposed. So potentially, it could be quite early on that even if someone has quite mild symptoms, maybe a bit of a cough, that ' s enough for some virus to be getting out and particularly, some of **the** work that we ' ve done trying to look at sort of close gatherings, so very tight-knit meals, there was an example in a ski chalet – and even in those situations, you might have someone mildly ill, but enough virus is getting out and somehow exposing others, we ' re still trying to work out exactly how, but there ' s enough there to cause some infection. CA : But if someone ' s mildly ill, don ' t they still have symptoms? Isn ' t there evidence that even before they know that they ' re ill, something is going on? There was a German paper published this week that seemed to suggest that even really early on, you take a swab from **the** back of someone ' s throat and they have hundreds of thousands of these viruses already reproducing there. Like, can someone just literally just be breathing normally and there is some transmission of virus out into **the** air that they don ' t even know about and is either infecting people directly or settling on **surfaces**, is that possible? AK : I think that ' s what we ' re trying to pin down, how much that [**unclear**]. As you said, there ' s evidence that you can have people without symptoms and you can get virus out their throats. And so certainly there ' s potential that it can be breathed out, but is that a fairly rare event for that actual transmission to happen, or are we potentially seeing more infections **occur** through that route? So it ' s really early data, and I think it ' s a piece of **the** puzzle, but we ' re trying to work out where that fits in with what we know about **the** kind of other transmission events we ' ve seen. CA : Alright, so, duration is **the** duration of **the** period of infectiousness. We think is five to six days, is that what I heard you say? AK : Potentially around a week, depending on exactly what happens to people when they ' re infectious. CA : And there are cases of people testing positive way, way later, after they ' ve got infected. That may be true, but they are probably not as infectious then. Is that basically right, that ' s **the** way to think of this? AK : I think that ' s our working theory, that a lot of that infection is happening early on. And we see that for a number of respiratory infections, that when people obviously become severely ill, their behavior is very different to when they may be walking around and going about their normal day. CA : And so again, comparing that D number to other cases, like **the** flu, is flu similar? What ' s **the** D number for flu? AK : So for flu, it ' s probably slightly shorter in terms of **the** period that people are actively infectious. I mean, for flu, it ' s a very quick turnover from one case to **the** next, actually. Even a matter of about three days, potentially, from one infection to **the** person that they infect. And then at **the** other end of **the** scale, you get things like STDs, where that duration could be several months, potentially. CA : Right. OK, really nothing that unusual so far, in terms of this particular virus. Let ' s look at **the** O, opportunity. What is that? AK : So opportunity is a measure of how many chances **the** virus has to spread through interactions while someone is infectious. So typically, it ' s a measure of social behavior. On average, how many social contacts do people make that create opportunities for transmission while they ' re infectious. CA : So it ' s how many people have you got close enough to during a day, during a given day, to have a chance of infecting them. And that number could be, if people aren ' t taking precautions in a normal, sort of, urban setting, I mean, that could run into **the** hundreds, presumably? AK : Potentially, for some people. We ' ve done a number of studies looking at that in recent years, and **the** average, in terms of physical contacts, is about five people per day. Most people will have conversation or contacts generally with about 10, 15, but obviously, between cultures, we see quite a lot of variation in **the** level of physical greetings that might happen. CA : And presumably, that number again is no different for this virus than for any other. I mean, that ' s just a feature of **the** lives that we live. AK : I think for this one, if it ' s driven through these kind of interactions, and we ' ve seen for flu, for other respiratory infections, those kinds of fairly close contacts and everyday physical interactions seem to be **the** ones that are important for transmission. CA : Perhaps there is one difference. **The** fact that if you ' re infectious pre-symptoms, perhaps that means that actually, there are more opportunities here. This is part of **the** virus ' s genius, as it were, that by not letting on that it ' s inside someone, people continue to interact and go to work and take **the** subway and so forth, not even knowing that they ' re sick. AK : Exactly. And for something like flu, you see when people get ill, clearly, their social contacts drop off. So to have a virus that can be infectious while people are going around their everyday lives, really gives it an advantage in terms of transmission. CA : In your modeling, do you actually have this opportunities number higher than for flu? AK : So for **the** moment, we ' re kind of using similar values, so we ' re trying to look at, for example, physical contacts within different populations. But what we are doing is scaling **the** risk. So that ' s coming on to **the** T term. So that between each contact, what ' s **the** risk that a transmission event will **occur**. CA : Alright, so let ' s go on to this next number, **the** T, transmission **probability**. How do you define that? AK : So this measures **the** chance that, essentially, **the** virus will get across during a particular opportunity or a particular interaction. So you may well have a conversation with somebody, but actually, you don ' t cough or you don ' t sneeze or for some reason, **the** virus doesn ' t actually get across and expose **the** other person. And so, for this virus, as I mentioned, say people are having 10 conversations a day, but we ' re not seeing infected people infect 10 others a day. So it suggests that not all of those opportunities are actually resulting in **the** virus getting across. CA : But people say that this is an infectious virus. Like, what is that transmission **probability** number, again, compared with, say, **the** flu? AK : So, we did some analysis looking at these very close gatherings. We looked at about 10 different case studies, and we found that about a third of **the** contacts in those settings subsequently got infected in these early stages, when people weren ' t aware. So if you had these, kind of, big group meals, potentially, each contact had about, a kind of, one in three chance of getting exposed. For seasonal flu, that tends to be slightly lower, even within households and close settings, you don ' t necessarily get values that high. And even for something like SARS, those values have, kind of – **the** risk per interaction you had was lower than what we seem to be getting for coronavirus. Which intuitively makes sense, there must be a higher risk per interaction if this thing is spreading so easily. CA : Hm. OK, and then **the** fourth letter of DOTS is S for susceptibility. What ' s that? AK : So that is a measure of **the** proportion of **the** population who are susceptible. If you imagine you have this interaction with someone, **the** virus gets across, it exposes them, but some people may have been vaccinated or otherwise have some immunity and not develop infection themselves and not be infectious to others. So we ' ve got to account for this potential proportion of people who are not actually going to turn into cases themselves. CA : And obviously, there ' s no vaccine yet for this coronavirus, nor is anyone, at least initially, immune, as far as we know. So are you modeling that susceptibility number pretty high, is that part of **the** issue here? AK : Yeah, I think **the** evidence is that this is going to fully susceptible populations, and even in areas, for example, like China, where there ' s been a lot of transmission but there ' s been very strong control measures, we estimated that up to **the** end of January, probably about 95 percent of Wuhan are still susceptible. So there ' s been a lot of infection, but it hasn ' t really taken much of that component, of **the** DOTS, of those four things that drive transmission. CA : And so **the** way **the** mathematics works, I have to confess, amidst **the** stress of this whole situation, **the** nerd in me kind of loves **the** elegance of **the** mathematics here, because I ’ d never really thought about it this way, but you basically just multiply those numbers together to get **the reproduction** number. Is that right? AK : Exactly, yeah, you almost take **the** path of **the** infection during transmission as you multiply those together, and that gives you **the** number for that virus. CA : And so there ’ s just a total logic to that. It ’ s **the** number of days, duration that you ’ re infectious, it ’ s **the** number of people you ’ re seeing on average during those days that you have a chance to infect. Then you multiply that by **the** transmission **probability**, is virus getting into them, essentially, that ’ s what you mean by crossing over. And then by **the** susceptibility number. By **the** way, what do you think **the** susceptibility **probability** is for this case? AK : I think we have to assume that it ’ s near 100 percent in terms of spread, yeah. CA : Alright, you multiply those numbers together, and right now, it looks like, for this coronavirus, that you say two to three is **the** most plausible current number, which implies very rapid growth. AK : Exactly. In these uncontrolled outbreaks, we ’ re seeing now a number of countries in this stage – you are going to get this really rapid growth **occurring**. CA : And so how does that two to three compare with flu? And I guess, there ’ s seasonal flu, in **the** winter, when it ’ s spreading, and at other times during **the** year drops well below one as a **reproduction** number, right? But what is it during seasonal flu time? AK : During **the** early stage when it ’ s taking off at **the** start of **the** flu season, it ’ s probably, we reckon, somewhere between about maybe 1. 2, 1. 4. So it ’ s not incredibly transmissible, if you imagine you do have some immunity in your population from vaccination and from other things. So it can spread, it ’ s above one, but it ’ s not taking off, necessarily, as quickly as **the** coronavirus is. CA : So I want to come back to two of those elements, specifically opportunity and transmission **probability**, because those seem to have **the** most chance to actually do something about this infection rate. Before we go there, let ’ s talk about another key number on this, which is **the** fatality rate. First of all, could you define – I think there ’ s two different versions of **the** fatality rate that maybe confuse people. Could you define them? AK : So **the** one that we often talk about is what ’ s known as **the** case fatality rate, and that ’ s of **the** proportion who show up with symptoms as cases, what proportion of those will subsequently be fatal. And we also sometimes talk about what ’ s known as **the** infection fatality rate, which is, of everyone who gets infected, regardless of symptoms, how many of those infections will subsequently be fatal. But most of **the** values we see kicking around are **the** case fatality rate, or **the** CFR, as it ’ s sometimes known. CA : And so what is that fatality rate for this virus, and again, how does that compare with other pathogens? AK : So there ’ s a few numbers that have been bouncing around. One of **the** challenges in real time is you often don ’ t see all of your cases, you have people symptomatic not being reported. You also have a delay. If you imagine, for example, 100 people turn up to a hospital with coronavirus and none have died yet, that doesn ’ t imply that **the** fatality rate is zero, because you ’ ve got to wait to see what might happen to them. So when you adjust for that underreporting and delays, best estimate for **the** case fatality is about one percent. So about one percent of people with symptoms, on average, those outcomes are fatal. And that ’ s probably about 10 times worse than seasonal flu. CA : Yeah, so that ’ s a scary comparison right there, given how many people die of flu. So when **the** World Health Organization mentioned a higher number, a little while back, of 3. 4 percent, they were criticized a bit for that. Explain why that might have been misleading and how to think about it and adjust for that. AK : It ’ s incredibly common that people look at these raw numbers, they say,”How many deaths are there so far, how many cases,”and they look at that ratio, and even a couple of weeks ago, that number produced a two percent value. But if you imagine you have this delay effect, then even if you stop all your cases, you will still have these kind of fatal outcomes over time, so that number will creep up. This has **occurred** in every epidemic from pandemic flu to Ebola, we see this again and again. And I made **the** point to a number of people that this number is going to go up, because as China ’ s cases slow, it will look like it ’ s increasing, and that ’ s just kind of a statistical quirk. There ’ s nothing really kind of, behind a change, there ’ s no mutations or anything going on. CA : If I have this right, there are two effects going on. One is that **the** number of fatalities from **the** existing caseload will rise, which actually would boost that 3. 4 even higher. But then you have to offset that against **the** fact that, apparently, huge numbers of cases have just gone undetected and that we haven ’ t, due to bad testing, that **the** number of fatalities don ’ t – they probably reflect a much larger number of early cases. Is that it? AK : Exactly. So you have one thing pulling **the** number up and one thing pulling it down. And it means that on these kind of early values, if you actually just adjust for **the** delay and don ’ t think about these unreported cases, you start getting really very scary numbers indeed. You get up to 20, 30 percent potentially, which really doesn ’ t align with what we know about this virus in general. CA : Alright. There ’ s a lot more data in now. From your point of view, you think **the** likely fatality rate, at least in **the** earlier stage of an infection, is about two percent? AK : I think overall, I think we can put something probably in **the** 0. 5 to two percent range, and that ’ s on a number of different data sets. And that ’ s for people who are symptomatic. I think on average, one percent is a good number to work with. CA : OK, one percent, So flu is often quoted as a tenth of a percent, so it ’ s five to 10 times or more more dangerous than flu. And that danger is not symmetric across age groups, as is well known. It primarily affects **the** elderly. AK : Yeah, we ’ ve seen that one percent on average, but once you start getting into **the** over 60s, over 70s, that number really starts to shoot up. I mean, we ’ re estimating potentially in these older groups, you ’ re looking at maybe five, 10 percent fatality. And then of course, on top of that, you ’ ve got to add what are going to be **the** severe cases and people are going to require hospitalization. And those risks get very large in **the** older groups indeed. CA : Adam, put these numbers together for us. In your models, if you put together a **reproduction** rate of two to three and a fatality rate of 0. 5 percent to one percent and you run **the** simulation, what does it look like? AK : So if you have this uncontrolled transmission, and you have this **reproduction** number of two or three and you don ’ t do anything about it, **the** only way **the** outbreak ends is enough people get it and immunity builds up and **the** outbreak kind of ends on its own. And in that case, you would expect very large numbers of **the** population to be infected. It ’ s what we see, for example, with many other uncontained outbreaks, that it essentially burns through **the** population, you get large numbers infected and with this kind of fatality rate and hospitalization rate, that would really be hugely damaging if that were to **occur**. Certainly at **the** country level, we ’ re seeing – Italy is a good example at **the** moment, that if you have that early transmission that ’ s undetected, that rapid growth, you very quickly get to a situation where your health systems are overwhelmed. I think one of **the** nastiest aspects of this virus is that because you have **the** delay between infection and symptoms and people showing up in health care, if your health system is overwhelmed, even on that day, if you completely stop transmission, you ’ ve got all of these people who have already been exposed, so you ’ re still going to have cases and severe cases appearing for maybe another couple of weeks. So it ’ s really this huge accumulation of infection and burden that ’ s coming through **the** system on your population. CA : So there ' s another key number, actually, is how does **the** total case number compare to **the** capacity of a country ' s health system to process that number of cases. Presumably that issue makes a huge difference to **the** fatality rate, **the** difference between people coming in with severe illness and a health system that ' s able to respond and one that ' s overwhelmed. **The** fatality rate is going to be very different at that point. AK : If someone requires an ICU bed, that ' s a couple of weeks they ' re going to require it for and you ' ve got more cases coming through **the** system, so it very quickly gets very tough. CA : So talk about **the** difference between containment and mitigation. These are different terms that we ' re hearing a lot about. In **the** early stages of **the** virus, governments are focused on containment. What does that mean? AK : Containment is this idea that you can focus your effort on control very much on **the** cases and their contacts. So you ' re not causing disruption to **the** wider population, you have a case that comes in, you isolate them, you work out who they ' ve come into contact with, who ' s potentially these opportunities for exposure and then you can follow up those people, maybe quarantine them to make sure that no further transmission happens. So it ' s a very focused, targeted method, and for SARS, it worked remarkably well. But I think for this infection, because some cases are going to be missed or undetected, you ' ve really got to be capturing a large chunk of people at risk. If a few slip through **the** net, potentially, you ' re going to get an outbreak. CA : Are there any countries that have been able to employ this strategy and effectively contain **the** virus? AK : So Singapore have been doing a really remarkable job of this for **the** last six weeks or so. So as well as some wider measures, they ' ve been working incredibly hard to trace people who have come into contact. Looking at CCTV, going through to find out which taxi someone might have gotten, who might be at risk – really, really thorough follow-up. And for about six weeks, that has kept a lid on transmission. CA : So that ' s amazing. So someone comes into **the** country, they test positive – they go to work, and with a massive team, and trace everything to **the** level of actually saying,"Oh, you don ' t know what taxi you went in? Let us find that out for you."And presumably, when they find **the** taxi driver, they then have to try and figure out everyone else who was in that taxi? AK : So they will focus on close contacts of people most at risk, but they ' re really minimizing **the** chance that anyone slips through **the** net. CA : But even in Singapore, if I ' m not mistaken, numbers started to trend back down to zero, but I think recently, they ' ve picked up again a bit. It ' s still **unclear** whether they will actually be able to sustain containment. AK : Exactly. If we talk in terms of **the reproduction** number, we saw it dipped to maybe 0. 8, 0. 9, so under that crucial value of one. But in **the** last week or two, it does seem to be ticking up and they ' re getting more cases appearing. I think a lot of it is, even if they are containing it, **the** world is experiencing outbreaks and just keeps throwing sparks of infection, and it becomes harder and harder with that level of intensive effort to stamp them all out. CA : In **the** case of this virus, you know, there was warning to most countries in **the** world that this thing was happening. **The** news out of China very quickly became very bleak, and people had time to prepare. I mean, what would ideal preparation look like if you know that something like this is coming and you know that there ' s a lot on **the** line if you can successfully contain it before it really escapes? AK : I think two things would make a really big difference. One is having as thorough a follow-up and detection as possible. We ' ve done some modeling analyses, looking at how effective that kind of early containment is. And it can be, if you ' re identifying maybe 70 or 80 percent of **the** people who might have come into contact. But if you ' re not **detecting** those cases coming in, if you ' re not **detecting** their contacts – and a lot of **the** early focus, for example, was on travel history to China, and then it became clear that **the** situation was changing, but because you were relying on that as your definition of a case, it meant a lot of maybe other cases that matched **the** definition weren ’ t being tested because they didn ’ t seem to be potentially at risk. CA : So I mean, if you know that early detection is key to this, an essential early measure, I guess, would be to rapidly ensure that you had enough tests available and where needed, so that you could respond, be ready to swing into action as soon as someone was **detected**, you then have to very quickly, I guess, test their contacts and so forth, to have a chance of keeping this under control. AK : Exactly. In my line of work, we say there ’ s value in a negative test, because it shows that you ’ re looking for something and it ’ s not there. And so I think having small numbers of people tested doesn ’ t give you confidence that you ’ re not missing infections, whereas if you are doing really thorough follow-up on contacts, we ’ ve seen countries even like Korea now, huge numbers of people tested. So although there are still cases appearing, it gives them more confidence that they have some sense of where those infections are. CA : I mean, you ’ re in **the** UK right now, I ’ m in **the** US. How likely is it that **the** UK is going to be able to contain, how likely is it that **the** US is going to be able to contain this? AK : I think it ’ s pretty unlikely in both cases. I think **the** UK is going to have to introduce some additional measures. I think when that happens obviously depends a bit on **the** current situation, but we ’ ve tested almost 30, 000 people now. Frankly, I think **the** US may well be moving beyond that point, given how much evidence of extensive transmission that has, and I think without clear ideas of how much infection there is and that level of testing, it ’ s quite hard to actually see what **the** picture currently is in **the** US. CA : I mean, I definitely don ’ t want to get too political about this, but I mean, does this strike you as – you just said that **the** UK has tested 30, 000 people – **the** US is five or six times bigger and I think **the** total number of tests here is five or six thousand, or it was a few days ago. Does that strike you as bizarre? I don ’ t understand, honestly, how that happened in an educated country that has so much knowledge about infectious diseases. AK : It does, and I think there ’ s obviously a number of factors playing in there, logistics and so on, but there has been that period of warning that this is a threat and this is coming in. And I think countries need to make sure that they ’ ve got **the** capacity to really do as much detection as they can in those early stages, because that ’ s where you ’ re going to catch it and that ’ s where you ’ re going to have a better chance of containing it. CA : OK, so if you fail to contain, then you have to move to some kind of mitigation strategy. So what comes into play there? And I think I almost want to bring that back to two of your DOTS factors, opportunity and transmission **probability**, because it seems like **the** virus is what it is, **the** actual duration when someone is potentially infectious, we can ’ t do much about. **The** susceptibility side, we can ’ t do much about until there ’ s a vaccine. We could maybe talk about that in a bit. But **the** middle two of opportunity and transmission **probability**, we can do something about. Do you want to maybe talk about those in turn, of what that looks like, how would you build a mitigation strategy? I mean, first of all, thinking about opportunity, how do you reduce **the** number of opportunities to pass on **the** bug? AK : And so I think in that respect, it would be about massive changes in our social interactions. And if you think in terms of **the reproduction** number of being about two or three, to get that number below one, you ’ ve really got to cut some aspect of that transmission in half or in **two-thirds** to get that below one. And so that would require, of **the** opportunities that could spread **the** virus, so these kind of close contacts, everybody in **the** population, on average, will be needing to reduce those interactions potentially by **two-thirds** to bring it under control. That might be through working from home, from changing lifestyle and kind of where you go in crowded places and dinners. And of course, these measures, things like school closures, and other things that just attempt to reduce **the** social mixing of a population. CA : Well, actually, talk to me more about school closures, because that, if I remember, often in past pandemics has been cited as an absolutely key measure, that schools represent this sort of coming together of people, children are often – certainly when it comes to flu and colds – they ’ re carriers. But on this case, children don ’ t seem to be getting sick from this particular virus, or at least very few of them are. Do we know whether they can still be infectious? They can be **the** unintended carriers of it. Or actually, is there evidence that school closures may not be as important in this instance as it is in others? AK : So that point on what role children play is a crucial one, and there ’ s still not a good evidence base there. From following up of contacts of cases, there ’ s now evidence that children are getting infected, so when you ’ re testing, they are getting exposed, it ’ s not that somehow they ’ re just not getting **the** infection at all, but as you said, they ’ re not showing symptoms in **the** same way. And particularly for flu, when we see **the** implications of school closures, even in **the** UK in 2009 during swine flu, there was a dip in **the** outbreak during **the** school holidays, you could see it on **the** epidemic curve, it kind of comes back down in **the** summer and goes back up in **the** autumn. But of course, in 2009, there was some immunity in older groups. That kind of shifted more **the** transmission into **the** younger ones. So I think it ’ s really something we ’ re trying to work to understand. Obviously, it will reduce interactions, with school closures, but then there ’ s knock-on social effects, there ’ s potential knock-on changes in mixing, maybe grandparents and their role, in terms of alternative carers if parents have to work. So I think there ’ s a lot of pieces that need to be considered. CA : I mean, based on all of **the** different pieces of evidence you ’ ve seen, if it were down to you, would you be recommending that most countries at this point do look hard at extensive school closures as a precautionary measure, that it ’ s just worth it to do that as a sort of painful two, three, four, five-month strategy? What would you recommend? AK : I think **the** key thing, given **the** age distribution of risk and **the** severity in older groups is reduce interactions that bring **the** infection into those groups. And then amongst everyone else, reduce interactions as much as possible. I think **the** key thing is we ’ ve got so much of **the** disease burden in **the** kind of 60-plus group that it ’ s not just about everyone trying to avoid everyone ’ s interactions, but it ’ s **the** kind of behaviors that would drive infections into those groups. CA : Does that mean that people should think twice before, I don ’ t know, visiting a loved one in an old people ’ s home or in a residential facility? Like that, we should just pay super special attention to that, should all these facilities be taking great care about who they admit, taking temperature and checking for symptoms or something like that? AK : I think those measures definitely need to be considered. In **the** UK, we ’ re getting plans for potentially what ’ s known as a cocooning strategy for these older groups that we can really try and **seal** off interactions as much as possible from people who might be bringing infection in. And ultimately, because as you said, we can ’ t target these other aspects of transmission, it is just reducing **the** risk of exposure in these groups, and so I think anything at **the** individual level you can do to get people reducing their risk, if either they ’ re elderly or in other risk groups, I think is crucial. And I think more at **the** general level those kind of more large-scale measures can help reduce interactions overall, but I think if those reductions are happening and not reducing **the** risk for people who are going to get severe disease, then you ’ re still going to get this really remarkably severe burden. CA : I mean, do people have to almost apply this double lens as they think about this stuff?

There ’ s **the** risk to you as you go about your life, of you catching this bug. But there ’ s also **the** risk of you being, unintentionally, a carrier to someone who would suffer much more than you might. And that both those things have to be top of mind right now. AK : Yeah, and it ’ s not just whose hand you shake, it ’ s whose hand that person goes on to shake. And I think we need to think about these second-degree steps, that you might think you have low risk and you ’ re in a younger group, but you ’ re often going to be a very short step away from someone who is going to get hit very hard by this. And I think we really need to be socially minded and think this could be quite dramatic in terms of change of behavior, but it needs to be to reduce **the** impact that we ’ re potentially facing. CA : So **the** opportunity number, we bring down by just reducing **the** number of physical contacts we have with other people. And I guess **the** transmission **probability** number, how do we bring that down? That impacts how we interact. You mentioned hand-shaking, I ’ m guessing you ’ re going to say no handshaking. AK : Yeah, so changes like that. I mean, another one, I think, handwashing operates in a way that we might be still be doing activities that we ’ ve previously done, but handwashing reduces **the** chance that from one interaction to another, we might be spreading infection, so it ’ s all of these measures that mean that even if we ’ re having these exposures, we ’ re taking additional steps to avoid any transmission happening. CA : I still think most people don ’ t fully understand or don ’ t have a clear model of **the** pathway by which this thing spreads. So you think definitely people understand that you don ’ t breathe in **the** water droplets of someone who has just coughed or sneezed. So how does it spread? It gets onto **surfaces**. How? Do people just breathe out and it goes on from people who are sick, they touch their mouth or something like that, and then touch a **surface** and it gets on that way? How does it actually get onto **surfaces**? AK : I think a lot of it would be that you cough in your hand and it ends up on a **surface**. But I think **the** challenge, obviously, is untangling these questions of how transmission happens. You have transmission in a household, and is it that someone coughed and it got on a **surface**, is it direct contact, is it a handshake, and even for things like flu, that ’ s something that we work quite hard to try and unpick, how does social behavior correspond to infection risk. Because it ’ s clearly important, but pinning it down is really tough. CA : It ’ s almost like embracing **the** fact that for a lot of these things, we actually don ’ t know and that we ’ re all in this game of **probabilities**. Which, in a way, is why I think **the** math is so important here. That you have to think of this as these multiple numbers working together on each other, they all have their part to play. And any of them that you can take down by a percentage is likely contributing, not just to you but to everyone. And people don ’ t actually know in detail how **the** numbers go together, but they know that they probably all matter. We almost need people to, somehow, you know, embrace that uncertainty and then try to get some satisfaction by acting on every single part of it. AK : I think it ’ s this idea that if on average, you ’ re infecting, say, three people, what ’ s driving that and how can you chip away at that value? If you ’ re washing your hands, how much might that chip away in terms of **the** handshakes, you know, you may have had virus and you no longer do, or if you are changing your social behavior in a certain way, is that taking away a couple of interactions, is that taking away half? How can you really chip into that number as much as you possibly can? CA : Is there anything else to say about how we could reduce that transmission **probability** in our interactions? Like, what is **the** physical distance that it ’ s wise to stay away from other people if we can? AK : I think it ’ s hard to pin down exactly, but I think one thing to bear in mind is that there ’ s not so much evidence that this is a kind of aerosol and it goes really far – it ’ s reasonably short distances.

I don ’ t think it ’ s **the** case that you ’ re sitting a few meters away from someone and **the** virus is somehow going to get across. It ’ s in closer interactions, and it ’ s why we ’ re seeing so many transmission events **occur** in things like meals and really tight-knit groups. Because if you imagine that ’ s where you can get a virus out and onto **surfaces** and onto hands and onto faces, and it ’ s really situations like that we ’ ve got to think more about. CA : So in a way, some of **the** fears that people have may actually be overstated, like, if you ’ re in **the** middle of an **airplane** and someone at **the** front sneezes, I mean, that ’ s annoying, but it ’ s actually not **the** thing you should be most freaked out about. There are much smarter ways to pay attention to your well-being. AK : Yeah, if it was measles and **the** plane was susceptible people, you would see a lot of infections after that. I think it is, bear in mind, that this is, on average, people infecting two or three others, so it ’ s not **the** case of your maybe 50 interactions over a week, all of those people are at risk. But it ’ s going to be some of them, particularly those close contacts, that are going to be where transmission ’ s **occurring**. CA : So talk about, from a sort of national strategy point of view. There ’ s a lot of talk about **the** need to”flatten **the** curve.”What does that mean? AK : I think it refers to this idea that for your health systems, you don ’ t want all your cases to appear at **the** same time. So if we sat back and did nothing and just let **the** epidemic grow, and you had this growth rate that, at **the** moment, in some places is looking like maybe three to four days, you ’ re getting doubling. So every three or four days, **the** epidemic is doubling. It will skyrocket and you ’ ll end up with a whole bunch of really severely ill people needing hospital care all at **the** same time, and you just won ’ t have capacity for it. So **the** idea of flattening **the** curve is if we can slow transmission, if we can get that **reproduction** number down, then there may still be an outbreak, but it will be much flatter, it will be longer and there will be fewer severe cases showing up, which means that they can get **the** health care they need. CA : Does it imply that there will be fewer cases overall, or – When you look at **the** actual images of people showing what flattening **the** curve looks like, it almost looks as if you ’ ve got **the** same area still under **the** graph, i. e. that **the** same number of people, ultimately, are infected but over a longer period. Is that typically what happens, and even if you adopt all these strategies of social distancing and washing hands and etc. that **the** best you can hope for is that you slow **the** thing down, you actually will get as many people infected in **the** end? AK : Not necessarily – it depends on **the** measures that go in. There are some measures like, shutting down travel, which typically delay **the** spread rather than reduce it. So you ’ re still going to get **the** same outbreaks, but you ’ re stretching out **the** outbreaks. But there are other measures. If we talk about reducing interactions, if your **reproduction** number ’ s lower, you would expect fewer cases overall. And eventually, in your population, you will get some buildup of immunity, which would help you out if you think about **the** components, reducing susceptibility, alongside what ’ s going on elsewhere. So **the** hope is that **the** two things will work together. CA : So help me understand what **the** endgame is here. So, take China, for example. Whatever you make of **the** early suppression of data and so forth that seems pretty troubling there. **The** intensity of **the** response come January time or whatever, with **the** shutdown of this huge area of **the** country, seems to have actually been effective. **The** number of cases there are falling at a shockingly high rate in some ways. Falling to almost nothing. And I can ’ t understand that. You are talking about a country of, whatever, 1. 4 billion people. There have been a huge number of cases there, but it was a tiny **fraction** of **the** population have actually got sick. And yet, they ’ ve got **the** number way down. It ’ s not like every other person in China has somehow developed immunity. Is it that they have been absolutely disciplined about shutting down travel from **the** infected regions and somehow really dialed up, massively dialed up testing at any sign of any problem, so that literally, they are back in containment mode in most parts of China? I can ’ t get my head around it, help me understand it. AK : So we estimated, in **the** last two weeks of January, when these measures went in, **the reproduction** number went from about 2. 4 to 1. 1. So about 60 percent decline in transmission in **the** space of a week or two. Which is remarkable and really, a lot of it is likely to be driven by just fundamental change in social behavior, huge social distancing, really intensive follow-up, intensive testing. And it got to **the** point where it took enough off **the reproduction** number to cause **the** decline, and now, of course, we ’ re seeing, in many areas, a transition back to more of this kind of containment, because there ’ s few cases, it ’ s more manageable. But we ’ re also seeing them face a challenge, because a lot of these cities have basically been locked down for six weeks and there ’ s a limit to how long you can do that for. And so some of these measures are gradually starting to be lifted, which of course creates **the** risk that cases that are appearing from other countries may subsequently go in and reintroduce transmission. CA : But given how infectious **the** bug is, and how many theoretical pathways and connection points there are between people in Wuhan, even in shutdown, or relatively shut down, or **the** other places where there ’ s been some infection and **the** rest of **the** country, does it surprise you how quickly that curve has gone down to nearly zero? AK : Yes. Early on when we saw that flattening off in cases in those first few days, we did wonder whether it was just they hit a limit in testing capacity and they were reporting 1, 000 a day, because that ’ s all **the** kits they had. But it continued, thankfully, and it shows that it is possible to turn this over with that level of intervention. I think **the** key thing now is seeing how it works in other settings. Italy now are putting in really dramatic interventions. But of course, because of this delay effect, if you put them in today, you won ’ t necessarily see **the** effects on cases for another week or two. So I think working out what impact that ’ s had is going to be key for helping other countries work on how to contain this. CA : To have a picture, Adam, of how this is likely to play out over **the** next month or two, give us a couple of scenarios that are in your head. AK : I think **the** optimistic scenario is that we ’ re going to learn a lot from places like Italy that have unfortunately been hit very hard. And that countries are going to take this very seriously and that we ’ re not going to get this continued growth that ’ s going to overwhelm totally, that we ’ re going to be able to sufficiently slow it down, that we are going to get large numbers of cases, we ’ re probably going to get a lot of severe cases, but that will be more manageable, that ’ s **the** kind of optimistic scenario. I think if we have a point where countries either don ’ t take this seriously or populations don ’ t respond well to control measures or it ’ s not **detected**, we could get situations – I think Iran is probably **the** closest one at **the** moment – where there ’ s been extensive widespread transmission, and by **the** time it ’ s being responded to, those infections are already in **the** system and they are going to turn up as cases and severe illness. So I ’ m hoping we ’ re not at that point, but we ’ ve certainly got, at **the** moment, potentially about 10 countries on that trajectory to have **the** same outlook as Italy. So it ’ s really crucial what happens in **the** next couple of weeks. CA : Is there a real chance that quite a few countries end up having, this year, substantially more deaths from this virus than from seasonal flu? AK : I think for some countries that is likely, yeah. I think if control is not possible, and we ’ ve seen it happen in China, but that was really just an unprecedented level of intervention. It was really just changing **the** social fabric. I think people, many of us, don ’ t really appreciate, at a glance, just what that means, to reduce your interactions to that extent. I think many countries just simply won ’ t be able to manage that. CA : It ’ s almost a challenge to democracies, isn ’ t it –”OK, show us what you can do without that kind of draconian control. If you don ’ t like **the** thought of that, come on, citizens, step up, show us what you ’ re capable of, show that you can be wise about this and smart and self-disciplined, and get ahead of **the** damn bug.”AK : Yeah. CA : I mean, I ’ m not personally superoptimistic about that, because there ’ s such conflicting messaging coming out in so many different places, and people don ’ t like to short-term sacrifice. I mean, is there almost a case that – I mean, what ’ s your view on whether **the** media has played a helpful role here or an unhelpful role? Is it actually, in some ways, helpful to, if anything, overstate **the** concern, **the** fear, and actually make people panic a little bit? AK : I think it ’ s a really tough balance to strike, because of course, early on, if you don ’ t have cases, if you don ’ t have any evidence of potential pressure, it ’ s very hard to get that message and convince people to take it seriously if you ’ re overhyping it. But equally, if you ’ re waiting too long, and saying it ’ s not a concern yet, we ’ re OK for **the** moment, a lot of people think it ’ s just flu. By **the** time it hits hard, as I ’ ve said, you ’ re going to have weeks of an overburdened health system, because even if you take interventions, it ’ s too late to control **the** infections that have happened. So I think it ’ s a fine line, and my hope is there is this ramp-up in messaging, now people have these tangible examples like Italy, where they can see what ’ s going to happen if they don ’ t take it seriously. But certainly, of all **the** diseases I ’ ve seen, I think many of my colleagues who are much older than me and have memories of other outbreaks, it ’ s **the** scariest thing we ’ ve seen in terms of **the** impact it could have, and I think we need to respond to that. CA : It ’ s **the** scariest disease you ’ ve seen. Wow. I ’ ve got some questions for you from my friends on Twitter. Everyone is obviously super exercised about this topic. Hypothetically, if everyone stayed home for three weeks, would that effectively **wipe** this out? Is there a way to socially distance ourselves out of this? AK : Yeah, I think in certain countries with reasonably small household sizes, I think average in **the** UK, US is about two and a half, so even if you had a round of infection within **the** household, that would probably stamp it out. As a secondary benefit, you may well stamp out a few other infections, too. Measles only circulates in humans, so you may have some knock-on effect, if, of course, that were ever to be possible. CA : I mean, obviously that would be a huge dent to **the** economy, and this is in a way almost, like, one of **the** underlying challenges here is that you can ’ t optimize public policy for both economic health and fighting a virus. Like, those two things are, to some extent, in conflict, or at least, short-term economic health and fighting a virus. Those two things are in conflict, right? And societies need to pick one. AK : It is tough to convince people of that balance, **the** thing we always say of pandemic planning is it ’ s cheap to put this stuff in place now – otherwise, you ’ ve got to pay for it later. But unfortunately, as we ’ ve seen with this, that a lot of early money for response wasn ’ t there. And it ’ s only when it has an impact and when it ’ s going to get expensive that people are happy to take that cost on board, it seems. CA : OK, some more Twitter questions. Will **the** rising temperature in coming weeks and months slow down **the** COVID-19 spread? AK : I haven ’ t seen any convincing evidence that there ’ s that strong pattern with temperature, and we ’ ve seen it for other infections that there is this seasonal pattern, but I think **the** fact we ’ re getting widespread outbreaks makes it hard to identify, and of course, there ’ s other things going on. So even if one country doesn ’ t have as big an outbreak as another, that ’ s going to be influenced by control measures, by social behavior, by opportunities and these things as well. So it would be really reassuring if this was **the** case, but I don ’ t think we can say that just yet. CA : Continuing from Twitter, I mean, is there a standardized global recommendation for all countries on how to do this? And if not, why not? AK : I think that ' s what people are trying to piece together, first in terms of what works. It ' s only really in **the** last sort of few weeks we ' ve got a sense that this thing can be controllable with this extent of interventions, but of course, not all countries can do what China have done, some of these measures incur a huge social, economic, psychological burden on populations. And of course, there ' s **the** time limit. In China they ' ve had them in for six weeks it ' s tough to maintain that, so we need to think of these tradeoffs of all **the** things we can ask people to do, what ' s going to have **the** most impact on actually reducing **the** burden. CA : Another question : How did this happen and is it likely to happen again? AK : So it ' s likely that this originated with **the** virus that was circling in bats and then probably made its way through another species into humans somehow, there ' s a lot of bits of evidence around this, there ' s not kind of single, clear story, but even for SARS, it took several years for genomics to piece together **the exact** route that it happened. But certainly, I think it ' s plausible that it could happen again. Nature is throwing out these viruses constantly. Many of them aren ' t well-adapted to humans, don ' t pick up, you know, there may well have been a virus like this a few years ago that just happened to infect someone who just didn ' t have any contacts and didn ' t go any further. I think we are going to face these things and we need to think about how can we get in early at **the** stage where we ' re talking small numbers of cases, and even something like this is containable, rather than **the** situation we ' ve got now. CA : It seems like this isn ' t **the** first time that a virus seems to have emerged from, like, a wild meat market. That ' s certainly how it happens in **the** movies. And I think China has already taken some steps this time to try to crack down on that. I guess that ' s potentially quite a big deal for **the** future if that can be properly maintained. AK : It is, and we saw, for example, **the** H7N9 avian flu, over **the** last few years, in 2013, it was a big emerging concern, and China made a very extensive response in terms of changing how they operate their markets and vaccination of birds and that seems to have removed that threat. So I think these measures can be effective if they ' re identified early on. CA : So talk about vaccinations. That ' s **the** key measure, I guess, to change that susceptibility factor in your equation. There ' s obviously a race on to get these vaccinations out there, there are some candidate vaccinations there. How do you see that playing out? AK : I think there ' s certainly some promising development happening, but I think **the** timescales of these things are really on **the** order of maybe a year, 18 months before these things be widely available. Obviously, a vaccine has to go through these stages of trials, that takes time, so even if by **the** end of **the** year, we have something which is viable and works, we ' re still going to see a delay before everyone can get ahold of it. CA : So this really puzzles me, actually, and I ' d love to ask you as a mathematician about this as well. There are already several companies believing that they have plausible candidate vaccines. As you say, **the** process of testing takes forever. Is there a case that we ' re not thinking about this right when we ' re looking at **the** way that testing is done and that **the** safety calculations are made? Because it ' s one thing if you ' re going to introduce a brand new drug or something – yes, you want to test to make sure that there are no side effects, and that can take a long time by **the** time you ' ve done all **the** control trials and all **the** rest of it. If there ' s a global emergency, isn ' t there a case, both mathematically and ethically, that there should just be a different calculation, **the** question shouldn ' t be"Is there any possible case where this vaccine can do harm,"**the** question surely should be,"On **the** net **probabilities**, isn ' t there a case to roll this out at scale, to have a shot at nipping this thing in **the** bud?"I mean, what am I missing in thinking that way?

AK : I mean, we do see that in other situations, for example, **the** Ebola vaccine in 2015 showed, within a few months, very promising evidence and interim results of **the** trial in humans showed what seemed very high efficacy. And even though it hadn ’ t been licensed fully, it was employed for what is known as compassionate use in subsequent other outbreaks. So there are these mechanisms where vaccines can be fast-tracked in this way. But of course, we ’ re currently in a situation where we have no idea if these things will do anything at all. So I think we need to accrue enough evidence that it could have an impact, but obviously, fast-track that as much as possible. CA : But **the** skeptic in me still doesn ’ t fully get this. I don ’ t understand why there isn ’ t more energy behind bolder thinking on this. Everyone seems, despite **the** overall risk, incredibly risk-averse about how to build **the** response to it. AK : So with **the** caveat that, yeah, there ’ s a lot of good questions on this, and some of them are slightly outside my wheelhouse, but I agree that we need to do more to get timescales out. **The** example I always quote is it takes us six months to choose a seasonal flu strain and get **the** vaccines out there to people. We always have to try and predict ahead which strains are going to be circulating. And that ’ s for something we know how to make and has been manufactured for a long time. So there is definitely more that needs to be done to get these timescales shorter. But I think we do have to balance that, especially if we ’ re exposing large numbers of people to something to make sure that we ’ re confident it ’ s safe and that it ’ s going to have some benefit, potentially. CA : And so, finally, Adam, I guess going into this – There ’ s another set of infectious things happening around **the** world at **the** same time, which is ideas and **the** communication around this thing. They really are two very dynamic, interactive systems of infectiousness – there ’ s some very damaging information out there. Is it fair to think of this as battle of credible knowledge and measures against **the** bug, and just bad information – You know, part of what we have to think about here is how to suppress one set of things and boost **the** other, actually, turbocharge **the** other. How should we think of this? AK : I think we can definitely think of it almost as competition for our attention, and we see similarly, with diseases, you have viruses competing to infect susceptible hosts. And I think we ’ re now seeing, I guess over **the** last few years with fake news and misinformation and **the** emergence of awareness, more of a transition to thinking about how do we reduce that susceptibility if we have people that can be in these different states, how can we try and preempt better with information. I think **the** challenge for an outbreak is obviously, early on, we have very little good information, and it ’ s very easy for certainty and confidence to fill that vacuum. And so I think that is something – I know platforms are working on how can we get people exposed to good information earlier, so hopefully protect them against other stuff. CA : One of **the** big unknowns to me in **the** year ahead – let ’ s say that **the** year ahead includes many, many more weeks, for many people, of actually self-isolating. Those of us who are lucky enough to have jobs where you can do that. You know, staying home. By **the** way, **the** whole injustice of this situation, where so many people can ’ t do that and continue to make a living, is, I ’ m sure, going to be a huge deal in **the** year ahead and if it turns out that death rates are much higher in **the** latter group than in **the** former group, and especially in a country like **the** US, where **the** latter group doesn ’ t even have proper health insurance and so forth. That feels like right there, that could just become a huge debate, hopefully a huge source of change at some level. AK : I think that ’ s an incredibly important point, because it ’ s very easy – I similarly have a job where remote working is fairly easy, and it ’ s very easy to say we should just stop social interactions, but of course, that could have an enormous impact on people and **the** choices and **the** routine that they can have. And I think those do need to be accounted for, both now and what **the** effect is going to look like a few months down **the** line. CA : When all ' s said and done, is it fair to say that **the** world has faced, actually, much graver problems in **the** past, that on any scenario, it ' s highly likely that at some point in **the** next 18 months, let ' s say, a vaccine is there and starts to get wide distribution, that we will have learned lots of other ways to manage this problem? But at some point, next year probably, **the** world will feel like it ' s got on top of this and can move on. Is that likely to be it, or is this more likely to be, you know, it escapes, it ' s now an endemic nightmare that every year picks off far more people than are picked off by **the** flu currently. What are **the** likely ways forward, just taking a slightly longer-term view? AK : I think there ' s plausible ways you could see all of those potentially playing out. I think **the** most plausible is probably that we ' ll see very rapid growth this year and lots of large outbreaks that don ' t recur, necessarily. But there is a potential sequence of events that could end up with these kind of multiyear outbreaks in different places and reemerging. But I think it ' s likely we ' ll see most transmission concentrated in **the** next year or so. And then, obviously, if there ' s a vaccine available, we can move past this, and hopefully learn from this. I think a lot of **the** countries that responded very strongly to this were hit very hard by SARS. Singapore, Hong Kong, that really did leave an impact, and I think that ' s something they ' ve drawn on very heavily in their response to this. CA : Alright. So let ' s wrap up maybe by just encouraging people to channel their inner mathematician and especially think about **the** opportunities and **the** transmission **probabilities** that they can help shift. Just remind us of **the** top three or four or five or six things that you would love to see people doing. AK : I think at **the** individual level, just thinking a lot more about your interactions and your risk of infection and obviously, what gets onto your hands and once that gets onto your face, and how do you potentially create that risk for others. I think also, in terms of interactions, with things like handshakes and maybe contacts you don ' t need to have. You know, how can we get those down as much as possible. If each person ' s giving it to two or three others, how do we get that number down to one, through our behavior. And then it ' s likely that we ' ll need some larger-scale interventions in terms of gatherings, conferences, other things where there ' s a lot of opportunities for transmission. And really, I think that combination of that individual level, you know, if you ' re ill or potentially you ' re going to get ill, reducing that risk, but then also us working together to prevent it getting into those groups who, if it continues to be uncontrolled, could really hit some people very, very hard. CA : Yeah, there ' s a lot of things that we may need to gently let go of for a bit. And maybe try to reinvent **the** best aspects of them. Thank you so much. If people want to keep up with you, first of all, they can follow you on Twitter, for example. What ' s your Twitter handle? AK : So @AdamJKucharski, all one word. CA : Adam, thank you so much for your time, stay well. AK : Thank you. CA : Associate professor and TED Fellow Adam Kucharski. We ' d love to hear what you think of this bonus episode. Please tell us by rating and reviewing us in Apple Podcasts or your favorite podcast app. Those reviews are influential, actually. We certainly read every one, and truly appreciate your feedback. This week ' s show was produced by Dan O ' Donnell at Transmitter Media. Our production manager is Roxanne Hai Lash, our fact-checker Nicole Bode. This episode was mixed by Sam Bair. Our **theme** music is by Allison Layton-Brown. Special thanks to my colleague Michelle Quint. Thanks for listening to **the** TED Interview. We ' ll be back later this **spring** with a whole new season ' s worth of deep dives with great minds. I hope you ' ll **enjoy** them whether or not life is back to normal. I ' m Chris Anderson, thanks for listening and stay well.

Text Sample 75: POS Dim 1 – 1990 – Score 4.00 – 1990/t000287.txt

I ’ m going to go right into **the slides**. And all I ’ m going to try and prove to you with these **slides** is that I do just very straight stuff. And my ideas are â in my head, anyway â they ’ re very logical and relate to what ’ s going on and problem solving for clients. I either convince clients at **the** end that I solve their problems, or I really do solve their problems, because usually they seem to like it. Let me go right into **the slides**. Can you turn off **the** light? Down. I like to be in **the** dark. I don ’ t want you to see what I ’ m doing up here. Anyway, I did this house in Santa Monica, and it got a lot of notoriety. In fact, it appeared in a porno comic book, which is **the slide** on **the** right. This is in Venice. I just show it because I want you to know I ’ m concerned about context. On **the** left-hand side, I had **the** context of those little houses, and I tried to build a building that fit into that context. When people take pictures of these buildings out of that context they look really weird, and my premise is that they make a lot more sense when they ’ re photographed or seen in that space. And then, once I deal with **the** context, I then try to make a place that ’ s comfortable and private and fairly serene, as I hope you ’ ll find that **slide** on **the** right. And then I did a law school for Loyola in downtown L. A. I was concerned about making a place for **the** study of law. And we continue to work with this client. **The** building on **the** right at **the** top is now under construction. **The** garage on **the** right â **the** gray structure â will be torn down, finally, and several small classrooms will be placed along this avenue that we ’ ve created, this campus. And it all related to **the** clients and **the** students from **the** very first meeting saying they felt denied a place. They wanted a sense of place. And so **the** whole idea here was to create that kind of space in downtown, in a neighborhood that was difficult to fit into. And it was my theory, or my point of view, that one didn ’ t upstage **the** neighborhood â one made accommodations. I tried to be inclusive, to include **the** buildings in **the** neighborhood, whether they were buildings I liked or not. In **the** ’ 60s I started working with paper furniture and made a bunch of stuff that was very successful in Bloomingdale ’ s. We even made flooring, walls and everything, out of cardboard. And **the** success of it threw me for a loop. I couldn ’ t deal with **the** success of furniture â I wasn ’ t secure enough as an architect â and so I closed it all up and made furniture that nobody would like. So, nobody would like this. And it was in this, preliminary to these pieces of furniture, that Ricky and I worked on furniture by **the** slice. And after we failed, I just kept failing. **The** piece on **the** left â and that ultimately led to **the** piece on **the** right â happened when **the** kid that was working on this took one of those long strings of stuff and folded it up to put it in **the** wastebasket. And I put a piece of tape around it, as you see there, and realized you could sit on it, and it had a lot of resilience and strength and so on. So, it was an accidental discovery. I got into **fish**. I mean, **the** story I tell is that I got mad at postmodernism â at po-mo â and said that **fish** were 500 million years earlier than man, and if you ’ re going to go back, we might as well go back to **the** beginning. And so I started making these funny things. And they started to have a life of their own and got bigger â as **the** one glass at **the** Walker. And then, I sliced off **the** head and **the** tail and everything and tried to translate what I was learning about **the** form of **the fish** and **the** movement. And a lot of my architectural ideas that came from it â accidental, again â it was an intuitive kind of thing, and I just kept going with it, and made this proposal for a building, which was only a proposal. I did this building in Japan. I was taken out to dinner after **the** contract for this little restaurant was signed. And I love sake and Kobe and all that stuff. And after I got â I was really drunk â I was asked to do some sketches on napkins. And I made some sketches on napkins â little boxes and Morandi-like things that I used to do. And **the** client said,"Why no **fish**?"And so I made a drawing with a **fish**, and I left Japan. Three weeks later, I received a complete set of drawings saying we ' d won **the** competition. Now, it ' s hard to do. It ' s hard to translate a **fish** form, because they ' re so beautiful â perfect â into a building or **object** like this. And Oldenburg, who I work with a little once in a while, told me I couldn ' t do it, and so that made it even more exciting. But he was right â I couldn ' t do **the** tail. I started to get **the** head OK, but **the** tail I couldn ' t do. It was pretty hard. **The** thing on **the** right is a snake form, a ziggurat. And I put them together, and you walk between them. It was a dialog with **the** context again. Now, if you saw a picture of this as it was published in Architectural Record â they didn ' t show **the** context, so you would think,"God, what a pushy guy this is."But a friend of mine spent four hours wandering around here looking for this restaurant. Couldn ' t find it. So... As for craft and technology and all those things that you ' ve all been talking about, I was thrown for a complete loop. This was built in six months. **The** way we sent drawings to Japan : we used **the** magic **computer** in Michigan that does carved models, and we used to make foam models, which that thing scanned. We made **the** drawings of **the fish** and **the** scales. And when I got there, everything was perfect â except **the** tail. So, I decided to cut off **the** head and **the** tail. And I made **the object** on **the left** for my show at **the** Walker. And it ' s one of **the** nicest pieces I ' ve ever made, I think. And then Jay Chiat, a friend and client, asked me to do his headquarters building in L. A. For reasons we don ' t want to talk about, it got delayed. Toxic waste, I guess, is **the** key clue to that one. And so we built a temporary building â I ' m getting good at temporary â and we put a conference room in that ' s a **fish**. And, finally, Jay dragged me to my hometown, Toronto, Canada. And there is a story â it ' s a real story â about my grandmother buying a carp on Thursday, bringing it home, putting it in **the** bathtub when I was a kid. I played with it in **the** evening. When I went to sleep, **the** next day it wasn ' t there. And **the** next night, we had gefilte **fish**. And so I set up this interior for Jay ' s offices and I made a pedestal for a sculpture. And he didn ' t buy a sculpture, so I made one. I went around Toronto and found a bathtub like my grandmother ' s, and I put **the fish** in. It was a joke. I play with funny people like [Claes] Oldenburg. We ' ve been friends for a long time. And we ' ve started to work on things. A few years ago, we did a performance piece in Venice, Italy, called"Il Corso del Coltello"â **the** Swiss Army knife. And most of **the** imagery is â Claes ', but those two little boys are my sons, and they were Claes ' assistants in **the** play. He was **the** Swiss Army knife. He was a souvenir salesman who always wanted to be a painter, and I was Frankie P. Toronto. P for Palladio. Dressed up like **the** AT&T building by Claes â with a **fish** hat. **The** highlight of **the** performance was at **the** end. This beautiful **object**, **the** Swiss Army knife, which I get credit for participating in. And I can tell you â it ' s totally an Oldenburg. I had nothing to do with it. **The** only thing I did was, I made it possible for them to turn those blades so you could sail this thing in **the** canal, because I love sailing. We made it into a sailing craft. I ' ve been known to mess with things like chain link fencing. I do it because it ' s a curious thing in **the** culture, when things are made in such great quantities, absorbed in such great quantities, and there ' s so much denial about them. People hate it. And I ' m fascinated with that, which, like **the** paper furniture â it ' s one of those materials. And I ' m always drawn to that. And so I did a lot of dirty things with chain link, which nobody will forgive me for. But Claes made homage to it in **the** Loyola Law School. And that chain link is really expensive. It ' s in perspective and everything. And then we did a camp together for children with cancer. And you can see, we started making a building together. Of course, **the** milk can is his. But we were trying to collide our ideas, to put **objects** next to each other. Like a Morandi â like **the** little bottles â composing them like a still life. And it seemed to work as a way to put he and I together. Then Jay Chiat asked me to do this building on this funny lot in Venice, and I started with this three-piece thing, and you entered in **the** middle. And Jay asked me what I was going to do with **the** piece in **the** middle. And he pushed that. And one day I had a â oh, well, **the** other way. I had **the** binoculars from Claes, and I put them there, and I could never get rid of them after that. Oldenburg made **the** binoculars incredible when he sent me **the** first model of **the** real proposal. It made my building look sick. And it was this interaction between that kind of, up-the-ante stuff that became pretty interesting. It led to **the** building on **the left**. And I still think **the** Time magazine picture will be of **the** binoculars, you know, leaving out **the** â what **the** hell. I use a lot of metal in my work, and I have a hard time connecting with **the** craft. **The** whole thing about my house, **the** whole use of rough carpentry and everything, was **the** frustration with **the** crafts available. I said,"If I can ' t get **the** craft that I want, I ' ll use **the** craft I can get."There were plenty of models for that, in Rauschenberg and Jasper Johns, and many artists who were making beautiful art and sculpture with junk materials. I went into **the** metal because it was a way of building a building that was a sculpture. And it was all of one material, and **the** metal could go on **the** roof as well as **the** walls. **The** metalworkers, for **the** most part, do ducts behind **the** ceilings and stuff. I was given an opportunity to design an exhibit for **the** metalworkers ' unions of America and Canada in Washington, and I did it on **the** condition that they become my partners in **the** future and help me with all future metal buildings, etc. etc. And it ' s working very well to have these people, these craftsmen, interested in it. I just tell **the** stories. It ' s a way of connecting, at least, with some of those people that are so important to **the** realization of architecture. **The** metal continued into a building â Herman Miller, in Sacramento. And it ' s just a complex of factory buildings. And Herman Miller has this philosophy of having a place â a people place. I mean, it ' s kind of a trite thing to say, but it is real that they wanted to have a central place where **the** cafeteria would be, where **the** people would come and where **the** people working would interact. So it ' s out in **the** middle of nowhere, and you approach it. It ' s copper and galvanize. I used **the** galvanize and copper in a very light gauge, so it would buckle. I spent a lot of time undoing Richard Meier ' s aesthetic. Everybody ' s trying to get **the** panels perfect, and I always try to get them sloppy and fuzzy. And they end up looking like stone. This is **the** central area. There ' s a ramp. And that little dome in there is a building by Stanley Tigerman. Stanley was instrumental in my getting this job. And when I was awarded **the** contract I, at **the** very beginning, asked **the** client if they would let Stanley do a cameo piece with me. Because these were ideas that we were talking about, building things next to each other, making â it ' s all about [a] metaphor for a city, maybe. And so Stanley did **the** little dome thing. And we did it over **the** phone and by fax. He would send me a fax and show me something. He ' d made a building with a dome and he had a little tower. I told him,"No, no, that ' s too ongepotchket. I don ' t want **the** tower."So he came back with a simpler building, but he put some funny details on it, and he moved it closer to my building. And so I decided to put him in a depression. I put him in a hole and made a kind of a hole that he sits in. And so then he put two bridges â this all happened on **the** fax, going back and forth over a couple of weeks ' period. And he put these two bridges with pink guardrails on it. And so then I put this big billboard behind it. And I call it,"David and Goliath."And that ' s my cafeteria.

In Boston, we had that old building on **the left**. It was a very prominent building off **the** freeway, and we added a floor and cleaned it up and fixed it up and used **the** kind of â I thought â **the** language of **the** neighborhood, which had these cornices, projecting cornices. Mine got a little exuberant, but I used lead copper, which is a beautiful material, and it turns green in 100 years. Instead of, like, copper in 10 or 15. We redid **the** side of **the** building and re-proportioned **the** windows so it sort of fit into **the** space. And it surprised both Boston and myself that we got it approved, because they have very strict kind of design guideline, and they wouldn ’ t normally think I would fit them. **The** detailing was very careful with **the** lead copper and making panels and fitting it tightly into **the** fabric of **the** existing building. In Barcelona, on Las Ramblas for some film festival, I did **the** Hollywood sign going and coming, made a building out of it, and they built it. I flew in one night and took this picture. But they made it a third smaller than my model without telling me. And then more metal and some chain link in Santa Monica â a little shopping center. And this is a laser laboratory at **the** University of Iowa, in which **the fish** comes back as an abstraction in **the** back. It ’ s **the** support labs, which, by some coincidence, required no windows. And **the** shape fit perfectly. I just joined **the** points. In **the** curved part there ’ s all **the** mechanical equipment. That solid wall behind it is a pipe chase â a pipe canyon â and so it was an opportunity that I seized, because I didn ’ t have to have any protruding ducts or vents or things in this form. It gave me an opportunity to make a sculpture out of it. This is a small house somewhere. They ’ ve been building it so long I don ’ t remember where it is. It ’ s in **the** West Valley. And we started with **the** stream and built **the** house along **the** stream â dammed it up to make a lake. These are **the** models. **The** reality, with **the** lake â **the** workmanship is pretty bad. And it reminded me why I play defensively in things like my house. When you have to do something really cheaply, it ’ s hard to get perfect corners and stuff. That big metal thing is a passage, and in it is â you go downstairs into **the** living room and then down into **the** bedroom, which is on **the** right. It ’ s kind of like a whole built town. I was asked to do a hospital for schizophrenic adolescents at Yale. I thought it was fitting for me to be doing that. This is a house next to a Philip Johnson house in Minnesota. **The** owners had a dilemma â they asked Philip to do it. He was too busy. He didn ’ t recommend me, by **the** way. We ended up having to make it a sculpture, because **the** dilemma was, how do you build a building that doesn ’ t look like **the** language? Is it going to look like this beautiful estate is sub-divided? Etc. etc. You ’ ve got **the** idea. And so we finally ended up making it. These people are art collectors. And we finally made it so it appears very sculptural from **the** main house and all **the** windows are on **the** other side. And **the** building is very sculptural as you walk around it. It ’ s made of metal and **the** brown stuff is Fin-Ply â it ’ s that formed lumber from Finland. We used it at Loyola on **the** chapel, and it didn ’ t work. I keep trying to make it work. In this case we learned how to detail it. In Cleveland, there ’ s Burnham Mall, on **the left**. It ’ s never been finished. Going out to **the** lake, you can see all those new buildings we built. And we had **the** opportunity to build a building on this site. There ’ s a railroad track. This is **the** city hall over here somewhere, and **the** courthouse. And **the** centerline of **the** mall goes out. Burnham had designed a railroad station that was never built, and so we followed. Sohio is on **the** axis here, and we followed **the** axis, and they ’ re two kind of goalposts. And this is our building, which is a corporate headquarters for an insurance company. We collaborated with Oldenburg and put **the** newspaper on top, folded. **The** health club is fastened to **the** garage with a C-clamp, for Cleveland. You drive down. So it ’ s about a 10-story C-clamp. And all this stuff at **the** bottom is a museum, and an idea for a very fancy automobile entry. This owner has a pet peeve about bad automobile entries. And this would be a hotel. So, **the** centerline of this thing â we ' d preserve it, and it would start to work with **the** scale of **the** new buildings by Pelli and Kohn Pederson Fox, etc., that are underway. It ' s hard to do high-rise. I feel much more comfortable down here. This is a piece of property in Brentwood. And a long time ago, about ' 82 or something, after my house â I designed a house for myself that would be a village of several pavilions around a courtyard â and **the** owner of this lot worked for me and built that actual model on **the left**. And she came back, I guess wealthier or something â something happened â and asked me to design a house for her on this site. And following that basic idea of **the** village, we changed it as we got into it. I locked **the** house into **the** site by cutting **the** back end â here you see on **the** photographs of **the** site â slicing into it and putting all **the** bathrooms and dressing rooms like a retaining wall, creating a lower level zone for **the** master bedroom, which I designed like a kind of a barge, looking like a boat. And that ' s it, built. **The** dome was a request from **the** client. She wanted a dome somewhere in **the** house. She didn ' t care where. When you sleep in this bedroom, I hope â I mean, I haven ' t slept in it yet. I ' ve offered to marry her so I could sleep there, but she said I didn ' t have to do that. But when you ' re in that room, you feel like you ' re on a kind of barge on some kind of lake. And it ' s very private. **The** landscape is being built around to create a private garden. And then up above there ' s a garden on this side of **the** living room, and one on **the** other side. These aren ' t focused very well. I don ' t know how to do it from here. Focus **the** one on **the** right. It ' s up there. Left â it ' s my right. Anyway, you enter into a garden with a beautiful grove of trees. That ' s **the** living room. Servants ' quarters. A guest bedroom, which has this dome with marble on it. And then you enter into **the** living room and then so on. This is **the** bedroom. You come down from this level along **the** stairway, and you enter **the** bedroom here, going into **the** lake. And **the** bed is back in this space, with windows looking out onto **the** lake. These Stonehenge things were designed to give foreground and to create a greater depth in this shallow lot. **The** material is lead copper, like in **the** building in Boston. And so it was an intent to make this small piece of land â it ' s 100 by 250 â into a kind of an estate by separating these areas and making **the** living room and dining room into this pavilion with a high space in it. And this happened by accident that I got this right on axis with **the** dining room table. It looks like I got a Baldessari painting for free. But **the** idea is, **the** windows are all placed so you see pieces of **the** house outside. Eventually this will be screened â these trees will come up â and it will be very private. And you feel like you ' re in your own kind of village. This is for Michael Eisner â Disney. We ' re doing some work for him. And this is in Anaheim, California, and it ' s a freeway building. You go under this bridge at about 65 miles an hour, and there ' s another bridge here. And you ' re through this room in a split second, and **the** building will sort of reflect that. On **the** backside, it ' s much more humane â entrance, dining hall, etc. And then this thing here â I ' m hoping as you drive by you ' ll hear **the** picket fence effect of **the** sound hitting it. Kind of a fun thing to do. I ' m doing a building in Switzerland, Basel, which is an office building for a furniture company. And we struggled with **the** image. These are **the** early studies, but they have to sell furniture to normal people, so if I did **the** building and it was too fancy, then people might say,"Well, **the** furniture looks OK in his thing, but no, it ain ' t going to look good in my normal building."So we ' ve made a kind of pragmatic slab in **the** second phase here, and we ' ve taken **the** conference facilities and made a villa out of them so that **the** communal space is very sculptural and separate. And you ' re looking at it from **the** offices and you create a kind of interaction between these pieces. This is in Paris, along **the** Seine. Palais des Sports, **the** Gare de Lyon over here. **The** Minister of Finance â **the** guy that moved from **the** Louvre â goes in here. There ’ s a new library across **the** river. And back in here, in this already treed park, we ’ re doing a very dense building called **the** American Center, which has a theater, apartments, dance school, an art museum, restaurants and all kinds of â it ’ s a very dense program â bookstores, etc. In a very tight, small â this is **the** ground level. And **the** French have this extraordinary way of screwing things up by taking a beautiful site and cutting **the** corner off. They call it **the** plan coupe. And I struggled with that thing â how to get around **the** corner. These are **the** models for it. I showed you **the** other model, **the** one â this is **the** way I organized myself so I could make **the** drawing â so I understood **the** problem. I was trying to get around this plan coupe â how do you do it? Apartments, etc. And these are **the** kind of study models we did. And **the** one on **the left** is pretty awful. You can see why I was ready to commit suicide when this one was built. But out of it came finally this resolution, where **the** elevator piece worked frontally to this, parallel to this street, and also parallel to here. And then this kind of twist, with this balcony and **the** skirt, kind of like a ballerina lifting her skirt to let you into **the** foyer. **The** restaurants here â **the** apartments and **the** theater, etc. So it would all be built in stone, in French limestone, except for this metal piece. And it faces into a park. And **the** idea was to make this express **the** energy of this. On **the** side facing **the** street it ’ s much more normal, except I slipped a few mansards down, so that coming on **the** point, these housing units made a gesture to **the** corner. And this will be some kind of high-tech billboard. If any of you guys have any ideas for it, please contact me. I don ’ t know what to do. Jay Chiat is a glutton for punishment, and he hired me to do a house for him in **the** Hamptons. And it ’ s got a **fish**. And I keep thinking,”This is going to be **the** last **fish**.”It ’ s like a drug addict. I say,”I ’ m not going to do it anymore â I don ’ t want to do it anymore â I ’ m not going to do it.”And then I do it. There it is. But it ’ s **the** living room. And this piece here is â I don ’ t know what it is. I just added it so that we ’ d have enough money in **the** budget so we could take something out. This is Euro Disney, and I ’ ve worked with all of **the** guys that presented to you earlier. We ’ ve had a lot of fun working together. I think I ’ m from Mars for them, and they are for me, but somehow we all manage to work together, and I think, productively. So far. This is a shopping thing. You come into **the** Magic Kingdom and **the** hotel that Tony Baxter ’ s group is doing out here. And then this is a kind of a shopping mall, with a rodeo and restaurants. And another restaurant. What I did â because of **the** Paris skies being quite dull, I made a light grid that ’ s perpendicular to **the** train station, to **the** route of **the** train. It looks like it ’ s kind of been there, and then crashed all these simpler forms into it. **The** light grid will have a light, be lit up at night and give a kind of light ceiling. In Switzerland â Germany, actually â on **the** Rhine across from Basel, we did a furniture factory and a furniture museum. And I tried to â there ’ s a Nick Grimshaw building over here, there ’ s an Oldenburg sculpture over here â I tried to make a relationship urbanistically. And I don ’ t gave good **slides** to show â it ’ s just been completed â but this piece here is this building, and these pieces here and here. And as you pass by it ’ s always part â you see it as all of these pieces accrue and become part of an overall neighborhood. It ’ s plaster and just zinc. And you wonder, if this is a museum, what it ’ s going to be like inside? If it ’ s going to be so busy and crazy that you wouldn ’ t show anything, and just wait. I ’ m so cunning and clever â I made it quiet and wonderful. But on **the** outside it does scream out at you a bit. It ’ s actually basically three square rooms with a couple of skylights and stuff.

And from **the** building in **the** back, you see it as an iceberg floating by in **the** hills. I know I ’ m over time. See, that skylight goes down and becomes that one. So it ’ s pretty quiet inside. This is **the** Disney Hall â **the** concert hall. It ’ s a complicated project. It has a chamber hall. It ’ s related to an existing Chandler Pavilion that was built with a lot of love and tears and caring. And it ’ s not a great building, but I approached it optimistically, that we would make a compositional relationship between us that would strengthen both of us. And **the** plan of this â it ’ s a concert hall. This is **the** foyer, which is kind of a garden structure. There ’ s commercial at **the** ground floor. These are offices, which, really, in **the** competition, we didn ’ t have to design. But finally, there ’ s a hotel there. These were **the** kind of relationships made to **the** Chandler, composing these elevations together and relating them to **the** buildings that existed â to MOCA, etc. **The** acoustician in **the** competition gave us criteria, which led to this compartmentalized scheme, which we found out after **the** competition would not work at all. But everybody liked these forms and liked **the** space, and so that ’ s one of **the** problems of a competition. You have to then try and get that back in some way. And we studied many models. This was our original model. These were **the** three buildings that were **the** ideal â **the** Concertgebouw, Boston and Berlin. Everybody liked **the** surround. Actually, this is **the** smallest hall in size, and it has more seats than any of these because it has double balconies. Our client doesn ’ t want balconies, so â and when we met our new acoustician, he told us this was **the** right shape or this was **the** right shape. And we tried many shapes, trying to get **the** energy of **the** original design within an acoustical, acceptable format. We finally settled on a shape that was **the** proportion of **the** Concertgebouw with **the** sloping outside walls, which **the** acoustician said were crucial to this and later decided they weren ’ t, but now we have them. And our idea is to make **the** seating carriage very sculptural and out of wood and like a big boat sitting in this plaster room. That ’ s **the** idea. And **the** corners would have skylights and these columns would be structural. And **the** nice thing about introducing columns is they give you a kind of sense of proscenium from wherever you sit, and create intimacy. Now, this is not a final design â these are just on **the** way to being â and so I wouldn ’ t take it literally, except **the** feeling of **the** space. We studied **the** acoustics with laser stuff, and they bounce them off this and see where it all works. But you get **the** sense of **the** hall in section. Most halls come straight down into a proscenium. In this case we ’ re opening it back up and getting skylights in **the** four corners. And so it will be quite a different shape. **The** original building, because it was frog-like, fit nicely on **the** site and cranked itself well. When you get into a box, it ’ s harder to do it â and here we are, struggling with how to put **the** hotel in. And this is a teapot I designed for Alessi. I just stuck it on there. But this is how I do work. I do take pieces and bits and look at it and struggle with it and cut it away. And of course it ’ s not going to look like that, but it is **the** crazy way I tend to work. And then finally, in L. A. I was asked to do a sculpture at **the** foot of Interstate Bank Tower, **the** highest building in L. A. Larry Halprin is doing **the** stairs. And I was asked to do a **fish**, and so I did a snake. It ’ s a public space, and I made it kind of a garden structure, and you can go in it. It ’ s a kiva, and Larry ’ s putting some water in there, and it works much better than a **fish**. In Barcelona I was asked to do a **fish**, and we ’ re working on that, at **the** foot of a Ritz-Carlton Tower being done by Skidmore, Owings and Merrill. And **the** Ritz-Carlton Tower is being designed with exposed steel, non-fire proof, much like those old gas tanks. And so we took **the** language of this exposed steel and used it, perverted it, into **the** form of **the** **fish**, and created a kind of a 19th- century contraption that looks like, that will sit â this is **the** beach and **the** harbor out in front, and this is really a shopping center with department stores. And we split these bridges. Originally, this was all solid with a hole in it. We cut them loose and made several bridges and created a kind of a foreground for this hotel. We showed this to **the** hotel people **the** other day, and they were terrified and said that nobody would come to **the** Ritz-Carlton anymore, because of this **fish**. And finally, I just threw these in â Lou Danziger. I didn ’ t expect Lou Danziger to be here, but this is a building I did for him in 1964, I think. A little studio â and it ’ s sadly for sale. Time goes on. And this is my son working with me on a small fast-food thing. He designed **the** robot as **the** cashier, and **the** head moves, and I did **the** rest of it. And **the** food wasn ’ t as good as **the** stuff, and so it failed. It should have been **the** other way around â **the** food should have been good first. It didn ’ t work. Thank you very much.

Text Sample 76: POS Dim 1 – 2001 – Score 2.00 – 2001/t000083.txt

I thought I would read poems I have that relate to **the** subject of youth and age. I was sort of astonished to find out how many I have actually. **The** first one is dedicated to Spencer, and his grandmother, who was shocked by his work. My poem is called”Dirt.”My grandmother is washing my mouth out with soap ; half a long century gone and still she comes at me with that thick cruel **yellow** bar. All because of a word I said, not even said really, only repeated. But”Open,”she says,”open up!”her hand clawing at my head. I know now her life was hard ; she lost three children as babies, then her husband died too, leaving young sons, and no money. She ’ d stand me in **the** sink to pee because there was never room in **the** toilet. But oh, her soap! Might its bitter burning have been what made me a poet? **The** street she lived on was unpaved, her flat, two cramped rooms and a fetid kitchen where she stalked and caught me. Dare I admit that after she did it I never really loved her again? She lived to a hundred, even then. All along it was **the** sadness, **the** squalor, but I never, until now loved her again. When that was published in a magazine I got an irate letter from my uncle.”You have maligned a great woman.”It took some diplomacy. This is called”**The** Dress.”It ’ s a longer poem. In those days, those days which exist for me only as **the** most elusive memory now, when often **the** first sound you ’ d hear in **the** morning would be a storm of birdsong, then **the** soft clop of **the** hooves of **the** horse hauling a milk wagon down your block, and **the** last sound at night as likely as not would be your father pulling up in his car, having worked late again, always late, and going heavily down to **the** cellar, to **the** furnace, to shake out **the** ashes and damp **the** draft before he came upstairs to fall into bed — in those long-ago days, women, my mother, my friends ’ mothers, our neighbors, all **the** women I knew — wore, often much of **the** day, what were called housedresses, cheap, printed, pulpy, seemingly purposefully shapeless light cotton shifts that you wore over your nightgown and, when you had to go look for a child, hang wash on **the** line, or run down to **the** grocery store on **the** corner, under a coat, **the** twisted hem of **the** nightgown always lank and **yellowed**, dangling beneath. More than **the** curlers some of **the** women seemed constantly to have in their hair in preparation for some great event — a ball, one would think — that never came to pass ; more than **the** way most women ’ s faces not only were never made up during **the** day, but seemed scraped, bleached, and, with their plucked eyebrows, scarily masklike ; more than all that it was those dresses that made women so unknowable and forbidding, adepts of enigmas to which men could have no access, and boys no conception. Only later would I see **the** dresses also as a proclamation : that in your dim kitchen, your laundry, your bleak concrete yard, what you revealed of yourself was a fabulation ; your real sensual nature, veiled in those sexless vestments, was utterly your dominion. In those days, one hid much else as well : grown men didn ’ t embrace one another, unless someone had died, and not always then ; you shook hands or, at a ball game, thumped your friend ’ s back and exchanged blows meant to be codes for affection ; once out of childhood you ’ d never again know **the** shock of your father ’ s whiskers on your cheek, not until mores at last had **evolved**, and you could hug another man, then hold on for a moment, then even kiss. What release finally, **the** embrace : though we were wary — it seemed so audacious — how much unspoken joy there was in that affirmation of equality and communion, no matter how much misunderstanding and pain had passed between you by then. We knew so little in those days, as little as now, I suppose about healing those hurts : even **the** women, in their best dresses, with beads and sequins sewn on **the** bodices, even in lipstick and mascara, their hair aflow, could only stand wringing their hands, begging for peace, while father and son, like thugs, like thieves, like Romans, simmered and hissed and hated, inflicting sorrows that endured, **the** worst anyway, through **the** kiss and embrace, bleeding from brother to brother, into **the** generations. In those days there was still countryside close to **the** city, farms, cornfields, cows ; even not far from our building with its blurred brick and long shadowy hallway you could find tracts with hills and trees you could pretend were mountains and forests. Or you could go out by yourself even to a half-block-long empty lot, into **the** bushes : like a creature of leaves you ’ d lurk, crouched, crawling, simplified, savage, alone ; already there was wanting to be simpler, wanting, when they called you, never to go back. This is another longish one, about **the** old and **the** young. It actually happened right at **the** time we met. Part of **the** poem takes place in space we shared and time we shared. It ’ s called”**The** Neighbor.”Her five horrid, deformed little dogs who incessantly yap on **the** roof under my window. Her cats, God knows how many, who must piss on her rugs — her landing ’ s a sickening reek. Her shadow once, fumbling **the** chain on her door, then **the** door slamming fearfully shut, only **the** barking and **the** music — jazz — filtering as it does, day and night into **the** hall. **The** time it was Chris Connor singing”Lush Life”— how it brought back my college sweetheart, my first real love, who — till I left her — played **the** same record. And head on my shoulder, hand on my thigh, sang sweetly along, of regrets and depletions she was too young for, as I was too young, later, to believe in her pain. It startled, then bored, then repelled me. My starting to fancy she ’ d ended up in this fire-trap in **the** Village, that my neighbor was her. My thinking we ’ d meet, recognize one another, become friends, that I ’ d accomplish a penance. My seeing her, it wasn ’ t her, at **the** mailbox. Gray-yellow hair, army pants under a nightgown, her turning away, hiding her ravaged face in her hands, muttering an inappropriate”Hi.”Sometimes there are frightening goings-on in **the** stairwell. A man shouting,”Shut up!”**The** dogs frantically snarling, claws scrabbling, then her — her voice hoarse, harsh, hollow, almost only a tone, incoherent, a note, a squawk, bone on metal, metal gone molten, calling them back,”Come back darlings, come back dear ones. My sweet angels, come back.”Medea she was, next time I saw her. Sorceress, tranced, ecstatic, stock-still on **the** sidewalk ragged coat hanging agape, passersby flowing around her, her mouth torn suddenly open as though in a scream, silently though, as though only in her brain or breast had it erupted. A cry so pure, practiced, detached, it had no need of a voice, or could no longer bear one. These invisible links that allure, these transfigurations, even of anguish, that hold us. **The** girl, my old love, **the** last lost time I saw her when she came to find me at a party, her drunkenly stumbling, falling, sprawling, skirt hiked, eyes veined red, swollen with tears, her shame, her dishonor. My ignorant, arrogant coarseness, my secret pride, my turning away. Still life on a rooftop, dead trees in barrels, a bench broken, dogs, excrement, sky. What pathways through pain, what junctures of vulnerability, what crossings and counterings? Too many lives in our lives already, too many chances for sorrow, too many unaccounted-for pasts."Behold me,"**the** god of frenzied, inexhaustible love says, rising in bloody splendor,"Behold me."Her making her way down **the** littered vestibule stairs, one agonized step at a time. My holding **the** door. Her crossing **the** fragmented tiles, faltering at **the** step to **the** street, droning, not looking at me,"Can you help me?"Taking my arm, leaning lightly against me. Her wavering step into **the** world. Her whispering,"Thanks love."Lightly, lightly against me. I think I ' ll lighten up a little. Another, different kind of poem of youth and age. It ' s called"Gas."Wouldn ' t it be nice, I think, when **the** blue-haired lady in **the** doctor ' s waiting room bends over **the** magazine table and farts, just a little, and violently blushes. Wouldn ' t it be nice if intestinal gas came embodied in visible clouds, so she could see that her really quite inoffensive pop had only barely grazed my face before it drifted away. Besides, for this to have happened now is a nice coincidence. Because not an hour ago, while we were on our walk, my dog was startled by a backfire and jumped straight up like a horse **bucking**. And that brought back to me **the** stable I worked on weekends when I was 12, and a splendid piebald stallion, who whenever he was mounted would **buck** just like that, though more hugely of course, enormous, gleaming, resplendent. And **the** woman, her face abashedly buried in her"Elle"now, reminded me — I ' d forgotten that not **the** least part of my awe consisted of **the** fact that with every jump he took **the** horse would powerfully fart. Phwap! Phwap! Phwap! Something never mentioned in **the** dozens of books about horses and their riders I devoured in those days. All that savage grandeur, **the** steely glinting hooves, **the** eruptions driven from **the** creature ' s mighty innards, breath stopped, heart stopped, nostrils madly flared, I didn ' t know if I wanted to break him, or be him. This is called"Thirst."Many — most of my poems actually are urban poems. I happen to be reading a bunch that aren ' t."Thirst."Here was my relation with **the** woman who lived all last autumn and winter, day and night, on a bench in **the** 103rd Street subway station, until finally one day she vanished. We regarded each other, scrutinized one another. Me shyly, obliquely, trying not to be furtive. She boldly, unblinkingly, even pugnaciously, wrathfully even, when her bottle was empty. I was frightened of her. I felt like a child. I was afraid some repressed part of myself would go out of control, and I ' d be forever entrapped in **the** shocking seethe of her stench. Not excrement merely, not merely **surface** and orifice going unwashed, rediffusion of rum, there was will in it, and intention, power and purpose — a social, ethical rage and rebellion — despair too, though, grief, loss. Sometimes I ' d think I should take her home with me, bathe her, comfort her, dress her. She wouldn ' t have wanted me to, I would think. Instead, I ' d step into my train. How rich I would think, is **the** lexicon of our self-absolving. How enduring, our bland fatal assurance that reflection is righteousness being accomplished. **The** dance of our glances, **the** clash, pulling each other through our perceptual punctures, then holocaust, holocaust, host on host of ill, injured presences, squandered, consumed. Her vigil somewhere I know continues. Her occupancy, her absolute, faithful attendance. **The** dance of our glances, challenge, abdication, effacement, **the** perfume of our consternation. This is a newer poem, a brand new poem. **The** title is"This Happened."A student, a young woman in a fourth-floor hallway of her lycee, perched on **the** ledge of an open window chatting with friends between classes ; a teacher passes and chides her,"Be careful, you might fall,"almost banteringly chides her,"You might fall,"and **the** young woman, 18, a girl really, though she wouldn ' t think that, as brilliant as she is, first in her class, and"Beautiful, too,"she ' s often told, smiles back, and leans into **the** open window, which wouldn ' t even be open if it were winter — if it were winter someone would have closed it — leans into **the** window, farther, still smiling, farther and farther, though it takes less time than this, really an instant, and lets herself fall. Herself fall. A casual impulse, a fancy, never thought of until now, hardly thought of even now... No, more than impulse or fancy, **the** girl knows what she ' s doing, **the** girl means something, **the** girl means to mean, because it **occurs** to her in that instant, that beautiful or not, bright yes or no, she ' s not who she is, she ' s not **the** person she is, and **the** reason, she suddenly knows, is that there ' s been so much premeditation where she is, so much plotting and planning, there ' s hardly a person where she is, or if there is, it ' s not her, or not wholly her, it ' s a self inhabited, lived in by her, and seemingly even as she thinks it she knows what ' s been missing : grace, not premeditation but grace, a kind of being in **the** world spontaneously, with grace. Weightfully upon me was **the** world. Weightfully this self which graced **the** world yet never wholly itself. Weightfully this self which weighed upon me, **the** release from which is what I desire and what I achieve. And **the** girl remembers, in this infinite instant already now so many times divided, **the** sadness she felt once, hardly knowing she felt it, to merely inhabit herself. Yes, **the** girl falls, absurd to fall, even **the** earth with its compulsion to take unto itself all that falls must know that falling is absurd, yet **the** girl falling isn ' t myself, or she is myself, but a self I took of my own volition unto myself. Forever. With grace. This happened. I ' ll read just one more. I don ' t usually say that. I like to just end. But I ' m afraid that Ricky will come out here and shake his fist at me. This is called"Old Man,"appropriately enough."Special : big tits,"Says **the** advertisement for a soft-core magazine on our neighborhood newsstand. But forget her breasts. A lush, fresh-lipped blond, skin glowing gold, sprawls there, resplendent. 60 nearly, yet these hardly tangible, hardly better than harlots, can still stir me. Maybe a coming of age in **the** American sensual darkness, never seeing an unsmudged nipple, an uncensored vagina, has left me forever infected with an unquenchable lust of **the** eye. Always that erotic murmur, I ' m hardly myself if I ' m not in a state of incipient desire. God knows though, there are worse twists your obsessions can take. Last year in Israel, a young ultra-orthodox Rabbi guiding some teenage girls through **the** Shrine of **the** Shoah forbade them to look in one room. Because there were images in it he said were licentious. **The** display was a photo. Men and women stripped naked, some trying to cover their genitals, others too frightened to bother, lined up in snow waiting to be shot and thrown into a ditch. **The** girls, to my horror, averted their gaze. What carnal mistrust had their teacher taught them. Even that though. Another confession : Once in a book on pre-war Poland, a studio portrait, an absolute angel, an absolute angel with tormented, tormenting eyes. I kept finding myself at her page. That she died in **the** camps made her — I didn ' t dare wonder why — more present, more precious. Died in **the** camps, that too people — or Jews anyway — kept from their children back then. But it was like sex, you didn ' t have to be told. Sex and death, how close they can seem. So constantly conscious now of death moving towards me, sometimes I think I confound them. My wife ' s loveliness almost consumes me. My passion for her goes beyond reasonable bounds. When we make love, her holding me everywhere all around me, I ' m there and not there. My mind teems, jumbles of faces, voices, impressions, I live my life over, as though I were drowning. Then I am drowning, in despair at having to leave her, this, everything, all, unbearable, awful. Still, to be able to die with no special contrition, not having been slaughtered, or enslaved. And not having to know history ' s next mad rage or regression, it might be a relief. No. Again, no. I don ' t mean that for a moment. What I mean is **the** world holds me so tightly — **the** good and **the** bad — my own follies and weakness that even this counterfeit Venus with her sham heat, and her bosom probably plumped with gel, so moves me my breath catches. Vamp. Siren. Seductress. How much more she reveals in her glare of ink than she knows. How she incarnates our desperate human need for regard, our passion to live in beauty, to be beauty, to be cherished by glances, if by no more, of something like love, or love. Thank you.

Text Sample 77: POS Dim 1 – 2001 – Score 1.00 – 2001/t000092.txt
I coined my own definition of success in 1934, when I was teaching at a high school in South Bend, Indiana, being a little bit disappointed, and [disillusioned] perhaps, by **the** way parents of **the** youngsters in my English classes expected their youngsters to get an A or a B. They thought a C was all right for **the** neighbors ' children, because they were all average. But they weren ' t satisfied when their own — it would make **the** teacher feel that they had failed, or **the** youngster had failed. And that ' s not right. **The** good Lord in his infinite wisdom didn ' t create us all equal as far as intelligence is concerned, any more than we ' re equal for size, appearance. Not everybody could earn an A or a B, and I didn ' t like that way of judging, and I did know how **the** alumni of various schools back in **the** ' 30s judged coaches and athletic teams. If you won them all, you were considered to be reasonably successful — not completely. Because I found out — we had a number of years at UCLA where we didn ' t lose a game. But it seemed that we didn ' t win each individual game by **the** margin that some of our alumni had predicted — And quite frequently I really felt that they had backed up their predictions in a more materialistic manner. But that was true back in **the** 30s, so I understood that. But I didn ' t like it, I didn ' t agree with it. I wanted to come up with something I hoped could make me a better teacher, and give **the** youngsters under my supervision, be it in athletics or **the** English classroom, something to which to aspire, other than just a higher mark in **the** classroom, or more points in some athletic contest. I thought about that for quite a spell, and I wanted to come up with my own definition. I thought that might help. And I knew how Mr. Webster defined it, as **the** accumulation of material possessions or **the** attainment of a position of power or prestige, or something of that sort, worthy accomplishments perhaps, but in my opinion, not necessarily indicative of success. So I wanted to come up with something of my own. And I recalled — I was raised on a small farm in Southern Indiana, and Dad tried to teach me and my brothers that you should never try to be better than someone else. I ' m sure at **the** time he did that, I didn ' t — it didn ' t — well, somewhere, I guess in **the** hidden recesses of **the** mind, it popped out years later. Never try to be better than someone else, always learn from others. Never cease trying to be **the** best you can be — that ' s under your control. If you get too engrossed and involved and concerned in regard to **the** things over which you have no control, it will adversely affect **the** things over which you have control. Then I ran across this simple verse that said,"At God ' s footstool to confess, a poor soul knelt, and bowed his head. ' I failed! ' he cried. **The** Master said, ' Thou didst thy best, that is success. '"From those things, and one other perhaps, I coined my own definition of success, which is : Peace of mind attained only through self-satisfaction in knowing you made **the** effort to do **the** best of which you ' re capable. I believe that ' s true. If you make **the** effort to do **the** best of which you ' re capable, trying to improve **the** situation that exists for you, I think that ' s success, and I don ' t think others can judge that ; it ' s like character and reputation — your reputation is what you ' re perceived

to be ; your character is what you really are. And I think that character is much more important than what you are perceived to be. You ’ d hope they ’ d both be good, but they won ’ t necessarily be **the** same. Well, that was my idea that I was going to try to get across to **the** youngsters. I ran across other things. I love to teach, and it was mentioned by **the** previous speaker that I **enjoy** poetry, and I dabble in it a bit, and love it. There are some things that helped me, I think, be better than I would have been. I know I ’ m not what I ought to be, what I should be, but I think I ’ m better than I would have been if I hadn ’ t run across certain things. One was just a little verse that said,”No written word, no spoken plea can teach our youth what they should be ; nor all **the** books on all **the** shelves — it ’ s what **the** teachers are themselves.”That made an impression on me in **the** 1930s. And I tried to use that more or less in my teaching, whether it be in sports, or whether it be in **the** English classroom. I love poetry and always had an interest in that somehow. Maybe it ’ s because Dad used to read to us at night, by **coal oil lamp** — we didn ’ t have electricity in our farm home. And Dad would read poetry to us. So I always liked it. And about **the** same time I ran across this one verse, I ran across another one. Someone asked a lady teacher why she taught, and after some time, she said she wanted to think about that. Then she came up and said,”They ask me why I teach, and I reply, ’ Where could I find such splendid company? ’ There sits a statesman, strong, unbiased, wise ; another Daniel Webster, silver-tongued. A doctor sits beside him, whose quick, steady hand may mend a bone, or stem **the** life-blood ’ s flow. And there a builder ; upward rise **the** arch of a church he builds, wherein that minister may speak **the** word of God, and lead a stumbling soul to touch **the** Christ. And all about, a gathering of teachers, farmers, merchants, laborers — those who work and vote and build and plan and pray into a great tomorrow. And I may say, I may not see **the** church, or hear **the** word, or eat **the** food their hands may grow, but yet again I may ; And later I may say, I knew him once, and he was weak, or strong, or bold or proud or gay. I knew him once, but then he was a boy. They ask me why I teach and I reply, ’ Where could I find such splendid company? ’”And I believe **the** teaching profession — it ’ s true, you have so many youngsters, and I ’ ve got to think of my youngsters at UCLA — 30-some attorneys, 11 dentists and doctors, many, many teachers and other professions. And that gives you a great deal of pleasure, to see them go on. I always tried to make **the** youngsters feel that they ’ re there to get an education, number one ; basketball was second, because it was paying their way, and they do need a little time for social activities, but you let social activities take a little precedence over **the** other two, and you ’ re not going to have any very long. So that was **the** idea that I tried to get across to **the** youngsters under my supervision. I had three rules, pretty much, that I stuck with practically all **the** time. I ’ d learned these prior to coming to UCLA, and I decided they were very important. One was”Never be late.”Later on I said certain things — **the** players, if we were leaving for somewhere, had to be neat and clean. There was a time when I made them wear jackets and shirts and ties. Then I saw our chancellor coming to school in denims and turtlenecks, and thought, it ’ s not right for me to keep this other [rule] so I let them just — they had to be neat and clean. I had one of my greatest players that you probably heard of, Bill Walton. He came to catch **the** bus ; we were leaving for somewhere to play. And he wasn ’ t clean and neat, so I wouldn ’ t let him go. He couldn ’ t get on **the** bus, he had to go home and get cleaned up to get to **the** airport. So I was a stickler for that. I believed in that. I believe in time ; very important. I believe you should be on time, but I felt at practice, for example — we start on time, we close on time. **The** youngsters didn ’ t have to feel that we were going to keep them over. When I speak at coaching clinics, I often tell young coaches — and at coaching clinics, more or less, they ' ll be **the** younger coaches getting in **the** profession. Most of them are young, you know, and probably newly-married. And I tell them,"Don ' t run practices late, because you ' ll go home in a bad mood, and that ' s not good, for a young married man to go home in a bad mood. When you get older, it doesn ' t make any difference, but —"So I did believe : on time. I believe starting on time, and I believe closing on time. And another one I had was, not one word of profanity. One word of profanity, and you are out of here for **the** day. If I see it in a game, you ' re going to come out and sit on **the** bench. And **the** third one was, never criticize a teammate. I didn ' t want that. I used to tell them I was paid to do that. That ' s my job. I ' m paid to do it. Pitifully poor, but I am paid to do it. Not like **the** coaches today, for gracious sakes, no. It ' s a little different than it was in my day. Those were three things that I stuck with pretty closely all **the** time. And those actually came from my dad. That ' s what he tried to teach me and my brothers at one time. I came up with a pyramid eventually, that I don ' t have **the** time to go on that. But that helped me, I think, become a better teacher. It ' s something like this : And I had blocks in **the** pyramid, and **the** cornerstones being industriousness and enthusiasm, working hard and **enjoying** what you ' re doing, coming up to **the** apex, according to my definition of success. And right at **the** top, faith and patience. And I say to you, in whatever you ' re doing, you must be patient. You have to have patience to — we want things to happen. We talk about our youth being impatient a lot, and they are. They want to change everything. They think all change is progress. And we get a little older — we sort of let things go. And we forget there is no progress without change. So you must have patience, and I believe that we must have faith. I believe that we must believe, truly believe. Not just give it word service, believe that things will work out as they should, providing we do what we should. I think our tendency is to hope things will turn out **the** way we want them to much of **the** time, but we don ' t do **the** things that are necessary to make those things become reality. I worked on this for some 14 years, and I think it helped me become a better teacher. But it all revolved around that original definition of success. You know, a number of years ago, there was a Major League Baseball umpire by **the** name of George Moriarty. He spelled Moriarty with only one ' i '. I ' d never seen that before, but he did. Big league baseball players — they ' re very perceptive about those things, and they noticed he had only one ' i ' in his name. You ' d be surprised how many also told him that that was one more than he had in his head at various times. But he wrote something where I think he did what I tried to do in this pyramid. He called it"**The** Road Ahead, or **the** Road Behind."He said,"Sometimes I think **the** Fates must grin as we denounce them and insist **the** only reason we can ' t win, is **the** Fates themselves have missed. Yet there lives on **the** ancient claim : we win or lose within ourselves. **The** shining trophies on our shelves can never win tomorrow ' s game. You and I know deeper down, there ' s always a chance to win **the** crown. But when we fail to give our best, we simply haven ' t met **the** test, of giving all and saving none until **the** game is really won ; of showing what is meant by grit ; of playing through when others quit ; of playing through, not letting up. It ' s bearing down that wins **the** cup. Of dreaming there ' s a goal ahead ; of hoping when our dreams are dead ; of praying when our hopes have fled ; yet losing, not afraid to fall, if, bravely, we have given all. For who can ask more of a man than giving all within his span. Giving all, it seems to me, is not so far from victory. And so **the** Fates are seldom wrong, no matter how they twist and wind. It ' s you and I who make our fates — we open up or close **the** gates on **the** road ahead or **the** road behind."Reminds me of another set of threes that my dad tried to get across to us : Don ' t whine. Don ' t complain. Don ' t make excuses. Just get out there, and whatever you ' re doing, do it to **the** best of your ability. And no one can do more than that. I tried to get across, too, that — my opponents will tell you — you never heard me mention winning. Never mention winning. My idea is that you can lose when you outscore somebody in a game, and you can win when you ' re outscored. I ' ve felt that way on certain occasions, at various times. And I just wanted them to be able to hold their head up after a game. I used to say that when a game is over, and you see somebody that didn ' t know **the** outcome, I hope they couldn ' t tell by your actions whether you outscored an opponent or **the** opponent outscored you. That ' s what really matters : if you make an effort to do **the** best you can regularly, **the** results will be about what they should be. Not necessarily what you ' d want them to be but they ' ll be about what they should ; only you will know whether you can do that. And that ' s what I wanted from them more than anything else. And as time went by, and I learned more about other things, I think it worked a little better, as far as **the** results. But I wanted **the** score of a game to be **the** byproduct of these other things, and not **the** end itself. I believe it was one great philosopher who said — no, no — Cervantes. Cervantes said,"**The** journey is better than **the** end."And I like that. I think that it is — it ' s getting there. Sometimes when you get there, there ' s almost a let down. But it ' s **the** getting there that ' s **the** fun. As a basketball coach at UCLA, I liked our practices to be **the** journey, and **the** game would be **the** end, **the** end result. I liked to go up and sit in **the** stands and watch **the** players play, and see whether I ' d done a decent job during **the** week. There again, it ' s getting **the** players to get that self-satisfaction, in knowing that they ' d made **the** effort to do **the** best of which they are capable. Sometimes I ' m asked who was **the** best player I had, or **the** best teams. I can never answer that. As far as **the** individuals are concerned — I was asked one time about that, and they said,"Suppose that you, in some way, could make **the** perfect player. What would you want?"And I said,"Well, I ' d want one that knew why he was at UCLA : to get an education, he was a good student, really knew why he was there in **the** first place. But I ' d want one that could play, too. I ' d want one to realize that defense usually wins championships, and who would work hard on defense. But I ' d want one who would play offense, too. I ' d want him to be unselfish, and look for **the** pass first and not shoot all **the** time. And I ' d want one that could pass and would pass. I ' ve had some that could and wouldn ' t, and I ' ve had some that would and could. So, yeah, I ' d want that. And I wanted them to be able to shoot from **the** outside. I wanted them to be good inside too. I ' d want them to be able to rebound well at both ends, too. Why not just take someone like Keith Wilkes and let it go at that. He had **the** qualifications. Not **the** only one, but he was one that I used in that particular category, because I think he made **the** effort to become **the** best. There was a couple. I mention in my book,"They Call Me Coach,"two players that gave me great satisfaction, that came as close as I think anyone I ever had to reach their full potential : one was Conrad Burke, and one was Doug McIntosh. When I saw them as freshmen, on our freshmen team — freshmen couldn ' t play varsity when I taught. I thought,"Oh gracious, if these two players, either one of them"— they were different years, but I thought about each one at **the** time he was there —"Oh, if he ever makes **the** varsity, our varsity must be pretty miserable, if he ' s good enough to make it."And you know, one of them was a starting player for a season and a half. **The** other one, his next year, played 32 minutes in a national championship game, Did a tremendous job for us. **The** next year, he was a starting player on **the** national championship team, and here I thought he ' d never play a minute, when he was — so those are **the** things that give you great joy, and great satisfaction to see. Neither one of those youngsters could shoot very well. But they had outstanding shooting percentages, because they didn ’ t force it. And neither one could jump very well, but they kept good position, and so they did well rebounding. They remembered that every shot that ’ s taken, they assumed would be missed. I ’ ve had too many stand around and wait to see if it ’ s missed, then they go and it ’ s too late, somebody else is in there ahead of them. They weren ’ t very quick, but they played good position, kept in good balance. And so they played pretty good defense for us. So they had qualities that — they came close to — as close to reaching possibly their full potential as any players I ever had. So I consider them to be as successful as Lewis Alcindor or Bill Walton, or many of **the** others that we had ; there were some outstanding players. Have I rambled enough? I was told that when he makes his appearance, I was supposed to shut up.

So I understand that this meeting was planned, and **the** slogan was From Was to Still. And I am illustrating Still. Which, of course, I am not agreeing with because, although I am 94, I am not still working. And anybody who asks me,”Are you still doing this or that?”I don ’ t answer because I ’ m not doing things still, I ’ m doing it like I always did. I still have — or did I use **the** word still? I didn ’ t mean that. I have my file which is called To Do. I have my plans. I have my clients. I am doing my work like I always did. So this takes care of my age. I want to show you my work so you know what I am doing and why I am here. This was about 1925. All of these things were made during **the** last 75 years. But, of course, I ’ m working since 25, doing more or less what you see here. This is Castleton China. This was an exhibition at **the** Museum of Modern Art. This is now for sale at **the** Metropolitan Museum. This is still at **the** Metropolitan Museum now for sale. This is a portrait of my daughter and myself. These were just some of **the** things I ’ ve made. I made hundreds of them for **the** last 75 years. I call myself a maker of things. I don ’ t call myself an industrial designer because I ’ m other things. Industrial designers want to make novel things. Novelty is a concept of commerce, not an aesthetic concept. **The** industrial design magazine, I believe, is called”Innovation.”Innovation is not part of **the** aim of my work. Well, makers of things : they make things more beautiful, more elegant, more comfortable than just **the** craftsmen do. I have so much to say. I have to think what I am going to say. Well, to describe our profession otherwise, we are actually concerned with **the** playful **search** for beauty. That means **the** playful **search** for beauty was called **the** first activity of Man. Sarah Smith, who was a mathematics professor at MIT, wrote,”**The** playful **search** for beauty was Man ’ s first activity — that all useful qualities and all material qualities were developed from **the** playful **search** for beauty.”These are tiles. **The** word,”playful”is a necessary aspect of our work because, actually, one of our problems is that we have to make, produce, lovely things throughout all of life, and this for me is now 75 years. So how can you, without drying up, make things with **the** same pleasure, as a gift to others, for so long? **The** playful is therefore an important part of our quality as designer. Let me tell you some about my life. As I said, I started to do these things 75 years ago. My first exhibition in **the** United States was at **the** Sesquicentennial exhibition in 1926 — that **the** Hungarian government sent one of my hand-drawn pieces as part of **the** exhibit. My work actually took me through many countries, and showed me a great part of **the** world. This is not that they took me — **the** work didn ’ t take me — I made **the** things particularly because I wanted to use them to see **the** world. I was incredibly curious to see **the** world, and I made all these things, which then finally did take me to see many countries and many cultures.

I started as an apprentice to a Hungarian craftsman, and this taught me what **the** guild system was in Middle Ages. **The** guild system : that means when I was an apprentice, I had to apprentice myself in order to become a pottery master. In my shop where I studied, or learned, there was a traditional hierarchy of master, journeyman and learned worker, and apprentice, and I worked as **the** apprentice. **The** work as an apprentice was very primitive. That means I had to actually learn every aspect of making pottery by hand. We mashed **the** clay with our feet when it came from **the** hillside. After that, it had to be kneaded. It had to then go in, kind of, a mangle. And then finally it was prepared for **the** throwing. And there I really worked as an apprentice. My master took me to set ovens because this was part of oven-making, oven-setting, in **the** time. And finally, I had received a document that I had accomplished my apprenticeship successfully, that I had behaved morally, and this document was given to me by **the** Guild of Roof- Coverers, Rail-Diggers, Oven-Setters, Chimney Sweeps and Potters. I also got at **the** time a workbook which explained my rights and my working conditions, and I still have that workbook. First I set up a shop in my own garden, and made pottery which I sold on **the** marketplace in Budapest. And there I was sitting, and my then-boyfriend — I didn ’ t mean it was a boyfriend like it is meant today — but my boyfriend and I sat at **the** market and sold **the** pots. My mother thought that this was not very proper, so she sat with us to add propriety to this activity. However, after a while there was a new factory being built in Budapest, a pottery factory, a large one. And I visited it with several ladies, and asked all sorts of questions of **the** director. Then **the** director asked me, why do you ask all these questions? I said, I also have a pottery. So he asked me, could he please visit me, and then finally he did, and explained to me that what I did now in my shop was an anachronism, that **the** industrial revolution had broken out, and that I rather should join **the** factory. There he made an art department for me where I worked for several months. However, everybody in **the** factory spent his time at **the** art department. **The** director there said there were several women casting and producing my designs now in molds, and this was sold also to America. I remember that it was quite successful. However, **the** director, **the** chemist, model maker — everybody — concerned himself much more with **the** art department — that means, with my work — than making toilets, so finally they got a letter from **the** center, from **the** bank who owned **the** factory, saying, make toilet-setting behind **the** art department, and that was my end. So this gave me **the** possibility because now I was a journeyman, and journeymen also take their satchel and go to see **the** world. So as a journeyman, I put an ad into **the** paper that I had studied, that I was a down-to-earth potter ’ s journeyman and I was looking for a job as a journeyman. And I got several answers, and I accepted **the** one which was farthest from home and practically, I thought, halfway to America. And that was in Hamburg. Then I first took this job in Hamburg, at an art pottery where everything was done on **the** wheel, and so I worked in a shop where there were several potters. And **the** first day, I was coming to take my place at **the** turntable — there were three or four turntables — and one of them, behind where I was sitting, was a hunchback, a deaf-mute hunchback, who smelled very bad. So I doused him in cologne every day, which he thought was very nice, and therefore he brought bread and butter every day, which I had to eat out of courtesy. **The** first day I came to work in this shop there was on my wheel a surprise for me. My colleagues had thoughtfully put on **the** wheel where I was supposed to work a very nicely modeled natural man ’ s organs. After I brushed them off with a hand motion, they were very — I finally was now accepted, and worked there for some six months. This was my first job. If I go on like this, you will be here till midnight. So I will try speed it up a little Moderator : Eva, we have about five minutes. Eva Zeisel : Are you sure? Moderator : Yes, I am sure. EZ : Well, if you are sure, I have to tell you that within five minutes I will talk very fast. And actually, my work took me to many countries because I used my work to fill my curiosity. And among other things, other countries I worked, was in **the** Soviet Union, where I worked from ’ 32 to ’ 37 — actually, to ’ 36. I was finally there, although I had nothing to do — I was a foreign expert. I became art director of **the** china and glass industry, and eventually under Stalin ’ s purges — at **the** beginning of Stalin ’ s purges, I didn ’ t know that hundreds of thousands of innocent people were arrested. So I was arrested quite early in Stalin ’ s purges, and spent 16 months in a Russian prison. **The** accusation was that I had successfully prepared an Attentat on Stalin ’ s life. This was a very dangerous accusation. And if this is **the** end of my five minutes, I want to tell you that I actually did survive, which was a surprise. But since I survived and I ’ m here, and since this is **the** end of **the** five minutes, I will — Moderator : Tell me when your last trip to Russia was. Weren ’ t you there recently? EZ : Oh, this summer, in fact, **the** Lomonosov factory was bought by an American company, invited me. They found out that I had worked in ’ 33 at this factory, and they came to my studio in Rockland County, and brought **the** 15 of their artists to visit me here. And they invited myself to come to **the** Russian factory last summer, in July, to make some dishes, design some dishes. And since I don ’ t like to travel alone, they also invited my daughter, son-in-law and granddaughter, so we had a lovely trip to see Russia today, which is not a very pleasant and happy view. Here I am now, if this is **the** end? Thank you.

A Love Letter to my Garden by Debbie Millman In **the** beginning of time, there was no time. **The universe** began with every bit of energy contained in a very tiny, incredibly dense point. It was even smaller than this point. **The** point exploded with an unimaginable force and created everything we know and are made of. Seeds are a bit like that too. They ’ re tiny and densely packed with their entire existence. Time feels different now, while we shelter at home. Time is scary and uncertain. So we decided to plant some mint. We actually started a little garden a while ago, but now we have more time. We thought that these flowers had died, but they miraculously came back to life. A hopeful sign about **the** future, perhaps? We planted foxglove and it thrived. And then we went a little crazy. We planted tomatoes, carrots, beans, corn, lettuce and cucumbers, strawberries, blueberries and limes. It ’ s such a strange time in **the** world. There is so much beauty amidst so much fear. It ’ s so hard to know what to do. In **the** meantime, we watch and wait and remain grateful we ’ re able to make things with our hands. A love letter to New York City by Debbie Millman I ’ m a native New Yorker. I ’ ve lived here my entire life, yet **the** city never ceases to surprise me. Everywhere you look, there ’ s something to see. There is Tom Otterness **underground** and Lawrence Weiner underfoot. There are so many of us. Everyone wants to be someone. Everyone seeks to be heard. Everyone has an opinion, A point of view. And seemingly something to sell. But life is different now as we shelter at home. Under **the** same sky, at **the** same moment, at **the** same time. I ’ m thinking about how tough New York can be, how rough and unrelenting. But maybe that intensity is what fuels our tenacity. As we navigate through this crisis, I am hopeful we will find some solace together. A Love Letter to Travel by Debbie Millman My work has taken me all over **the** world. There have been many early departures, and many evenings in **the** air. In all my travels, I ’ ve been struck by so many things. I ’ ve observed how people lived in some of **the** most ancient places on **the planet**. This is Machu Picchu. This is Easter Island. This is Samoa. This is Angkor Wat. This is Petra in Jordan. **The** ancient city contained a church, a theater and tombs for **the** dead. Families lived in two and three-bedroom apartments. We ' ve come a long way. Some of **the** structures that remain are rather mysterious, some are otherworldly, some are glorious odes to love, some house **the** souls of **the** dead. Some have forced us to choose sides. Some have succumbed to **the** power of nature. And some have not. **The** view from **the** sky is so **abstract**. It reveals our connections, our continuity and our scale. Nevertheless, it ' s hard to see **the** big picture right now. It ' s such a difficult time in **the** world as we pause and dismantle and rebuild our culture. I think back to my travels. I ' ve seen how different we are, how diverse and distinct. But I ' ve also seen our commonalities. How much worship means in Tibet, in Pakistan, in Italy, in China, in Cambodia and in Peru. How much peace means to our future. How much we regret **the** mistakes of our past. And now, insisting on what matters no matter what. There is still so much beauty in **the** world. So much love. I ' m hopeful for **the** next generation. For every creature, large and small. And for **the planet** we call home. A Love Letter to Storytelling by Debbie Millman"A need to tell and hear stories is essential to **the** species Homo Sapiens. **The** sound of story is **the** dominant sound of our lives."- Joseph Campbell I ' ve loved telling stories all of my life. I ' ve loved writing them and drawing them, and I love teaching my students how to make them. Now I conduct visual storytelling workshops all over **the** world. Over **the** years, **the** students have invented many new ways of expressing their stories. They tell their truths. They reveal secrets. They bare their souls. They share stories of pain, of feeling seen, of not being smart enough. Stories of being scared, feeling pretty or not. No matter where I teach, I ' ve come to realize how many of their stories are universal. They convey so many shared experiences : rejection, judgment, insecurity, prejudice, forgetting and remembering. But there are also stories of hope, strength, awareness, courage and realizations. Their stories reflect who they really are, how deeply they want to feel connected. And now, as they share their visions for a more optimistic future, their stories are becoming **the** stories of our times.

Text Sample 80: POS Dim 1 – 2025 – Score -6.00 – 2025/t003001.txt

- I don ' t remember exactly, but... I use **the** most expensive hair color in **the** world. It ' s not that I care about **the** money, it ' s that I care about my hair. It ' s not just **the** color. I expect great color. What ' s worth more to me is **the** way my hair feels. Feels good around my neck. I can ' t remember it. I can ' t finish it all. If only we had more time. - Why don ' t we have more time? - I ' m dying. I ' m croaking! - It ' s tough, coming home. But this is what you do for a parent that you love. But, you know? She ' s not my mother. Technically. In my own family, there ' s a lot of dysfunction, a lot of mental illness, a lot of substance abuse. Every generation. My parents divorced when I was about five. My mother moved us out of state, so we had to fly to New York to see my father ' cause he was already working in advertising, and New York was **the** only place to be. - Many of **the** commercials you see on television begin life here. - Advertising is one of **the** main sources of messaging about who you should be. - Nowadays, most of you women lead two lives, combining homemaking with **the** role of glamorous hostess. - And in **the** ' 60s, **the** ads were often made from a male point of view. - In **the** pre-production meeting, everybody who has anything to do with **the** commercial is there. - It was mostly men. These superstar art directors and writers. Like my father, Gene Case."Mad Men"was like home movies, and he was Don Draper. He was very witty, but I don ’ t think my father realized how powerful his words were. He knew it professionally. But with his kids, he could be incredibly cutting. Flay you just with a phrase. But it ’ s **the** time with my mother that was **the** nightmare. She had a horrible childhood, but she sure as hell didn ’ t make any effort to overcome that in her relations with us. You know, it was really horrifying to my mother that I was not popular. But I was also really awkward because she had been undermining my confidence for all my life. She would pick apart your personality in detail. I was lazy, I looked bad, I acted bad, I was awkward. Emotionally, just out for **blood**. At a certain point in **the** night, I would know,"OK, **the** situation is dangerous. I need to get outta here."I had this fantasy when I was in fourth grade that I vividly remember that some kind of outside agency was gonna come in and determine from all **the** salt on my pillow that I was crying myself to sleep every night and do something about it. No, it was awful. It was awful. And that was **the** point where Ilon came into my life. - Ilon, do you need anything to eat? - I don ’ t think so, but look up this wallpaper, Waverly Fabrics, and see if they have a rose pattern. - OK. Oh, what about this one here? - That ’ s not it. - No? - No, first of all, I was an art dir... I was a creative director at an advertising agency. **The** first thing I know is what I ’ m looking at. Ilon **the** girl. I don ’ t remember particularly being into advertising, but somehow I found myself in it. And I seemed to be very good at it. First of all, I ’ d always listened to everybody. And I noticed that I saw things differently than other people. - Women could get somewhere in advertising, but they were marginalized. - Women were given a lesser role. All **the** men were always arguing with you and always taking credit. - And one of **the** things that was coming through loud and clear is that women are for men. - Glory, glory, hallelujah Glory, glory, hallelujah Glory, glory, hallelujah His truth is marching on - Men were always **the** ones who everyone was pleasing. - What will your eyes say to him tonight? Wait till **the** fellas take a look at this plunging backline. - You look at ads from that period, and it ’ s jaw-dropping. - This is one of our nation ’ s most beautiful sights, **the** kind of girl who keeps her figure. - But that ’ s what feminism was pushing back against. - I was a feminist. I knew women were equal if not superior to men from **the** time I was a little girl. - And in advertising, she wanted to be a trailblazer that way. At one point, she worked in **the** same agency with my father, and that ’ s how they met. - He was a good writer, and I was a good writer. I liked **the** fact that he was good at what he did and cared about it. We got engaged, and then we got married. - I ’ m sitting there in **the** background. I ’ m grinning. I ’ m so thrilled because I adored her instantly. I thought she was super cool. And she treated me like I mattered. - She was a sweet little girl, and she deserved some caretaking. My mother was kinda terrible, so I knew that she needed support, and I gave her support. And that was what we did. - She was interested in me. She listened to me. Treated me like I was lovable. - She didn ’ t have anyone to recognize her being, to support her, to see who she could be, who she was. - She was very interested in what I would do with my life, and **the** assumption was that it would be something worthwhile. She just went way, way beyond **the** call of duty to make me feel like I was worth it. And she did that for a lot of other women, too. - I was working at McCann Erickson. We were given an assignment. L ’ Oréal, they wanted a campaign for Preference, it ’ s a hair color. - She ’ s in this room full of men brainstorming for this ad. - **The** men were busy flirting with **the** women, telling us we all looked like models and we didn ’ t look like advertising people, you know? - They ’ re like,"Oh, this woman is gonna be standing by an open window, and **the** wind will be blowing **the** curtains."And she ’ s thinking, you know, this is just making **the** woman totally an **object**. - I was feeling angry. I ’ m not interested in writing anything about looking good for men. Fuck ’ em. Fuck you too. - Why fuck me? - Well, you ’ re a man. - Yeah, but I ’ m here trying to help you tell your story. - Yeah, that ’ s good. I like that part. I was pissed. We weren ’ t there to just dance for **the** men. - It is what she said. She just thought,”Fuck you.”And wrote this. - I just opened my eyes and knew. Because I ’ m worth it. **The** campaign got approved, but all **the** men were always telling you that you were doing something wrong or they knew how to do it better. - **The** agency insisted on a male voiceover. - She uses **the** most expensive hair color in **the** world, Preference by L ’ Oréal. - You know, it was just totally different. - Smooth and silky, but with body. It feels good against her neck. Actually, she doesn ’ t mind spending more for L ’ Oréal. Because she ’ s worth it. - It was wrong. This was not for men but for women and for other human beings. - I use **the** most expensive hair color in **the** world, Preference by L ’ Oréal. It ’ s not that I care about **the** money, it ’ s that I care about my hair. It ’ s not just **the** color, I expect great color. What ’ s worth more to me is **the** way my hair feels. Smooth and silky, but with body. It feels good against my neck. Actually, I don ’ t mind spending more for L ’ Oréal. Because I ’ m worth it. - I wrote that. - It was everywhere. It was a national campaign. - Yes, it ’ s expensive, but I ’ m worth it. - What they realized after they started running it was that that was only **the** tip of **the** iceberg. - It was supporting women, finally. - And I ’ m worth it. And I ’ m worth it. I ’ m worth it. - It ’ s a four-word feminist manifesto, defying this social pressure to think about yourself in relation to men. - You ’ re worth it. I ’ m worth it. I ’ m worth it. - It was a very big success. - At a certain point, L ’ Oréal adopted it as **the** tagline for their entire business. - Parce que je le vaux bien. - Even today, that ’ s their motto. - Because I ’ m worth it. - ’ Cause you ’ re worth it. - You ’ re worth it. - We ’ re worth it. - And I ’ m worth it. - She wrote **the** most influential tagline in women ’ s beauty advertising. - I ’ m worth it. - It ’ s magic, that phrase. - Those words just get better with age, don ’ t they? - I ’ m worth it. Because you are and always will be. - She came up with that line because she believed it. She believed it about herself, and she believed that women should believe it. She did that for me. You know, even after they split up, she was still a big part of my life. I ’ ve always kind of felt like I dodged a **bullet** that I have watched take down other members of my family. She saved me. And today, I am a professor of English at Williams College. I teach Victorian literature, and I also teach women ’ s, gender and sexuality studies. She was my mother. She also taught me how to be a mother. I had been very uncertain about motherhood for myself because my role model for that was so nightmarish. But Ilon really taught me, I can do this. I can be a good mother. She made me believe that I was worth it. And I was not either **the** first or **the** last. - I have to go away now. Go to my room. - It ’ s been lovely. - It ’ s been lovely. Oh... I ’ m not interested in advertising. I don ’ t give a shit. It wasn ’ t like it was my whole life. It was just a portion. It ’ s about humans ; it ’ s not about advertising. It ’ s about caring for people because... we ’ re all worth it, or no one is worth it.

- I don ’ t remember exactly, but... I use the most expensive hair color in the world. It ’ s not that I care about the money, it ’ s that I care about my hair. It ’ s not just the color. I expect great color. What ’ s worth more to me is the way my hair feels. Feels good around my neck. I can ’ t remember it. I can ’ t finish it all. If only we had more time. - Why don ’ t we have more time? - I ’ m dying. I ’ m **croaking**! - It ’ s tough, coming home. But this is what you do for a parent that you love. But, you know? She ’ s not my mother. Technically. In my own family, there ’ s a lot of dysfunction, a lot of mental illness, a lot of substance abuse. Every generation. My parents divorced when I was about five. My mother moved **us** out of state, so we had to fly to New York to see my father ’ cause he was already working in advertising, and New York was the only place to be. - Many of the commercials you see on television begin life here. - Advertising is one of the main sources of messaging about who you should be. - Nowadays, most of you women lead two lives, combining homemaking with the role of glamorous hostess. - And in the ’ 60s, the ads were often made from a male point of view. - In the pre-production meeting, everybody who has anything to do with the commercial is there. - It was mostly men. These superstar art directors and writers. Like my father, Gene Case.”Mad Men”was like home movies, and he was Don Draper. He was very witty, but I don ’ t think my father realized how powerful his words were. He knew it professionally. But with his kids, he could be incredibly cutting. **Flay** you just with a phrase. But it ’ s the time with my mother that was the nightmare. She had a horrible childhood, but she sure as hell didn ’ t make any effort to overcome that in her relations with **us**. You know, it was really horrifying to my mother that I was not popular. But I was also really awkward because she had been undermining my confidence for all my life. She would pick apart your personality in detail. I was lazy, I looked bad, I acted bad, I was awkward. Emotionally, just out for blood. At a certain point in the night, I would know,”OK, the situation is dangerous. I need to get outta here.”I had this fantasy when I was in fourth grade that I vividly remember that some kind of outside agency was gonna come in and determine from all the salt on my pillow that I was crying myself to sleep every night and do something about it. No, it was awful. It was awful. And that was the point where Ilon came into my life. - Ilon, do you need anything to eat? - I don ’ t think so, but look up this wallpaper, Waverly Fabrics, and see if they have a rose pattern. - OK. Oh, what about this one here? - That ’ s not it. - No? - No, first of all, I was an art **dir**... I was a creative director at an advertising agency. The first thing I know is what I ’ m looking at. Ilon the girl. I don ’ t remember particularly being into advertising, but somehow I found myself in it. And I seemed to be very good at it. First of all, I ’ d always listened to everybody. And I noticed that I saw things differently than other people. - Women could get somewhere in advertising, but they were marginalized. - Women were given a lesser role. All the men were always arguing with you and always taking credit. - And one of the things that was coming through loud and clear is that women are for men. - Glory, glory, hallelujah Glory, glory, hallelujah Glory, glory, hallelujah His truth is marching on - Men were always the ones who everyone was pleasing. - What will your eyes say to him tonight? Wait till the fellas take a look at this plunging backline. - You look at ads from that period, and it ’ s jaw-dropping. - This is one of our nation ’ s most beautiful sights, the kind of girl who keeps her figure. - But that ’ s what feminism was pushing **back** against. - I was a feminist. I knew women were equal if not superior to men from the time I was a little girl. - And in advertising, she wanted to be a trailblazer that way. At one point, she worked in the same agency with my father, and that ’ s how they met. - He was a good writer, and I was a good writer. I liked the fact that he was good at what he did and cared about it. We got engaged, and then we got married. - I ’ m sitting there in the background. I ’ m grinning. I ’ m so thrilled because I adored her instantly. I thought she was super cool. And she treated me like I mattered. - She was a sweet little girl, and she deserved some caretaking. My mother was kinda terrible, so I knew that she needed support, and I gave her support. And that was what we did. - She was interested in me. She listened to me. Treated me like I was lovable. - She didn ' t have anyone to recognize her being, to support her, to see who she could be, who she was. - She was very interested in what I would do with my life, and the assumption was that it would be something worthwhile. She just went way, way beyond the call of duty to make me feel like I was worth it. And she did that for a lot of other women, too. - I was working at McCann Erickson. We were given an assignment. L ' Oréal, they wanted a campaign for Preference, it ' s a hair color. - She ' s in this room full of men brainstorming for this ad. - The men were busy flirting with the women, telling **us** we all looked like models and we didn ' t look like advertising people, you know? - They ' re like,"Oh, this woman is gonna be standing by an open window, and the wind will be blowing the curtains."And she ' s thinking, you know, this is just making the woman totally an object. - I was feeling angry. I ' m not interested in writing anything about looking good for men. Fuck ' em. Fuck you too. - Why fuck me? - Well, you ' re a man. - Yeah, but I ' m here trying to help you tell your story. - Yeah, that ' s good. I like that part. I was pissed. We weren ' t there to just dance for the men. - It is what she said. She just thought,"Fuck you."And wrote this. - I just opened my eyes and knew. Because I ' m worth it. The campaign got approved, but all the men were always telling you that you were doing something wrong or they knew how to do it better. - The agency insisted on a male voiceover. - She uses the most expensive hair color in the world, Preference by L ' Oréal. - You know, it was just totally different. - Smooth and silky, but with body. It feels good against her neck. Actually, she doesn ' t mind spending more for L ' Oréal. Because she ' s worth it. - It was wrong. This was not for men but for women and for other human beings. - I use the most expensive hair color in the world, Preference by L ' Oréal. It ' s not that I care about the money, it ' s that I care about my hair. It ' s not just the color, I expect great color. What ' s worth more to me is the way my hair feels. Smooth and silky, but with body. It feels good against my neck. Actually, I don ' t mind spending more for L ' Oréal. Because I ' m worth it. - I wrote that. - It was everywhere. It was a national campaign. - Yes, it ' s expensive, but I ' m worth it. - What they realized after they started running it was that that was only the tip of the iceberg. - It was supporting women, finally. - And I ' m worth it. And I ' m worth it. I ' m worth it. - It ' s a four-word feminist manifesto, defying this social pressure to think about yourself in relation to men. - You ' re worth it. I ' m worth it. I ' m worth it. - It was a very big success. - At a certain point, L ' Oréal adopted it as the tagline for their entire business. - Parce que je le vaux bien. - Even today, that ' s their motto. - Because I ' m worth it. - ' Cause you ' re worth it. - You ' re worth it. - We ' re worth it. - And I ' m worth it. - She wrote the most influential tagline in women ' s beauty advertising. - I ' m worth it. - It ' s magic, that phrase. - Those words just get better with age, don ' t they? - I ' m worth it. Because you are and always will be. - She came up with that line because she believed it. She believed it about herself, and she believed that women should believe it. She did that for me. You know, even after they split up, she was still a big part of my life. I ' ve always kind of felt like I dodged a bullet that I have watched take down other members of my family. She saved me. And today, I am a professor of English at Williams College. I teach Victorian literature, and I also teach women ' s, gender and sexuality studies. She was my mother. She also taught me how to be a mother. I had been very uncertain about motherhood for myself because my role model for that was so nightmarish. But Ilon really taught me, I can do this. I can be a good mother. She made me believe that I was worth it. And I was not either the first or the last. - I have to go away now. Go to my room. - It ’ s been lovely. - It ’ s been lovely. Oh... I ’ m not interested in advertising. I don ’ t give a shit. It wasn ’ t like it was my whole life. It was just a portion. It ’ s about humans ; it ’ s not about advertising. It ’ s about caring for people because... we ’ re all worth it, or no one is worth it.

A Love Letter to my Garden by Debbie Millman In the beginning of time, there was no time. The universe began with every bit of energy contained in a very tiny, incredibly dense point. It was even smaller than this point. The point exploded with an unimaginable force and created everything we know and are made of. Seeds are a bit like that too. They ’ re tiny and densely packed with their entire existence. Time feels different now, while we shelter at home. Time is scary and uncertain. So we decided to plant some mint. We actually started a little garden a while ago, but now we have more time. We thought that these flowers had died, but they miraculously came **back** to life. A hopeful sign about the future, perhaps? We planted foxglove and it thrived. And then we went a little crazy. We planted tomatoes, carrots, beans, corn, lettuce and cucumbers, strawberries, blueberries and limes. It ’ s such a strange time in the world. There is so much beauty amidst so much fear. It ’ s so hard to know what to do. In the meantime, we watch and wait and remain grateful we ’ re able to make things with our hands. A love letter to New York City by Debbie Millman I ’ m a native New Yorker. I ’ ve lived here my entire life, yet the city never ceases to surprise me. Everywhere you look, there ’ s something to see. There is Tom Otterness underground and Lawrence Weiner underfoot. There are so many of **us**. Everyone wants to be someone. Everyone seeks to be heard. Everyone has an opinion, A point of view. And seemingly something to sell. But life is different now as we shelter at home. Under the same sky, at the same moment, at the same time. I ’ m thinking about how tough New York can be, how rough and unrelenting. But maybe that intensity is what fuels our tenacity. As we navigate through this crisis, I am hopeful we will find some solace together. A Love Letter to Travel by Debbie Millman My work has taken me all over the world. There have been many early departures, and many evenings in the air. In all my travels, I ’ ve been struck by so many things. I ’ ve observed how people lived in some of the most ancient places on the planet. This is Machu Picchu. This is Easter Island. This is Samoa. This is Angkor Wat. This is Petra in Jordan. The ancient city contained a church, a theater and tombs for the dead. Families lived in two and three-bedroom apartments. We ’ ve come a long way. Some of the structures that remain are rather mysterious, some are otherworldly, some are glorious odes to love, some house the souls of the dead. Some have forced **us** to choose sides. Some have succumbed to the power of nature. And some have not. The view from the sky is so abstract. It reveals our connections, our continuity and our scale. Nevertheless, it ’ s hard to see the big picture right now. It ’ s such a difficult time in the world as we pause and dismantle and rebuild our culture. I think **back** to my travels. I ’ ve seen how different we are, how diverse and distinct. But I ’ ve also seen our commonalities. How much worship means in Tibet, in Pakistan, in Italy, in China, in Cambodia and in Peru. How much peace means to our future. How much we regret the mistakes of our past. And now, insisting on what matters no matter what. There is still so much beauty in the world. So much love. I ’ m hopeful for the next generation. For every creature, large and small. And for the planet we call home. A Love Letter to Storytelling by Debbie Millman”A need to tell and hear stories is essential to the species Homo Sapiens. The sound of story

is the dominant sound of our lives.”- Joseph Campbell I ’ ve loved telling stories all of my life. I ’ ve loved writing them and drawing them, and I love teaching my students how to make them. Now I conduct visual storytelling workshops all over the world. Over the years, the students have invented many new ways of expressing their stories. They tell their truths. They reveal secrets. They bare their souls. They share stories of pain, of feeling seen, of not being smart enough. Stories of being scared, feeling pretty or not. No matter where I teach, I ’ ve come to realize how many of their stories are universal. They convey so many shared experiences : rejection, judgment, insecurity, prejudice, forgetting and remembering. But there are also stories of hope, strength, awareness, courage and realizations. Their stories reflect who they really are, how deeply they want to feel connected. And now, as they share their visions for a more optimistic future, their stories are becoming the stories of our times.

I ’ d like to do pretty much what I did the first time, which is to choose a **lighthearted** theme. Last time, I talked about death and dying. This time, I ’ m going to talk about mental illness. But it has to be technological, so I ’ ll talk about electroshock therapy. You know, ever since man had any notion that some of his other people, his colleagues, could be different, could be strange, could be severely depressed or what we now recognize as schizophrenia, he was certain that this kind of illness had to come from evil spirits getting into the body. So, the way of treating these diseases in early times was to, in some way or other, **exorcise** those evil spirits, and this is still going on, as you know. But it wasn ’ t enough to use the priests. When medicine became somewhat scientific, in about 450 BC, with Hippocrates and those boys, they tried to look for herbs, plants that would literally shake the bad spirits out. So, they found certain plants that could cause convulsions. And the herbals, the botanical books of up to the late Middle Ages, the Renaissance are filled with prescriptions for causing convulsions to shake the evil spirits out. Finally, in about the sixteenth century, a physician whose name was Theophrastus Bombastus Aureolus von Hohenheim, called Paracelsus, a name probably familiar to some people here — — good, old Paracelsus found that he could predict the degree of convulsion by using a measured amount of camphor to produce the convulsion. Can you imagine going to your closet, pulling out a mothball, and chewing on it if you ’ re feeling depressed? It ’ s better than Prozac, but I wouldn ’ t recommend it. So what we see in the **seventeenth**, eighteenth century is the continued search for medications other than camphor that ’ ll do the trick. Well, along comes Benjamin Franklin, and he comes close to convulsing himself with a bolt of electricity off the end of his kite. And so people begin thinking in terms of electricity to produce convulsions. And then, we fast-forward to about 1932, when three Italian psychiatrists, who were largely treating depression, began to notice among their patients, who were also epileptics, that if they had an epileptic — a series of epileptic fits, a lot of them in a row — the depression would very frequently lift. Not only would it lift, but it might never return. So they got very interested in producing convulsions, measured types of convulsions. And they thought,”Well, we ’ ve got electricity, we ’ ll plug somebody into the wall. That always makes hair stand up and people shake a lot.”So, they tried it on a few pigs, and none of the pigs were killed. So, they went to the police and they said,”We know that at the Rome railroad station, there are all these lost souls wandering around, muttering gibberish. Can you bring one of them to **us**?”Someone who is, as the Italians say,”cagoots.”So they found this”ca-

goots"guy, a 39-year-old man who was really hopelessly schizophrenic, who was known, had been known for months, to be literally defecating on himself, talking nothing that made any sense, and they brought him into the hospital. So these three psychiatrists, after about two or three weeks of observation, laid him down on a table, connected his temples to a very small source of current. They thought,"Well, we ' ll try 55 volts, **two-tenths** of a second. That ' s not going to do anything terrible to him."So they did that. Well, I have the following from a firsthand observer, who told me this about 35 years ago, when I was thinking about these things for some research project of mine. He said,"This fellow"— remember, he wasn ' t even put to sleep —"after this major grand mal convulsion, sat right up, looked at these three fellas and said, ' What the fuck are you assholes trying to do? '"If I could only say that in Italian. Well, they were happy as could be, because he hadn ' t said a rational word in the weeks of observation. So they plugged him in again, and this time they used 110 volts for half a second. And to their amazement, after it was over, he began speaking like he was perfectly well. He relapsed a little bit, they gave him a series of treatments, and he was essentially cured. But of course, having schizophrenia, within a few months, it returned. But they wrote a paper about this, and everybody in the Western world began using electricity to convulse people who were either schizophrenic or severely depressed. It didn ' t work very well on the schizophrenics, but it was pretty clear in the ' 30s and by the middle of the ' 40s that electroconvulsive therapy was very, very effective in the treatment of depression. And of course, in those days, there were no antidepressant drugs, and it became very, very popular. They would anesthetize people, convulse them, but the real difficulty was that there was no way to paralyze muscles. So people would have a real grand mal seizure. Bones were broken. Especially in old, fragile people, you couldn ' t use it. And then in the 1950s, late 1950s, the so-called muscle relaxants were developed by pharmacologists, and it got so that you could induce a complete convulsion, an electroencephalographic convulsion — you could see it on the brain waves — without causing any convulsion in the body except a little bit of twitching of the toes. So again, it was very, very popular and very, very useful. Well, you know, in the middle ' 60s, the first antidepressants came out. Tofranil was the first. In the late ' 70s, early ' 80s, there were others, and they were very effective. And patients ' rights groups seemed to get very upset about the kinds of things that they would witness. And so the whole idea of electroconvulsive, electroshock therapy disappeared, but has had a renaissance in the last 10 years. And the reason that it has had a renaissance is that probably about 10 percent of the people, severe depressives, do not respond, regardless of what is done for them. Now, why am I telling you this story at this meeting? I ' m telling you this story, because actually ever since Richard called me and asked me to talk about — as he asked all of his speakers — to talk about something that would be new to this audience, that we had never talked about, never written about, I ' ve been planning this moment. This reason really is that I am a man who, almost 30 years ago, had his life saved by two long courses of electroshock therapy. And let me tell you this story. I was, in the 1960s, in a marriage. To use the word bad would be perhaps the understatement of the year. It was dreadful. There are, I ' m sure, enough divorced people in this room to know about the hostility, the anger, who knows what. Being someone who had had a very difficult childhood, a very difficult adolescence — it had to do with not quite poverty but close. It had to do with being brought up in a family where no one spoke English, no one could read or write English. It had to do with death and disease and lots of other things. I was a little prone to depression. So, as things got worse, as we really began to hate each other, I became progressively depressed over a period of a couple of years, trying to save this marriage, which was inevitably not to be saved. Finally, I would schedule — all my major surgical cases, I was scheduling them for 12, one o ' clock in the afternoon, because I couldn ' t get out of bed before about 11 o ' clock. And anybody who ' s been depressed here knows what that ' s like. I couldn ' t even pull the covers off myself. Well, you ' re in a university medical center, where everybody knows everybody, and it ' s perfectly clear to my colleagues, so my referrals began to decrease. As my referrals began to decrease, I clearly became increasingly depressed until I thought, my God, I can ' t work anymore. And, in fact, it didn ' t make any difference because I didn ' t have any patients anymore. So, with the advice of my physician, I had myself admitted to the acute care psychiatric unit of our university hospital. And my colleagues, who had known me since medical school in that place, said,"Don ' t worry, chap. Six weeks, you ' re **back** in the operating room. Everything ' s going to be great."Well, you know what bovine stercus is? That proved to be a lot of bovine stercus. I know some people who got tenure in that place with lies like that. So I was one of their failures. But it wasn ' t that simple. Because by the time I got out of that unit, I was not functional at all. I could hardly see five feet in front of myself. I shuffled when I walked. I was bowed over. I rarely bathed. I sometimes didn ' t shave. It was dreadful. And it was clear — not to me, because nothing was clear to me at that time anymore — that I would need long-term hospitalization in that awful place called a mental hospital. So I was admitted, in 1973, in the spring of 1973, to the Institute of Living, which used to be called the Hartford Retreat. It was founded in the eighteenth century, the largest psychiatric hospital in the state of Connecticut, other than the huge public hospitals that existed at that time. And they tried everything they had. They tried the usual psychotherapy. They tried every medication available in those days. And they did have Tofranil and other things — Mellaril, who knows what. Nothing happened except that I got jaundiced from one of these things. And finally, because I was well known in Connecticut, they decided they better have a meeting of the senior staff. All the senior staff got together, and I later found out what happened. They put all their heads together and they decided that there was nothing that could be done for this surgeon who had essentially separated himself from the world, who by that time had become so overwhelmed, not just with depression and feelings of worthlessness and inadequacy, but with obsessional thinking, obsessional thinking about coincidences. And there were particular numbers that every time I saw them, just got me dreadfully upset — all kinds of ritualistic observances, just awful, awful stuff. Remember when you were a kid, and you had to step on every line? Well, I was a grown man who had all of these rituals, and it got so there was a throbbing, there was a ferocious fear in my head. You ' ve seen this painting by Edvard Munch, The Scream. Every moment was a scream. It was impossible. So they decided there was no therapy, there was no treatment. But there was one treatment, which actually had been pioneered at the Hartford hospital in the early 1940s, and you can imagine what it was. It was pre-frontal lobotomy. So they decided — I didn ' t know this, again, I found this out later — that the only thing that could be done was for this 43-year-old man to have a pre-frontal lobotomy. Well, as in all hospitals, there was a resident assigned to my case. He was 27 years old, and he would meet with me two or three times a week. And of course, I had been there, what, three or four months at the time. And he asked to meet with the senior staff, and they agreed to meet with him because he was very well thought of in that place. They thought he had a really extraordinary future. And he dug in his heels and said,"No. I know this man better than any of you. I have met with him over and over again. You ' ve just seen him from time to time. You ' ve read reports and so forth. I really honestly believe that the basic problem here is pure depression, and all of the obsessional thinking comes out of it. And you know, of course, what ' ll happen if you do a pre- frontal lobotomy. Any of the results along the spectrum, from pretty bad to terrible, terrible, terrible is going to happen. If he does the best he can, he will have no further obsessions, probably no depression, but his affect will be dulled, he will never go **back** to surgery, he will never be the loving father that he was to his two children, his life will be changed. If he has the usual result, he will end up like ' One Flew Over the Cuckoo ' s Nest. ' And you know about that, just essentially in a stupor the rest of his life."Well, he said,"Can ' t we try a course of electroshock therapy?"And you know why they agreed? They agreed to humor him. They just thought,"Well, we ' ll give a course of 10. And so we ' ll lose a little time. Big deal. It doesn ' t make any difference."So they gave the course of 10, and the first — the usual course, incidentally, was six to eight and still is six to eight. Plugged me into the wires, put me to sleep, gave me the muscle relaxant. Six didn ' t work. Seven didn ' t work. Eight didn ' t work. At nine, I noticed — and it ' s wonderful that I could notice anything — I noticed a change. And at 10, I noticed a real change. And he went **back** to them, and they agreed to do another 10. Again, not a single one of them — I think there are about seven or eight of them — thought this would do any good. They thought this was a temporary change. But, lo and behold, by 16, by 17, there were demonstrable differences in the way I felt. By 18 and 19, I was sleeping through the night. And by 20, I had the sense, I really had the sense that I could overcome this, that I was now strong enough that by an act of will, I could blow the obsessional thinking away. I could blow the depression away. And I ' ve never forgotten — I never will forget — standing in the kitchen of the unit, it was a Sunday morning in January of 1974, standing in the kitchen by myself and thinking,"I ' ve got the strength now to do this."It was as though those tightly coiled wires in my head had been disconnected and I could think clearly. But I need a formula. I need some thing to say to myself when I begin thinking obsessionally, obsessively. Well, the Gilbert and Sullivan fans in this room will remember"Ruddigore,"and they will remember Mad Margaret, and they will remember that she was married to a fellow named Sir Despard Murgatroyd. And she used to go nuts, every five minutes or so in the play, and he said to her,"We must have a word to bring you **back** to reality, and the word, my dear, will be ' Basingstoke. '"So every time she got a little nuts, he would say,"Basingstoke!"And she would say,"Basingstoke, it is."And she would be fine for a little while. Well, you know, I ' m from the Bronx. I can ' t say"Basingstoke."But I had something better. And it was very simple. It was,"Ah, fuck it!"Much better than"Basingstoke,"at least for me. And it worked — my God, it worked. Every time I would begin thinking obsessionally — again, once more, after 20 shock treatments — I would say,"Ah, fuck it."And things got better and better, and within three or four months, I was discharged from that hospital, and I joined a group of surgeons where I could work with other people in the community, not in New Haven, but fairly close by. I stayed there for three years. At the end of three years, I went **back** to New Haven, had remarried by that time. I brought my wife with me, actually, to make sure I could get through this. My children came **back** to live with **us**. We had two more children after that. Resuscitated the career, even better than it had been before. Went right **back** into the university and began to write books. Well, you know, it ' s been a wonderful life. It ' s been, as I said, close to 30 years. I stopped doing surgery about six years ago and became a full-time writer, as many people know. But it ' s been very exciting. It ' s been very happy. Every once in a while, I have to say,"Ah, fuck it."Every once in a while, I get somewhat depressed and a little obsessional. So, I ' m not free of all of this. But it ' s worked. It ' s always worked. Why have I chosen, after never, ever talking about this, to talk about it now? Well, those of you who know some of these books know that one is about death and dying, one is about the human body and the human spirit, one is about the way mystical thoughts are constantly in our minds, and they have always to do with my own personal experiences. One might think reading these books — and I ’ ve gotten thousands of letters about them by people who do think this — that based on my life ’ s history as I ’ ve portrayed in the books, my early life ’ s history, I am someone who has overcome adversity. That I am someone who has drunk, drank, drunk of the bitter **dregs** of near-disaster in childhood and emerged not just unscathed but strengthened. I really have it figured out, so that I can advise people about death and dying, so that I can talk about mysticism and the human spirit. And I ’ ve always felt guilty about that. I ’ ve always felt that somehow I was an impostor because my readers don ’ t know what I have just told you. It ’ s known by some people in New Haven, obviously, but it is not generally known. So one of the reasons that I have come here to talk about this today is to — frankly, selfishly — unburden myself and let it be known that this is not an **untroubled** mind that has written all of these books. But more importantly, I think, is the fact that a very significant proportion of people in this audience are under 30, and there are many, of course, who are well over 30. For people under 30, and it looks to me like almost all of you — I would say all of you — are either on the cusp of a magnificent and exciting career or right into a magnificent and exciting career : anything can happen to you. Things change. Accidents happen. Something from childhood comes **back** to haunt you. You can be thrown off the track. I hope it happens to none of you, but it will probably happen to a small percentage of you. To those to whom it doesn ’ t happen, there will be adversities. If I, with the **bleakness** of spirit, with no spirit, that I had in the 1970s and no possibility of recovery, as far as that group of very experienced psychiatrists thought, if I can find my way **back** from this, believe me, anybody can find their way **back** from any adversity that exists in their lives. And for those who are older, who have lived through perhaps not something as bad as this, but who have lived through difficult times, perhaps where they lost everything, as I did, and started out all over again, some of these things will seem very familiar. There is recovery. There is redemption. And there is resurrection. There are resurrection themes in every society that has ever been studied, and it is because not just only do we fantasize about the possibility of resurrection and recovery, but it actually happens. And it happens a lot. Perhaps the most popular resurrection theme, outside of specifically religious ones, is the one about the phoenix, the ancient story of the phoenix, who, every 500 years, resurrects itself from its own ashes to go on to live a life that is even more beautiful than it was before. Richard, thanks very much.

So I understand that this meeting was planned, and the slogan was From Was to Still. And I am illustrating Still. Which, of course, I am not agreeing with because, although I am 94, I am not still working. And anybody who asks me,”Are you still doing this or that?”I don ’ t answer because I ’ m not doing things still, I ’ m doing it like I always did. I still have — or did I use the word still? I didn ’ t mean that. I have my file which is called To Do. I have my plans. I have my clients. I am doing my work like I always did. So this takes care of my age. I want to show you my work so you know what I am doing and why I am here. This was about 1925. All of these things were made during the last 75 years.

But, of course, I ’ m working since 25, doing more or less what you see here. This is Castleton China. This was an exhibition at the Museum of Modern Art. This is now for sale at the Metropolitan Museum. This is still at the Metropolitan Museum now for sale. This is a portrait of my daughter and myself. These were just some of the things I ’ ve made. I made hundreds of them for the last 75 years. I call myself a maker of things. I don ’ t call myself an industrial designer because I ’ m other things. Industrial designers want to make novel things. Novelty is a concept of commerce, not an aesthetic concept. The industrial design magazine, I believe, is called”Innovation.”Innovation is not part of the aim of my work. Well, makers of things : they make things more beautiful, more elegant, more comfortable than just the craftsmen do. I have so much to say. I have to think what I am going to say. Well, to describe our profession otherwise, we are actually concerned with the playful search for beauty. That means the playful search for beauty was called the first activity of Man. Sarah Smith, who was a mathematics professor at MIT, wrote,”The playful search for beauty was Man ’ s first activity — that all useful qualities and all material qualities were developed from the playful search for beauty.”These are tiles. The word,”playful”is a necessary aspect of our work because, actually, one of our problems is that we have to make, produce, lovely things throughout all of life, and this for me is now 75 years. So how can you, without drying up, make things with the same pleasure, as a gift to others, for so long? The playful is therefore an important part of our quality as designer. Let me tell you some about my life. As I said, I started to do these things 75 years ago. My first exhibition in the United States was at the Sesquicentennial exhibition in 1926 — that the Hungarian government sent one of my hand-drawn pieces as part of the exhibit. My work actually took me through many countries, and showed me a great part of the world. This is not that they took me — the work didn ’ t take me — I made the things particularly because I wanted to use them to see the world. I was incredibly curious to see the world, and I made all these things, which then finally did take me to see many countries and many cultures. I started as an apprentice to a Hungarian craftsman, and this taught me what the guild system was in Middle Ages. The guild system : that means when I was an apprentice, I had to apprentice myself in order to become a pottery master. In my shop where I studied, or learned, there was a traditional hierarchy of master, journeyman and learned worker, and apprentice, and I worked as the apprentice. The work as an apprentice was very primitive. That means I had to actually learn every aspect of making pottery by hand. We mashed the clay with our feet when it came from the hillside. After that, it had to be **kneaded**. It had to then go in, kind of, a mangle. And then finally it was prepared for the throwing. And there I really worked as an apprentice. My master took me to set ovens because this was part of oven-making, oven-setting, in the time. And finally, I had received a document that I had accomplished my apprenticeship successfully, that I had behaved morally, and this document was given to me by the Guild of Roof- Coverers, Rail-Diggers, Oven-Setters, Chimney Sweeps and Potters. I also got at the time a workbook which explained my rights and my working conditions, and I still have that workbook. First I set up a shop in my own garden, and made pottery which I sold on the marketplace in Budapest. And there I was sitting, and my then-boyfriend — I didn ’ t mean it was a boyfriend like it is meant today — but my boyfriend and I sat at the market and sold the pots. My mother thought that this was not very proper, so she sat with **us** to add propriety to this activity. However, after a while there was a new factory being built in Budapest, a pottery factory, a large one. And I visited it with several ladies, and asked all sorts of questions of the director. Then the director asked me, why do you ask all these questions? I said, I also have a pottery. So he asked me, could he please visit me, and then finally he did, and explained to me that what I did now in my shop was an anachronism, that the industrial revolution had broken out, and that I rather should join the factory. There he made an art department for me where I worked for several months. However, everybody in the factory spent his time at the art department. The director there said there were several women casting and producing my designs now in molds, and this was sold also to America. I remember that it was quite successful. However, the director, the chemist, model maker — everybody — concerned himself much more with the art department — that means, with my work — than making toilets, so finally they got a letter from the center, from the bank who owned the factory, saying, make toilet-setting behind the art department, and that was my end. So this gave me the possibility because now I was a journeyman, and journeymen also take their satchel and go to see the world. So as a journeyman, I put an ad into the paper that I had studied, that I was a down-to-earth potter ’ s journeyman and I was looking for a job as a journeyman. And I got several answers, and I accepted the one which was farthest from home and practically, I thought, halfway to America. And that was in Hamburg. Then I first took this job in Hamburg, at an art pottery where everything was done on the wheel, and so I worked in a shop where there were several potters. And the first day, I was coming to take my place at the turntable — there were three or four turntables — and one of them, behind where I was sitting, was a hunchback, a deaf-mute hunchback, who smelled very bad. So I doused him in cologne every day, which he thought was very nice, and therefore he brought bread and butter every day, which I had to eat out of courtesy. The first day I came to work in this shop there was on my wheel a surprise for me. My colleagues had thoughtfully put on the wheel where I was supposed to work a very nicely modeled natural man ’ s organs. After I brushed them off with a hand motion, they were very — I finally was now accepted, and worked there for some six months. This was my first job. If I go on like this, you will be here till midnight. So I will try speed it up a little Moderator : Eva, we have about five minutes. Eva Zeisel : Are you sure? Moderator : Yes, I am sure. EZ : Well, if you are sure, I have to tell you that within five minutes I will talk very fast. And actually, my work took me to many countries because I used my work to fill my curiosity. And among other things, other countries I worked, was in the Soviet Union, where I worked from ’ 32 to ’ 37 — actually, to ’ 36. I was finally there, although I had nothing to do — I was a foreign expert. I became art director of the china and glass industry, and eventually under Stalin ’ s purges — at the beginning of Stalin ’ s purges, I didn ’ t know that hundreds of thousands of innocent people were arrested. So I was arrested quite early in Stalin ’ s purges, and spent 16 months in a Russian prison. The accusation was that I had successfully prepared an Attentat on Stalin ’ s life. This was a very dangerous accusation. And if this is the end of my five minutes, I want to tell you that I actually did survive, which was a surprise. But since I survived and I ’ m here, and since this is the end of the five minutes, I will — Moderator : Tell me when your last trip to Russia was. Weren ’ t you there recently? EZ : Oh, this summer, in fact, the Lomonosov factory was bought by an American company, invited me. They found out that I had worked in ’ 33 at this factory, and they came to my studio in Rockland County, and brought the 15 of their artists to visit me here. And they invited myself to come to the Russian factory last summer, in July, to make some dishes, design some dishes. And since I don ’ t like to travel alone, they also invited my daughter, son-in-law and granddaughter, so we had a lovely trip to see Russia today, which is not a very pleasant and happy view. Here I am now, if this is the end? Thank you.

I coined my own definition of success in 1934, when I was teaching at a high school in South Bend, Indiana, being a little bit disappointed, and [disillusioned] perhaps, by the way parents of the youngsters in my English classes expected their youngsters to get an A or a B. They thought a C was all right for the neighbors ' children, because they were all average. But they weren ' t satisfied when their own — it would make the teacher feel that they had failed, or the youngster had failed. And that ' s not right. The good Lord in his infinite wisdom didn ' t create **us** all equal as far as intelligence is concerned, any more than we ' re equal for size, appearance. Not everybody could earn an A or a B, and I didn ' t like that way of judging, and I did know how the alumni of various schools **back** in the ' 30s judged coaches and athletic teams. If you won them all, you were considered to be reasonably successful — not completely. Because I found out — we had a number of years at UCLA where we didn ' t lose a game. But it seemed that we didn ' t win each individual game by the margin that some of our alumni had predicted — And quite frequently I really felt that they had **backed** up their predictions in a more materialistic manner. But that was true **back** in the 30s, so I understood that. But I didn ' t like it, I didn ' t agree with it. I wanted to come up with something I hoped could make me a better teacher, and give the youngsters under my supervision, be it in athletics or the English classroom, something to which to aspire, other than just a higher mark in the classroom, or more points in some athletic contest. I thought about that for quite a spell, and I wanted to come up with my own definition. I thought that might help. And I knew how Mr. Webster defined it, as the accumulation of material possessions or the attainment of a position of power or prestige, or something of that sort, worthy accomplishments perhaps, but in my opinion, not necessarily indicative of success. So I wanted to come up with something of my own. And I recalled — I was raised on a small farm in Southern Indiana, and Dad tried to teach me and my brothers that you should never try to be better than someone else. I ' m sure at the time he did that, I didn ' t — it didn ' t — well, somewhere, I guess in the hidden recesses of the mind, it popped out years later. Never try to be better than someone else, always learn from others. Never cease trying to be the best you can be — that ' s under your control. If you get too engrossed and involved and concerned in regard to the things over which you have no control, it will adversely affect the things over which you have control. Then I ran across this simple verse that said,"At God ' s **footstool** to confess, a poor soul knelt, and bowed his head. ' I failed! ' he cried. The Master said, ' Thou didst thy best, that is success. '"From those things, and one other perhaps, I coined my own definition of success, which is : Peace of mind attained only through self-satisfaction in knowing you made the effort to do the best of which you ' re capable. I believe that ' s true. If you make the effort to do the best of which you ' re capable, trying to improve the situation that exists for you, I think that ' s success, and I don ' t think others can judge that ; it ' s like character and reputation — your reputation is what you ' re perceived to be ; your character is what you really are. And I think that character is much more important than what you are perceived to be. You ' d hope they ' d both be good, but they won ' t necessarily be the same. Well, that was my idea that I was going to try to get across to the youngsters. I ran across other things. I love to teach, and it was mentioned by the previous speaker that I enjoy poetry, and I dabble in it a bit, and love it. There are some things that helped me, I think, be better than I would have been. I know I ' m not what I ought to be, what I should be, but I think I ' m better than I would have been if I hadn ' t run across certain things. One was just a little verse that said,"No written word, no spoken plea can teach our youth what they should be ; nor all the books on all the shelves — it ' s what the teachers are themselves."That made an impression on me in the 1930s. And I tried to use that more or less in my teaching, whether it be in sports, or whether it be in the English classroom. I love poetry and always had an interest in that somehow. Maybe it ' s because Dad used to read to **us** at night, by coal oil lamp — we didn ' t have electricity in our farm home. And Dad would read poetry to **us**. So I always liked it. And about the same time I ran across this one verse, I ran across another one. Someone asked a lady teacher why she taught, and after some time, she said she wanted to think about that. Then she came up and said,"They ask me why I teach, and I reply, ' Where could I find such splendid company? ' There sits a statesman, strong, unbiased, wise ; another Daniel Webster, silver-tongued. A doctor sits beside him, whose quick, steady hand may mend a bone, or stem the life-blood ' s flow. And there a builder ; upward rise the arch of a church he builds, wherein that minister may speak the word of God, and lead a stumbling soul to touch the Christ. And all about, a gathering of teachers, farmers, merchants, laborers — those who work and vote and build and plan and pray into a great tomorrow. And I may say, I may not see the church, or hear the word, or eat the food their hands may grow, but yet again I may ; And later I may say, I knew him once, and he was weak, or strong, or bold or proud or gay. I knew him once, but then he was a boy. They ask me why I teach and I reply, ' Where could I find such splendid company? '"And I believe the teaching profession — it ' s true, you have so many youngsters, and I ' ve got to think of my youngsters at UCLA — 30-some attorneys, 11 dentists and doctors, many, many teachers and other professions. And that gives you a great deal of pleasure, to see them go on. I always tried to make the youngsters feel that they ' re there to get an education, number one ; basketball was second, because it was paying their way, and they do need a little time for social activities, but you let social activities take a little precedence over the other two, and you ' re not going to have any very long. So that was the idea that I tried to get across to the youngsters under my supervision. I had three rules, pretty much, that I stuck with practically all the time. I ' d learned these prior to coming to UCLA, and I decided they were very important. One was"Never be late."Later on I said certain things — the players, if we were leaving for somewhere, had to be neat and clean. There was a time when I made them wear jackets and shirts and ties. Then I saw our chancellor coming to school in denims and turtlenecks, and thought, it ' s not right for me to keep this other [rule] so I let them just — they had to be neat and clean. I had one of my greatest players that you probably heard of, Bill Walton. He came to catch the bus ; we were leaving for somewhere to play. And he wasn ' t clean and neat, so I wouldn ' t let him go. He couldn ' t get on the bus, he had to go home and get cleaned up to get to the airport. So I was a stickler for that. I believed in that. I believe in time ; very important. I believe you should be on time, but I felt at practice, for example — we start on time, we close on time. The youngsters didn ' t have to feel that we were going to keep them over. When I speak at coaching clinics, I often tell young coaches — and at coaching clinics, more or less, they ' ll be the younger coaches getting in the profession. Most of them are young, you know, and probably newly-married. And I tell them,"Don ' t run practices late, because you ' ll go home in a bad mood, and that ' s not good, for a young married man to go home in a bad mood. When you get older, it doesn ' t make any difference, but —"So I did believe : on time. I believe starting on time, and I believe closing on time. And another one I had was, not one word of profanity. One word of profanity, and you are out of here for the day. If I see it in a game, you ' re going to come out and sit on the bench. And the third one was, never criticize a teammate. I didn ’ t want that. I used to tell them I was paid to do that. That ’ s my job. I ’ m paid to do it. Pitifully poor, but I am paid to do it. Not like the coaches today, for gracious sakes, no. It ’ s a little different than it was in my day. Those were three things that I stuck with pretty closely all the time. And those actually came from my dad. That ’ s what he tried to teach me and my brothers at one time. I came up with a pyramid eventually, that I don ’ t have the time to go on that. But that helped me, I think, become a better teacher. It ’ s something like this : And I had blocks in the pyramid, and the cornerstones being **industriousness** and enthusiasm, working hard and enjoying what you ’ re doing, coming up to the apex, according to my definition of success. And right at the top, faith and patience. And I say to you, in whatever you ’ re doing, you must be patient. You have to have patience to — we want things to happen. We talk about our youth being impatient a lot, and they are. They want to change everything. They think all change is progress. And we get a little older — we sort of let things go. And we forget there is no progress without change. So you must have patience, and I believe that we must have faith. I believe that we must believe, truly believe. Not just give it word service, believe that things will work out as they should, providing we do what we should. I think our tendency is to hope things will turn out the way we want them to much of the time, but we don ’ t do the things that are necessary to make those things become reality. I worked on this for some 14 years, and I think it helped me become a better teacher. But it all revolved around that original definition of success. You know, a number of years ago, there was a Major League Baseball umpire by the name of George Moriarty. He spelled Moriarty with only one ’ i ’. I ’ d never seen that before, but he did. Big league baseball players — they ’ re very perceptive about those things, and they noticed he had only one ’ i ’ in his name. You ’ d be surprised how many also told him that that was one more than he had in his head at various times. But he wrote something where I think he did what I tried to do in this pyramid. He called it”The Road Ahead, or the Road Behind.”He said,”Sometimes I think the Fates must grin as we denounce them and insist the only reason we can ’ t win, is the Fates themselves have missed. Yet there lives on the ancient claim : we win or lose within ourselves. The shining trophies on our shelves can never win tomorrow ’ s game. You and I know deeper down, there ’ s always a chance to win the crown. But when we fail to give our best, we simply haven ’ t met the test, of giving all and saving none until the game is really won ; of showing what is meant by grit ; of playing through when others quit ; of playing through, not letting up. It ’ s bearing down that wins the cup. Of dreaming there ’ s a goal ahead ; of hoping when our dreams are dead ; of praying when our hopes have fled ; yet losing, not afraid to fall, if, bravely, we have given all. For who can ask more of a man than giving all within his span. Giving all, it seems to me, is not so far from victory. And so the Fates are seldom wrong, no matter how they twist and wind. It ’ s you and I who make our fates — we open up or close the gates on the road ahead or the road behind.”Reminds me of another set of threes that my dad tried to get across to **us** : Don ’ t whine. Don ’ t complain. Don ’ t make excuses. Just get out there, and whatever you ’ re doing, do it to the best of your ability. And no one can do more than that. I tried to get across, too, that — my opponents will tell you — you never heard me mention winning. Never mention winning. My idea is that you can lose when you outscore somebody in a game, and you can win when you ’ re **outscored**. I ’ ve felt that way on certain occasions, at various times. And I just wanted them to be able to hold their head up after a game. I used to say that when a game is over, and you see somebody that didn ’ t know the outcome, I hope they couldn ’ t tell by your actions whether you **outscored** an opponent or the opponent **outscored** you. That ’ s what really matters : if you make an effort to do the best you can regularly, the results will be about what they should be. Not necessarily what you ’ d want them to be but they ’ ll be about what they should ; only you will know whether you can do that. And that ’ s what I wanted from them more than anything else. And as time went by, and I learned more about other things, I think it worked a little better, as far as the results. But I wanted the score of a game to be the byproduct of these other things, and not the end itself. I believe it was one great philosopher who said — no, no — Cervantes. Cervantes said,”The journey is better than the end.”And I like that. I think that it is — it ’ s getting there. Sometimes when you get there, there ’ s almost a let down. But it ’ s the getting there that ’ s the fun. As a basketball coach at UCLA, I liked our practices to be the journey, and the game would be the end, the end result. I liked to go up and sit in the stands and watch the players play, and see whether I ’ d done a decent job during the week. There again, it ’ s getting the players to get that self-satisfaction, in knowing that they ’ d made the effort to do the best of which they are capable. Sometimes I ’ m asked who was the best player I had, or the best teams. I can never answer that. As far as the individuals are concerned — I was asked one time about that, and they said,”Suppose that you, in some way, could make the perfect player. What would you want?”And I said,”Well, I ’ d want one that knew why he was at UCLA : to get an education, he was a good student, really knew why he was there in the first place. But I ’ d want one that could play, too. I ’ d want one to realize that defense usually wins championships, and who would work hard on defense. But I ’ d want one who would play offense, too. I ’ d want him to be **unselfish**, and look for the pass first and not shoot all the time. And I ’ d want one that could pass and would pass. I ’ ve had some that could and wouldn ’ t, and I ’ ve had some that would and could. So, yeah, I ’ d want that. And I wanted them to be able to shoot from the outside. I wanted them to be good inside too. I ’ d want them to be able to rebound well at both ends, too. Why not just take someone like Keith Wilkes and let it go at that. He had the qualifications. Not the only one, but he was one that I used in that particular category, because I think he made the effort to become the best. There was a couple. I mention in my book,”They Call Me Coach,”two players that gave me great satisfaction, that came as close as I think anyone I ever had to reach their full potential : one was Conrad Burke, and one was Doug McIntosh. When I saw them as freshmen, on our freshmen team — freshmen couldn ’ t play varsity when I taught. I thought,”Oh gracious, if these two players, either one of them”— they were different years, but I thought about each one at the time he was there —”Oh, if he ever makes the varsity, our varsity must be pretty miserable, if he ’ s good enough to make it.”And you know, one of them was a starting player for a season and a half. The other one, his next year, played 32 minutes in a national championship game, Did a tremendous job for **us**. The next year, he was a starting player on the national championship team, and here I thought he ’ d never play a minute, when he was — so those are the things that give you great joy, and great satisfaction to see. Neither one of those youngsters could shoot very well. But they had outstanding shooting percentages, because they didn ’ t force it. And neither one could jump very well, but they kept good position, and so they did well rebounding. They remembered that every shot that ’ s taken, they assumed would be missed. I ’ ve had too many stand around and wait to see if it ’ s missed, then they go and it ’ s too late, somebody else is in there ahead of them. They weren ’ t very quick, but they played good position, kept in good balance. And so they played pretty good defense for **us**. So they had qualities that — they came close to — as close to reaching possibly their full potential as any players I ever had. So I consider them to be as successful as Lewis Alcindor or Bill Walton, or many of the others that we had ; there were some outstanding players. Have I rambled enough? I was told that when he makes his appearance, I was supposed to shut up.

I ’ m going to go right into the slides. And all I ’ m going to try and prove to you with these slides is that I do just very straight stuff. And my ideas are â in my head, anyway â they ’ re very logical and relate to what ’ s going on and problem solving for clients. I either convince clients at the end that I solve their problems, or I really do solve their problems, because usually they seem to like it. Let me go right into the slides. Can you turn off the light? Down. I like to be in the dark. I don ’ t want you to see what I ’ m doing up here. Anyway, I did this house in Santa Monica, and it got a lot of notoriety. In fact, it appeared in a porno comic book, which is the slide on the right. This is in Venice. I just show it because I want you to know I ’ m concerned about context. On the left-hand side, I had the context of those little houses, and I tried to build a building that fit into that context. When people take pictures of these buildings out of that context they look really weird, and my premise is that they make a lot more sense when they ’ re photographed or seen in that space. And then, once I deal with the context, I then try to make a place that ’ s comfortable and private and fairly serene, as I hope you ’ ll find that slide on the right. And then I did a law school for Loyola in downtown L. A. I was concerned about making a place for the study of law. And we continue to work with this client. The building on the right at the top is now under construction. The garage on the right â the gray structure â will be torn down, finally, and several small classrooms will be placed along this avenue that we ’ ve created, this campus. And it all related to the clients and the students from the very first meeting saying they felt denied a place. They wanted a sense of place. And so the whole idea here was to create that kind of space in downtown, in a neighborhood that was difficult to fit into. And it was my theory, or my point of view, that one didn ’ t upstage the neighborhood â one made accommodations. I tried to be inclusive, to include the buildings in the neighborhood, whether they were buildings I liked or not. In the ’ 60s I started working with paper furniture and made a bunch of stuff that was very successful in Bloomingdale ’ s. We even made flooring, walls and everything, out of cardboard. And the success of it threw me for a loop. I couldn ’ t deal with the success of furniture â I wasn ’ t secure enough as an architect â and so I closed it all up and made furniture that nobody would like. So, nobody would like this. And it was in this, preliminary to these pieces of furniture, that Ricky and I worked on furniture by the slice. And after we failed, I just kept failing. The piece on the left â and that ultimately led to the piece on the right â happened when the kid that was working on this took one of those long strings of stuff and folded it up to put it in the wastebasket. And I put a piece of tape around it, as you see there, and realized you could sit on it, and it had a lot of resilience and strength and so on. So, it was an accidental discovery. I got into fish. I mean, the story I tell is that I got mad at postmodernism â at po-mo â and said that fish were 500 million years earlier than man, and if you ’ re going to go **back**, we might as well go **back** to the beginning. And so I started making these funny things. And they started to have a life of their own and got bigger â as the one glass at the Walker. And then, I sliced off the head and the tail and everything and tried to translate what I was learning about the form of the fish and the movement. And a lot of my architectural ideas that came from it â accidental, again â it was an intuitive kind of thing, and I just kept going with it, and made this proposal for a building, which was only a proposal. I did this building in Japan. I was taken out to dinner after the contract for this little restaurant was signed. And I love sake and Kobe and all that stuff. And after I got â I was really drunk â I was asked to do some sketches on napkins. And I made some sketches on napkins â little boxes and Morandi-like things that I used to do. And the client said,”Why no fish?”And so I made a drawing with a fish, and I left Japan. Three weeks later, I received a complete set of drawings saying we ’ d won the competition. Now, it ’ s hard to do. It ’ s hard to translate a fish form, because they ’ re so beautiful â perfect â into a building or object like this. And Oldenburg, who I work with a little once in a while, told me I couldn ’ t do it, and so that made it even more exciting. But he was right â I couldn ’ t do the tail. I started to get the head OK, but the tail I couldn ’ t do. It was pretty hard. The thing on the right is a snake form, a ziggurat. And I put them together, and you walk between them. It was a dialog with the context again. Now, if you saw a picture of this as it was published in Architectural Record â they didn ’ t show the context, so you would think,”God, what a pushy guy this is.”But a friend of mine spent four hours wandering around here looking for this restaurant. Couldn ’ t find it. So... As for craft and technology and all those things that you ’ ve all been talking about, I was thrown for a complete loop. This was built in six months. The way we sent drawings to Japan : we used the magic computer in Michigan that does carved models, and we used to make foam models, which that thing scanned. We made the drawings of the fish and the scales. And when I got there, everything was perfect â except the tail. So, I decided to cut off the head and the tail. And I made the object on the left for my show at the Walker. And it ’ s one of the nicest pieces I ’ ve ever made, I think. And then Jay Chiat, a friend and client, asked me to do his headquarters building in L. A. For reasons we don ’ t want to talk about, it got delayed. Toxic waste, I guess, is the key clue to that one. And so we built a temporary building â I ’ m getting good at temporary â and we put a conference room in that ’ s a fish. And, finally, Jay dragged me to my hometown, Toronto, Canada. And there is a story â it ’ s a real story â about my grandmother buying a carp on Thursday, bringing it home, putting it in the bathtub when I was a kid. I played with it in the evening. When I went to sleep, the next day it wasn ’ t there. And the next night, we had gefilte fish. And so I set up this interior for Jay ’ s offices and I made a pedestal for a sculpture. And he didn ’ t buy a sculpture, so I made one. I went around Toronto and found a bathtub like my grandmother ’ s, and I put the fish in. It was a joke. I play with funny people like [Claes] Oldenburg. We ’ ve been friends for a long time. And we ’ ve started to work on things. A few years ago, we did a performance piece in Venice, Italy, called”Il Corso del Coltello”â the Swiss Army knife. And most of the imagery is â Claes ’, but those two little boys are my sons, and they were Claes ’ assistants in the play. He was the Swiss Army knife. He was a souvenir salesman who always wanted to be a painter, and I was Frankie P. Toronto. P for Palladio. Dressed up like the AT&T building by Claes â with a fish hat. The highlight of the performance was at the end. This beautiful object, the Swiss Army knife, which I get credit for participating in. And I can tell you â it ’ s totally an Oldenburg. I had nothing to do with it. The only thing I did was, I made it possible for them to turn those blades so you could sail this thing in the canal, because I love sailing. We made it into a sailing craft. I ’ ve been known to mess with things like chain link fencing. I do it because it ’ s a curious thing in the culture, when things are made in such great quantities, absorbed in such great quantities, and there ’ s so much denial about them. People hate it. And I ’ m fascinated with that, which, like the paper furniture â it ’ s one of those materials. And I ’ m always drawn to that. And so I did a lot of dirty things with chain link, which nobody will forgive me for. But Claes made homage to it in the Loyola Law School. And that chain link is really expensive. It ’ s in perspective and everything. And then we did a camp together for children with cancer. And you can see, we started making a building together. Of course, the milk can is his. But we were trying to collide our ideas, to put objects next to each other. Like a Morandi â like the little bottles â composing them like a still life. And it seemed to work as a way to put he and I together. Then Jay Chiat asked me to do this building on this funny lot in Venice, and I started with this three-piece thing, and you entered in the middle. And Jay asked me what I was going to do with the piece in the middle. And he pushed that. And one day I had a â oh, well, the other way. I had the binoculars from Claes, and I put them there, and I could never get rid of them after that. Oldenburg made the binoculars incredible when he sent me the first model of the real proposal. It made my building look sick. And it was this interaction between that kind of, up-the-ante stuff that became pretty interesting. It led to the building on the left. And I still think the Time magazine picture will be of the binoculars, you know, leaving out the â what the hell. I use a lot of metal in my work, and I have a hard time connecting with the craft. The whole thing about my house, the whole use of rough carpentry and everything, was the frustration with the crafts available. I said,”If I can ’ t get the craft that I want, I ’ ll use the craft I can get.”There were plenty of models for that, in Rauschenberg and Jasper Johns, and many artists who were making beautiful art and sculpture with junk materials. I went into the metal because it was a way of building a building that was a sculpture. And it was all of one material, and the metal could go on the roof as well as the walls. The metalworkers, for the most part, do ducts behind the ceilings and stuff. I was given an opportunity to design an exhibit for the metalworkers ’ unions of America and Canada in Washington, and I did it on the condition that they become my partners in the future and help me with all future metal buildings, etc. etc. And it ’ s working very well to have these people, these craftsmen, interested in it. I just tell the stories. It ’ s a way of connecting, at least, with some of those people that are so important to the realization of architecture. The metal continued into a building â Herman Miller, in Sacramento. And it ’ s just a complex of factory buildings. And Herman Miller has this philosophy of having a place â a people place. I mean, it ’ s kind of a trite thing to say, but it is real that they wanted to have a central place where the cafeteria would be, where the people would come and where the people working would interact. So it ’ s out in the middle of nowhere, and you approach it. It ’ s copper and galvanize. I used the galvanize and copper in a very light gauge, so it would buckle. I spent a lot of time undoing Richard Meier ’ s aesthetic. Everybody ’ s trying to get the panels perfect, and I always try to get them sloppy and fuzzy. And they end up looking like stone. This is the central area. There ’ s a ramp. And that little dome in there is a building by Stanley Tigerman. Stanley was instrumental in my getting this job. And when I was awarded the contract I, at the very beginning, asked the client if they would let Stanley do a cameo piece with me. Because these were ideas that we were talking about, building things next to each other, making â it ’ s all about [a] metaphor for a city, maybe. And so Stanley did the little dome thing. And we did it over the phone and by fax. He would send me a fax and show me something. He ’ d made a building with a dome and he had a little tower. I told him,”No, no, that ’ s too ongepotchket. I don ’ t want the tower.”So he came **back** with a simpler building, but he put some funny details on it, and he moved it closer to my building. And so I decided to put him in a depression. I put him in a hole and made a kind of a hole that he sits in. And so then he put two bridges â this all happened on the fax, going **back** and forth over a couple of weeks ' period. And he put these two bridges with pink guardrails on it. And so then I put this big billboard behind it. And I call it,"David and Goliath."And that ' s my cafeteria. In Boston, we had that old building on the left. It was a very prominent building off the freeway, and we added a floor and cleaned it up and fixed it up and used the kind of â I thought â the language of the neighborhood, which had these cornices, projecting cornices. Mine got a little exuberant, but I used lead copper, which is a beautiful material, and it turns green in 100 years. Instead of, like, copper in 10 or 15. We redid the side of the building and re-proportioned the windows so it sort of fit into the space. And it surprised both Boston and myself that we got it approved, because they have very strict kind of design guideline, and they wouldn ' t normally think I would fit them. The detailing was very careful with the lead copper and making panels and fitting it tightly into the fabric of the existing building. In Barcelona, on Las Ramblas for some film festival, I did the Hollywood sign going and coming, made a building out of it, and they built it. I flew in one night and took this picture. But they made it a third smaller than my model without telling me. And then more metal and some chain link in Santa Monica â a little shopping center. And this is a laser laboratory at the University of Iowa, in which the fish comes **back** as an abstraction in the **back**. It ' s the support labs, which, by some coincidence, required no windows. And the shape fit perfectly. I just joined the points. In the curved part there ' s all the mechanical equipment. That solid wall behind it is a pipe chase â a pipe canyon â and so it was an opportunity that I seized, because I didn ' t have to have any protruding ducts or vents or things in this form. It gave me an opportunity to make a sculpture out of it. This is a small house somewhere. They ' ve been building it so long I don ' t remember where it is. It ' s in the West Valley. And we started with the stream and built the house along the stream â dammed it up to make a lake. These are the models. The reality, with the lake â the workmanship is pretty bad. And it reminded me why I play defensively in things like my house. When you have to do something really cheaply, it ' s hard to get perfect corners and stuff. That big metal thing is a passage, and in it is â you go downstairs into the living room and then down into the bedroom, which is on the right. It ' s kind of like a whole built town. I was asked to do a hospital for schizophrenic adolescents at Yale. I thought it was fitting for me to be doing that. This is a house next to a Philip Johnson house in Minnesota. The owners had a dilemma â they asked Philip to do it. He was too busy. He didn ' t recommend me, by the way. We ended up having to make it a sculpture, because the dilemma was, how do you build a building that doesn ' t look like the language? Is it going to look like this beautiful estate is sub-divided? Etc. etc. You ' ve got the idea. And so we finally ended up making it. These people are art collectors. And we finally made it so it appears very sculptural from the main house and all the windows are on the other side. And the building is very sculptural as you walk around it. It ' s made of metal and the brown stuff is Fin-Ply â it ' s that formed lumber from Finland. We used it at Loyola on the chapel, and it didn ' t work. I keep trying to make it work. In this case we learned how to detail it. In Cleveland, there ' s Burnham Mall, on the left. It ' s never been finished. Going out to the lake, you can see all those new buildings we built. And we had the opportunity to build a building on this site. There ' s a railroad track. This is the city hall over here somewhere, and the courthouse. And the centerline of the mall goes out. Burnham had designed a railroad station that was never built, and so we followed. Sohio is on the axis here, and we followed the axis, and they ' re two kind of goalposts. And this is our building, which is a corporate headquarters for an insurance company. We collaborated with

Oldenburg and put the newspaper on top, folded. The health club is fastened to the garage with a C-clamp, for Cleveland. You drive down. So it ’ s about a 10-story C-clamp. And all this stuff at the bottom is a museum, and an idea for a very fancy automobile entry. This owner has a pet peeve about bad automobile entries. And this would be a hotel. So, the centerline of this thing â we ’ d preserve it, and it would start to work with the scale of the new buildings by Pelli and Kohn Pederson Fox, etc., that are underway. It ’ s hard to do high-rise. I feel much more comfortable down here. This is a piece of property in Brentwood. And a long time ago, about ’ 82 or something, after my house â I designed a house for myself that would be a village of several pavilions around a courtyard â and the owner of this lot worked for me and built that actual model on the left. And she came **back**, I guess wealthier or something â something happened â and asked me to design a house for her on this site. And following that basic idea of the village, we changed it as we got into it. I locked the house into the site by cutting the **back** end â here you see on the photographs of the site â slicing into it and putting all the bathrooms and dressing rooms like a retaining wall, creating a lower level zone for the master bedroom, which I designed like a kind of a barge, looking like a boat. And that ’ s it, built. The dome was a request from the client. She wanted a dome somewhere in the house. She didn ’ t care where. When you sleep in this bedroom, I hope â I mean, I haven ’ t slept in it yet. I ’ ve offered to marry her so I could sleep there, but she said I didn ’ t have to do that. But when you ’ re in that room, you feel like you ’ re on a kind of barge on some kind of lake. And it ’ s very private. The landscape is being built around to create a private garden. And then up above there ’ s a garden on this side of the living room, and one on the other side. These aren ’ t focused very well. I don ’ t know how to do it from here. Focus the one on the right. It ’ s up there. Left â it ’ s my right. Anyway, you enter into a garden with a beautiful grove of trees. That ’ s the living room. Servants ’ quarters. A guest bedroom, which has this dome with marble on it. And then you enter into the living room and then so on. This is the bedroom. You come down from this level along the stairway, and you enter the bedroom here, going into the lake. And the bed is **back** in this space, with windows looking out onto the lake. These Stonehenge things were designed to give foreground and to create a greater depth in this shallow lot. The material is lead copper, like in the building in Boston. And so it was an intent to make this small piece of land â it ’ s 100 by 250 â into a kind of an estate by separating these areas and making the living room and dining room into this pavilion with a high space in it. And this happened by accident that I got this right on axis with the dining room table. It looks like I got a Baldessari painting for free. But the idea is, the windows are all placed so you see pieces of the house outside. Eventually this will be screened â these trees will come up â and it will be very private. And you feel like you ’ re in your own kind of village. This is for Michael Eisner â Disney. We ’ re doing some work for him. And this is in Anaheim, California, and it ’ s a freeway building. You go under this bridge at about 65 miles an hour, and there ’ s another bridge here. And you ’ re through this room in a split second, and the building will sort of reflect that. On the backside, it ’ s much more humane â entrance, dining hall, etc. And then this thing here â I ’ m hoping as you drive by you ’ ll hear the picket fence effect of the sound hitting it. Kind of a fun thing to do. I ’ m doing a building in Switzerland, Basel, which is an office building for a furniture company. And we struggled with the image. These are the early studies, but they have to sell furniture to normal people, so if I did the building and it was too fancy, then people might say,”Well, the furniture looks OK in his thing, but no, it ain ’ t going to look good in my normal building.”So we ’ ve made a kind of pragmatic slab in the second phase here, and we ’ ve taken the conference facilities and made a villa out of them so that the communal space is very sculptural and separate. And you ’ re looking at it from the offices and you create a kind of interaction between these pieces. This is in Paris, along the Seine. Palais des Sports, the Gare de Lyon over here. The Minister of Finance â the guy that moved from the Louvre â goes in here. There ’ s a new library across the river. And **back** in here, in this already treed park, we ’ re doing a very dense building called the American Center, which has a theater, apartments, dance school, an art museum, restaurants and all kinds of â it ’ s a very dense program â bookstores, etc. In a very tight, small â this is the ground level. And the French have this extraordinary way of screwing things up by taking a beautiful site and cutting the corner off. They call it the plan coupe. And I struggled with that thing â how to get around the corner. These are the models for it. I showed you the other model, the one â this is the way I organized myself so I could make the drawing â so I understood the problem. I was trying to get around this plan coupe â how do you do it? Apartments, etc. And these are the kind of study models we did. And the one on the left is pretty awful. You can see why I was ready to commit suicide when this one was built. But out of it came finally this resolution, where the elevator piece worked frontally to this, parallel to this street, and also parallel to here. And then this kind of twist, with this balcony and the skirt, kind of like a ballerina lifting her skirt to let you into the foyer. The restaurants here â the apartments and the theater, etc. So it would all be built in stone, in French limestone, except for this metal piece. And it faces into a park. And the idea was to make this express the energy of this. On the side facing the street it ’ s much more normal, except I slipped a few mansards down, so that coming on the point, these housing units made a gesture to the corner. And this will be some kind of high-tech billboard. If any of you guys have any ideas for it, please contact me. I don ’ t know what to do. Jay Chiat is a glutton for punishment, and he hired me to do a house for him in the Hamptons. And it ’ s got a fish. And I keep thinking,”This is going to be the last fish.”It ’ s like a drug addict. I say,”I ’ m not going to do it anymore â I don ’ t want to do it anymore â I ’ m not going to do it.”And then I do it. There it is. But it ’ s the living room. And this piece here is â I don ’ t know what it is. I just added it so that we ’ d have enough money in the budget so we could take something out. This is Euro Disney, and I ’ ve worked with all of the guys that presented to you earlier. We ’ ve had a lot of fun working together. I think I ’ m from Mars for them, and they are for me, but somehow we all manage to work together, and I think, productively. So far. This is a shopping thing. You come into the Magic Kingdom and the hotel that Tony Baxter ’ s group is doing out here. And then this is a kind of a shopping mall, with a rodeo and restaurants. And another restaurant. What I did â because of the Paris skies being quite dull, I made a light grid that ’ s perpendicular to the train station, to the route of the train. It looks like it ’ s kind of been there, and then crashed all these simpler forms into it. The light grid will have a light, be lit up at night and give a kind of light ceiling. In Switzerland â Germany, actually â on the Rhine across from Basel, we did a furniture factory and a furniture museum. And I tried to â there ’ s a Nick Grimshaw building over here, there ’ s an Oldenburg sculpture over here â I tried to make a relationship urbanistically. And I don ’ t gave good slides to show â it ’ s just been completed â but this piece here is this building, and these pieces here and here. And as you pass by it ’ s always part â you see it as all of these pieces accrue and become part of an overall neighborhood. It ’ s plaster and just zinc. And you wonder, if this is a museum, what it ’ s going to be like inside? If it ’ s going to be so busy and crazy that you wouldn ’ t show anything, and just wait. I ’ m so cunning and clever â I made it quiet and wonderful. But on the outside it does scream out at you a bit. It ’ s actually basically three square rooms with a couple of skylights and stuff. And from the building in the **back**, you see it as an iceberg floating by in the hills. I know I ’ m over time. See, that skylight goes down and becomes that one. So it ’ s pretty quiet inside. This is the Disney Hall â the concert hall. It ’ s a complicated project. It has a chamber hall. It ’ s related to an existing Chandler Pavilion that was built with a lot of love and tears and caring. And it ’ s not a great building, but I approached it optimistically, that we would make a compositional relationship between **us** that would strengthen both of **us**. And the plan of this â it ’ s a concert hall. This is the foyer, which is kind of a garden structure. There ’ s commercial at the ground floor. These are offices, which, really, in the competition, we didn ’ t have to design. But finally, there ’ s a hotel there. These were the kind of relationships made to the Chandler, composing these elevations together and relating them to the buildings that existed â to MOCA, etc. The acoustician in the competition gave **us** criteria, which led to this compartmentalized scheme, which we found out after the competition would not work at all. But everybody liked these forms and liked the space, and so that ’ s one of the problems of a competition. You have to then try and get that **back** in some way. And we studied many models. This was our original model. These were the three buildings that were the ideal â the Concertgebouw, Boston and Berlin. Everybody liked the surround. Actually, this is the smallest hall in size, and it has more seats than any of these because it has double balconies. Our client doesn ’ t want balconies, so â and when we met our new acoustician, he told **us** this was the right shape or this was the right shape. And we tried many shapes, trying to get the energy of the original design within an acoustical, acceptable format. We finally settled on a shape that was the proportion of the Concertgebouw with the sloping outside walls, which the acoustician said were crucial to this and later decided they weren ’ t, but now we have them. And our idea is to make the seating carriage very sculptural and out of wood and like a big boat sitting in this plaster room. That ’ s the idea. And the corners would have skylights and these columns would be structural. And the nice thing about introducing columns is they give you a kind of sense of proscenium from wherever you sit, and create intimacy. Now, this is not a final design â these are just on the way to being â and so I wouldn ’ t take it literally, except the feeling of the space. We studied the acoustics with laser stuff, and they bounce them off this and see where it all works. But you get the sense of the hall in section. Most halls come straight down into a proscenium. In this case we ’ re opening it **back** up and getting skylights in the four corners. And so it will be quite a different shape. The original building, because it was frog-like, fit nicely on the site and cranked itself well. When you get into a box, it ’ s harder to do it â and here we are, struggling with how to put the hotel in. And this is a teapot I designed for Alessi. I just stuck it on there. But this is how I do work. I do take pieces and bits and look at it and struggle with it and cut it away. And of course it ’ s not going to look like that, but it is the crazy way I tend to work. And then finally, in L. A. I was asked to do a sculpture at the foot of Interstate Bank Tower, the highest building in L. A. Larry Halprin is doing the stairs. And I was asked to do a fish, and so I did a snake. It ’ s a public space, and I made it kind of a garden structure, and you can go in it. It ’ s a kiva, and Larry ’ s putting some water in there, and it works much better than a fish. In Barcelona I was asked to do a fish, and we ’ re working on that, at the foot of a Ritz-Carlton Tower being done by Skidmore, Owings and Merrill. And the Ritz-Carlton Tower is being designed with exposed steel, non-fire proof, much like those old gas tanks. And so we took the language of this exposed steel and used it, perverted it, into the form of the fish, and created a kind of a 19th- century contraption that looks like, that will sit â this is the beach and the harbor out in front, and this is really a shopping center with department stores. And we split these bridges. Originally, this was all solid with a hole in it. We cut them loose and made several bridges and created a kind of a foreground for this hotel. We showed this to the hotel people the other day, and they were terrified and said that nobody would come to the Ritz-Carlton anymore, because of this fish. And finally, I just threw these in â Lou Danziger. I didn ’ t expect Lou Danziger to be here, but this is a building I did for him in 1964, I think. A little studio â and it ’ s sadly for sale. Time goes on. And this is my son working with me on a small fast-food thing. He designed the robot as the cashier, and the head moves, and I did the rest of it. And the food wasn ’ t as good as the stuff, and so it failed. It should have been the other way around â the food should have been good first. It didn ’ t work. Thank you very much.

Text Sample 87: NEG Dim 1 – 2020 – Score -1.00 – 2020/t004215.txt

Several years ago a young man came to see me in my clinic. He told me he was running for his life. He said that he fled his home, because there, homosexuality wasn ’ t just illegal, in some cases it was punishable by death. So when his sexual orientation was exposed, his family rejected him, his boss fired him and angry mobs repeatedly attacked him in the streets. And each time the police arrived only to arrest him, detain and torture him further. And he knew that if he couldn ’ t escape the cycle of violence, he would surely be killed. So he had to do what he needed to do to survive. He left everything behind. All of his friends, his family, his career. He fled his home, he escaped to the United States and here he applied for asylum. But like many people fleeing this kind of persecution, he couldn ’ t carry much. He had some basic ID, barely any money and a few other belongings. He certainly didn ’ t bring official documents from the police who tortured him. No videos from the mob that tried to kill him. He didn ’ t have this kind of evidence to help support his claims, yet here he was, sitting in my clinic, showing me some of the most powerful evidence of his persecution. That was the physical and psychological scars that he brought with him. You see, he suffered from chronic, debilitating pain. He had severe scars scattered over his body, poorly healing wounds that got infected over and over again. He suffered from severe depression and continued to have regular, paralyzing flashbacks and nightmares from PTSD. So we continued our work. We met regularly for months, documenting each of these pieces of medical evidence. We went over the details of every attack, photographed his scars, documented his injuries and wounds, and we were even able to start chronicling his slow but steady recovery while under our care. Working closely with his lawyers, I submitted a detailed affidavit, including the findings of this forensic medical evaluation, and we included it as part of his asylum application. And then we waited for several long years while he navigated the courts. And then one day I got an email from him. It said that he was granted asylum. And everyone in the clinic was overjoyed. He said in his email that this was the first time in years that he didn ’ t fear deportation and death. It was the first time in years that he truly felt safe, that he had the security to rebuild his life all over again. And it was only through this medical and legal advocacy that we were able to help restore his legal status and his rights, that he could do that, all through asylum. Now for many people fleeing persecution, they come to programs and clinics like this telling unimaginable tales of violence and different reasons they were persecuted. But one thing is always the same. The violence meted against them was done with complete impunity, sometimes by the hands of the state directly through police or military officials. In other cases, the state just turns a blind eye and condones the acts of paramilitary groups or even violent domestic partners. In other cases, state is completely powerless to protect the vulnerable from powerful gangs. Now we know that social determinants of health play a huge role in determining the health and well-being of our patients : housing, income, education, race, social inclusion. But the same can be true for equal protection in the law – due process. Especially in societies for the most vulnerable, the marginalized and even those who are actively targeted, their access to these human rights protections that can mean the difference between sickness and health, and often it ' s the difference between life and death. And for millions of people who endure persecution and torture, the only way to heal is to acknowledge the human rights abuses that have occurred and to help restore the rights and protections that were so violated. After the atrocities of World War II, the asylum system was set up as one pathway to that kind of relief. But these days it seems like that pathway has turned into an obstacle course, setting people up to fail. Asylum seekers oftentimes don ' t know how to start, let alone complete the process that can drag on for years. They ' re not entitled to lawyers, so they don ' t know their rights. Increasingly, they ' re even being barred from setting foot in places of potential refuge. They ' re arrested or prosecuted, even deported before they ever get to see an asylum officer. And even if they do make it through the process, asylum grant rates can be as low as 20 percent and far worse for some. It ' s almost like the system was designed to keep people from exercising their right. But there is something that many of these people can do. Something that can potentially increase their chances of success to 90 percent or more. So what makes the difference? Getting a lawyer and having a medical evaluation. It ' s as simple as that. The man who came to my clinic and won his asylum case. Doctors and lawyers working together to present all of the evidence, including the medical evidence, to the courts allows judges to make informed and just decisions. And it ' s this kind of medical-legal partnership that ' s now more important than ever, because we live in a time of epic, forced migration due to violence and conflict. In 2018 there were 70 million people worldwide forcibly displaced due to war, conflict and persecution. It includes 40 million internally displaced, 25 million refugees and three million asylum seekers. Here in the United States, we see the impact of escalating violence in places like El Salvador, Guatemala and Honduras, where murder rates can be as high as those in Syria and Afghanistan. Where police corruption and gang violence are on the rise, where poverty and child abuse are widespread and tolerated, where basic systems of governance – public safety, child protection – are ineffective. It ' s no surprise then that many of the most vulnerable in some of these societies – children, women and other targeted groups – they ' re growing increasingly desperate and fleeing in unprecedented numbers. Like over the past 10 years, the numbers of unaccompanied children trying to seek safety at our southwest border has increased 18-fold, from 3, 300 in 2009 to over 62, 000 this past year. That ' s in addition to nearly half a million people traveling as families. Men, women and children trying to seek refuge at our borders, but who are stranded in a humanitarian crisis. And what makes matters worse is that they ' re caught in this fog of claims and counterclaims about who they are, what they ' ve experienced, where the proof is and what they deserve. Do they deserve our help? Sometimes people make claims that they ' re not fleeing human rights abuses but are simply economic migrants. Others say these children are actually being exploited and trafficked by their parents. Others say they ' re not even children at all ; they ’ re hardened criminals, they ’ re gang members trying to infiltrate our country. To cut through some of this fog, my colleagues and I conducted a study. We looked at data from children seeking asylum who had medical evaluations. And this is what the evidence told **us**. 80 percent of these children had evidence of exposure to repeated physical violence : assault and torture. 60 percent of the girls and at least 10 percent of the boys had evidence of repeated exposure to sexual violence. One young girl, telling a story and having corroborating evidence of being detained, beaten and raped over the course of three years, trafficked to other men and even having the threats of the murder of her entire family if she should ever escape or try to seek help. 90 percent of these children had evidence of psychological harm from indirect violence, including such severe threats, but also witnessing untold atrocities with their very eyes. One young boy described the terror and the grief and the utter fear of seeing the mutilated bodies and faces of his younger brother, his aunt, his uncle, his cousin, all killed in a single gang attack meant to send the community a message. And of course the psychological toll is immense. 19 percent of these children had signs of anxiety disorder ; 41 percent, depression and 64 percent, PTSD. 21 percent also had signs of suicidality as children. To put this into some perspective, returning combat veterans, they have PTSD on the order of 10 to 20 percent. These children at three to six times more likely to have PTSD than a soldier returning from war. Now despite this burden and despite this trauma, there are many others, still. Children who come to seek safety and enter into our immigration system only to find further abuse and even torture reminiscent of the places that they fled. You might remember some of those headlines, some of those images this past year. Children being ripped from the arms of their parents. Toddlers, infants in cold and unsanitary cages. The absence of food, water clothing and even soap. There ’ s also increasing reports of medical negligence, preventable complications, child abuse, sexual abuse and even child deaths in US custody. Sadly, many of these abuses and crimes aren ’ t new. Some date **back** many years and even across administrations. But something ’ s changed. The scope and scale of these abuses and crimes, the systematic and seemingly purposeful endangerment of asylum seekers and also the impunity with which it ’ s being done has raised the harm to an entirely new level. It reminds me of one of the girls in the study who told **us** how she pleaded with one of her attackers, asking him to stop, asking why she was targeted. And do you what his response was? He says,”We can do this, because there ’ s no one here to protect you.”We can ’ t let this be true of children and other asylum seekers trying to find help at our borders. But what do we do? As a physician, I ’ m often dealing with difficult decisions with some of my sickest and most complex patients. Of course we want to keep our focus on their health, their well-being, their quality of life, but sometimes it requires a deeper exploration of their values to really understand how to move forward. In a similar way, our nation is facing a crisis with the increasing number of asylum seekers at our borders and in our communities, and it compels **us** to re-examine some of our own fundamental values. What does it mean when we value health and safety? What does it mean when we value security, life, liberty, the life of children? What about this one – what does it mean when we say we value law and order? Does that also include respecting due process rights for an asylum seeker? Now for some, when they hear these terms they immediately gravitate towards wanting to build more walls, deploying more border patrol, deporting more people even if it means separating children from their families, subjecting them to psychological torture or deporting them to places where they might die. All in the name of security. All in our name. But for me and for many others, when I think of these values, that pushes me in an entirely new direction and renews my commitment to try to meet the needs of these asylum seekers with every tool I have at my disposal. So that when we say that we value life and liberty, we ' ll see these people who have taken unimaginable risks to flee imminent danger and harm to try to find safety. We ' ll meet them where they are and provide food, water, shelter, clothing. And we ' ll certainly meet them with medical care and mental health care that they so desperately need. When we say that we value the rule of law, and not just the privileges it provides a few but the responsibilities it requires of all of **us**, we ' ll make sure that we have a functioning immigration system. We ' ll make sure that we have trained judges. We ' ll make sure that we ' re not settling for the illusion of law and order that maybe a tall wall or a militarized border might provide **us**. We want the real thing. We want judges to be able to evaluate the evidence, including the medical evidence, and we want them to administer justice... fairly. When we say that we value health and well-being, that we don ' t want to perpetuate harm, then we ' ll deploy trauma-informed strategies at all levels of the immigration system. It might start with retraining border patrol agents or immigration officials, but it needs more medical, mental health and child welfare experts across the whole system. And when we say that we value justice, we won ' t let ourselves be turned into the torturers that many of these children and other people fled. We ' ll open up our **detention** centers and our courts to experts and advocates to hold ourselves accountable. And we may find that we need to shut down most of them and close these camps. I believe that by working in effective partnerships with lawyers, doctors, human rights advocates and many others, that we can work together to meet these asylum seekers ' needs, that we can meet our historical, humanitarian and legal obligations to them. And when we do, I think something powerful will unfold. Not only will these asylum seekers – like the man who came to my clinic and won his asylum case, like the children in the study or the many thousands of others seeking a new life, they ' ll be able to find that safety and security. We ' ll recognize the abuses that have occurred, and we ' ll restore the rights and protections that were lost. And I think that we ' ll be in wonder when we see them in the fullness of their humanity. Not just their strengths and weaknesses, their hopes and joys, not just the trauma that we acknowledge, but we ' ll also stand with them and we ' ll be inspired by their resilience. They ' ll blossom, and they ' ll add to the richness of this nation. I think by staying true to our fundamental values in the way that I ' ve described, that ' s how we build a sane and humane immigration system. That ' s how we remain the golden door. And that ' s how it happens that we remain the shining light of the world. Thank you.

Text Sample 88: NEG Dim 1 – 2020 – Score -1.00 – 2020/t004214.txt

So often, I ' ll take a fitness class, or I ' ll go to a music venue, or, really, anywhere that plays music in the background, and I ' ll find myself loving the rhythms and the melodies and the beats... And then I take a second to listen to the lyrics, lyrics that, for example, place **us** in a position of subservience that we would never tolerate in any other context. And I ' m aghast at the degree to which we normalize sexism in our culture. I listen to this music and I ' m like, I don ' t want to have to turn up to the sound of my own oppression. You know, music is one of the most powerful forms of communication, because it has the potential to either uplift or oppress. Music caters to the emotions. Music caters to the soul. Music opens up our soul. It opens up our channels to receive information about somebody else ' s walk of life, to inform our own roles. And while I have no problem with male fantasy, what I do have a problem with is that, according to a recent study, only 2. 6 percent of all music producers identify as women. That means an even smaller percentage identify as trans or gender nonconforming. And why does this matter? Because, if we don ’ t own and control our own narrative, somebody else will tell our stories for **us**, and they will get it wrong, perpetuating the very myths that hold **us back**. And I ’ m not here to tell other people how to make their music. But I am here to provide and design the alternative. One strategy I take in my music is making uplifting, energetic, percussive global beats and placing lyrics on top of them that genuinely describe my life ’ s experiences without contributing to the oppression of anybody else. It ’ s funny, because it ’ s the same reason as to why we excuse so many problematic lyrics ; it ’ s because we love how the beats make **us** feel. An example of this is my song”Top Knot Turn Up.”I turned off my phone ’ s notifications so I have more time / No bubbles to trouble my clear state of mind / One thing to know, I ’ m not here to please / Hair tied up, I do it properly / My time is not your property / When I ’ m productive like my ovaries, eyy! / Give a grown girl room to breathe, basic rights and her liberty / Free from insecurity that the world ’ s projecting onto me / Please do not trouble me when I am focused / The future is female you already know this / I ’ m fighting against the corruption on SCOTUS / Turned up in my top knot since when I first wrote this / It ’ s a top knot turn up It ’ s a top knot turn up, turn up, turn up. It ’ s a top knot turn up It ’ s a top knot turn up, turn up, turn up. It ’ s a top knot turn up It ’ s a top knot turn up, eyyy. It ’ s a top knot turn up. I want **us** to keep making sex-positive, beautiful music about joy and freedom. I want **us** to embrace our own pleasure just as much as we embrace our own pain. I want **us** to celebrate the authentic, nuanced, multidimensional aspects of our human existence, rather than perform false narratives of degrading sexuality in order to feel accepted or loved. And another strategy that I take in my music to combat the misogyny that exists on the airwaves is to visually depict the very world I wished we lived in. In the music video for my song”See Me Thru,”which is like a vibe-y, queer electronic R and B song, I cast two of my dear friends, Ania and Dejha, to play the role of the lovers, because they ’ re married in real life. But what you don ’ t know is that they also are behind the camera concepting and directing the entire video. Heyyyyy ohhhh My emotions were tired Music should be safe and accessible for all to experience. As you can see, it ’ s not about losing the sex appeal or swag that music has, it ’ s about writing messages that infuse tenderness and positivity into music that motivates **us** and challenges **us**. And while we as musicians absolutely have the responsibility to make music that isn ’ t disempowering, the consumers can be part of the change, too. Firstly, we get to choose which songs we want to mute and which songs we want to turn louder. We get to say,”I respect myself enough to say I don ’ t want to listen to this, and I don ’ t want this to be in anybody else ’ s space, either.”Secondly, we can simply ask ourselves :”Does this music or this message contribute to the oppression of somebody else? Why am I tolerating it?”And finally, we can all be choosing to make playlists or DJ-ing music that provides the right vibe or mood that we ’ re looking for in that moment without the problematic messaging. Why does this matter? Because it ’ s teaching algorithms in our streaming systems and our world exactly what it is that we do want to listen to, creating long-term change and a feedbacking mechanism that impacts the entire industry. This is not a message for just a small group of people. This is a message that affects everybody, because when we protect and liberate our most vulnerable genders, we liberate everybody.

Text Sample 89: NEG Dim 1 – 2020 – Score -1.00 – 2020/t004316.txt

No matter how hard you might try, you can ’ t just flip a switch when you step into the office and turn your emotions off. Feeling feelings is part of being human. [The Way We Work] A pervasive myth exists that emotions don ’ t belong at work, and this often leads **us** to mistakenly equate professionalism with being stoic or even cold. But research shows that in the moments when our colleagues drop their glossy professional presentation, we ’ re actually much more likely to believe what they ’ re telling **us**. We feel connected to the people around **us**. We try harder, we perform better and we ’ re just generally kinder. So it ’ s about time that we learn how to embrace emotion at work. Now, that ’ s not to say you should suddenly become a feelings fire hose. A line exists between sharing, which builds trust, and oversharing, which destroys it. If you suddenly let your feelings run wild at work and give people far more information than they bargained for, you make everyone around you uncomfortable and you also undermine yourself. You ’ re more likely to be seen as weak or lacking self awareness, so, great to say you weren ’ t feeling well last night – you don ’ t need to go into every lurid detail about how you got reacquainted with your half-digested dinner. So there ’ s a wide spectrum of emotional expression. On one hand, you have under-emoters, or people who have a hard time talking about their feelings, and on the other end are over-emoters, those who constantly share everything that ’ s going on inside, and neither of these make for a healthy workplace. So what ’ s the balance between these two extremes? It ’ s something called selective vulnerability. Selective vulnerability is opening up while still prioritizing stability and psychological safety, both for you and for your colleagues. Luckily, anyone can learn to be selectively vulnerable, with practice. Here are four ways to get started. First, flag your feelings without becoming emotionally leaky. Bad moods are contagious, and even if you ’ re not vocalizing what you ’ re feeling, chances are your body language or your expressions are a dead giveaway. So if you are crossing your arms or hammering on your keyboard, your coworkers are going to know you ’ re upset. And if you don ’ t say anything, they might start to think it ’ s about them and get worried. So if you are reacting to a non-work-related event, so traffic for example, just flag it. You don ’ t need to go into detail. You can say something as simple as”I ’ m having a bad morning. It has nothing to do with you.”Now if it ’ s a work-related event that ’ s causing you to feel strong emotions, that brings **us** to point number two. Try to understand the need behind your emotion, and then address that need. If you suddenly start to find everyone around you irritating, sit **back** and reflect on that. And it might be that you ’ re irritable because you ’ re anxious, and you ’ re anxious because you ’ re worried about hitting a looming deadline. And in that case, you can go **back** to your team to address that need and say something like,”I want to make sure I get everything done ahead of the deadline. Can you help me put together a realistic plan to do that?”If you ’ re thinking of sharing, try and put yourself in the other person ’ s shoes. So if what you ’ re about to say would help you feel more supported and better understand the situation, then go ahead and share it. But if it gives you any kind of pause, you might want to leave it out. And finally, read the room and provide a path forward. If everyone on your team has been pulling long hours, and you notice that one of your colleagues seems particularly deflated or anxious, you can acknowledge that and show some empathy, but then try to give them something actionable that they could hold on to. And in this case, you could suggest that you go to your manager and ask that your weekly meeting be pushed **back** a day so you both have more time to work. You ’ re showing you ’ re invested in their success, but also that you care about their well-being. When we can be honest about what we feel, and freely suggest ideas, make mistakes and just not have to hide every piece of who we are, we ’ re much more likely to stay at the company for a long time. We ’ re also happier and more productive. So take a moment to reflect on the emotional expression that you bring to work each day. And if you are prone to oversharing, try editing. And if you ’ re a little bit more reserved, look for moments when you can open up to your colleagues and be a bit vulnerable. And chances are, there will be a big difference in how people respond to you. And selective vulnerability might just become one of your most valuable tools.

I ’ m a lawyer based in Chicago, and two months ago I represented a Vietnamese immigrant woman in her divorce. As she was testifying about how her husband brutally raped her, the judge repeatedly told her to stop speaking. She should only speak when I asked her a question. Can you imagine having to publicly share one of the most painful, traumatic moments in your life and being told over and over again to basically shut up? It felt so wrong, but also so familiar for me. My mother, she had no say in her divorce. She didn ’ t have a lawyer, so she signed papers giving away everything because she thought she would otherwise be deported **back** to Vietnam. I thought by becoming a lawyer, I could help people like my mother. But then I realized I was actually part of the problem. As lawyers, we take over speaking for our clients. And courtroom procedures, rules of evidence means that we have all the power in what happens in their cases. We take terrible situations from people ’ s lives and we translate it into legal language. But, in doing so, we rewrite our clients as caricatures. The most helpless, most victimized versions of themselves. This is the American legal system. And that ’ s why, eight years ago, I founded Beyond Legal Aid in the belief that it doesn ’ t have to be this way, and lawyers can actually change it, working within, making it so that clients can speak for themselves. How does this work? First, instead of working nine to five in offices downtown, we travel, go to our clients where they live. And during evenings, nights and weekends when they are available. And they can be active participants in the legal process. Next, let me share a little secret. Well, at least for the non-lawyers. Attorneys like to be in charge. We go to law school, we hang up fancy law degrees, and we wear fancy suits – obviously much fancier than what I ’ m wearing – because we want to be in control. But it ’ s our clients whose lives are being judged and impacted by what I do. They need to be full partners in charge of their own cases. We can give advice, empower them to navigate the legal system. But ultimately, we need to follow their lead and defer to their decisions. Let me give you an example. One of our clients, let ’ s call him Atticus, he was facing deportation in a case where the law was completely against **us**. Atticus had been in ICE **detention** for several months because the immigration judge denied him bond. So he and OCAD, the Organized Communities Against Deportation, the community group we were working with on his case, wanted to try for bond a second time. I and the other lawyers were like,”No, no, no, no, no, no, no. You can ’ t do that. The law is bad, the judge has already said no once, and we don ’ t want to piss him off by questioning his decision.”But they wanted to proceed, so we deferred to their decision. However, instead of my sharing his situation on his behalf, we convinced the judge to hear a live conversation between Atticus and his US citizen son, let ’ s call him Jem. Jem spoke about how he wanted to commit suicide because he couldn ’ t live without his father anymore. Atticus broke down, sobbing in despair because he felt responsible for what was happening with his son and yet couldn ’ t be there for him. The judge was forced to hear directly how Atticus and Jem loved each other and how much they needed each other. He heard it unadulterated, in full, without any questions, without any interruptions by any lawyers. Unfortunately, he denied bond a second time. But – and of course there ' s a"but,"right, otherwise, I wouldn ' t be telling you this story. The judge then cancelled Atticus ' s deportation. I cannot tell you how utterly, absolutely shocking that legal victory was. I was like,"Oh my God, I can ' t believe this happened."And... I ' m going to say something now, which lawyers don ' t say very often but probably should say a lot more often. I was wrong. My client and his community, they knew better. If we had not followed their lead and tried for bond a second time, the judge would have never heard Atticus tell his own story and be so moved by what was going on that he defied the law to allow Atticus to stay in the country with his son. Atticus being able to tell his own story, created a decision that was impossible, at least what we thought as attorneys. Atticus sharing and talking his own case created justice where the law was wrong. And that ' s why the legal system has to change, so that people like Atticus can share their own stories, have agency over their own cases. In the meantime, we as lawyers need to make it happen in our work, in our cases right now. Thank you.

For people who want to have a baby, false messages about fertility can be especially powerful. So I want to say upfront that the COVID-19 vaccine is safe for fertility. [Body Stuff with Dr. Jen Gunter] The data on this is clear. COVID-19 vaccination saves lives for everyone, especially pregnant people and their babies. But the fog of the pandemic has made it extra challenging to dispel the misinformation surrounding the COVID-19 vaccine. So I want to address some of these worries by talking about how a vaccine becomes a vaccine in the first place. To show that each step of creating the vaccine is closely evaluated for safety. One of the early stages of vaccine development involves exploratory research. In the case of the coronavirus that causes COVID-19, researchers already had years of knowledge and insight to work from. Scientists already knew a lot about other coronaviruses. And because of knowledge sharing, they were able to simply download the virus ' s genetic code off a website. They were also able to take advantage of the advances made in mRNA vaccine technology, which you might have heard about. While mRNA vaccines are new to the public, researchers have been studying and working with them for decades. I want to underscore this point. One worry about the vaccine is that it felt rushed. But while the COVID-19 vaccine was developed rapidly, its creation was based on decades of research. Once the exploratory stage is finished, researchers move on to the preclinical stage, where testing is done in petri dishes or on animals. The goal of preclinical tests is to see if the vaccine truly works on the pathogen – in this case, the virus that causes COVID-19 – and also to test the safety of a vaccine. This is where researchers perform toxicity testing, using a dosage far greater than what they might use in humans to make sure it ' s safe. By testing on animals, they ' re able to see if vaccines have any impact on functions like the reproductive system. You might be surprised to learn that the chemical signaling that happens in a rat uterus is very similar to what happens in a human uterus. Here ' s what ' s important. Researchers don ' t move on from the preclinical testing phase until they prove that the vaccine is unlikely to harm anyone. This is a rigorous process that goes through FDA approval. Once the FDA approves, the next step is the clinical development or clinical trials, testing in humans, which is a three-phase process. Phase one starts with a small group of people, usually less than 100 very healthy adults. By phase three, researchers are working with thousands or even tens of thousands of people. Because of the urgency of COVID-19, researchers save time by overlapping these phases, using early data from each phase to design for the next. In other words, no steps were skipped. Now, it ’ s true that clinical trials for the COVID-19 vaccines didn ’ t include pregnant people, and that ’ s not unusual. Pregnant people are currently part of a protected class that typically aren ’ t included in testing new vaccines or new drugs. I completely understand the worries around this, but remember, testing in animals is a proven way to ensure vaccine safety. The preclinical data for the COVID-19 mRNA vaccine showed no impact on fertility in animals that would lead researchers to suspect there would be issues with humans. Even after the vaccine has been approved by the FDA and made available to the public, there ’ s still work to be done. These are called phase four trials, where researchers and regulatory agencies track how the public responds to the vaccine long-term. Monitoring side effects, collecting and analyzing data from a much wider population. And now we have even more data to reassure **us** about fertility. After the COVID-19 vaccine was rolled out, there were reports online of people experiencing irregular periods or changes in their menstrual cycle. This, understandably, made people nervous about a potential effect on fertility or an unknown effect of the vaccine. We didn ’ t have any data about irregular menstrual cycles from clinical trials to point to, and that is problematic. But given the rush to get the data, it would have been hard to collect because people would have had to track cycles before the vaccine. Differences people notice in their menstrual cycles are valid, and it ’ s scary and uncertain to notice a change in our bodies. And because the endometrium, the lining of the uterus that sheds during a period, is part of our immune system, it is theoretically possible a vaccine could have a temporary effect in the same way a vaccine causes temporary swelling in the lymph nodes for some people or a temporary fever. Researchers responded to the concerns raised online and looked into data from almost 4, 000 people who tracked their cycles using an app and compared data from the vaccinated group to those who didn ’ t get vaccinated. On average, the menstrual cycles of people who were vaccinated varied in length by less than one day, which is interesting but not medically significant since normal menstrual cycles vary by up to seven days each cycle. The only group that was more likely to show a meaningful difference in their menstrual cycle length were those who received two doses of the vaccine in one cycle. Even then, what they observed was temporary. Their cycles went **back** to normal within three cycles. And we ’ ve continued to gather data. We now see the importance of vaccination for those who are pregnant as the risk of mortality in pregnancy with COVID-19 is 1. 6 percent. That ’ s 22 times higher than the risk of mortality in pregnancy for those without COVID. And unvaccinated mothers and pregnant people who do get COVID-19 have a much higher chance of being admitted to the intensive care unit. We also now have data showing that infants from people vaccinated during pregnancy do have antibodies to help protect them from COVID-19. If your goal is a healthy pregnancy, one of the best ways to achieve that is by getting vaccinated. And we can have confidence that the COVID-19 vaccines have been rigorously tested and are being closely followed.

Text Sample 92: NEG Dim 1 – 2022 – Score -1.00 – 2022/t003749.txt

It ’ s dark days for democracy. And our crisis is global. If you ’ re like me, you can feel it in your bones. My expertise focuses on democracy in the United

States, where I live and work. And while we ’ ve long lifted up our own system on a pedestal as an example for the world, we ’ re one of those democracies that ’ s currently in a yearslong decline. So much of the conversation in the media and among experts is about our broken two-party system. Democrats vs. Republicans. And so much of the conversation about voting is about the outcomes : the winners and the losers. These are the wrong conversations if we want to tackle the threat to US democracy today. Because we have a much more fundamental challenge, and it ’ s quickly growing. The United States election infrastructure is crumbling. By infrastructure, I mean the technology, the physical infrastructure, like facilities, and most importantly, the human infrastructure, the people who manage the US voting process. Election infrastructure is so essential that it ’ s been designated critical infrastructure by the US Department of Homeland Security. That puts it on par with systems like our power grid and water supply in the eyes of the federal government. But they haven ’ t invested in it like it ’ s critical. The average portion of a county budget spent on election operations is about half of one percent. To put that into context, we spend about the same amount to maintain parking facilities as we do our election system. If we zoom out a little bit, the US election system is actually pretty unique by global standards. Unlike some other places, we have no central election authority that ’ s responsible for managing the logistics of voting for our entire country. Instead, we have thousands and thousands of local departments that each have some independent mix for figuring out how to make voting work where they live. These departments are staffed by professional election officials with support from volunteer poll workers during peak election season. So with no government-run how-to for how to administer elections, we end up seeing widely different voting experiences throughout the US, where voting can legitimately work one way in one community and look totally different somewhere else. For over a decade, my work has focused on providing technology and training and other resources to state and local election officials to support them in their work serving voters. In my current role, that has looked like working with election departments in every corner of the country, that together serve about 75 percent of our eligible voters. This has given me a really unique window into what it actually takes these public servants on the front lines to do things like keep voter rolls up to date and quickly and accurately count ballots and inform their communities about how the process works. This year-round work is hard. And it ’ s often super thankless. And the last two years have been some of the worst. Election officials who serve millions of voters currently lack the basic technology that they need to reliably do their work. It either doesn ’ t exist, or it ’ s shockingly outdated. In the year 2020, we supported a small New England town replace their hand crank ballot box that they had been using since the early 1900s to count ballots. One was literally held together by duct tape. Even worse, the people that underpin our voting process, the election officials, are currently under attack. In exchange for being outspoken about the integrity of the process that they managed in 2020, which, by the way, turned out to be our highest turnout election in the US in over a century and the most secure election ever administered in our history, according to our national security community – In exchange for the grit and determination that it took to make that possible during a global pandemic, today, election officials are receiving death threats, their children are being bullied, and some have had to flee their homes. A recent survey shows that one in three election officials, one in three, currently feel unsafe doing their work. It ’ s appalling. And enough is enough. We are at a tipping point for US democracy and frankly, democracy globally. I don ’ t know about you, but I personally don ’ t feel comfortable just standing around, leaving things to chance. And I especially don ’ t feel comfortable standing by, asking election officials to keep figuring out how to make it work alone, while our system is getting pushed to its brink. We need to rally around a set of shared values and standards, a North Star, so that every single voter, regardless of their zip code, has access to a process that ’ s both fair and trustworthy. Election officials need a place where they can come together to keep their skills fresh so that they ’ re ready to tackle whatever challenges might come, whether it ’ s training to bolster cybersecurity or to combat disinformation or to help them keep voters safe during a pandemic. And every election department, rural, urban, large, small, needs access to 21st century secure technology so that every single community has access to the basics. Like, a website where voters can find out answers about how voting works where they live. Or data-driven tools that election officials can use to make sure that we don ’ t have lines that snake around city blocks outside of polling places. Last summer, I was at my first conference since the start of the pandemic, and I was going up the escalator and I locked eyes with this election official who I absolutely adore. Let ’ s call her Sarah. I ran and I gave Sarah a huge hug, and I realized that probably 60 seconds passed before we let go. And when we did, I was crying and so was Sarah. Sarah ’ s life got flipped totally upside down after the 2020 election, when a vicious conspiracy theory about her office went viral. Almost immediately, the death threats started to roll in, and they were unrelenting and they were very specific about the harm that they wished upon Sarah and her husband and their children. And still, Sarah never **backed** down from telling the truth about the process that she led. In that moment, I was so overwhelmed with gratitude and love and admiration for Sarah that I couldn ’ t help the tears. But I think if I ’ m being super, super honest, I was just so happy that my friend was still here to hug. Election officials deserve a warm, welcoming community where their hard work is celebrated and encouraged, not vilified. And all of this is exactly why I ’ m so excited that we are inviting every single election department in the United States to join the US Alliance for Election Excellence. The Alliance is a place where election officials and technologists and designers and other experts are working hand in hand to revitalize US democracy. And we ’ re doing it by focusing on the basics, a shared North Star, the tools that it actually takes to get the job done, and a community of support that has each other ’ s **back**, whatever might come. It is absolutely crucial that we rebuild the foundation of US democracy, and that ’ s exactly what we ’ re going to do. The Alliance is not only ready to meet this moment, we ’ re ready to create a foundation so strong, that we can make it another 200 years. Together. Thank you.

I ’ m here to tell you how change is happening at a local level in Pakistan, because women are finding their place in the political process. I want to take you all on a journey to the place I was raised, northwest Pakistan, called Dir. Dir was founded in the 17th century. It was a princely state until its merger with Pakistan in 1969. Our prince, Nawab Shah Jahan, reserved the right to wear white, the color of honor, but only for himself. He didn ’ t believe in educating his people. And at the time of my birth in 1979, only five percent of boys and one percent of girls received any schooling at all. I was one among that one percent. Growing up, I was very close to my father. He is a pharmacy doctor, and he sent me to school. Every day, I would go to his clinic when my lessons finished. He ’ s a wonderful man and a well-respected community leader. He was leading a welfare organization, and I would go with him to the social and political gatherings to listen and talk to the local men about our social and economic problems. However, when I was 16, my father asked me to stop coming with him to the public gatherings. Now, I was a young woman, and my place was in the home. I was very upset. But most of my family members, they were happy with this decision. It was very difficult for me to sit **back** in the home and not be involved. It took two years that finally my family agreed that my father could reconnect me with women and girls, so they could share their problems and together we could resolve them. So, with his blessings, I started to reconnect with women and girls so we could resolve their problems together. When women show up, they bring their realities and views with them. And yet, I have found all too often, women underestimate their own strength, their potential and their self-respect. However, while connecting with these women and girls, it became very clear to me that if there was to be any hope to create a better life for these women and girls and their families, we must stand up for our own rights — and not wait for someone else to come and help **us**. So I took a huge leap of faith and founded my own organization in ' 94 to create our very own platform for women empowerment. I engaged many women and girls to work with me. It was hard. Many of the women working with me had to leave once they got married, because their husbands wouldn ' t let them work. One colleague of mine was given away by her family to make amends for a crime her brother had committed. I couldn ' t help her. And I felt so helpless at that time. But it made me more determined to continue my struggle. I saw many practices like these, where these women suffered silently, bearing this brutality. But when I see a woman struggling to change her situation instead of giving up, it motivates me. So I ran for a public office as an independent candidate in Lower Dir in the local elections in 2001. Despite all the challenges and hurdles I faced throughout this process, I won. And I served in the public office for six years. But unfortunately, we women, elected women, we were not allowed to sit in the council together with all the members and to take part in the proceedings. We had to sit in a separate, ladies-only room, not even aware what was happening in the council. Men told me that,"You women, elected women members, should buy sewing machines for women."When I knew what they needed the most was access to clean drinking water. So I did everything I could do to prioritize the real challenges these women faced. I set up five hand pumps in the two dried up wells in my locality. Well, we got them working again. Before long, we made water accessible for over 5, 000 families. We proved that anything the men could do, so could we women. I built alliances with other elected women members, and last year, we women were allowed to sit together with all the members in the council. And to take part in the legislation and planning and budgeting, in all the decisions. I saw there is strength in numbers. You know yourselves. Lack of representation means no one is fighting for you. Pakistan is — We ' re 8, 000 miles away from where I ' m here with you today. But I hope what I ' m about to tell you will resonate with you, though we have this big distance in miles and in our cultures. When women show up, they bring the realities and hopes of half a population with them. In 2007, we saw the rise of the Taliban in Swat, Dir and nearby districts. It was horrifying. The Taliban killed innocent people. Almost every day, people collected the dead bodies of their loved ones from the streets. Most of the social and political leaders struggling and working for the betterment of their communities were threatened and targeted. Even I had to leave, leaving my children behind with my in-laws. I closed my office in Dir and relocated to Peshawar, the capital of my province. I was in trauma, kept thinking what to do next. And most of the family members and friends were suggesting,"Shad, stop working. The threat is very serious."But I persisted. In 2009, we experienced a historic influx of internally displaced persons, from Swat, Dir and other nearby districts. I started visiting the camps almost every day, until the internally displaced persons started to go **back** to their place of origin. I established four mother-child health care units, especially to take care of over 10, 000 women and children nearby the camps. But you know, during all these visits, I observed that there was very little attention towards women ’ s needs. And I was looking for what is the reason behind it. And I found it was because of the underrepresentation of women in both social and political platforms, in our society as a whole. And that was the time when I realized that I need to narrow down my focus on building and strengthening women ’ s political leadership to increase their political representation, so they would have their own voice in their future. So we started training around 300 potential women and youth for the upcoming local elections in 2015. And you know what? Fifty percent of them won. And they are now sitting in the councils, taking part actively in the legislation, planning and budgeting. Most of them are now investing their funds on women ’ s health, education, skill development and safe drinking water. All these elected women now share, discuss and resolve their problems together. Let me tell you about two of the women I have been working with : Saira Shams. You can see, this young lady, age 26, she ran for a public office in 2015 in Lower Dir, and she won. She completed two of the community infrastructure schemes. You know, women, community infrastructure schemes... Some people think this is men ’ s job. But no, this is women ’ s job, too, we can do it. And she also fixed two of the roads leading towards girls schools, knowing that without access to these schools, they are useless to the girls of Dir. And another young woman is Asma Gul. She is a very active member of the young leaders forum we established. She was unable to run for the public office, so she has become the first female journalist of our region. She speaks and writes for women ’ s and girls ’ issues and their rights. Saira and Asma, they are the living examples of the importance of inclusion and representation. Let me tell you this, too. In the 2013 general elections in Pakistan and the local elections in 2015, there were less than 100 women voters in Dir. But you know what? I ’ m proud to tell you that this year, during the general elections, there were 93, 000 women voters in Dir. So our struggle is far from over. But this shift is historic. And a sign that women are standing up, showing up and making it absolutely clear that we all must invest in building women ’ s leadership. In Pakistan and here in the United States, and everywhere in the world, this means women in politics, women in business and women in positions of power making important decisions. It took me 23 years to get here. But I don ’ t want any girl or any woman to take 23 years of her life to make herself heard. I have had some dark days. But I have spent every waking moment of my life working for the right of every woman to live her full potential. Imagine with me a world where thousands of **us** stand up and they support other young women together, creating opportunities and choices that benefit all. And that, my friends, can change the world. Thank you.

This is my favorite protest shirt. It says,”Protect your people.”We made it in the basement of our community center. I ’ ve worn it at rallies, at protests and marches, at candlelight vigils with families who have lost loved ones to police violence. I ’ ve seen how this ethic of community organizing has been able to change arresting practices, hold individual officers accountable and allow families to feel strong and supported in the darkest moments of their lives. But when a family would come to our center and say,”My loved one got arrested, what can we do?”we didn ’ t know how to translate the power of community organizing that we saw on the streets into the courts. We figured we ’ re not lawyers, and so that ’ s not our arena to make change. And so despite our belief in collective action, we would allow people that we cared about to go to court alone. Nine out of ten times — and this is true nationally — they couldn ’ t afford their own attorney, and so they ’ d have a public defender, who is doing heroic work, but was often under-resourced and stretched bare with too many cases. They would face prosecutors aiming for high conviction rates, mandatory minimum sentences and racial bias baked into every stage of the process. And so, facing those odds, stripped away from the power of community, unsure how to navigate the courts, over 90 percent of people that face a criminal charge in this country will take a plea deal. Meaning, they ’ ll never have their fabled day in court that we talk about in television shows and in movies. And this is the untold part of the story of mass incarceration in America — how we became the largest jailer in the world. Over two million people currently incarcerated in this country. And projections that say one out of three black men will see the inside of a prison cell at some point in their life on this trajectory. But we have a solution. We decided to be irreverent to this idea that only lawyers can impact the courts. And to penetrate the judicial system with the power, intellect and ingenuity of community organizing. We call the approach”participatory defense.”It ’ s a methodology for families and communities whose loved ones are facing charges, and how they could impact the outcome of those cases and transform the landscape of power in the courts. How it works is, families whose loved ones are facing criminal charges will come to a weekly meeting, and it ’ s half support group, half strategic planning session. And they ’ ll build a community out of what otherwise would be an isolating and lonely experience. And they ’ ll sit in a circle, and write the names of their loved ones on a board, who they ’ re there to support. And collectively, the group will find out ways to tangibly and tactfully impact the outcome of that case. They ’ ll review police reports to find out inconsistencies ; they ’ ll find areas that require more investigation by the defense attorney ; and they ’ ll go to court with each other, for the emotional support but also so that the judge knows that the person standing before them is part of a larger community that is invested in their well-being and success. And the results have been remarkable. We ’ ve seen charges get dismissed, sentences significantly reduced, acquittals won at trial and, sometimes, it has been literally lifesaving. Like in the case of Ramon Vasquez. Father of two, family man, truck driver and someone who was wrongfully charged with a gang- related murder he was totally innocent of, but was facing a life sentence. Ramon ’ s family came to those meetings shortly after his arrest and his **detention**, and they worked the model. And through their hard work, they found major contradictions in the case, gaping holes in the investigation. And were able to disprove dangerous assumptions by the detectives. Like that the red hat that they found when they raided his home somehow affiliated him to a gang lifestyle. Through their photos and their records, they were able to prove that the red hat was from his son ’ s Little League team that Ramon coached on the weekends. And they produced independent information that proved that Ramon was on the other side of town at the time of the alleged incident, through their phone records and receipts from the stores that they attended. After seven long months of hard work from the family, Ramon staying strong inside jail, they were able to get the charge dismissed. And they brought Ramon home to live the life that he should have been living all along. And with each new case, the families identified new ways to flex the knowledge of the community to have impact on the court system. We would go to a lot of sentencing hearings. And when we would leave the sentencing hearing, on the walk **back** to the parking lot after someone ' s loved one just got sent to prison, the most common refrain we would hear wasn ' t so much,"I hate that judge,"or"I wish we had a new lawyer."What they would say was,"I wish they knew him like we know him."And so we developed tools and vehicles for families to tell the fuller story of their loved one so they would be understood as more than just a case file. They started making what we call social biography packets, which is families making a compilation of photos and certificates and letters that show past challenges and hardships and accomplishments, and future prospects and opportunities. And the social biography [packets] were working so well in the courts, that we evolved it into social biography videos. Ten-minute mini documentaries, which were interviews of people in their homes, and at their churches and at their workplace, explaining who the person was in the backdrop of their lives. And it was a way for **us** to dissolve the walls of the court temporarily. And through the power of video, bring the judge out of the court and into the community, so that they would be able to understand the fuller context of someone ' s life that they ' re deciding the fate of. One of the first social biography projects that came out of our camp was by Carnell. He had come to the meetings because he had pled to a low-level drug charge. And after years of sobriety, got arrested for this one drug possession charge. But he was facing a five-year prison sentence because of the sentencing schemes in California. We knew him primarily as a dad. He ' d bring his daughters to the meetings and then play with them at the park across the street. And he said,"Look, I could do the time, but if I go in, they ' re going to take my girls."And so we gave him a camera and said,"Just take pictures of what ' s like being a father."And so he took pictures of making breakfast for his daughters and taking them to school, taking them to after-school programs and doing homework. And it became this photo essay that he turned in to his lawyer who used it at the sentencing hearing. And that judge, who originally indicated a five-year prison sentence, understood Carnell in a whole new way. And he converted that five-year prison sentence into a six-month outpatient program, so that Carnell could be with his daughters. His girls would have a father in their life. And Carnell could get the treatment that he was actually seeking. We have one ceremony of sorts that we use in participatory defense. And I told you earlier that when families come to the meetings, they write the names of their loved ones on the board. Those are names that we all get to know, week in, week out, through the stories of the family, and we ' re rooting for and praying for and hoping for. And when we win a case, when we get a sentence reduced, or a charge dropped, or we win an acquittal, that person, who ' s been a name on the board, comes to the meeting. And when their name comes up, they ' re given an eraser, and they walk over to the board and they erase their name. And it sounds simple, but it is a spiritual experience. And people are applauding, and they ' re crying. And for the families that are just starting that journey and are sitting in the **back** of the room, for them to know that there ' s a finish line, that one day, they too might be able to bring their loved one home, that they could erase the name, is profoundly inspiring. We ' re training organizations all over the country now in participatory defense. And we have a national network of over 20 cities. And it ' s a church in Pennsylvania, it ' s a parents ' association in Tennessee, it ' s a youth center in Los Angeles. And the latest city that we just added to the national network to grow and deepen this practice is Philadelphia. They literally just started their first weekly participatory defense meeting last week. And the person that we brought from California to Philadelphia to share their testimony, to inspire them to know what ' s possible, was Ramon Vasquez, who went from sitting in a jail in Santa Clara County, California, to inspiring a community about what ’ s possible through the perseverance of community across the country. And with all the hubs, we still use one metric that we invented. It ’ s called time saved. It ’ s a saying that we actually still say at weekly meetings. And what we say when a family comes in a meeting for the first time is : if you do nothing, the system is designed to give your loved one time served. That ’ s the language the system uses to quantify time of incarceration. But if you engage, if you participate, you can turn time served into time saved. That ’ s them home with you, living the life they should be living. So, Carnell, for example, would represent five years of time saved. So when we totaled our time saved numbers from all the different participatory defense hubs, through the work in the meetings and at court and making social biography videos and packets, we had 4, 218 years of time saved from incarceration. That is parents ’ and children ’ s lives. Young people going to college instead of prison. We ’ re ending generational cycles of suffering. And when you consider in my home state of California, it costs 60, 000 dollars to house someone in the California prison system, that means that these families are saving their states a ton of money. I ’ m not a mathematician, I haven ’ t done the numbers, but that is money and resources that could be reallocated to mental health services, to drug treatment programs, to education. And we ’ re now wearing this shirt in courts all across the country. And people are wearing this shirt because they want the immediacy of protecting their people in the courtroom. But what we ’ re telling them is, as practitioners, they ’ re building a new field, a new movement that is going to forever change the way justice is understood in this country. Thank you.

A traumatic brain injury, or TBI, is a disruption in brain function caused by an external blow to the head. And when you hear that definition, you might think about sports and professional athletes, since it ’ s the kind of injury we ’ re used to seeing on the playing field. And this imagery has really come to define TBI in the public consciousness. I myself do research on TBI in retired and college athletes. I stood on a TED stage in 2010, talking about concussions in kids ’ sports. So I have to say, as someone who researches and treats these injuries, that I ’ ve been really gratified to see the growing awareness of TBI and specifically, the short- and long-term risks to athletes. Today, though, I want to introduce you to a larger but no less controversial group of people impacted by traumatic brain injury, who don ’ t often show up in the headlines. I ’ ve come to recognize these inmates and probationers as surprisingly among the most vulnerable members of society. For the last six years, my colleagues and I have been doing research that has completely changed the way we think about the criminal justice system and the people in it. And it may change the way you think about those things, too. So I ’ ll start with a shocking statistic : 50 to 80 percent of people in criminal justice have a traumatic brain injury. Up to 80 percent. In the general public, in this room, for example, that number is less than five percent. And I ’ m not just talking about getting your bell rung. These are the kinds of injuries that require hospitalization. Most of them are the product of a physical assault, and some of them are actually sustained in jail. All of these numbers are even higher among the women in criminal justice. Almost every single woman in the criminal justice system has been exposed to interpersonal violence and abuse. More than half of these women have been exposed to repeated brain injuries. In this way, these women ’ s brains look like the brains of retired NFL players, and they ’ ll likely face the same risks for dementing diseases as they age. The same risks. TBI, together with mental illness and substance abuse and trauma, makes it hard for people to think. They have cognitive impairments like poor judgment and poor impulse control, problems that make criminal justice a revolving door. People get arrested and booked into jail. They oftentimes get into trouble while they ’ re in there. They get into fights. They fall out of their bunk. And then they get released and do stupid things, like forgetting mandatory check- ins, and they get rearrested. Statistically speaking, they ’ re actually more likely to be rearrested than not. A colleague calls this”serving a life sentence 30 days at a time.”And oftentimes, these folks don ’ t know why this is so hard for them. They feel out of control and frustrated. So knowing that TBI is at the root of so many of these challenges, the mission for a group of **us** in Colorado has been to disrupt that cycle, to jam the revolving the door. So working together with my state and local partners, we crafted a plan to meet everyone ’ s needs : the system, the inmates and probationers, my graduate students. In this program, we assess how each person ’ s brain works so that we can recommend basic modifications to make this system more effective and safer. And here when I say”safer,”I mean safer not only for the inmates, but safer also for correctional staff. In some ways, this is such a simple approach. We ’ re not treating the brain injury, we ’ re treating the underlying problem that gets people into all of this trouble in the first place. We do quick neuropsychological screening tests to identify strengths and weaknesses in the way an inmate thinks. Using that information, we write two reports. One, a report for the system with specific recommendations on how to manage that inmate. The other is a letter to the inmate with specific suggestions for how to manage themselves. For example, if our test result suggests that a probationer has a hard time remembering the things they hear, that would be an auditory memory deficit. In that case, our letter to the court might suggest that that probationer get handouts of important information. And our letter to that probationer would say, among other things, that they should carry a notebook to record that information for themselves. Now, most importantly, is that I pause here to be really clear about one point. This program does not minimize responsibility or make excuses for anyone ’ s behavior. This is about changing longstanding negative perceptions and building self-advocacy. It ’ s actually about taking responsibility. The inmates move from,”I ’ m a total screwup, I ’ m a loser,”to,”Here ’ s what I don ’ t do well, and here ’ s what I have to do about it.”And the system comes to see an inmate ’ s problematic behavior as the things they can ’ t do versus the things they won ’ t do. And that change — seeing behavior as a deficit rather than outright defiance — is everything in these settings. We hear from inmates around the country, and they write, and more than anything, they want to know how to help themselves. This is an excerpt from a letter from Troy in Virginia, an excerpt from a 50-page letter. And he writes,”Can you tell me what you think of all the head traumas I ’ ve dealt with? What can I do? Can you help me?”Closer to home, we have thousands of stories like this, and smart stories, stories that have a great outcome. Here ’ s Vinny. Vinny was hit by a car when he was 15, and from that moment forward, spent more time in jail than in school. With some basic skill-building, after our assessment revealed that he had some pretty significant memory impairments, Vinny learned to use the alarm and reminder function on his iPhone to track important appointments, and he keeps a checklist to break larger tasks into smaller, manageable ones. And with basic tools like that under his belt, Vinny ’ s been out of jail for two years, clean for nine months, and recently **back** to work. What ’ s so striking for Vinny is that this is his first time off of court supervision since his injury more than 15 years ago. He made it out of the revolving door. He says now,”I can do anything. I just have to work a lot harder at it.”And here ’ s Thomas. Thomas has some pretty significant attention and behavior problems after an injury landed him in a coma for more than a month. After relearning how to walk, his first stop? Court. He couldn ’ t imagine a future where he wasn ’ t in trouble. He now carries a calendar to avoid being held in contempt for missed court dates, and he schedules a break into his day every day to recharge before he gets agitated. And nobody knows the revolving door better than the person sitting at the front of the courtroom. This is my good friend and colleague Judge Brian Bowen. Now, Judge Bowen was already on a mission to make the system work for everyone, and when he heard about this program, he saw the perfect fit. He actually sits down with all of his prosecutors to help them see that there ’ s basically two categories of defendants in the courtroom : the ones we ’ re afraid of — oftentimes, rightfully so — and the ones we ’ re mad at. These are the ones who miss all of their scheduled appointments and they blow through the best-laid probation plans. And Judge Bowen believes that, with a little more support, we could move people in this latter category, the maddening category, through and ultimately out of the system. He proved that with Navy veteran Mike. Judge Bowen saw the correlation between Mike ’ s history of a massive 70-foot fall and his long-standing pattern of difficulty showing up on the right day for court appointments and complying with mandatory therapy requirements, for example. And instead of sentencing him to more and more jail time, Judge Bowen sent him home with maps and checklists and handouts and recommended instead vocational rehabilitation and flexible scheduling for those therapies. And this with those supports, Mike ’ s **back** to work for the first time since his injury while he was in the service. He ’ s repairing relationships with his family, and just last month, he graduated from Judge Bowen ’ s veteran ’ s court. This program shows **us** the overwhelming prevalence of traumatic brain injuries and cognitive deficits and the accumulation of brokenness in the criminal justice system. And it highlights the extraordinary power of resilience and responsibility. In Mike and Thomas and Vinny, even Judge Bowen ’ s story, you saw the transformation made possible by a change in perception and some simple accommodations. All told, in this program, these inmates and probationers come to see themselves differently. The system sees them differently, and when you meet them in the community, I hope you see them differently, too. Thanks, guys.

Text Sample 96: NEG Dim 1 – 2023 – Score -1.00 – 2023/t003511.txt

All around the world, there ’ s a huge disability employment gap. In most countries, the unemployment rate for people with disabilities is twice that of people without disabilities. Often it ’ s as high as 80 percent. There are over a billion people in the world living with a disability. To have 80 percent of **us** unemployed, that ’ s so much untapped potential. [The Way We Work] As someone with a paralyzed arm and living with a mental health disability who ’ s worked in the financial sector and entertainment and tech, I know that having a disability doesn ’ t bar you from doing good work. So it ’ s shocking to me that this disability employment gap is so persistent. In the US, the Americans with Disabilities Act prohibits discrimination in hiring and requires employers to provide reasonable accommodations. And studies show that companies who prioritize disability inclusion are more profitable overall. So what exactly is the problem? Recruiters, human resources staff, managers, they tend to think of hiring people with disabilities as a social good or as something they have to do to meet a quota. But they should be hiring disabled people because of our strengths and all of the value and innovation we can bring. Here are three things every workplace can do to truly welcome people with disabilities. It ’ s not comprehensive, but it ’ s a start. First, stop making assumptions. Our culture tends to treat disability as a medical diagnosis, a tragedy or a charity case. And all of these things are rooted in pity. They prevent **us** from being seen as peers and equals. These assumptions lead to a lot of avoidance. People tend to not ask **us** about our lives and hobbies outside of work or don ’ t invite **us** to company social outings. There ’ s so much fear about saying the wrong thing, that instead people say nothing at all. They treat disabled people like we ’ re invisible when all we want is to be seen and heard and accepted like anyone else. These assumptions also make people jump to conclusions about what we can and can ’ t do without even asking. For me, assuming I can ’ t type because I can ’ t use one of my arms or assuming a blind person can ’ t be an engineer. When to succeed at work, you need to have people who see your full potential because without that, nobody wins. So please, take the time to get to know **us**, invite **us** to things, ask **us** the same kind of questions you would of any colleague. What drew you to this work? What are your goals? What do you hope to do from here? And listen to our answers but also respect our boundaries. If there ’ s something we ’ re not comfortable discussing, we ’ ll let you know. And any time you feel unsure, just ask **us** privately so we can make those decisions. You can even start by saying,”I ’ m still learning how to get better at talking about disability.”Second, rethink accessibility and accommodations starting now. Disability takes so many different forms. It can be about someone ’ s sight, hearing or mobility. It can be ADHD, dyslexia or chronic pain. About 62 percent of employees with disabilities have ones that are not apparent. So even if you don ’ t think there are people with disabilities in your organization, there probably are. And that ’ s why I strongly recommend that workplaces create spaces with disability and accessibility in mind. That way you ’ re paving the way for future employees, clients and customers who might benefit from accommodations, too. At one of my first jobs at an investment bank, the company did something cool. Within a month of starting, I and all other new hires got an ergonomic assessment of our workstations. They actually had a person thinking about my access needs in multiple ways, like getting a foot rest and keyboard wrist pad, which a lot of colleagues got, to asking if I might benefit from speech to text technology because I type with one hand. I ’ ve always tried to find these little hacks to make my work environment more comfortable, but the fact that this person offered so many options proactively, it made me feel so welcome without making me feel like my needs were”special.”It would be amazing if every employer could do some version of this. I mean, why not? But there are also more simple things that can make an impact. Like, what about listing accessibility information if you ’ re hosting an event? Or automatically turning on captions for video meetings? Another way to think about this is : What do my employees need in order to thrive? It starts with equipping people with a variety of tools. Third, embrace flexibility, like disabled people have had to do our whole lives. People with disabilities have been advocating for remote work environments and flexible hours for decades now, and it took a pandemic for the world to realize it could happen. All of a sudden, this thing that seemed so wild has become commonplace. And this isn ’ t the first time I can think of when an accommodation for people with disabilities ended up improving life for society at large. Audiobooks, curb cuts, closed captioning, even electric toothbrushes. Disability is so often the root of innovation. So as we get **back** to the office, let ’ s remember that all of **us** can thrive with flexibility. For people with disabilities, let ’ s provide the option to work remotely at the hours when we can be the most productive from wherever works best. I mean, some of **us** do great working from our bed. And really, let ’ s hold on to the openness that we can work around everyone ’ s needs. Let ’ s keep finding ways to embrace flexibility as part of our company ’ s culture. We know that companies need to work harder on hiring **us**, retaining **us**, promoting **us**, paying **us** fairly and amplifying our efforts. To do that, we need to stop making assumptions, rethink accessibility and embrace flexibility. That is what will help close the disability employment gap.

Do you know the secret to successfully pitching an idea? Well, it ’ s something kind of unexpected. It ’ s FOMO : the fear of missing out. [The Way We Work] As someone who invests in companies early in their journeys, I listen to nearly 2, 000 pitches a year, and I work countless hours with company founders to help them make their pitch even more compelling. You may equate pitching with a slick deck based on some standard format, but whether you ’ re pitching a company or trying to get buy-in for a passion project at work, so much of pitching is a storytelling exercise. You need to bring people along with you. You need to tell your audience a story that not only will draw them in, but it will make them feel that if they don ’ t say yes, they will be missing out on something really big. [Step 1 : Know your audience] When people think about pitching, they ’ re thinking inwards, they think about their nerves, how smoothly they ’ re talking or what it takes to get to a yes. But the secret of successful pitching is to flip it outward. Who are you pitching to? What do they care about? How can you speak to what motivates them? For example, if you ’ re pitching your start-up idea to a venture capitalist who has lots of money to invest and needs big returns, they probably care about **backing** the next Uber or DoorDash. So you should focus your story on the size of the market opportunity. If you ’ re pitching to a philanthropist or a nonprofit, their motivation is likely about large social impact. So focus on showing how your product or idea will improve things in a lasting way. If you ’ re pitching a project at work, focus on the people you ’ re pitching the project to. What do they care about? More customer loyalty, more revenue, or perhaps a promotion? Tell them how your project will help them attain the goal that they want in a way that makes it almost inevitable. Give them that feeling of :”If I don ’ t support this, I ’ m going to miss out on something I care about deeply.”[Step 2 : Think about the hero ’ s journey] Pitching is much like telling a story. Just like a movie tells a story. You ’ re charting the hero ’ s journey in three acts. First, you start by telling about the hero ’ s world, the status quo. In this case, the current situation that your product, idea or service will be addressing. Then introduce tension and conflict, showing all the problems that existing products aren ’ t yet addressing. This will lead you to the big confrontation. You, the hero, swooping in to save the day. And from there, give the resolution. How are things changed as a result of your actions? How does your product, idea or service solve the problems you highlighted earlier? One of the best pitches I ’ ve heard followed this arc perfectly. The story started with a disturbing status quo. Depending on where and how it ’ s produced, one gallon of milk can take roughly 1, 000 gallons of water to produce and can create about six kilograms of CO_2 equivalent or more in the process. In this case, the hero was the CEO and their team of scientists and food industry experts who have come up with a way to engineer plants to produce the animal proteins. They showed how a small crop of soybeans could create lots of delicious cheese and how this could feed the global population in a sustainable and yummy way. To anyone who cares about both the environment

and good food, it was an irresistible story. It made me feel like I needed to be part of it or I would be missing out on a big opportunity. [Step 3 : Shore up your weakest point] When people are done charting their hero ’ s journey, I make them identify their biggest weakness. Is it that they ’ re missing somebody on their team or that it ’ s very competitive or that they ’ re trying to do something that has never been done before? Most people ’ s instinct is to gloss over it or even skip it altogether. But that ’ s exactly the wrong thing to do because the audience will notice it and will ask you about it. Instead, face it directly. Tell your audience,”Hey, you may think this is a problem, but here ’ s exactly what I ’ m going to do about it.”And by showing the strengths and weaknesses of your story and not hiding anything, you inspire confidence not only in you but also in your story. The best storytellers, they live in the future, and they come here not to just tell **us** about it, but to show **us** the steps to get there. And this makes the audience lean forward. And all they need to do to be part of this amazing story is say yes.

This week, on Sunday, Alexey Navalny – politician, opposition leader and my father – will have been in prison for 1, 000 days. Almost three years. I miss him every single day. I ’ m scared that my father won ’ t be able to come to my graduation ceremony or walk me down the aisle at my wedding. But if being my father ’ s daughter has taught me anything, it is to never succumb to fear and sadness. And I ’ ve experienced both, fear and sadness. One of the most fearful moments of my short yet eventful life was on August 20, 2020. That day, I woke up in my childhood bedroom in Moscow. Like many of **us** do first thing in the morning, I rolled over to the bedside table and reached for my phone. I looked at the screen and was surprised at how many notifications I had. Twitter, Instagram, Telegram, you name it. My feeling of confusion started to slowly turn into a sense of worry. Alexey Navalny had suddenly fell unconscious on the plane and was taken to the emergency room at the hospital. My heart dropped to my feet. Without blinking an eye, I jumped out of my bed and ran to my parents ’ bedroom to tell my mom that I was able to look after my younger brother, Zahar, while she was away. But by then, she was already at the airport. The plane on which my father had collapsed had to make an emergency landing in a city in Siberia. And after two days, an international uproar and my mom fighting tooth and nail to get him out of there, he was finally transferred to the clinic called Charité in Berlin, Germany. There, at the special laboratory of the German armed forces, they confirmed that he was indeed poisoned by a military-grade nerve agent of the Novichok group. He spent three weeks in a coma. And after months and months of recovery, he went **back** to work with the Anti-Corruption Foundation. Founded over a decade ago, the Anti-Corruption Foundation has been doing incredibly important and dangerous work of spreading information and exposing the corrupt nature of the Russian government. We ’ ve produced over 500 investigations, helped organize hundreds of protests in Moscow and run election campaigns. We provide free legal assistance to those who, like my father, have been imprisoned for peacefully protesting the regime. We ’ ve created a sanctions list of 6, 000 government officials, propagandists, entrepreneurs, various artists and more people who ’ ve supported and worked with Putin over the years. And the list works. Governments all over the world have used our list when imposing sanctions. Because Putin and his associates, they live lavishly. They own condos in Miami and penthouses in Manhattan. They own vineyards in France

and villas on Lake Como. They buy enormous yachts and country houses with gold toilets. They buy private jets to send their corgis to dog competitions. Yes, you heard that right. In 2016, the Anti-Corruption Foundation had released an investigation that Russia ’ s deputy prime minister owned an undeclared jet valued at over 60 million dollars and used it primarily to send his dogs to international competitions. All of this while most citizens in Russia scramble and live on wages of under 200 dollars. According to independent polling done by the ACF sociology center, only 15 percent of the population believe in Putin ’ s propaganda. That means that 85 percent of the population either opposes the regime, doesn ’ t think it really affects them, don ’ t follow politics or simply don ’ t know what to believe. This is why we ask our supporters, who are ordinary citizens, to spread our investigations and news content to their family members, friends and loved ones, because we know that if we can reach those who are on the fence or persuade those who have been brainwashed by Putin, we ’ ll get that much closer to changing the regime. One of my favorite chants my dad used to do during the 2011 to 2014 protests in Moscow was :”One for all and all for one.”This is a phrase that we ’ re all familiar with, but most of **us** often forget. Dictators like Putin want **us** to forget it. They want **us** to forget how strong we can be when we work together. They want **us** to forget how much we can accomplish when we stand side by side. Because it is that much harder for any dictator to fight an international united front than each of **us** individually. Now you might think to yourself,”Dasha, why should I care about this? Geographically, United States is quite far away from Putin. Is he really that threatening to **us**, or are you just trying to raise unnecessary alarm?”And to that, I want to respond with another thought. If we don ’ t stand up for them now, then who will be left to stand up for **us** later? Cyber attacks, spreading of propaganda and disinformation, meddling in the elections, bribing your government officials. This has been and is continuing to happen. The West, Europe and the United States have tried talking to Putin. And where did that get **us**? The illegal annexation of Crimea in 2014 and now a full-scale war in Ukraine. Tyrants and dictators don ’ t want diplomatic relations. All they want is power. I often catch myself thinking how I shouldn ’ t have gone **back** to school that fall. I should have stayed with my family while my dad was recovering. I should have gotten on that plane with him **back** to Russia and hugged him before he got unlawfully and outrageously arrested at the airport. That day when he went **back**, on January 17, 2021, thousands of people showed up at the airport to support him. When I was younger, I didn ’ t really understand how my dad could be so optimistic about the future. He was constantly threatened, arrested, followed. Our family would be followed by men dressed in all black, wearing baseball caps and a ridiculous-looking fanny packs when we would go to the cinema. And after a while, my dad decided to make a game out of it. Whenever we would get on the subway, we waited until the last moment and quickly got out of the car right before the doors closed, so that FSB agents were left behind. A unique childhood experience. I think one of the main reasons for my dad ’ s success is that he has always been incredible at channeling his emotions into hard work and motivation. He wouldn ’ t get sad, and he was certainly never afraid. Instead, he would get fired up. Fired up because he saw a group of ex-KGB corrupt criminals come into power and destroy his country. Seeing that motivated him so much more to work that much harder to stop them. And that is what makes a true patriot. Of course I understand that, first and foremost, the change needs to come from within the country. And that is precisely why, knowing all the risks, my dad went **back** to Russia 996 days ago. Because he simply couldn ’ t not go **back**. My dad is an incredibly courageous and selfless man, and I can only dream to be like him one day. He doesn

’ t run or hide. And unlike my father, Putin is a coward. A coward – A coward who, with his cronies, can no longer hide from the consequences of what they have done to my country and democracy around the world. And you, everyone who ’ s sitting here today or watching this online, you can help. Now. You, unlike millions [and] millions of those who have been threatened and murdered and silenced in Russia, you have a voice. Please don ’ t take your freedom for granted. Russia is my home. It ’ s where I was born. It ’ s where I grew up. It ’ s where I became the person I am today. And I will promise you that I will continue to speak up, tell the truth, and I will continue fighting until Russia is a free and democratic country. Thank you very much, free Alexey Navalny.

Cloe Shasha Brooks : Hello, welcome. You are watching a TED interview series called How to Deal with Difficult Feelings. I ’ m Cloe Shasha Brooks, your host and a curator at TED. And today we ’ ll be focusing specifically on anxiety. So first I ’ ll be speaking with author and model Naomi Shimada about the anxiety associated with social media. She coauthored a book called”Mixed Feelings : Exploring the emotional impact of our digital habits.”It ’ s all about how the internet has created a new layer of perfectionist pressure on our lives and how we can better manage our relationship with our online worlds. Hello, Naomi. Great to see you. Naomi Shimada : Hello, Cloe, great to see you, too. I ’ m honored to be here. CSB : Oh, well, thanks for joining **us**. So, Naomi, you have written and spoken about the relationship between social media and anxiety a whole bunch, such as the anxiety to post online or not to post. So can you tell **us** a little bit more about that? NS : So I always want to start by saying, even though I have written about it, I still don ’ t really feel like an expert because this is just – I always want to decenter my voice as an expert because I ’ m just feeling this out like everyone else. But in my experience, social media and anxiety are connected, you know, or social media exacerbates anxious feelings. It exacerbates the human condition. And so things that we may have insecurities and anxieties around, like, you know, our relationships, our bodies, our work, the things that make up our sense of self, I think the anxiety we feel or we can feel when we use social media can sometimes act as a marker for things that show **us** where we need to do work or where we feel insecure. And sometimes it ’ s just a message being reflected **back** to **us**. And also, like I said, social media exacerbates the human condition. You know, as humans, I think we so often just want to be loved and cared for and seen and adored or just acknowledged. So social media has also become, you know, our main mode of communication, our method of work. Some of those things, those lines can start to become very blurred. CSB : Absolutely. Yeah, and in addition to making lives look shiny and perfect, social media also seems to fuel a lot of FOMO, or fear of missing out. And I ’ m curious what you ’ d suggest for people who experience a lot of anxiety from seeing videos and images of other people having a ton of fun and, you know, not knowing how to deal with that. NS : I think, like I said slightly earlier, the feelings of anxiety when they come up, like, what is that message, you know, taking that step **back** and being, like, why do I feel this way? Why is this making me feel like this? And kind of reading into it. And in my personal experience, the thing that works for me is just taking a step **back**, taking a moment, you know, if something is making me feel bad, for example, if social media – if we thought of it as a substance, for example, if something was making you feel bad, what would you do about it? Would you stop using it? You know, I think there ’ s levels to this because sometimes, you

know, we may have work now that is so intertwined with social media and it can ’ t just be like, oh, stop using it. And I know that there ’ s a spectrum. And I ’ m also navigating this constantly myself when as a public-facing person, my job is so intertwined with social media and it ’ s something I want to do less and less. So I ’ m navigating that kind of boundary for me all the time. So it ’ s just negotiating, sometimes it ’ s not as clear cut, you know, it may for you start as take the weekends off, or you know, I actually personally most of the time don ’ t have social media on my phone. And just when I have to do something for work, that ’ s when I interact with it, especially this year that ’ s been so heavy, you know, and where there is no”off”button and every new day bringing such bad news, like, I ’ m a very sensitive person, so I have to do the things I know that I need to take care of myself, which is not scroll. Also, I ’ ve had an injury in my hand, which means I can ’ t actually scroll, so I ’ m like,”This is a sign! I ’ m just not supposed to be interacting like that right now.”So just listening and knowing that you don ’ t have to fall under the pressure. Like, I think so often we think that if we don ’ t post, we don ’ t exist. Our existence, you know – we only exist when other people see **us** existing. Like, that, that whole line, like,”Oh, if you didn ’ t post about it, it didn ’ t happen.”That concept. We ’ ve started to internalize, you know, especially my generation of millennials, gen-Z, like, if you didn ’ t post it, it didn ’ t happen. And so it ’ s just like going **back** and being like, OK, is that true? Why do I feel the need to share this? And asking those questions. And that ’ s what I do. So like I said, I ’ m not an expert, I too I ’ m working this out and every day feels totally different. But asking those questions is a great place to start. CSB : Thank you for that. So we have a question from the audience. Let ’ s bring that up. OK, so related to this, from Facebook,”What question should we be asking ourselves before we post on social media?”NS : So I like to ask myself, like, why do I want to share this right now? Is this something – as a person that has grown up on the internet, on social media, so often how I validated myself and my sense of self was posting something and people reacting to it. And I think that ’ s just very murky territory. I think like, you know, why do I feel the need to share this? Is this something that feels also private to me? You know, in my opinion, on whether, and I guess, you know, I have not the biggest social media following, but a social media following, that sometimes, when I ’ m like, does that person, for me, does my family member want to be shown online, for example, like, or is this a private moment? I think navigating, like, do I feel not good about myself right now and is posting a picture of myself looking, like, hot, or whatever the equivalent of looking really happy – I think sometimes so often we post about the things that we are yearning for, whether that ’ s attention, love, craving. And I think there ’ s deeper underlying messages behind posting sometimes, you know, and that it is a projection of the things that we want in our lives, for example, posting photos of people you want better relationships with or, you know, there ’ s a big spectrum of experience. But for me, I just try to ask myself, why do I feel the need to make this public right now? Is this something that I am proud of? And it ’ s no critique. This is really questions that are just a gauge where I ’ m at or where someone else is at with it. Like, is this something that actually I just need to pay attention to in my own life privately, of, like, this is something I should be working on or thinking about, or there ’ s just deeper questions about context, I think, that are important. CSB : Yeah, yeah. And I think as we ’ re now at our final question, which is something that I think is related to what you ’ re saying around when to post or not to post, but from a different angle, which is, you know, a lot of people have anxiety about whether or not to post their social justice activism on their accounts and regardless of the activism they might be already doing outside of social media, right? And some people just find it performative. But at the same time, there was a fear of looking apathetic if people are not posting about social justice on social media. So how do you suggest people deal with that anxiety and think about that? NS : I mean, that ’ s definitely an anxiety of our generation, right? Anxieties around posting about social justice. I think the big question here is asking ourselves, like, what am I doing in my own life? You know, and again, there is a spectrum, because there ’ s a lot of people who are sharing a lot of important information via social media. So you have, like, organizers and then everybody else. But if you are – Once again, you know, I can ’ t speak for everybody, but just I think it ’ s – I read this quote by an activist in Oregon, a lifetime organizer called Grace Lee Boggs, and she said that, you know, that a lot of times in our lives we don ’ t prioritize the importance of self-reflection and revolution. And I think, you know, we so care about optics. We don ’ t want people to think that we are racists, sizeist, sexist, etc. But to not create and redo this kind of harm in the world, we need to understand and really reflect on these systems that we ’ ve all internalized to some effect. So to understand, like, where am I on the spectrum? How do I benefit? All of these things actually really take time and deep, you know, self-reflection and work. And that kind of questioning, I think, is something that I find it helpful to be offline because I ’ m like, otherwise, I ’ m just listening to what everybody else is saying. Like, are these my thoughts and my feelings or am I just internalizing what other people are just shouting into the atmosphere and into the internet? I think, there ’ s moments where obviously, a lot the uprisings in June would not have happened if it wasn ’ t for the information that was shared and that action, of course, was so important. But I think there ’ s different phases, you know. And when it ’ s just about shame and optics, that ’ s not how we change the world. For **us** to change the world, we need to inhabit and act on these reflections. So I think there are again, more questions to ask ourselves, like, do I just not want people to think that I do this? And often we are in echo chamber of the people who follow **us** and people we follow, right? So a lot of the times we ’ re just sharing and shouting into the atmosphere of people who have the same ideals as **us**. And that energy can be used in a different way. And also sometimes inhibits, I think, real harder conversations from happening, because I think social media isn ’ t often an intimate enough of a space to be able to ask each other questions that we ’ re afraid to ask. Or mistakes, it ’ s not favorable to making mistakes anymore, which is my critique and sadness about social media. You know, our biggest fear is being called out for something. But this call-out culture, sometimes, not always, I understand its role and place in society, but sometimes doesn ’ t allow for **us** to have more engaged conversations around these systems that we ’ ve internalized. And we all make mistakes and we all have to learn and sometimes it doesn ’ t allow for that to happen. CSB : Yeah, yeah, yeah. Well, I think that ’ s beautifully said and we ’ ve come to the end of our time here. But I am so grateful to you for this conversation, Naomi, and thank you for sharing all this. I ’ ll talk to you soon. Take care. NS : Thank you, Cloe and everyone. Much love.

Text Sample 100: NEG Dim 1 – 2021 – Score -1.00 – 2021/t004053.txt

I ’ ve spent the last couple of years traveling around the world giving talks to big corporations and little bitty start-ups and lots of leadership teams and women ’ s groups, and what I ’ ve been talking to people about, I ’ ve been trying really hard to convince people that we can change the way we work. But every time I do a talk, somebody comes backstage or follows me offstage and says,”You know, I ’ m so inspired by what you say. It ’ s so great, it makes so much sense. But we can ’ t.””We can ’ t because we ’ re regulated.””We can ’ t because our CFO says we can ’ t do it.””We can ’ t because we ’ re in Europe.””We can ’ t because we ’ re a service industry.””We can ’ t because we ’ re a nonprofit.”And then last year came the pandemic. And the pandemic changed everything all over the world. Service people started realizing that they had to suit up and wear masks and take temperatures and wash their hands. We had to start standing six feet apart in lines. We started working from home. We started working virtually. And we started learning all kinds of things because we had to. All that muscle around innovation and flexibility and creativity that we didn ’ t think we had, we had all along. And we now have realized that we can. So what have we learned? I mean, what did we learn right away? First of all, we learned we ’ re not family. The family is the toddler walking around behind you in the Zoom call with the pet. The family is somebody needing their diaper changed. The family is making sure you ’ re taking care of your mom. That ’ s your family. This is your team. And we ’ ve also learned that that separation between family and work has become this balancing act. And that when we used to say,”Well, this is my work home and this is my family home, and those are two completely different things,”for many of **us**, it ’ s exactly the same thing. You ’ re no longer at home and at work. For many of **us**, work is at home and the home is – and it ’ s confusing, and it ’ s creating a whole different level of complexity and coordination so that we understand that it ’ s easier actually to work when we can separate the work that we do as a team from the work that we do in our family. Furthermore, in order to be able to do all that, we have to recognize that we ’ re all adults. And here ’ s the deal about adults. Adults have responsibilities, adults have obligations. Adults have things that they have to commit to. And do you know that every single person that works for you, from the shop floor to the executive suite, is a grown-up? But we have been operating as if they aren ’ t. We operate as if only the smart adults are the people who are at the C Suite. And as we move through the organization, everybody sort of gets a little dumbed down and the rules get a lot stricter and we have to have more control. And the truth is, everybody ’ s a grown-up, we can see it now. Everybody has all of these things to figure out and coordinate. And so now we ’ re expecting from people adult behavior. We ’ re now focusing on the results that matter, not the work. And the way we track it now is we don ’ t walk by and see who ’ s working. We pay attention to what people are doing. And I think that that ’ s always been the best metric. And you know what? For the first time in my life, the concept of best practices is out the window. And you know what? We don ’ t care what Google ’ s doing because we ’ re not Google. We don ’ t care what some other company is doing. Nobody ’ s doing it best. We ’ re all figuring it out as we go along and we ’ re figuring it out for our organizations in our teams at this time. So in order for people to deliver the right results, in order for people ’ s hard work to matter, it has to be in the context of what success looks like for your organization. So if we start to think about context, it ’ s really important that we think about how we teach that. If we can teach everybody in the company how to read a profit and loss statement, if we can teach them what the different teams do, and what they ’ re setting out to accomplish, then people within their own small teams, and within themselves, can figure out what excellence looks like for them. And so then we can start operating relatively independently as a whole organization because we ’ re all moving in the same direction, trying to do the same thing. And there ’ s a really critically important part of making that work, and that ’ s communication. And everything about communication has changed. We tend to think that communication is this waterfall from the top to the bottom. The executives would tell somebody and the next level would tell somebody and we ’ d go all the way down to the shop floor and everybody would understand what ’ s going on. Well, it may not have worked that well then, but it certainly doesn ’ t work that well now. So now we have to recognize it ’ s a different heartbeat. What has it been before and what should it be now? How do we make sure that the messages are clear and consistent? Because that ’ s how people operate. That ’ s how those adults who get the freedom and the responsibility to produce great results operate best is when they understand what they need to know in order to make the best decisions. So that communication, that skill around being a great communicator is something that each of **us** needs to get better at. One of the things we have to do is think about what the right discipline is for that. If you used to communicate to your team by walking by and asking how they ’ re doing or if they had heard something, you ’ re going to have to schedule that now, it ’ s going to have to have discipline. We ’ ve got to check in with the people on the shop floor to make sure they ’ re hearing what they need to hear because it ’ s not going to automatically happen. One of the ideas I have is just jot down at the end of every day a sentence of what worked and what didn ’ t work. And you don ’ t have to look at it for a month. But when you look **back**, over a month, you want to look for,”Wow, that was surprising. I didn ’ t really think that would be as effective as it is.”Or maybe it would be, like,”We keep trying to have this in-person meeting in Zoom, and it turns out that there ’ s 14 people on the call and only two of them are talking. Maybe it ’ s an email.”So we have to rethink all of the ways, not just the work we ’ re doing, but the ways we ’ re doing it. So now I ’ m starting to hear a lot of nostalgia around the way it used to be. There are things we aren ’ t doing now that don ’ t matter. Maybe we don ’ t need to go **back** for five levels of approval. Maybe we don ’ t need to go **back** and do that annual performance review. Maybe we don ’ t need to do a whole bunch of things that were part of the way we do business that just aren ’ t making a difference. You know what? The way we used to do it not only is not the way of the future, but we ’ re discovering so many wonderful things right now. Let ’ s not lose it. We want to create a new organization, new workforce, that ’ s excited about taking all of the things that we ’ ve learned using that muscle, going forward. One of the most important things that we can do is realize the things that we aren ’ t doing now. The stuff that we ’ ve stopped doing and not go **back** and do it again. What if we don ’ t go **back**? What if we go forward and rethink the way we work? Thank you.

Text Sample 101: NEG Dim 1 – 2021 – Score -1.00 – 2021/t003982.txt

[SHAPE YOUR FUTURE] I ’ m going to start by telling you a story about Danielle. When she was a senior in college, Danielle ’ s dad passed away, which left her mom with no way to support herself. So Danielle had to drop out of college and pick up three jobs as a barista, a bartender and a car washer. Altogether, the three jobs paid Danielle 23, 000 dollars per year, which wasn ’ t a whole lot, but it allowed her to feed her mom and keep a roof over their head. And for Danielle, that was enough. But early one morning when Danielle was driving home from one of her jobs, a deer ran in front of her car. She swerved off the road and crashed into a barn. And Danielle doesn ’ t remember exactly what happened next, but when she woke up in a hospital a few hours later, a doctor told her that she had damaged her brain stem and C1 vertebrae. Now, the good news is that Danielle was going to leave the hospital alive. But the bad news is that Danielle had 55, 000 dollars in medical bills. Now, Danielle tried so hard for the next two years to try and pay **back** that debt, but it was impossible. It was impossible for Danielle to pay **back** 55, 000 dollars in medical bills, earning just 23, 000 dollars per year. She felt trapped. One freak accident put Danielle on the verge of homelessness, hunger, poverty. And when you ’ re in Danielle ’ s shoes, bankruptcy is a lifeline. It ’ s a powerful legal tool that allows you to relieve your debt and re-enter the economy. Medical emergency, a job loss, a divorce. These are financial shocks that could happen to any of **us**. And when you ’ re living paycheck to paycheck and don ’ t have a whole lot of savings, like so many Americans, a financial shock can ruin your life. Bankruptcy gives you a second chance. But when Danielle went to go find a bankruptcy lawyer, she, like so many others filing for bankruptcy, learned that it was going to cost her 1, 500 dollars. She didn ’ t have that kind of money. I mean, what a cruel irony. In America, it costs you 1, 500 dollars to tell the court that you have no money. When you walk into a court, everyone from the judge to the clerk to the forms themselves will tell you to go find a lawyer, no matter how little money you have. One of the great civil rights injustices in America is that we don ’ t have equal rights under the law. What we have is equal rights if you can afford a lawyer. Whether you ’ re evicted from your home in an abusive relationship or need access to bankruptcy, you have no right to a free lawyer in most civil cases. And because there aren ’ t even close to enough pro bono or legal aid lawyers around, four out of five low-income Americans can ’ t get the legal help they need to access their civil legal rights. Four years ago, I helped start an organization to fight for new civil right in America, the right to solve your own legal problem when you can ’ t afford a lawyer. We started with bankruptcy. Our nonprofit Upsolve has built an app to help people file for bankruptcy on their own for free. People like Danielle. Our app asks people questions about their finances in language they can understand and then uses this information to help generate their forms. Last year, Danielle used Upsolve to file for bankruptcy on her own for free. She got her final letter from the court, relieving all of her medical debt, right after Christmas Day. Today, Danielle has the highest paying job she ’ s ever had and she ’ s on track to finish her degree. There are so many opportunities to create a more just legal system by empowering people to solve their own legal problems whenever possible. This is especially true in nonadversarial areas of the law, things like no-asset bankruptcies, uncontested divorces and Social Security disability. But there are two main barriers that stand in the way. The first is legal complexity. We ’ ve designed our forms in courts around lawyers, not regular people. Many legal forms are like modern day literacy tests. When you can ’ t understand them, you can ’ t access your rights. Every year, poorly designed forms, courts and processes deny millions of Americans their life, their liberty and their property. Legal complexity is a civil rights injustice. To start solving this problem, we need to require basic user testing in courts and reviser assumption in areas of poverty law that everybody will be able to afford a lawyer. A second barrier is a closed culture. We ’ ve been met with pushback from some folks who believe that you need to go see a lawyer no matter what legal problem you have. Imagine you had to go see a doctor to cure a plain old headache rather than being able to buy Advil at your local pharmacy. Telling a person who is poor to go find a lawyer when they obviously can ’ t afford one is out of touch, iIntimidating, unfair and wrong. It ’ s also a racial injustice. Black and brown communities disproportionately cannot afford the legal fees they need to access their civil legal rights. Many legal fees are like modern day poll taxes. When you can ’ t afford to pay the fees, you can access your rights. And we have a decision to make about how open and equal we want our system of justice to be. The only way we ’ re ever going to have equal rights in America is if we get rid of the modern day literacy tests and poll taxes that dominate our courts and legal system. We need a new civil right in America, the right to solve your own legal problem when you can ’ t afford a lawyer. Because in America, our rights are supposed to be inalienable, our protections are supposed to be equal, and we all deserve a chance at life, liberty and the pursuit of happiness, whether or not we can afford the legal fees. Thank you.

We all know that saving is important and is something that we should be doing. And yet, overall, we ’ re doing less and less of it. [The Way We Work] We know what we need to do. The question is : How do we do it? And that ’ s what I ’ m here to teach you. Your savings behavior isn ’ t a question of how smart you are or how much willpower you have. The amount we save depends on the environmental cues around **us**. Let me give you an example. We ran a study in which, in one group, we showed people their income on a monthly basis. In another group, we showed people their income on a weekly basis. And what we found was that people who saw their income on a weekly basis were able to budget better throughout the month. Now, it ’ s important to know that we didn ’ t change how much money people were receiving, we just changed the environment in which they understood their income. And environmental cues like this have an impact. So I ’ m not going to share tricks with you that you already know. I ’ m not going to tell you how to open up a savings account or how to start saving for your retirement. What I am going to share with you is how to bridge this gap from your intentions to save and your actions. Are you ready? Here ’ s number one : harness the power of pre-commitment. Fundamentally, we think about ourselves in two different ways : our present self and our future self. In the future, we ’ re perfect. In the future, we ’ re going to save for retirement, we ’ re going to lose weight, we ’ re going to call our parents more. But we oftentimes forget that our future self is exactly the same person as our present self. We know that one of the best times to save is when you get your tax return. So we tried an A / B test. In the first group, we texted people in early February, hopefully before they even filed for their taxes. And we asked them,”If you get a tax refund, what percentage would you like to save?”Now this is a really hard question. They didn ’ t know if they would receive a tax refund or how much. But we asked the question anyway. In the second group, we asked people right after they received their refund,”What percentage would you like to save?”Now, here ’ s what happened. In that second condition, when people just received their tax refund, they wanted to save about 17 percent of their tax refund. But in the condition when we asked people before they even filed their taxes, savings rates increased from 17 percent to 27 percent when we asked in February. Why? Because you ’ re committing for your future self, and of course your future self can save 27 percent. These large changes in savings behavior came from the fact that we changed the decision-making environment. We want you to be able to harness that same power. So take a moment and think about the ways in which you can sign up your future self for something that you know today will be a little bit hard. Sign up for an app that lets you make savings decisions in advance. The trick is, you have to have that binding contract. Number two : use transition moments to your advantage. We did an experiment with a website that helps older adults share their housing. We ran two ads on social media, targeted to the same population of 64-year-olds. In one group, we said,”Hey, you ’ re getting older. Are you ready for retirement? House sharing can help.”In the second group, we got a little bit more specific and said,”You ’ re 64 turning 65. Are you ready for

retirement? House sharing can help.”What we ’ re doing in that second group is highlighting that a transition is happening. All of a sudden, we saw click-through rates, and ultimately sign-up rates, increase when we highlight that. In psychology, we call this the”fresh start effect.”Whether it ’ s the start of a new year or even a new season, your motivation to act increases. So right now, put a meeting request on your calendar for the day before your next birthday. Identify the one financial thing you most want to do. And commit yourself to it. The third and final trick : get a handle on small, frequent purchases. We ’ ve run a few different studies and found that the number one purchase people say they regret, after bank fees, is eating out. It ’ s a frequent purchase we make almost every day, and it ’ s death by a thousand cuts. A coffee here, a burrito there... It adds up and decreases our ability to save. **Back** when I lived in New York City, I looked at my expenses and saw that I spent over 2, 000 dollars on ride-sharing apps. It was more than my New York City rent. I vowed to make a change. And the next month, I spent 2, 000 dollars again — no change, because the information alone didn ’ t change my behavior. I didn ’ t change my environment. So now that I was 4, 000 dollars in the hole, I did two things. The first is that I unlinked my credit card from my car-sharing apps. Instead, I linked a debit card that only had 300 dollars a month. If I needed more, I had to go through the whole process of adding a new card, and we know that every click, every barrier, changes our behavior. We aren ’ t machines. We don ’ t carry around an abacus every day, adding up what we ’ re spending, in comparison to what we wanted. But what our brains are very good at is counting up the number of times we ’ ve done something. So I gave myself a limit. I can only use ride-sharing apps three times a week. It forced me to ration my travels. I got a handle on my car-sharing expenses to the benefit of my husband, because of the environmental changes that I did. So get a handle on whatever that purchase is for you, and change your environment to make it harder to do so. Those are my tips for you. But I want you to remember one thing. As human beings, we can be irrational when it comes to saving and spending and budgeting. But luckily, we know this about ourselves, and we can predict how we ’ ll act under certain environments. Let ’ s do that with saving. Let ’ s change our environment to help our future selves.

Text Sample 103: NEG Dim 1 – 2019 – Score -1.00 – 2019/t000920.txt

Hello. I ’ d like to introduce you to someone. This is Jomny. That ’ s”Jonny”but spelled accidentally with an”m,”in case you were wondering, because we ’ re not all perfect. Jomny is an alien who has been sent to earth with a mission to study humans. Jomny is feeling lost and alone and far from home, and I think we ’ ve all felt this way. Or, at least I have. I wrote this story about this alien at a moment in my life when I was feeling particularly alien. I had just moved to Cambridge and started my doctoral program at MIT, and I was feeling intimidated and isolated and very much like I didn ’ t belong. But I had a lifeline of sorts. See, I was writing jokes for years and years and sharing them on social media, and I found that I was turning to doing this more and more. Now, for many people, the internet can feel like a lonely place. It can feel like this, a big, endless, expansive void where you can constantly call out to it but no one ’ s ever listening. But I actually found a comfort in speaking out to the void. I found, in sharing my feelings with the void, eventually the void started to speak **back**. And it turns out that the void isn ’ t this endless lonely expanse at all, but instead it ’ s full of all sorts of other people, also staring out into it and also wanting to be heard. Now, there have been many bad things that have come from social media. I ’ m not trying to dispute that at all. To be online at any given point is to feel so much sadness and anger and violence. It can feel like the end of the world. Yet, at the same time, I ’ m conflicted because I can ’ t deny the fact that so many of my closest friends are people that I had met originally online. And I think that ’ s partly because there ’ s this confessional nature to social media. It can feel like you are writing in this personal, intimate diary that ’ s completely private, yet at the same time you want everyone in the world to read it. And I think part of that, the joy of that is that we get to experience things from perspectives from people who are completely different from ourselves, and sometimes that ’ s a nice thing. For example, when I first joined Twitter, I found that so many of the people that I was following were talking about mental health and going to therapy in ways that had none of the stigma that they often do when we talk about these issues in person. Through them, the conversation around mental health was normalized, and they helped me realize that going to therapy was something that would help me as well. Now, for many people, it sounds like a scary idea to be talking about all these topics so publicly and so openly on the internet. I feel like a lot of people think that it is a big, scary thing to be online if you ’ re not already perfectly and fully formed. But I think the internet can be actually a great place to not know, and I think we can treat that with excitement, because to me there ’ s something important about sharing your imperfections and your insecurities and your vulnerabilities with other people. Now, when someone shares that they feel sad or afraid or alone, for example, it actually makes me feel less alone, not by getting rid of any of my loneliness but by showing me that I am not alone in feeling lonely. And as a writer and as an artist, I care very much about making this comfort of being vulnerable a communal thing, something that we can share with each other. I ’ m excited about externalizing the internal, about taking those invisible personal feelings that I don ’ t have words for, holding them to the light, putting words to them, and then sharing them with other people in the hopes that it might help them find words to find their feelings as well. Now, I know that sounds like a big thing, but ultimately I ’ m interested in putting all these things into small, approachable packages, because when we can hide them into these smaller pieces, I think they are easier to approach, I think they ’ re more fun. I think they can more easily help **us** see our shared humanness. Sometimes that takes the form of a short story, sometimes that takes the form of a cute book of illustrations, for example. And sometimes that takes the form of a silly joke that I ’ ll throw on the internet. For example, a few months ago, I posted this app idea for a dog-walking service where a dog shows up at your door and you have to get out of the house and go for a walk. If there are app developers in the audience, please find me after the talk. Or, I like to share every time I feel anxious about sending an email. When I sign my emails”Best,”it ’ s short for”I am trying my best,”which is short for”Please don ’ t hate me, I promise I ’ m trying my best!”Or my answer to the classic icebreaker, if I could have dinner with anyone, dead or alive, I would. I am very lonely. And I find that when I post things like these online, the reaction is very similar. People come together to share a laugh, to share in that feeling, and then to disburse just as quickly. Yes, leaving me once again alone. But I think sometimes these little gatherings can be quite meaningful. For example, when I graduated from architecture school and I moved to Cambridge, I posted this question :”How many people in your life have you already had your last conversation with?”And I was thinking about my own friends who had moved away to different cities and different countries, even, and how hard it would be for me to keep in touch with them. But other people started replying and sharing their own experiences. Somebody talked about a family member they had a falling out with. Someone talked about a loved one who had passed away quickly and unexpectedly. Someone else talked about their friends from school who had moved away as well. But then something really nice started happening. Instead of just replying to me, people started replying to each other, and they started to talk to each other and share their own experiences and comfort each other and encourage each other to reach out to that friend that they hadn ’ t spoken to in a while or that family member that they had a falling out with. And eventually, we got this little tiny microcommunity. It felt like this support group formed of all sorts of people coming together. And I think every time we post online, every time we do this, there ’ s a chance that these little microcommunities can form. There ’ s a chance that all sorts of different creatures can come together and be drawn together. And sometimes, through the muck of the internet, you get to find a kindred spirit. Sometimes that ’ s in the reading the replies and the comments sections and finding a reply that is particularly kind or insightful or funny. Sometimes that ’ s in going to follow someone and seeing that they already follow you **back**. And sometimes that ’ s in looking at someone that you know in real life and seeing the things that you write and the things that they write and realizing that you share so many of the same interests as they do, and that brings them closer together to you. Sometimes, if you ’ re lucky, you get to meet another alien. [when two aliebns find each other in a strange place, it feels a litle more like home] But I am worried, too, because as we all know, the internet for the most part doesn ’ t feel like this. We all know that for the most part, the internet feels like a place where we misunderstand each other, where we come into conflict with each other, where there ’ s all sorts of confusion and screaming and yelling and shouting, and it feels like there ’ s too much of everything. It feels like chaos, and I don ’ t know how to square away the bad parts with the good, because as we know and as we ’ ve seen, the bad parts can really, really hurt **us**. It feels to me that the platforms that we use to inhabit these online spaces have been designed either ignorantly or willfully to allow for harassment and abuse, to propagate misinformation, to enable hatred and hate speech and the violence that comes from it, and it feels like none of our current platforms are doing enough to address and to fix that. But still, and maybe probably unfortunately, I ’ m still drawn to these online spaces, as many others are, because sometimes it just feels like that ’ s where all the people are. And I feel silly and stupid sometimes for valuing these small moments of human connection in times like these. But I ’ ve always operated under this idea that these little moments of humanness are not superfluous. They ’ re not retreats from the world at all, but instead they ’ re the reasons why we come to these spaces. They are important and vital and they affirm and they give **us** life. And they are these tiny, temporary sanctuaries that show **us** that we are not as alone as we think we are. And so yes, even though life is bad and everyone ’ s sad and one day we ’ re all going to die — [look. life is bad. everyones sad. We ’ re all gona die, but i alredy bought this inflatable bouncey castle so are u gona take Ur shoes off or not] I think the inflatable metaphorical bouncy castle in this case is really our relationships and our connections to other people. And so one night, when I was feeling particularly sad and hopeless about the world, I shouted out to the void, to the lonely darkness. I said,”At this point, logging on to social media feels like holding someone ’ s hand at the end of the world.”And this time, instead of the void responding, it was people who showed up, who started replying to me and then who started talking to each other, and slowly this little tiny community formed. Everybody came together to hold hands. And in these dangerous and unsure times, in the midst of it all, I think the thing that we have to hold on to is other people. And I know that is a small thing made up of small moments, but

I think it is one tiny, tiny sliver of light in all the darkness. Thank you. Thank you.

I want to start by telling you two things about myself before I get into the full talk. And the first is that I ’ ve been writing about manners and civility for more than 20 years, as a book author and as a magazine columnist. The second is, my friends know to be very wary of inviting me over for dinner because any faux pas that happens at the table is likely to wind up in print. So, I ’ m watching, I can see **back** there and I can see through the portals, too. So, speaking of dinner parties, I want to take you **back** to 2015 and a dinner party that I went to. To place this in time, this was when Caitlyn Jenner was first coming out, shedding her identity as a Kardashian and moving into her life as a transgender activist. I wrote a column in People magazine at the time, talking about the importance of names and how names are our identity. And that to misuse them or not to use them erases **us** in a certain way. And especially with Caitlyn Jenner, I talked about Caitlyn, but also the use of her pronouns. Her pronouns. So I ’ m at this dinner — delicious, wonderful, fun — when my host goes on a rant about Caitlyn Jenner. And she is saying that it is disrespectful for Caitlyn Jenner to force her to use a new name and to use these new pronouns. She ’ s not buying it, and I ’ m listening, and because I do meditation, I took my sacred pause before I responded. And I reminded her that when she got married, she changed her name, and that she took the name of her husband. And that ’ s the name all of **us** now use. We don ’ t use it just because it ’ s her legal name, but we use it because it ’ s respectful. Ditto for Miss Jenner. She didn ’ t buy it and we didn ’ t speak for years. So... I am known as the Civilist. And it ’ s probably a word that you ’ re not that familiar with. It ’ s not in common parlance and it comes from the Latin and the French, and it means an individual who tries to live by a moral code, who is striving to be a good citizen. The word”civility”is derived from that, and the original definition of civility is citizens willing to give of themselves for the good of the city, for the good of the commonwealth, for the larger good. So, in this talk, you ’ re going to learn three new ways to be civil, I hope, and it will be according to the original definition of civility. My first problem is : civility is an obsolete word. My second problem is : civility has become a dirty word in this country. And that is whether you lean right or whether you lean left. And in part, that ’ s because modern usage equates civility with decorum, with formal politeness, formal behavior. We ’ ve gotten away from the idea of citizenship. So, let me start by talking a little bit about my friends on the right, who have conflated civility with what they call political correctness. And to them, callouts for civility are really very much like what George Orwell wrote in”1984”— he called it”newspeak.”And this was an attempt to change the way we talk by forcibly changing the language that we use. To change our ideas by changing the meaning of words. And I think my dinner host might have had some of that rattling around there. And I first personally understood, though, the right ’ s problem with civility when I wrote a column about then-candidate Donald Trump. And he had just said he did not have time for total political correctness, and he did not believe the country did either. And I took that to heart, it was very — The audience was very engaged about that online, as you can imagine. There was a thousand responses, and this one stood out to me because it was representative :”Political correctness is a pathological system that lets liberals dominate a conversation, label, demonize and shout down the opposition.”So I think, to the right, civility translates into censure. So that ' s the right. Now, my friends on the left also have a problem with it. And for example, there have been those who have harassed Trump administration officials who support the President ' s border wall. They ' ve been called out as rude, they ' ve been called out as nasty, they ' ve been called out as worse. And after one such incident last year, even the Washington Post — you know, left- leaning Washington Post — wrote an editorial and sided with decorum. And they argued that officials should be allowed to dine in peace. Hm."You know, the wall is the real incivility here. The tear-gassing of kids, the separation of families."That ' s what the protestors say. And imagine if we had sided, in this country, with decorum and courtesy throughout our history. You know, I think about the suffragettes. They marched, they picketed. They were chastised, they were arrested for pursuing the vote for women in the 1920s. You know, I also think about the Reverend Martin Luther King Jr., the father of American nonviolent civil disobedience. He was labeled as uncivil in his attempt to promote racial and economic justice. So I think you get a sense of why civility has become a problem, a dirty word, here. Now, does this mean we can ' t disagree, that we can ' t speak our minds? Absolutely not. I recently spoke with Dr. Carolyn Lukensmeyer. She ' s kind of the guru of civility in this country, and the executive director of a body called the National Institute for Civil Discourse. And she told me,"Civility does not mean appeasement or avoiding important differences. It means listening and talking about those differences with respect."In a healthy democracy, we need to do that. And I call that respectful engagement. But civil discourse also needs rules, it needs boundaries. For instance, there ' s a difference between language that is simply rude or demeaning, and speech that invokes hatred and intolerance. And specifically of groups. And I ' m thinking of racial and ethnic groups, I ' m thinking of the LGBTQ community, I ' m thinking of the disabled. We snowflakes call this speech"hate speech."And hate speech can lead to violence. So, to that point, in the fall of 2018, I wrote a column about Dr. Christine Blasey Ford. You may remember her, she was one of the women who accused Supreme Court nominee Brett Kavanaugh of sexual assault. And among the responses, I received this message, a personal message, which you can see here on the slide. It ' s been largely redacted. This message was 50 words long. 10 of them were the f-bomb. And the Democrats were called out, President Obama was called out, and I was referred to in a pretty darn vulgar and coarse way. There was an explicit threat in that message, and that is why my editors at The Post sent it to authorities. This came shortly before the pipe bombs were sent to other media outlets, so everybody was really kind of on guard there. And the larger context was, only a few months before, five staffers had been killed at a Maryland newspaper. They had been shot dead by a reader with a grudge."Shut up or else."And it was around that same time that a different reader of mine started stalking me online. And at first, it was... I ' ll call it light and fluffy. It was around this time last year and I still had my Christmas decorations up and he sent me a message saying,"You should take your Christmas decorations down."And then he noticed that my dog was off leash one day, and then he commented that I had gone to the market. And then he wrote me one that said,"If anyone were to shoot and kill you, it would not be a loss at all."I wish that were the end of the story. Because then, a few months later, he came to my door, my front door, in a rage and tried to break the door down. I now own mace, a security system and a Louisville Slugger baseball bat."Shut up or else."So, what ' s to be done to forestall civility from turning ugly, from turning violent? My first rule is to deescalate language. And I ' ve stopped using trigger words in print. And by trigger words, I mean"homophobe,"I mean"racist,"I mean"xenophobe,"I mean"sexist."All of those words. They set people off. They

’ re incendiary and they do not allow **us** to find common ground. They do not allow **us** to find a common heart. And so to this point, when John McCain died in 2018, his supporters noted that he never made personal attacks. But his opponents agreed as well, and I though that was what was really noteworthy. He challenged people ’ s policies, he challenged their positions, but he never made it personal. And so that ’ s the second rule. So the problem of civility is not only an American one. In the Netherlands, there are calls for a civility offensive right now, and as one Dutch philosopher has put it, the country has fallen under a spell of”verhuftering.”Now, this is not a word that I knew before and I did quite a bit of research. It loosely means bullying and the disappearance of good manners. It actually means much worse than that, but that ’ s what I ’ m saying here. When you have a specific word, though, to describe a problem like that, you know you really have a problem. And in the United Kingdom, the [2016] Brexit vote... you know, has divided a nation even more so. And one critic of the breakup called those who favor it — I just love this phrase —”the frightened parochial lizard brain of Britain.”The frightened parochial lizard brain of Britain. That ’ s personal. And it makes me miss”Downton Abbey”and its patina of civility. But therein lies the third rule : don ’ t mistake decorum for civility. Even if you have a dowager countess as fabulous as Dame Maggie Smith. [Don ’ t be defeatist. It ’ s so middle class.] So let me end with one last story. Not that long ago, I was at a bakery, and they make these amazing scones. So, long line — there are a lot of scones. And one by one, the scones were disappearing until there was one woman in between me and that last scone. Praise the Lord, she said,”I ’ ll have a croissant.”So when it became my turn, I said,”I ’ ll take that scone.”The guy behind me — I ’ d never turned around, never seen him — he shouted,”That ’ s my scone! I ’ ve been waiting in line 20 minutes.”And I was like,”Who are you? I ’ ve been waiting in line 20 minutes, and you ’ re behind me.”So, I grew up here in New York, and went to high school not that far from here. And I may seem, you know, very civil here and so on, but I can hip check anybody for a taxicab in this room, on these streets. So I was surprised when I said to this guy...”Would you like half?””Would you like half?”I didn ’ t think about it, it just came out. And then, he was very puzzled, and I could see his face change and he said to me,”Well, how about if I buy another pastry and we ’ ll share both of them?”And he did, and we did. And we sat and talked. We had nothing in common. We had nothing in common : nationality, sexual orientation, occupation. But through this moment of kindness, through this moment of connection, we developed a friendship, we have stayed in touch. Although he was appalled to learn that I ’ m called the Civilist after that. But I call this the joy of civility. The joy of civility. And it led me to wonder, what is the good we forgo, not just the trouble we avoid, when we choose to be uncivil. And by good, I mean friendship, I mean connection. I mean sharing 1000 calories. But I also mean it in a larger way. You know, as communities and as a country and as a world. What are we missing out on? So, today, we are engaged in a great civil war of ideas and identity. And we have no rules for them. You know, there are rules for war. Think about the Geneva Conventions. They ensure that every soldier is treated humanely, on and off the battlefield. So, frankly, I think we need a Geneva Convention of civility, to set the rules for discourse for the parameters of that. To help **us** become better citizens of our communities and of our countries. And if I have anything to say about it, I would base those rules on the original definition of civility, from the Latin and from the French. Civility : citizens willing to give of themselves for the greater good. For the good of the city. So I think civility, with that understanding, is not a dirty word. And I hope the civilist will not become, or will not stay, obsolete. Thank you.

Text Sample 105: NEG Dim 1 – 2017 – Score -1.00 – 2017/t000962.txt

After decades of research and billions of dollars spent in clinical trials, we still have a problem with cancer drug delivery. We still give patients chemotherapy, which is so non-specific that even though it kills the cancer cells, it kind of kills the rest of your body, too. And yes, we have developed more selective drugs, but it ’ s still a challenge to get them into the tumor, and they end up accumulating in the other organs as well or passing through your urine, which is a total waste. And fields like mine have emerged where we try to encapsulate these drugs to protect them as they travel through the body. But these modifications cause problems that we make more modifications to fix. So what I ’ m really trying to say is we need a better drug delivery system. And I propose, rather than using solely human design, why not use nature ’ s? Immune cells are these versatile vehicles that travel throughout our body, patrolling for signs of disease and arriving at a wound mere minutes after injury. So I ask you guys : If immune cells are already traveling to places of injury or disease in our bodies, why not add an extra passenger? Why not use immune cells to deliver drugs to cure some of our biggest problems in disease? I am a biomedical engineer, and I want to tell you guys a story about how I use immune cells to target one of the largest problems in cancer. Did you know that over 90 percent of cancer deaths can be attributed to its spread? So if we can stop these cancer cells from going from the primary tumor to a distant site, we can stop cancer right in its tracks and give people more of their lives **back**. To do this special mission, we decided to deliver a nanoparticle made of lipids, which are the same materials that compose your cell membrane. And we ’ ve added two special molecules. One is called e-selectin, which acts as a glue that binds the nanoparticle to the immune cell. And the second one is called trail. Trail is a therapeutic drug that kills cancer cells but not normal cells. Now, when you put both of these together, you have a mean killing machine on wheels. To test this, we ran an experiment in a mouse. So what we did was we injected the nanoparticles, and they bound almost immediately to the immune cells in the bloodstream. And then we injected the cancer cells to mimic a process through which cancer cells spread throughout our bodies. And we found something very exciting. We found that in our treated group, over 75 percent of the cancer cells we initially injected were dead or dying, in comparison to only around 25 percent. So just imagine : these fewer amount of cells were available to actually be able to spread to a different part of the body. And this is only after two hours of treatment. Our results were amazing, and we had some pretty interesting press. My favorite title was actually,”Sticky balls may stop the spread of cancer.”I can ’ t tell you just how smug my male colleagues were, knowing that their sticky balls might one day cure cancer. But I can tell you they made some pretty, pretty, exciting, pretty ballsy t- shirts. This was also my first experience talking to patients where they asked how soon our therapy would be available. And I keep these stories with me to remind me of the importance of the science, the scientists and the patients. Now, our fast-acting results were pretty interesting, but we still had one lingering question : Can our sticky balls, our particles actually attached to the immune cells, actually stop the spread of cancer? So we went to our animal model, and we found three important parts. Our primary tumors were smaller in our treated animals, there were fewer cells in circulation, and there was little to no tumor burden in the distant organs. Now, this wasn ’ t just a victory for **us** and our sticky balls. This was also a victory to me in drug delivery, and it represents a paradigm shift, a revolution — to go from just using drugs, just injecting them and hoping they go to the right places in the body, to using immune cells as special delivery drivers in your body. For this example, we used two molecules, e-selectin and trail, but really, the possibility of drugs you can use are endless. And I talked about cancer, but where disease goes, so do immune cells. So this could be used for any disease. Imagine using immune cells to deliver crucial wound-healing agents after a spinal cord injury, or using immune cells to deliver drugs past the blood-brain barrier to treat Parkinson ' s or Alzheimer ' s disease. These are the ideas that excite me about science the most. And from where I stand, I see so much promise and opportunity. Thank you.

Text Sample 106: NEG Dim 1 – 2017 – Score -1.00 – 2017/t001027.txt

So, I ' m afraid. Right now, on this stage, I feel fear. In my life, I ain ' t met many people that will readily admit when they are afraid. And I think that ' s because deep down, they know how easy it spreads. See, fear is like a disease. When it moves, it moves like wildfire. But what happens when, even in the face of that fear, you do what you ' ve got to do? That ' s called courage. And just like fear, courage is contagious. See, I ' m from East St. Louis, Illinois. That ' s a small city across the Mississippi River from St. Louis, Missouri. I have lived in and around St. Louis my entire life. When Michael Brown, Jr., an ordinary teenager, was gunned down by police in 2014 in Ferguson, Missouri — another suburb, but north of St. Louis — I remember thinking, he ain ' t the first, and he won ' t be the last young kid to lose his life to law enforcement. But see, his death was different. When Mike was killed, I remember the powers that be trying to use fear as a weapon. The police response to a community in mourning was to use force to impose fear : fear of militarized police, imprisonment, fines. The media even tried to make **us** afraid of each other by the way they spun the story. And all of these things have worked in the past. But like I said, this time it was different. Michael Brown ' s death and the subsequent treatment of the community led to a string of protests in and around Ferguson and St. Louis. When I got out to those protests about the fourth or fifth day, it was not out of courage ; it was out of guilt. See, I ' m black. I don ' t know if y ' all noticed that. But I couldn ' t sit in St. Louis, minutes away from Ferguson, and not go see. So I got off my ass to go check it out. When I got out there, I found something surprising. I found anger ; there was a lot of that. But what I found more of was love. People with love for themselves. Love for their community. And it was beautiful — until the police showed up. Then a new emotion was interjected into the conversation : fear. Now, I ' m not going to lie ; when I saw those armored vehicles, and all that gear and all those guns and all those police I was terrified — personally. And when I looked around that crowd, I saw a lot of people that had the same thing going on. But I also saw people with something else inside of them. That was courage. See, those people yelled, and they screamed, and they were not about to **back** down from the police. They were past that point. And then I could feel something in me changing, so I yelled and I screamed, and I noticed that everybody around me was doing the same thing. And there was nothing like that feeling. So I decided I wanted to do something more. I went home, I thought : I ' m an artist. I make shit. So I started making things specific to the protest, things that would be weapons in a spiritual war, things that would give people voice and things that would fortify them for the road ahead. I did a project where I took pictures of the hands of protesters and put them up and down the boarded-up buildings and community shops. My goal was to raise awareness and to raise the morale. And I think, for a minute at least, it did just that. Then I thought, I want to uplift the stories of these people I was watching being courageous in the moment. And myself and my friend, and filmmaker and partner Sabaah Folayan did just that with our documentary,"Whose Streets?"I kind of became a conduit for all of this courage that was given to me. And I think that ' s part of our job as artists. I think we should be conveyors of courage in the work that we do. And I think that we are the wall between the normal folks and the people that use their power to spread fear and hate, especially in times like these. So I ' m going to ask you. Y ' all the movers and the shakers, you know, the thought leaders : What are you gonna do with the gifts that you ' ve been given to break **us** from the fear the binds **us** every day? Because, see, I ' m afraid every day. I can ' t remember a time when I wasn ' t. But once I figured out that fear was not put in me to cripple me, it was there to protect me, and once I figured out how to use that fear, I found my power. Thank you.

A lot of people call me a"justice architect."But I don ' t design prisons. I don ' t design jails. I don ' t design **detention** centers, and I don ' t even design courthouses. All the same, I get a call every week, saying,"OK, but you design better prisons, right? You know, like those pretty ones they ' re building in Europe."And I always pause. And I invite them, and I invite you today, to imagine a world without prisons. What does that justice feel and look like? What do we need to build to get there? I ' d like to show you some ideas today of things that we ' re building. And I ' m going to start with an early prototype. This I built when I was five. I call it"the healing hut."And I built it after I got sent home from school for punching this kid in the face because he called me the N-word. OK, he deserved it. It happened a lot, though, because my family had desegregated a white community in rural Virginia. And I was really scared. I was afraid. I was angry. And so I would run into the forest, and I would build these little huts. They were made out of twigs and leaves and blankets I had taken from my mom. And as the light would stream into my refuge, I would feel at peace. Despite my efforts to comfort myself, I still left my community as soon as I could, and I went to architecture school and then into a professional career designing shopping centers, homes for the wealthy and office buildings, until I stepped into a prison for the first time. It was the Chester State Correctional Institution in Pennsylvania. And my friend, she invited me there to work with some of her incarcerated students and teach them about the positive power of design. The irony is so obvious, right? As I approached this concrete building, these tiny little windows, barbed wire, high walls, observation towers, and on the inside, these cold, hard spaces, little light or air, the guards are screaming, the doors are clanking, there ' s a wall of cells filled with so many black and brown bodies. And I realized that what I was seeing was the end result of our racist policies that had caused mass incarceration. But as an architect, what I was seeing was how a prison is the worst building type we could have created to address the harm that we ' re doing to one another. I thought,"Well, could I design an alternative to this, other than building a prettier prison?"It didn ' t feel good to me ; it still doesn ' t feel good. But **back** then, I just didn ' t know what to do. What do we build instead of this? And then I heard about restorative justice. I felt at peace again, because here was an alternative system that says when a crime is committed, it is a breach of relationship, that the needs of those who have been harmed must be addressed first ; that those who have committed the offense have an obligation to make amends. And what they are are really intense dialogues, where all stakeholders come together to find a way to repair the breach. Early data shows that restorative justice builds empathy ; that it reduces violent reoffending by up to 75 percent ; that it eases PTSD in survivors of the most severe violence. And because of these reasons, we see prosecutors and judges and district attorneys starting to divert cases out of court and into restorative justice so that some people never touch the system altogether. And so I thought,"Well, damn — why aren ' t we designing for this system?"Instead of building prisons, we should be building spaces to amplify restorative justice. And so I started in schools, because suspensions and expulsions have been fueling the pathway to prison for decades. And many school districts — probably some of your own — are turning to restorative justice as an alternative. So, my first project — I just turned this dirty little storage room into a peacemaking room for a program in a high school in my hometown of Oakland. And after we were done, the director said that the circles she was holding in this space were more powerful in bringing the community together after fighting at school and gun violence in the community, and that students and teachers started to come here just because they saw it as a space of refuge. So what was happening is that the space was amplifying the effects of the process. OK, then I did something that architects always do, y ' all. I was like, I ' m going to build something massive now, right? I ' m going to build the world ' s first restorative justice center all by myself. And it ' s going to be a beautiful figure on the skyline, like a beacon in the night. Thousands of people will come here instead of going to court. I will single-handedly end mass incarceration and win lots of design awards. And then I checked myself — because here ' s the deal : we are incarcerating more of our citizens per capita than any country in the world. And the fastest-growing population there are black women. Ninety-five percent of all these folks are coming home. And most of them are survivors of severe sexual, physical and emotional abuse. They have literally been on both sides of the harm. So I thought, uh, maybe I should ask them what we should build instead of prisons. So I returned with a restorative justice expert, and we started to run the country ' s first design studios with incarcerated men and women around the intersection of restorative justice and design. And it was transformative for me. I saw all these people behind walls in a totally different way. These were souls deeply committed to their personal transformation and being accountable. They were creative, they were visionary. Danny is one of those souls. He ' s been incarcerated at San Quentin for 27 years for taking a life at the age of 21. From the very beginning, he ' s been focused on being accountable for that act and doing his best to make amends from behind bars. He brought that work into a design for a community center for reconciliation and wellness. It was a beautiful design, right? So it ' s this green campus filled with these circular structures for victim and offender dialogue. And when he presented the project to me, he started crying. He said,"After being in the brutality of San Quentin for so long, we don ' t think reconciliation will happen. This design is for a place that fulfills the promise of restorative justice. And it feels closer now."I know for a fact that just the visualization of spaces for restorative justice and healing are transformative. I ' ve seen it in our workshops over and over again. But I think we know that just visualizing these spaces is not enough. We have to build them. And so I started to look for justice innovators. They are not easy to find. But I found one. I found the Center for Court Innovation. They were bringing Native American peacemaking practices into a non-Native community for the very first time in the United States. And I approached them, and I said,"OK, well, as you set up your process, could I work with the community to design a peacemaking center?"And they said yes. Thank God, because I had no backup to these guys. And so, in the Near Westside of Syracuse, New York, we started to run design workshops with the community to both locate and reenvision an old drug house to be a peacemaking center. The Near Westside Peacemaking Project is complete. And they are already running over 80 circles a year, with a very interesting outcome, and that it is the space itself that ’ s convincing people to engage in peacemaking for the very first time in their lives. Isabel and her daughter are some of those community members. And they had been referred to peacemaking to heal their relationship after a history of family abuse, sexual abuse and other issues that they ’ d been having in their own family and the community. And, you know, Isabel didn ’ t want to do peacemaking. She was like,”This is just like going to court. What is this peacemaking stuff?”But when she showed up, she was stressed, she was anxious. But when she got in, she kind of looked around, and she settled in. And she turned to the coordinator and said,”I feel comfortable here — at ease. It ’ s homey.”Isabel and her daughter made a decision that day to engage and complete the peacemaking process. And today, their relationship is transformed ; they ’ re doing really well and they ’ re healing. So after this project, I didn ’ t go into a thing where I ’ m going to make a huge peacemaking center. I did want to have peacemaking centers in every community. But then a new idea emerged. I was doing a workshop in Santa Rita Jail in California, and one of our incarcerated designers, Doug, said,”Yeah, you know, repairing the harm, getting **back** on my feet, healing — really important. But the reality is, Deanna, when I get home, I don ’ t have anywhere to go. I have no job — who ’ s going to hire me? I ’ m just going to end up **back** here.”And you know what, he ’ s right, because 60 to 75 percent of those returning to their communities will be unemployed a year after their release. We also know, if you can ’ t meet your basic economic needs, you ’ re going to commit crime — any of **us** would do that. So instead of building prisons, what we could build are spaces for job training and entrepreneurship. These are spaces for what we call”restorative economics.”Located in East Oakland, California,”Restore Oakland”will be the country—s first center for restorative justice and restorative economics. So here ’ s what we ’ re going to do. We ’ re going to gut this building and turn it into three things. First, a restaurant called”Colors,”that will break the racial divide in the restaurant industry by training low-wage restaurant workers to get living-wage jobs in fine dining. It does not matter if you have a criminal record or not. On the second floor, we have bright, open, airy spaces to support a constellation of activist organizations to amplify their cry of”Healthcare Not Handcuffs,”and”Housing as a human right.”And third, the county ’ s first dedicated space for restorative justice, filled with nature, color, texture and spaces of refuge to support the dialogues here. This project breaks ground in just two months. And we have plans to replicate it in Washington D. C., Detroit, New York and New Orleans. So you ’ ve seen two things we can build instead of prisons. And look, the price point is better. For one jail, we can build 30 restorative justice centers. That is a better use of your tax dollars. So I want to build all of these. But building buildings is a really heavy lift. It takes time. And what was happening in the communities that I was serving is we were losing people every week to gun violence and mass incarceration. We needed to serve more people and faster and keep them out of the system. And a new idea emerged from the community, one that was a lot lighter on its feet. Instead of building prisons, we could build villages on wheels. It ’ s called the Pop-Up Resource Village, and it brings an entire constellation of resources to isolated communities in the greater San Francisco area, including mobile medical, social services and pop-up shops. And so what we ’ re doing now is we ’ re building this whole village with the community, starting with transforming municipal buses into classrooms on wheels that bring GED and high school education across turf lines. We will serve thousands of more students with this.

We ’ re creating mobile spaces of refuge for women released from jail in the middle of the night, at their most vulnerable. Next summer, the village will launch, and it pops up every single week, expanding to more and more communities as it goes. So look out for it. So what do we build instead of prisons? We ’ ve looked at three things : peacemaking centers, centers for restorative justice and restorative economics and pop-up villages. But I ’ m telling you, I have a list a mile long. This is customized housing for youth transitioning out of foster care. These are reentry centers for women to reunite with their children. These are spaces for survivors of violence. These are spaces that address the root causes of mass incarceration. And not a single one of them is a jail or a prison. Activist, philosopher, writer Cornel West says that”Justice is what love looks like in public.”So with this in mind, I ask you one more time to imagine a world without prisons, and join me in creating all the things that we could build instead. Thank you.
